DRAFT

ABSTRACT

Areal, geotechnical, and cultural factors pertaining to 33 Department of Defense (DoD) and 35 Bureau of Land Management (BLM) Valleys in Arizona, Nevada, and New Mexico siting regions were evaluated to rank Valleys according to their relative favorability for siting of the MX system. Suitable Valley areas totalling 10,000 square nautical miles ( $\text{nm}^2$ ) were delineated based on established criteria, derivative maps were produced at a scale of 1:62,500 and areas of suitable Valleys were measured. A matrix analysis utilizing a computer program was developed to obtain Valley ranking scores based on 15 ranking factors and corresponding weighting factors. Maps of the three siting regions, at a scale of 1:1,000,000, depict suitable Valley areas.

Over 70 percent of all Arizona BLM and DoD, and Nevada BLM ~~lands~~ <sup>Valleys</sup> rank in the upper 50 percent of the total. Nevada DoD and New Mexico BLM and DoD rank predominantly in the lower 50 percent. Seventy-four percent ( $7423 \text{ nm}^2$ ) of the total suitable Valley area is in the upper 50 percent; 30 percent ( $2248 \text{ nm}^2$ ) of this is DoD land of which 76 percent ( $1715 \text{ nm}^2$ ) is in Arizona. Eighty-eight percent ( $1514 \text{ nm}^2$ ) of the Arizona DoD land is in Luke Bombing and Gunnery Range.

It is recognized that the heavy weight placed on areal factors dominates the final ranking and smaller key suitable Valleys are important considerations. Matrix analysis scores and final rankings are used with judgement to recommend Arizona DoD and BLM and Nevada BLM core areas for possible wing deployment consideration. It is also suggested that the New Mexico siting region be considered low priority, and Arizona siting region high priority for Phase 1 and Phase 2 field studies.

10/1/74

FOREWORD

This report was prepared for the Department of the Air Force, Space and Missile Systems Organization (SAMSO) in compliance with conditions of the statement of work as part of Contract No. F04701-74-D-0013 and deals with siting of the MX Land Mobile Advanced ICBM system.

The report was prepared by Kenneth L. Wilson, Project Manager; James R. Miller, Project Geologist; and John W. LaViolette and Gary E. Christenson, Staff Geologists. The graphics were prepared by Edd V. Joy, Gordon M. Brown, and Bruce A. Bowen. TRW Systems personnel monitored the study for SAMSO.

A list of applicable MX siting reports is presented in Appendix A to avoid extensive referencing of the geotechnical and siting reports. A partial list of the abbreviations and term definitions used in this report is presented in Table 1. Figure 1 and Table 2 illustrate the relationship of suitable siting area to siting valleys and geographic valleys.

TABLE 1

List of Abbreviations and Definitions

AZB	Arizona BLM Siting Area (Gila Bend Study Area)
AZD	Arizona DoD Siting Area
BLM	Bureau of Land Management
DoD	Department of Defense
Final Score	The summation of all matrix scores times their corresponding weighting factors for each Valley
Four-Quad	Four combined USGS 15-minute quadrangle maps (scale 1:62,500) comprising Volume II Geotechnical Report large graphics
LBGR	Luke Bombing and Gunnery Range
Matrix Score	Value from 0 to 10 for each ranking factor in the matrix analysis assigned to the smoothed area in each Valley
NBGR	Nellis Bombing and Gunnery Range
NVB	Nevada BLM Siting Area (Nellis Group)
NVD	Nevada DoD Siting Area
NMB	New Mexico BLM Siting Area (White Sands Extension Area)
NMD	New Mexico DoD Siting Area
Ranking Factor	Category used in ranking suitable Valley areas in matrix analysis, i.e., Columns A-O
Ranking Score	Summation of matrix scores for each Valley in the matrix analysis
Siting Region (Siting Area)	Three DoD and Three BLM study areas in Arizona, Nevada, and New Mexico.
Siting Valley (or Available Area)	The portion of a Valley described in Volume II Geotechnical Reports (DoD and BLM) considered available for siting of the MX system (see Figure 1).
Suitable Valley Area (or Suitable Area)	The portion of available area within the siting Valley remaining after application of all criteria defining unsuitable area (see Figure 1)

Suitable Contiguous Area	Suitable area in a siting Valley which is connected to an adjacent given siting Valley by less than ten percent topographic grade
Terrain Analysis Rating	A rating of basin-fill units based on analysis of terrain characteristics such as drainage incision, drainage density, surface slope, drainage shape, surface CBR values, etc.
Terrain Analysis Scaling Factor	Values of 0.25, 0.5, 0.75, 1.0 assigned to terrain analysis ratings of very poor, poor, fair, and good, respectively
Valley	See Figure 1 and Table 2
Weighting Factor	A value, specific to each ranking factor, multiplied by the matrix score in order to give appropriate relative importance to each factor when deriving a ranking score
WSMR/FBMR	White Sands Missile Range/Fort Bliss Military Reservation
YPG	Yuma Proving Grounds

### EXPLANATION

-  Minimum distance from cities with population greater than 25,000: 16 nm (33 km)
-  Minimum distance from cities with population of 5,000 to 25,000: 3 nm (5.5 km)
-  Minimum distance from populated areas up to 5,000 and WSMR Extension boundaries: 2985 feet (905 m)
-  Minimum distance from traveled public highways and railroads: 1780 feet (545 m)
-  Excluded areas, national forests, national monuments, Indian reservations: Minimum distance from boundaries: 2985 feet (905 m). Small excluded areas less than 2 sq. nm total area have no minimum distance from boundary and are indicated only by the symbol.
-  State land
-  Private land
-  Non-BLM, Non-DoD Federal land (e.g. ERDA)

