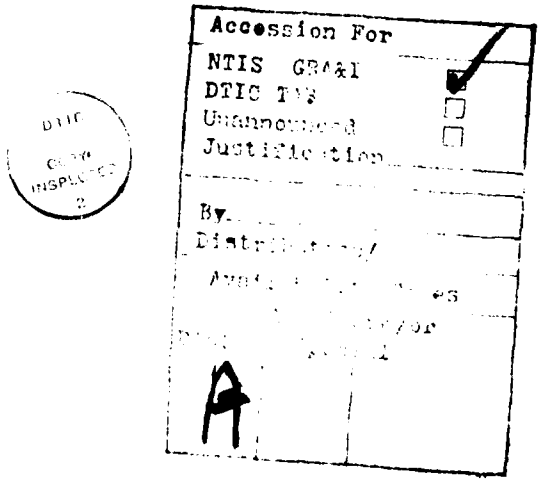
Washington, D.C. 20016

PREFACE

This volume is the last of six volumes that describe the LMI Sortie-Generation Model System. Volume I, Executive Summary, discusses the problem the system is designed to address and provides an overview of the principal parts of the system. Volume II, Sortie-Generation Model User's Guide, provides sufficient information to allow a user to run the Sortie-Generation Model (SGM). Volume III, Sortie-Generation Model Analyst's Manual, describes the mathematical structures, derivations, assumptions, limitations, and data sources of the system at a very detailed level. Volume IV, Sortie-Generation Model Programmer's Manual, specifies the details of the computer programs, file structures, job control language, and operating environment of the system. Volume V describes the maintenance subsystem and explains the construction of the maintenance input file to the SGM. Volume VI describes the spares subsystem and shows a user how to build the spares file that is used by the SGM.

Potential users are cautioned that no volume is intended to provide, by itself, all of the information needed for a comprehensive understanding of the operation of the SGM.



ACKNOWLEDGMENTS

We are indebted to our colleague at LMI, Mr. William B. Fisher, for his many helpful insights and contributions to both the conceptual and technical content of this work, and to Mr. Peter L. Eirich, formerly of LMI, who first suggested the structure of the merge routine used in the Distribution Model.

SPARES SUBSYSTEM

SPARES SUBSYSTEM DESCRIPTION

INTRODUCTION

The purpose of the spares subsystem is to provide a means of translating budget-program 15 (BP15) resources and depot-purchased equipment maintenance (DPEM) resources into a spares posture. By a spares posture we mean a set of stock levels by national stock number (NSN) and location. Locations include all bases world-wide and all depots. The spares subsystem is shown schematically in Figure 1. It consists of several components, each of which will be discussed.

The Aircraft Availability Model

The Aircraft Availability Model produces an availability-vs.-cost curve for each model/design (MD) aircraft in the Air Force inventory (e.g., F-4 or B-52), for each model/design/series (MDS) such as F-4D or F-4E, or for any combination of MDs and MDSs. Given the assumptions made in the model, each point on the curve is an optimum; i.e., it represents the least-cost mix of spares and depot-level repair for that level of aircraft availability and it also represents the maximal availability achievable for that total cost of procurement and repair.

The input data for the Availability Model are derived from the Air Force Logistics Command's D041, D041A, and K004 data systems. They specify, for each recoverable item in the system, the current worldwide asset position including war reserve stocks, failure factors, pipeline times, flying hour programs, item applications by weapon system, base repair fractions, item unit costs and repair costs, and other factors that affect the resource allocation solution and resulting mix of spares. The Availability Model takes explicit