### SYMBOLS

-  Valley boundary
-  Siting valley boundary
-  Area with greater than ten percent topographic grade, within Valley.
-  -10 Greater than ten percent topographic grade.
-  Suitable area

### RELATIONSHIPS OF VALLEYS AND SITING VALLEYS TO GEOGRAPHIC VALLEYS

Valley Terminology

DoD Lands

A Valley (designated by capitalized "V") is a sub-area of a DoD siting area. It is bound by one or both of the following:

1. A hydrologic drainage divide (most often the crest of an intervening mountain range); and/or a
2. DoD boundary or any other artificially established boundaries such as public highways, township and range lines or national monument borders.

BLM Lands

A Valley (designated by capitalized "V") is a sub-area of a BLM siting area. It is bound by one or more of the following:

1. Areas of greater than ten percent topographic grade;
2. Large exclusion areas such as National Forests, Indian reservations or quantity-distance exclusion areas;
3. DoD boundary or any other (artificially) established boundaries such as public highways, township and range lines, latitude lines; and
4. A hydrologic drainage divide (most often at a low relief intervalley connection).

1.0 INTRODUCTION

1.1 BACKGROUND

This report presents evaluations and rankings of 68 Valleys included in three Department of Defense and three Bureau of Land Management siting areas (Figure 2) with respect to their relative suitability for siting of the MX land mobile advanced ICBM system. Conclusions and recommendations, formulated after evaluation of all available data, are also presented.

A premise of the MX siting study has been to begin with large candidate siting regions and, utilizing data gathered in an ever increasing degree of detail, eliminate areas based on screening or exclusion criteria. Some 26,000 square nautical miles (nm<sup>2</sup>) of land made up the initial candidate siting regions (Figure 2) in New Mexico, (4462 nm<sup>2</sup>), Arizona (7220 nm<sup>2</sup>), and Nevada (14,098 nm<sup>2</sup>). Data were gathered and analyzed, and after matching data with known or assumed topographic and cultural criteria defining unsuitable land, considerable siting area was determined.

The combined DoD and BLM, <sup>potential</sup> available siting area totals 18,390 nm<sup>2</sup> and is made up of increments of land called Valleys which roughly correspond to geographic valleys between mountain ranges. SAMSO's programmed area reduction was from the original candidate siting regions to 12,000 to 14,000 nm<sup>2</sup> of suitable area for a Phase 1 field program. From this suitable area, a <sup>size</sup> selection of 4000 to 6000 nm<sup>2</sup> of system deployment area is to be made. This study delineates approximately 10,000 nm<sup>2</sup> of suit-

able area for Phase 1 field work from the 18,390 nm<sup>2</sup> of available area and also ranks the 68 Valleys comprising this area in order of preference for siting, based on areal, geotechnical, and cultural factors. The actual area reduction schedule is summarized on Table 3. Since the areal values in Table 3 are sums of many smaller numbers and even though the implied accuracy is not required, the number of significant figures has been retained.

\* BLM area had not been subdivided by siting area.

## 1.2 PURPOSE AND SCOPE

This study will consider all BLM and DoD Valley areas discussed in the Volume II Geotechnical Reports (Appendix A). The purposes of this study are to:

1. Delineate, based on established criteria, the boundaries of land suitable for siting of the MX system;
2. Further delineate, based on geologic and engineering judgement, a "smoothed" inner area which would be the most favorable area (suitable area) for Phase 1 field studies; and
3. Evaluate all areas Valley-by-Valley by applying existing data to selected matrix ranking factors, weighting each matrix score, and summing the scores in various ways for each Valley (Section 2.0);
4. Rank all of the BLM and DoD Valleys based on the matrix analysis according to their relative favorability for siting of the MX system considering areal, geotechnical, and cultural factors; and
5. Present an analysis of the ranking including conclusions and recommendations (Section 3.0).

The following ranking factors are categories considered in the matrix analysis (Column letters refer to Table 6):

1. Suitable Valley Area (Column A)
2. Suitable Contiguous Area (Column B)
3. Amount and Quality of Data from Data Summary Sheets:
  - a. Ownership and Control (Column C)
  - b. Geology and Soils Engineering (Column D)

- c. Depth to Rock (Column E)
- d. Depth to Water (Column F)
- e. Surface Hydrology (Column G)
- 4. Favorability of Conditions Based on Existing Data
  - a. Ownership and Control (Column H)
  - b. Geology and Soils Engineering (Column I)
  - c. Depth to Rock (Column J)
  - d. Depth to Water (Column K)
  - e. Surface Hydrology (Column L)
- 5. Potential Impact to Existing BLM or DoD Activities
  - a. Military (Column M)
  - b. Non-Military (Column N)
- 6. Distance from Civilian or Military Support Facilities (Column O)

The above items are based primarily on regional data. The data categories (ranking factors) are compiled from specific data included in the siting and geotechnical reports prepared in the six siting areas and represent geotechnical and cultural elements which can be used to determine siting, deployment, vulnerability, and hardness. However, extensive site specific data will be required before fielding the MX system.