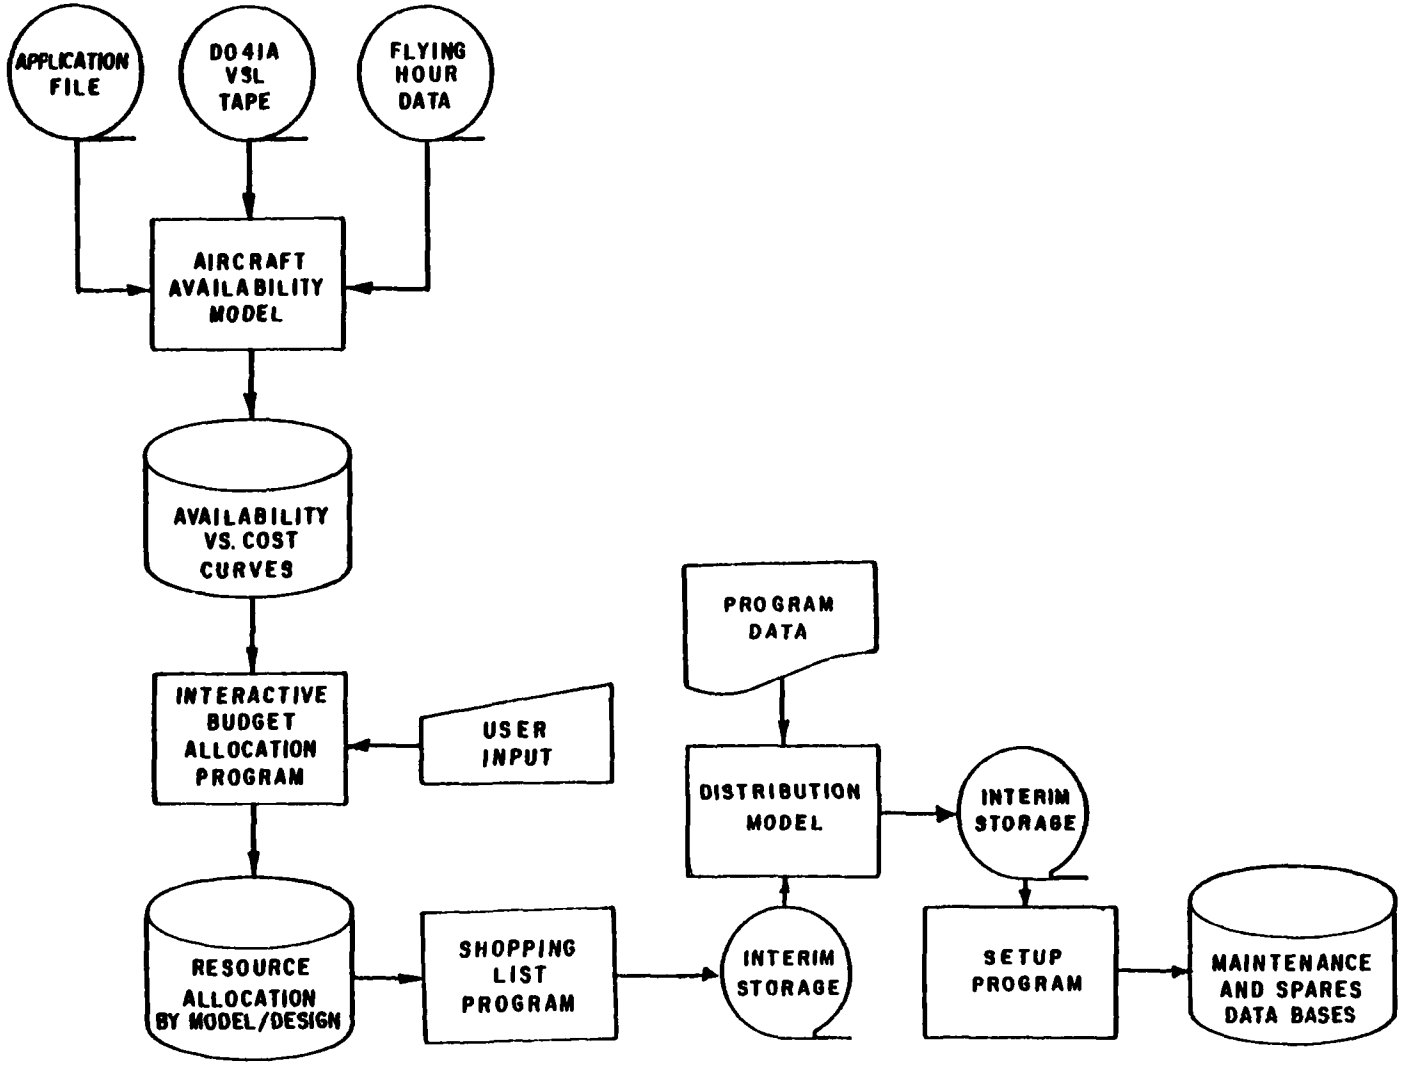

FIGURE 1
SPARES SUBSYSTEM

account of item commonality, i.e., the application of a component to more than one kind of aircraft, and also estimates the effects of lateral resupply. It is, in short, a powerful, flexible, resource allocation tool for recoverable spares procurement and depot-level repair.

The Interactive Budget Allocation Program

This program enables a user to specify the amount of money he wishes to allocate to each MD. The program enables the user to choose an availability increment or a budget increment, either positive or negative, will display the current budget allocation and availability for each MD, and will also display the new budget allocation and availability that would result from application of the increment to each MD. The user then selects the MD(s) to which he wishes the increment to be applied. The program keeps track of and displays the total amount of budget dollars allocated to the entire force; that total includes the sum of procurement dollars and depot-level-repair dollars and the two values are optimized beyond the control of the user. The user proceeds iteratively changing and allocating the increment to MDs of his choice until he reaches the budget constraint or a set of availability goals.

The most important feature of the interactive program is the ease with which a user is able to allocate resources across a rather large number (roughly 40) of different MDs in a way that takes military worth explicitly into account. For any specified budget or availability increment, the user is able to see exactly what his tradeoff opportunities and costs are at any point in the decision process.

When the user has allocated a budget, the program stores the results of his final decision so that, at any future time, the set of spares by stock

number and the detailed depot-level-repair program may be produced. The remainder of the process consists of three major steps: (1) The Shopping List Program, (2) the Distribution Model, and (3) the Setup Programs.

The remainder of this volume is dedicated to explaining these three steps. We assume that the Aircraft Availability Model has been run on current data and that the user has specified availability levels for all aircraft and, implicitly, a total budget level. The next step in the process is to run the Shopping List Program.

THE SHOPPING LIST PROGRAM

The output of the Interactive Budget Allocation Program, a function of the user's allocation decisions, is subsequently used by the Shopping List Program to extract from the Availability Model output the quantity of spares of each component that results from the decision process and the set of availability-vs.-cost curves that were input to the interactive program. Thus, the Shopping List Program produces a world-wide stockage level for every recoverable component in the Air Force system.

The Shopping List Program used by the SGM is a simplified version of a Shopping List Program that is used routinely with the Aircraft Availability Model for budget planning and other purposes. It is simplified to the extent that it generates a shopping list of line-replaceable units (LRUs) only, i.e., it does not output shop-replaceable units (SRUs). It outputs for each LRU the expected delay in base repair due to SRU backorders. The shopping list for SRUs isn't needed by the SGM because the expected delay in base repair of the LRU fully accounts for the impact of the SRU asset position.

As the user goes through the decision process involved in specifying availability levels and allocating a total budget, each of his decisions is

numbered and stored by the Interactive Budget Allocation Program. The Shopping List Program simply retrieves the stock levels associated with a particular decision.

Inputs

Prior to running the Shopping List Program, the user needs to know the job name (JOBNAME) and the tape number of the level-one, tape one (T1-1) from the Aircraft Availability Model run, the interactive decision number of the decision he wishes to implement from the Interactive Budget Allocation Program, and the area code (AREACODE) of the output tape of the Shopping List Program. It is assumed that the user knows his IDENT code and NAME.