### 1.3 METHODS AND PROCEDURES

The ranking analysis was performed using the four-quad graphics, text, data summary sheets, and appendices from the DoD and BLM Volume II Geotechnical Reports. Two worksheets at a scale of 1:62,500, termed base and derivative worksheets, were produced for each of the 69 four-quad areas. The suitable siting area remaining after application of criteria defining unsuitable area was accurately delineated on the base worksheet. Unsuitable area criteria were developed following discussions with SAMSO and TRW personnel and represent the most current constraints to siting the MX land mobile missile system; these criteria are listed in Section 2.1.2. To construct the base worksheet, overlays from the four-quad graphics depicting ownership and cultural features (DoD; BLM), geology (DoD; BLM), hydrology (DoD; BLM), and topography (DoD) were superimposed and areas not excluded by established criteria were outlined. The borders of the base suitable area were delineated using coded line symbols representing the individual criteria upon which the boundary line was based. A description of the line symbols used is shown in Table 4.

A derivative worksheet was constructed from each base worksheet. This involved "smoothing" of the base suitable area boundaries based on geologic and engineering interpretation relative to which areas would be most favorable for Phase 1 field studies. The derivative suitable area in most cases varied less than five percent from the base suitable area. Principal changes occurred where a sinuous ten percent topographic grade line was

TABLE 4

## Line Symbols for Boundaries of Suitable Area

<u>Line Symbols</u>	<u>Line Description</u>
—————	Ten percent grade.
— · — · — · — · —	100-foot depth to water.
— — — — —	100-foot depth to rock.
— — — — —	National parks or monuments and Indian reservations (E5).
— · · · — · · · — · · · —	Corridors 1780 feet wide on each side of all U. S. highways, state routes and railroads (E4).
— — — — —	Minimum distance from inhabited areas (E1, E2, E3).
-X-X-X-X-X-X-X-	Estimated 100-foot depth to water.

Where two line symbols meet, a perpendicular separation line was drawn (e.g., ————— | — · — · — · — · — | —).

smoothed to eliminate small valley re-entrants and other irregularities along the valley margin. Depth to rock, depth to water, and ownership and culturally controlled boundaries generally were not changed.

A comparison between the suitable area on the base and derivative worksheets for representative four-quad areas is shown in Table 5. All worksheets are on file and available at Fugro National, and are not included with this report.

To facilitate data compilation, Valleys were assigned numbers from one to 68 based on alphabetical groupings of the designated DoD and BLM Valleys in Arizona, Nevada, and New Mexico. These Valley numbers occur on the Valley Analysis Matrix (Table 6,

8

TABLE 5

Comparison of Suitable Areas on Base and Derivative Worksheets

Four-Quad Sheet (Arizona)	Area (nm <sup>2</sup> )		Percent Reduction
	Base Worksheet	Derivative Worksheet	
GB-5	408	406	0.5
GB-6	333	329	1.2
GB-9	193	184	4.7
GB-10	389	356	8.5

Section 2.0) and on all report graphics (Drawings 1, 2, and 3), and should not be mistaken for actual ranking values. In this numbering system, Valleys which cross the DoD/BLM boundary and are contiguous were considered to be separate Valleys in the matrix analysis.

Vekol Valley (Arizona, DoD) and Mohave Wash Valley (Arizona, BLM) were eliminated from ranking consideration since neither contained suitable area after applying the criteria defining unsuitable area. These Valleys were assigned matrix scores of zero for all subsequent ranking factors.

## 2.0 MATRIX ANALYSIS

### 2.1 RANKING FACTORS OF VALLEYS

#### 2.1.1 GENERAL

As presented in Section 1.2 the factors, with their matrix column letter designations, considered in ranking of all Valleys are:

1. Suitable Valley area (Column A);
2. Amount of suitable contiguous area (Column B);
3. Amount and quality of data (Columns C-G);
4. Favorability of data (Columns H-L);
5. Potential impact (Columns M and N); and
6. Distance from civilian or military support facilities (Column O).

Each of the ranking factors is discussed in detail in following sections (2.1.2 through 2.1.7). Matrix scores from zero to ten have been assigned to each of the 15 categories (A through O) for each Valley and are presented in matrix form in Table 6 (Matrix Analysis). Factors have been appropriately weighted to yield the Final Score shown on Table 6.

Valleys are ranked in five ways based on ranking scores presented in the matrix analysis (Table 6). The combined Areal plus Geotechnical Score and the Final Score involve the use of weighting factors since not all categories in the matrix analysis are of equal importance. The ~~various~~ rankings ~~are~~ ~~listed below~~ (capital letters refer to column headings in Table 6) and listings of Valleys in order of numerical rank (W) for each of these ranking scores are included in Appendix D (including Wildlife Ranges) and Appendix E (excluding Wildlife Ranges):

WEIGHTING FACTORS

2.7 2.2 .1 .1 .1 .1 .1 1.0 1.0 .5 .5 .5 .4 .3 .3

WEIGHTING FACTORS

- A = SUITABLE VALLEY AREA
- R = SUITABLE COUNTRY/PLAINS AREA
- C = HUMIDITY AND CLIMATE (AMOUNT AND QUALITY)
- D = SPRING AND RILLS ENGINEERING (AMOUNT AND QUALITY)
- F = DEPTH TO ROCK (AMOUNT AND QUALITY)
- F = DEPTH TO WATER (AMOUNT AND QUALITY)
- G = SURFACE HYDROLOGY (AMOUNT AND QUALITY)
- H = HUMIDITY AND CLIMATE (FAVORABILITY)
- I = GEOLOGY AND SOILS ENGINEERING (FAVORABILITY)
- J = DEPTH TO MUD (FAVORABILITY)
- F = DEPTH TO WATER (FAVORABILITY)
- L = SURFACE HYDROLOGY (FAVORABILITY)
- M = POTENTIAL IMPACT (MILITARY)
- N = POTENTIAL IMPACT (CIVILIAN)
- O = DISTANCE TO SUPPORT FACILITIES (MILITARY AND CIVILIAN)

RANKING SCORES

- P = AREAL RANKING SCORE (A+R)
- O = GEOTECHNICAL RANKING SCORE (O+C+F+I+J+K+L)
- R = CULTURAL RANKING SCORE (C+H+M+N)
- S = AREAL + GEOTECHNICAL SCORE (P+O WITH WEIGHTING)
- T = FINAL SCORE (P+O+R WITH WEIGHTING)

- P. Areal Ranking Score (A + B)
- Q. Geotechnical Ranking Score (D + E + F + G + I + J + K + L)
- R. Cultural Ranking Score (C + H + M + N + O)
- S. Areal plus Geotechnical Score (P + Q with weighting factors)
- T. Final Score (P + Q + R with weighting factors)

The weighted Final Score (T) was determined using the following equation:

$$T = m_A (w_A) + m_B (w_B) + \dots + m_O (w_O)$$

where  $m$  = unweighted matrix score (Table 6)

$w$  = weighting factor (Table 6)

The weighted Areal plus Geotechnical Score (S) was determined in a similar manner with the exclusion of all cultural factors (C, H, M, N, and O).

The numerical ranking scores, including appropriate weighting factors, were determined by computer, allowing a degree of flexibility and versatility when considering various weighting factors (areal, geotechnical, and cultural). Rankings in Appendices D, E, F, and G are copies of computer output. An additional copy of Table 6 is included in Appendix D to allow continuous reference while reviewing the following sections.

Values used for weighting factors (Table 6) were determined through discussions with TRW and SAMSO personnel after performing several iterations using different sets of weighting factors. The values selected indicate the great importance placed on areal

considerations since siting feasibility is fundamentally dependent on whether or not sufficient suitable area is present to deploy the system. Favorability of ownership and surficial geotechnical and soils engineering data are considered important since these ranking factors directly affect the difficulty and cost of land acquisition and construction and maintenance. Other geotechnical factors such as depth to rock, depth to water, and flooding potential are less precisely known and after initial consideration, are of less direct importance in defining the suitable Valley area. Cultural factors such as distance to support facilities and potential impacts are also considered of secondary importance since both can conceivably be mitigated given the potentially large scope of the project. However, it should be remembered that the direct environmental impacts are not considered here and later considerations may require that the weighting factor applied to this category increase significantly. Amount and quality of data are considered the ranking factors least important since neither relate directly to siting considerations, but are principally indicators of the reliability of the cultural and geotechnical data used to derive the applicable matrix scores and to delineate the limits of the suitable area.

#### 2.1.2 SUITABLE AREA

Suitable area or suitable Valley area (Figure 1) is hereafter the "smoothed" area (derivative) remaining after removing those parts of a Valley having:

1. Depth to rock less than 100 feet (including pediments);
2. Depth to water less than 100 feet;

13  
13

- 3. Areas with greater than 10 percent topographic grade;
- 4. Cultural and quantity-distance exclusions:
  - a. Minimum distance of 2965 feet from National Forest, Monument, Indian Reservation, and DoD boundaries;
  - b. Minimum distance of 1965 feet from inhabited buildings;
  - c. Corridors 1780 feet of each side of all traveled public highways and railroads;
  - d. Minimum distance of 18 nm from cities with populations greater than 25,000;
  - e. Minimum distance of 3 nm from cities with populations between 5000 and 25,000; and
  - f. Minimum distance of 2965 feet from populated areas up to 5000.

These areas are shown at a scale of 1:1,000,000 in Drawings 1, 2, and 3. The actual suitable area values for the six siting areas are shown in Table 7. Suitable areas of individual Valleys are given in Appendix B, along with total Valley areas for comparison.

Suitable Valley areas represent reductions in size of the Valleys ranging from approximately 20 percent to 100 percent. This suitable Valley area was converted to a score of zero to ten by multiplying the suitable Valley area by a constant equal to ten times the reciprocal of the largest suitable Valley area (Mohawk-Tule Valley - No. 9) as shown in the following example for Castle Dome (Valley No. 1) in the Arizona Siting Region:

$$126 \text{ nm}^2 \text{ (Castle Dome)} \times 10 \times \frac{1}{521 \text{ nm}^2 \text{ (Mohawk/Tule)}} = 242 \text{ or } 2$$

TABLE 7

Suitable Area (nm<sup>2</sup>) in Siting Areas

	Arizona		Nevada		New Mexico		Total	
	a	b	a	b	a	b	a	b
DoD	2132	1612	1218	937	668	668	4018	3217
BLM	1801	1801	4074	3862	112	112	5987	5776
Total	3933	3413	5292	4799	780	780	10,005	8992

- a. Area including wildlife ranges (Cabeza Prieta, Desert National Wildlife Range, Wild Horse Range, see Figure 3).
- b. Area excluding wildlife ranges.

Matrix scores for this ranking factor appear on Table 6 (Matrix Analysis) in Column A. Valleys receiving a score of zero in this column were also assigned a score of zero in all subsequent columns. The scores for Column A in the Matrix Analysis excluding Wildlife Ranges (Appendix E) were recomputed for the suitable area remaining after excluding Wildlife Areas.