Job Submission Procedures

Figure 2 shows what entries are required to submit the Shopping List Program. The system's output to the user's terminal is shown without underlining; the user's responses are underlined. These responses are only

FIGURE 3. JCL FOR SHOPPING LIST PROGRAM

THE DISTRIBUTION MODEL

The Distribution Model operates on the output of the Shopping List Program. Its purpose is to find the distribution of stock levels for all items among all bases and the depot such that the value of expected base-level backorders is minimized. The Distribution Model takes explicit account of the world-wide distribution of aircraft by MDS and their collocation by base.

The Distribution Model allocates the asset position specified by the Shopping List Program to the depot and the particular bases so as to minimize total expected backorders. The Distribution Model does this one component at

a time. First, all the data about a particular component are read in. These data include:

- The total number of assets worldwide as specified by the Shopping List.
- The total demand rate, the repair times, the percentage of repairs at each echelon, the condemnation rate, the production lead time, etc., as specified by the VSL Tape.
- The MDS, Quantity Per Aircraft (QPA), and the Future Application Percentage (FAP) of each MDS application for that component as specified by the Application Tape.
- The distribution of the MDSs to the various bases, and their flying hour programs as specified by the Aircraft File.
- The demand rate per flying hour as specified by the DO41-01 Records Tape.

The Model computes the demand rate at each individual base and at the depot. The world-wide assets are allocated to the bases and the depot using an algorithm which is equivalent to trying all possible distributions and picking the one with the lowest total expected backorders. The results of this distribution are written to tape and the model reads in the next component.

The user must generate the Aircraft File (called ACLIST) from information contained in the Air Force Program Document (PD). Each base in the file is assigned a number and a list of the bases and their numbers is saved in a file (referred to as the Base List). Examples of an Aircraft File and a Base List are contained in Appendices C and D.

The output of the Distribution Model is a file of all recoverable components by NSN that reflects the stock levels of that NSN allocated to every base world-wide and the depot stock level. This file reflects directly the input budget originally allocated by the user of the Interactive Budget Allocation Program.

Inputs

Prior to running the Distribution Model the user needs to know the tape numbers of the VSL tape, the D041 system "01" tape, and the application file that were input to the Aircraft Availability Model and of the output tape from the Shopping List Program. He also needs the file name of the file that reflects the distribution of aircraft and flying hours among bases (ACLIST) and the area code (AREACODE) for the output tape of the Distribution Model. Again, it is assumed that the user knows his IDENT code and NAME.

Job Submission Procedures

Figure 4 shows the entries required to run the Distribution Model. As before, the system's output to the user's terminal is shown without underlining; the user's responses are underlined.

The JCL for the Distribution Model is shown in Figure 5. A listing of its source program is provided in Appendix E. Appendix F contains a sample of the Distribution Model's output.

THE SETUP PROGRAMS

The Setup Program provides an interface between the general spares data base generated by the Distribution Model and a particular spares data base needed by the SGM. The principal function of the Setup Program is to read the Distribution Model output tape selecting the data for the base and MDS(s) of interest and saving those data on a disc file suitable for use by the SGM.

The file created by the Setup Program contains data for each LRU for the base and MDS(s) of interest. The data are stored one component at a time

with one record per component. The data for each component are:

1. NSN - The national stock number of the component.

2. DEMAND - The demand (break) rate in failures per flying hour.

3. QPA - The quantity installed on each aircraft.

4. FAP - The "Future Application Percentage", the percentage of the missions on which the component is installed.

5. NSPARES - The number of spares of that component (on hand, in repair, and on order) at that base.

6. RESUPPLY - The expected number of units in resupply at the start of the scenario.

FIGURE 5. JCL FOR THE DISTRIBUTION MODEL

7. BNRTS - The percentage of breaks which are "Not Repairable This Station" at the base.

8. BRESDAYS - The expected number of days it takes to repair a component at base (including any delay awaiting SRUs).

9. DRESDAYS - The expected number of days between when a component is declared NRTS (when an order is made to the depot) and when the replacement arrives from the depot (including any delay at the depot due to lack of spares there).