### 2.1.3 AMOUNT OF SUITABLE CONTIGUOUS AREA

Suitable contiguous area is the sum of the suitable area in Valleys which are adjacent and connected by areas of less than ten percent topographic grade to the Valley under consideration. Although the suitable Valley areas are not necessarily contiguous, the Valleys within which they occur are contiguous. Total areas for each Valley (by Valley number) and suitable contiguous Valley areas are tabulated in Appendix B. Matrix scores for suitable contiguous area were assigned in the same manner as for suitable Valley area by multiplying the suitable contiguous area by a constant equal to ten times the reciprocal of the suitable contiguous area of Ranegras Plain - No. 22 (the Valley with the most suitable contiguous area). These scores appear in Column B of Table 6 (Matrix Analysis). An example of such a calculation using Castle Dome, Arizona yields:

$$148 \text{ nm}^2 \text{ (Castle Dome)} \times 10 \times \frac{1}{1446 \text{ nm}^2 \text{ (Ranegras Plain)}} = 1.02 \text{ or } 1$$

The scores for Column B were also recomputed for Appendix E, when applicable.

2.1.4 AMOUNT AND QUALITY OF DATA

Matrix scores shown on Table 6 representing the amount and quality of data were derived from Data Summary Sheets. These scores are based on data for the entire Valley, but are considered to be valid for the suitable Valley areas. Scores from one to ten were assigned to each of the following Data Summary Sheet categories:

- 1. Ownership and Control;
- 2. Geology and Soils Engineering;
- 3. Depth to Rock;
- 4. Depth to Water; and
- 5. Surface Hydrology.

On the Data Summary Sheets an open circle (O) represents insufficient data, whereas half (◐) or full (●) circles represent estimated or known values derived from the available data, respectively. The value denoting the amount and quality of data was based on the percentage of full and half circles to the total number of circles (i.e., the total number of subcategories within each of the five major categories) according to the formula:

$$\text{Raw Score} = \frac{\text{Full Circles} + 1/2 (\text{Half Circles})}{\text{Total Circles}} \times 10$$

The matrix scores in Columns C, D, E, and F were determined by assigning a score of one to ten, based on the rounded value of the raw score. Categories of data on the Data Summary Sheets differed slightly between DoD and BLM reports. All amount

and quality of data tabulations were done by comparing categories in the Volume II reports and only data categories which were common to both DoD and BLM reports were used in order to equate data and to arrive at a valid comparative assessment. No data categories meaningful to the ranking were dropped.

#### 2.1.4.1 Ownership and Control

Sub-categories under Ownership and Control were taken from the Ownership and Cultural Features Data Sheets in Volume II DoD reports, and Ownership, Cultural Features, and Topography Data Sheets in Volume II BLM reports. Quality of data symbols representing area of Valley, area of siting Valley, ownership, cultural improvements (location, type, and use of roads, railroads, and utilities), and area and use of contiguous DoD/BLM or Co-Use land were compiled and considered in the matrix analysis (Table 6, Column C). <sup>Other data such as</sup> ~~Data regarding Valley topographic conditions (BLM Data Sheets)~~, cultural and quantity distance exclusions (DoD Data Sheets), and military/governmental use areas (DoD Data Sheets) were not utilized primarily because the amount and quality of such data did not change from Valley to Valley, or because such data were not included in both DoD and BLM Data Summary Sheets.

#### 2.1.4.2 Geology and Soils Engineering

Geology and Soils Engineering Data Summary Sheets from DoD and BLM reports were used to calculate amount and quality of data scores. Separate values were calculated for geology and for soils engineering which were averaged to yield the final matrix score

(Table 6, Column D). Geology Data Summary Sheet categories denoting conditions of exposed rock (lithology, location, and seismic velocity), pediment (location and extent), basin-fill deposits (type, thickness, seismic velocity, and lithology), and presence of capable or potentially capable faults (length, location, type, attitude, and minimum age of displacement) were considered. Amount and quality of data on Soils Engineering Data Summary Sheets is not depicted through the use of symbols similar to those on all other sheets. Data included on these sheets were evaluated based on a ratio of the number of categories which contained known values derived from the literature to the total number of categories. Categories considered included sieve analyses, Atterberg limits, dry density, permeability, shear strength, shrink-swell potential, compressibility, compression/shear wave velocities, water content, and presence of deleterious substances.

#### 2.1.4.3 Depth to Rock

Data for this category were taken from the Geology Data Summary Sheets. Rock at depths of zero to 250 feet, 250 to 500 feet, and at unknown depths were considered in evaluating the amount and quality of data. A matrix score (Table 6, Column E) was calculated from these data categories, with an additional one point being assigned to Valleys for which at least one Defense Mapping Agency (DMA) gravity profile was available (BLM) or could be produced (DoD).

#### 2.1.4.4 Depth to Water

Data symbols characterizing the depth to groundwater information

were compiled for increments of zero to 25 feet, 25 to 50 feet, 50 to 100 feet, greater than 100 feet, and for non-existent water or water at unknown depths in each Valley. The matrix scores for depth to water appear in Column F on Table 6.

#### 2.1.4.5 Surface Hydrology

Existence of surface water and hydrologic characteristics of stream channels are of importance in evaluating surface hydrologic conditions. In terms of surface water, quality of data symbols representing existing playas (duration, extent, depth, source, and water quality) and existing rivers, streams, and springs (duration, flow rate, water quality) were tabulated. Pertinent hydrologic characteristics of stream channels including depth of incision, width, and gradient as well as channel bottom characteristics and channel spacing data symbols were tabulated. All of the symbols for these categories were considered, as well as the symbols for the preliminary flood susceptibility rating. The results of the tabulations for surface hydrology appear in Column G (Table 6).

#### 2.1.5 FAVORABILITY OF DATA

The same categories considered in quality of data have been tabulated for favorability of data. Data for each were derived from the Volume II Geotechnical Reports, and supplemented by additional area calculations and geotechnical considerations within the suitable Valley areas delineated on derivative worksheets.

#### 2.1.5.1 Ownership and Control

The amount of non-DoD and non-BLM controlled land in each Valley is variable, and large percentages of such land detract from the suitability of the area for siting. A maximum score in this category was assigned to Valleys with 100 percent DoD or BLM ownership or control, with lower rankings being given based on the percentage of non-DoD and non-BLM land. Land ownership data were taken from Volume II Data Summary Sheets and were calculated for the entire Valley area. Since the majority of private ownership is in the suitable areas, these figures are applicable. The ratio of the area of DoD and BLM land to the total suitable siting area was used to derive the matrix score (Table 6, Column H). An example computation using Castle Dome, Arizona is as follows:

$$\frac{126 \text{ nm}^2 \text{ (DoD Land)}}{126 \text{ nm}^2 \text{ (Suitable Area)}} \times 10 = 10$$

#### 2.1.5.2 Geology and Soils Engineering

Ratings in this category (Table 6, Column I) were based on geology and soils engineering data incorporated into the Terrain Analysis and presented in the Volume II Geotechnical Reports. The purpose of these Terrain Analyses was to evaluate various geologic, hydrologic, and soils engineering characteristics of the basin-fill units present in each Valley. The final ratings were ordered qualitatively from very poor (least suitable) to good (most suitable). A very poor rating in the Terrain Analysis indicates a basin-fill unit with an irregular surface (great slope variations and relatively great depths of stream

incision) and unfavorable soils engineering properties (low California Bearing Ratio, non-cohesive soils) such as are found in sand dunes. Playas (favorable slope conditions, unfavorable soils engineering and drainage conditions) and old alluvial fan surfaces (unfavorable slopes, favorable soils engineering and drainage characteristics) received intermediate ratings (poor to fair). Intermediate and young alluvial fans were rated good due to good drainage characteristics, favorable soils conditions, and a lack of significant stream incision. Terrain Analysis ratings were assigned scaling factors according to Table 8.

For purposes of the matrix evaluation, the area of each basin-fill unit in the suitable Valley area was measured; these areas are tabulated in Appendix C. The areas of basin-fill deposits were then multiplied by the designated terrain analysis scaling factor and added to yield a scaled area for each Valley (Appendix C). To derive the matrix score for this ranking factor (Table 6, Column I), the ratio of scaled area to total area was used. Low ratios represent a high percentage of unfavorable basin-fill units, whereas high ratios (high scaled area) represent a predominance of favorable basin-fill material in the area. These ratios were converted to scores of one to ten by multiplying the ratios by ten and rounding to the nearest integer. An example of the computation using Castle Dome, Arizona is as follows:

$$\frac{8 \text{ nm}^2 (0.5) + 93 \text{ nm}^2 (1.0) + 25 \text{ nm}^2 (0.75)}{126} = \frac{116 \text{ (scaled area)}}{126 \text{ (suitable area)}} \times 10 = 9.2 \text{ or } 9$$

TABLE 8

Terrain Analysis Scaling Factors

Basin-Fill Unit (Map Symbol)	Terrain Analysis Rating*	Terrain Analysis Scaling Factor
Undifferentiated (A <sub>Q</sub> )	Fair	0.75
Stream Channel and Flood-plain Deposits (A1)	Poor	0.5
Terrace Deposits (A2)	Fair	0.75
Wind-Blown Deposits (A3)	Very Poor	0.25
Playa Deposits (A4)	Very Poor	0.25
Mantled Playa Deposits (A4 <sub>m</sub> )	Poor	0.5
Oldest Alluvial Fan Deposits (A5 <sub>o</sub> , A5 <sub>t</sub> )	Poor	0.5
Intermediate Alluvial Fan Deposits (A5 <sub>i</sub> , A5 <sub>Q</sub> )	Fair	0.75
Youngest Alluvial Fan Deposits (A5 <sub>y</sub> , A5 <sub>Q</sub> )	Good	1.0
Undifferentiated Alluvial Fan Deposits (A5 <sub>u</sub> )	Fair	0.75

\* See Terrain Analysis Section of Volume II Geotechnical Reports for complete derivation of terrain analysis ratings.

#### 2.1.5.3 Depth to Rock

Depth to rock (or thickness of basin fill) estimates were taken from data included in Volume II Geology Data Summary Sheets and applicable appendices. All pediment and shallow rock areas (rock less than 100 feet deep) were excluded in the delineation of suitable Valley area. It is assumed for purposes of this analysis that a Valley with a large percentage of known shallow rock occurrences (i.e. less than 250 feet) has a relatively shallow depth-to-rock profile. Conversely, relatively great depths to rock near basin margins indicate, in general, thick alluvium or a deep Valley profile. Matrix scores (Table 6, Column J) were computed as one-tenth of the percentage of deep rock. For example, a Valley in which 83 percent was underlain by rock at depths of greater than 250 feet received a score of 8. Scores were cross-checked with available DMA profiles and the generally favorable correlations indicate the validity of the basic assumption.