If a setup run is being made for a single MDS at a particular base (see the first example in the Job Submission Procedures section) and the component is not installed on any other MDS at that base then the Setup Program simply transfers the data from the Distribution Model output tape to the SGM Spares Input File. However, certain cases require the Setup Program to make calculations based on some important assumptions. The explanations follow.

The organization to be set up need not possess only one MDS. For example, the SGM run desired may be for an F-15 wing consisting of 54 F-15As and six F-15Bs. The QPAs and FAPs for a component of these MDSs may not be the same. The SGM needs a single QPA and a single FAP which represents the components application to the entire wing. The Setup Program sets the QPA for the wing to the maximum of the QPAs for the individual MDSs. The FAP is chosen so as to give the correct total number installed. In the example, if a component's QPA and FAP for the F-15A were one and 1.0, respectively, and to the F-15B two and 0.8, respectively, then the QPA for the wing would be two, and to get the FAP we compute:

$$\text{Total Installed} = (1 \times 1.0 \times 54) + (2 \times 0.8 \times 6) = 63.6$$

$$= 2 \times \text{FAP} \times 60$$

$$\text{FAP} = 0.53$$

For a particular component, the Distribution Model considers the demands for that component at each base and the depot, and distributes the assets so as to minimize the total expected backorders for that component. If, at a particular base, there is only one aircraft type that uses the component, then all the spares allocated to that base by the Distribution Model are designated for use by that aircraft, and the total expected number in resupply at that

base are from that aircraft. However, if the component is common to two or more aircraft types then the input to the SGM for one of those aircraft types should reflect the sharing of the spares and the number of units in resupply. This sharing is modeled in the following way.

For a component that is common to more than one aircraft type at a particular base, each aircraft type is responsible for a proportion of the total demands for that component at that base. The spares at that base are partitioned (rounded to the nearest integer) to the aircraft types in proportion to their shares of the demands. The expected number in resupply for an aircraft type is chosen so that the expected backorders for that aircraft type (given the number of spares just computed) will be equal to the total expected backorders at that base times that aircraft type's share. In the previous example, suppose the share for the F-15 wing is .5; that is, half of the expected demands for that component at that base come from other aircraft. Now, suppose the expected number in resupply is 3.45236 and there are six spares. The F-15 wing gets three spares and the number of units in resupply for the wing is that number which would give an EBO for the wing equal to .5 times the EBO for the whole base. The EBO for the whole base is the EBO for six spares and an expected number in resupply of 3.45236. (The base EBO equals 0.10.) The EBO for the wing is 0.05 and the expected number in resupply which, with three spares, yields that EBO is 1.25290.

For the component and base in this example, the inputs to the SGM would include:

```
      QPA = 2
      FAP = 0.53
  NSPARES = 3
RESUPPLY = 1.25290
```

The principal assumption in letting the EBO and the number of spares prorate linearly with the share of demands is that there is no economy of scale benefit from the sharing of the spares pool at a base. While this assumption is very inaccurate for peacetime operations, in a surge scenario it is quite good. In computing NSPARES, the Setup Program rounds to the nearest integer. This obviously introduces some error. The error attributable to the linearity of the prorating is less than the error of the rounding.

In addition to modeling an organization of aircraft at a particular base, the SGM can be used to model a "notional" base. For a particular set of MDSs, the notional base should produce sorties at a rate that is the average of all the bases that have any of the MDSs in the set. This allows the user to estimate the total world-wide sortie production of a particular set of MDSs by making a single notional SGM run and multiplying the results by the number of bases which have any of the MDSs in the set. In setting up the spares inputs to the SGM for a notional base, one depends heavily on the linear prorating assumption. However, it is with the notional base model that we have validated the accuracy of that assumption.