#### 2.1.5.4 Depth to Water

Valleys were rated on the basis of depth to groundwater in portions of suitable Valley areas remaining after application of the 100-foot depth to groundwater criteria. Known or estimated depths were taken from the Volume II Groundwater Hydrology Data Summary Sheets. Where data did not exist in a particular Valley, regional groundwater conditions were used to extrapolate a probable depth to water. Matrix scores were assigned according to Table 9.

TABLE 9

## Depth to Water

General Depth (feet)	Matrix Score
100-200	1
100-300	2 to 3
100-400	4 to 6
>400	7 to 10

Matrix scores for depth to water ratings appear in Column K on Table 6.

#### 2.1.5.5 Surface Hydrology

Flooding potential is the primary concern related to surface hydrologic conditions that is not accounted for in the terrain analysis. Flooding potential was determined by using the relative percentages of stream channel and floodplain deposits (A1) and playa deposits (A4, A4<sub>m</sub>) in the suitable Valley area.

These basin-fill deposits represent the active parts of the hydrologic system, that is, sediment transport and deposition.

The areas of these deposits (A1, A4, A4<sub>m</sub>) have the greatest likelihood of experiencing flooding in the future. The total area covered by such deposits is shown in Appendix C. Scores equal 10 minus the ratio (x 10) of the area of these flood deposits (A1, A4, A4<sub>m</sub>) to the total suitable Valley area.

Valleys such as Cave or Jakes Valley (Nevada BLM) which do not contain large amounts of suitable area (75 and 106 nm<sup>2</sup> respectively) and of which half or more is either stream channel or playa deposits received low scores (< 5). Large Valleys lacking playas, such as Ranegras Plain (Arizona DoD), scored high

(9-10) since generally less than ten percent of the suitable area was covered by stream channel and floodplain deposits. An example computation for Castle Dome, Arizona is as follows:

$$10 - \frac{8 \text{ nm}^2 \text{ (Al deposits)} \times 10}{126 \text{ nm}^2 \text{ (suitable area)}} = 9.4 \text{ or } 9$$

Results of the analysis of surface hydrology appear in Column L on Table 6.

#### 2.1.6 POTENTIAL IMPACT ON EXISTING BLM OR DOD ACTIVITIES

This ranking factor analyzes the potential impact of a land based MX system upon existing Valley activities. Two subcategories are considered: 1) present military use (Table 6, Column M), and 2) present non-military use (Table 6, Column N). Military activities are present to some degree in all DoD Valleys and in a limited number of BLM Valleys. Non-military use includes public recreation, wildlife protection areas, grazing land, and private agricultural and residential land. If the MX system can co-exist with present Valley activities with only slight modifications or adjustments, a rating of zero or low has been assigned. Impacts resulting in shifting military activities or in severe effects on the Valley's present use and purpose will result in a moderate to high rating. Table 10 defines impact ratings and shows the assigned score for each.

These scores will only reflect environmental conditions as they relate to established, officially designated land areas. The matrix analysis does not specifically address environmental factors since all such impacts to siting of an MX system in a Valley are not available. This analysis is concerned only with

TABLE 10

## Potential Impact

<u>Military</u>	<u>Non-Military</u>
High (1 to 3) - Relocation of permanent testing facilities would be required. Decontamination of extensive areas required prior to field investigation and construction. Conditions present in greater than 75 percent of Valley.	High (1 to 3) - Area with conflicting public land use. These conditions present in greater than 75 percent of Valley.
Moderate (4 to 6) - MX system could co-exist with present activities. Decontamination restricted to target areas. Activities in 25 to 75 percent of Valley.	Moderate (4 to 6) - High short-term impact, but MX system could co-exist. Affects 25 to 75 percent of Valley.
Low (7 to 9) - Decontamination or moving present activities required in less than 25 percent of Valley. Low level of military activity.	Low (7 to 9) - Less than 25 percent of Valley affected by conflicting land use. Includes leased land.
None (10) - No military activity. Includes most BLM land.	None (10) - No impact presently known.

considerations for siting an MX system in a Valley and the gross or immediate impacts.

In the Matrix Analysis excluding Wildlife Ranges (Appendix E), the potential impact scores were re-evaluated. Although this alone tended to raise scores, the effect of the loss of suitable area with a higher weighting factor, over-shadowed potential impact, thereby resulting in a lower Final Score for Valleys which include Wildlife Ranges.

2.1.7 DISTANCE FROM CIVILIAN OR  
MILITARY SUPPORT FACILITIES

Facilities to support activities during investigation, construction, and operation of the MX system will be required and sites with such facilities both accessible and nearby will be more favorable than sites that are isolated and accessible only with difficulty. For this matrix score, existing civilian and military population centers were rated according to their support potential. A rating of one was assigned to facilities capable of lending support during field investigations. These facilities must contain at least one motel, one restaurant, and one service station. A rating of two was given to facilities capable of lending support during investigation, construction, and operation of the system. Such facilities must contain some construction-related businesses (sand and gravel operations, heavy equipment, ready-mix or concrete contractors, etc.) as well as support for personnel. The ratings of the various existing support facilities (Table 11) were derived from direct field experience of Fugro National personnel.

The distance factor was applied according to Table 12. All distances are straight-line measurements from support facilities to the approximate geographical center of the siting Valley. To determine the score in Column O (Table 6), distance factors were multiplied by the support facility rating factor, yielding values from one to ten for each Valley for each support facility as shown in the following example for Castle Dome, Arizona.