For the notional base, the computation of the number of spares and the expected number in resupply is essentially the same as for a particular base except the spares and EBO are prorated in proportion to a share of the world-wide total.

First, the total number of spares and total EBO at all the bases are computed. Next, the percentage of the total world-wide expected demands for that component that come from the aircraft type of interest is computed. Also, the total number of bases that use both the component and aircraft type (NBASES) is computed. The share of the total world-wide demands for the component due to one notional base equals the percentage of total demands due

to the aircraft type of interest, divided by NBASES. The number of spares for the notional base is then prorated from the world-wide total proportional to this share, exactly the same way as for a particular base. The EBO is prorated the same way and the expected number in resupply is chosen to give the correct EBO, exactly as in the particular base computation.

Inputs

In order to run the Setup Program for a particular base, the user needs to have the tape number of the output file produced by the Distribution Model. One may wish to copy that tape so that, in the event that one needs to run Setup Programs repeatedly, there will be no delay waiting for one run to finish with the tape before it can be used for another. The user also needs the base number from the Base List for the particular base of interest, and he needs to specify each MDS at the particular base. He also needs to specify a value for flying hours per day. The use that is made of this value is to sort components according to the likelihood that they will suffer shortages that will constrain the sortie-generation capability of the organization. The actual value specified need only be approximate. Finally, the user must be prepared to specify his choice of a file name for the output file that the Setup Program will write on disc for use by the SGM. The entries required to run the Setup Program for a particular base are shown in Figure 6.

In order to run the Setup Program for a notional base, the user does not need to specify a base number; however, he does need to specify all MDSs he wishes to have combined in the notional base. In the example shown in Figure 7, the intention is to construct a notional F-4 base; thus, the user specifies the RF-4C, F-4E, and F-4G to be included.

Job Submission Procedures

The example shown in Figure 6 is for a base with a single MDS of interest; hence, the JCL carries the name SET1UP. The JCL is shown in Figure 8. Other examples of JCL are shown in Figures 9 through 11 for particular bases with two, three, or four MDSs. The user can easily construct JCL for particular bases with more than four MDSs by straightforward extension.

Figure 7 shows the entries required to run the Setup Program for a notional base. In the example chosen, the F-4 is the weapon system of interest. Since there are three MDSs involved, as mentioned previously, the JCL has the name SET3UPN. The JCL for one, two, three, and four MDSs are shown in Figures 12 through 15. Again, the user can create JCL for more than four MDSs by simple extension.

FIGURE 15. JCL FOR A SETUP PROGRAM FOR A NOTIONAL BASE FOR AN MD WITH FOUR MDSs

A listing of the source code for the Setup Program for a particular base is contained in Appendix G. Appendix H contains the source program for a notional base.

Appendices J and K contain samples of output file listings produced by the Setup Programs for a particular base and a notional base, respectively.

WAR RESERVE SPARES

War reserve spares are easily modelled by the SGM system. In running the Aircraft Availability Model, the user must exclude war reserve spares from the asset position. Then, the Air Force Logistics Command's D029 system output file is used to determine the range and depth of the particular war reserve spares kit (WRSK) of interest and those quantities by stock number are simply added to the output file of the Setup Program. If the UE strength of the base of interest is different from the UE strength for which the WRSK was designed,

the user must adjust the quantities in the WRSK as he deems appropriate. The addition of war reserve spares to the output of the Setup Program can be done with a simple program of the user's design or even with the system's edit capability.

13. Narrative

The Sortie-Generation Model System provides the capability for relating aircraft spares and maintenance manpower levels to the maximal sortie-generation capability of tactical air forces over time.

This volume describes the process of constructing a spares data base for input to the Sortie-Generation Model.