2 (facility rating) x 5 (distance factor) = 10

The highest value was chosen and entered in the matrix ranking. The uniformly high values for New Mexico and Arizona reflect the relative abundance of support facilities and the small area covered by siting Valleys. Remote Valleys and the lack of population centers generally makes this factor lower in Nevada, where ratings of six or below indicate very remote locations.

TABLE 11

75 - 100	2
> 100	1

2.1.8 RESULTS OF MATRIX ANALYSIS

It can readily be seen from the final scores (Table 4, Column T) that no Valley is completely favorable from all aspects. Weighting factors were selected to yield a total possible final score of 100, but the highest score attained was 79.5 (Mohawk-Tule Valley, No. 9). Sixty-three percent of final ranking scores clustered within ten points either side of the 50 percent mark, with an equal number of ranking scores above and below 50 percent (Table 13).

TABLE 13

## Distribution of Final Scores (T)

Final Scores (T)	Number of Valleys	DoD/ BLM	Percentage of Valleys
<30	2	1/1	3
30-40	6	4/2	9
40-50	26	19/7	38
<50%			
>50%			
50-60	17	5/12	25
60-70	14	4/10	21
>70	3	2/3	4

SECRET

The high degree of correlation between areal ranking scores (Table 6, Column P) and final scores (Column T) reflects the choice of weighting factors. High final scores generally reflect large amounts of suitable Valley area and suitable contiguous Valley area. Of the top twenty Valleys based on final score, 18 correlate directly with the highest areal ranking. Other ranking factors included in the matrix analysis became important in differentiating Valleys of roughly equivalent suitable Valley area and suitable contiguous area. Collectively, the Valleys of the Gila Bend Group (Arizona BLM) generally rank highest with more than 80 percent of the Valleys ranking above 50 percent (Table 9). The Nellis Group Valleys (Nevada BLM) also rank high with nearly 70 percent above 50 percent. Final scores for DoD Valleys in Arizona, Nevada, and New Mexico fall at or below 50 percent due to the relatively small amounts of suitable area.

Rankings in Table 6 do not reflect exclusions of existing wildlife ranges and proposed wilderness areas in Arizona (Cabeza Prieta) and Nevada (Desert National Wildlife Range and Wild Horse Range). If such areas are excluded, the Valley ranking changes significantly (Appendix E). Although nearly the same Valleys remained in the top twenty and distribution relative to 50 percent remained roughly the same, Arizona DoD Valleys moved down considerably in the ranking due to removal of the Cabeza Prieta. Suitable Valley area (Column A) and suitable contiguous areas (Column B) in Valleys peripheral to the wildlife ranges change, and conditions of ownership and control

TABLE 14

Distribution of Final Scores (T) in Each Siting Region

Final Score (T)	Number (%) of Valleys					
	Arizona		Nevada		New Mexico	
	DoD	BLM	DoD	BLM	DoD	BLM
<30	1(7)	1(18)	0	0	0	0
30-40	0	0	2(17)	2(7)	1(16)	1(100)
40-50	6(43)	0	9(75)	7(26)	4(67)	0
<50%	<hr/>					
>50%	<hr/>					
50-60	4(29)	4(50)	1(8)	8(30)	0	0
60-70	1(7)	2(25)	0	10(37)	1(17)	0
>70	<u>2(14)</u>	<u>1(13)</u>	<u>0</u>	<u>0</u>	<u>0</u>	<u>0</u>
Total	14(100)	8(100)	12(100)	27(100)	6(100)	1(100)

(Column H) and potential impact (Column N) generally become more favorable in Valleys whose suitable area was reduced by exclusion of wildlife ranges. There is little or no effect in the remaining ranking factors and therefore no changes in these matrix scores were made.

Four additional iterations of the matrix analysis were run for the BLM Valleys and DoD Valleys as separate groups. The four iterations include (Appendix F and G):

- 1) DoD Valleys (including Wildlife Areas)
- 2) DoD Valleys (excluding Wildlife Areas)
- 3) BLM Valleys (including Wildlife Areas)
- 4) BLM Valleys (excluding Wildlife Areas).

The only major change represented by these iterations is the exclusion of suitable BLM land contiguous to suitable DoD land

and vice versa. The purpose is to consider BLM and DoD land separately and rank valleys only in relation to other BLM and DoD lands respectively. In nearly all cases elimination of contiguous suitable areas not controlled by the particular agency (DoD or BLM) did not significantly change the ranking. Only Cactus Flat (24), Emigrant (25), and Kawich (29) Valleys lost significant amounts of suitable contiguous area and dropped in the ranking. Thus, ranking scores in Appendices F and G do not differ greatly from those on other matrix and ranking iterations. These were run principally as a useful aid in visualizing the relative rankings in the event that either BLM or DoD land in any particular siting area became less desirable or became excluded at some point.

Additional columns were added to the tables of rankings (Appendix D, E, F, and G) to indicate suitable Valley area (Column U), suitable area excluding wildlife or wilderness areas (Column V) and numerical rank (Column W). These columns were provided to facilitate visualization and tabulation of total suitable Valley areas based on various composite groupings of Valleys and inclusion or omission of wildlife areas.

## 2.2 REGIONAL ANALYSIS

### 2.2.1 GENERAL

Several factors of importance to the siting, construction and maintenance of an MX system were not directly considered in the matrix analysis due to their regional significance and limited applicability to a Valley-by-Valley analysis. These geotechnical factors are mode and occurrence of caliche, distribution of sand dunes and playas, grain size distribution of the basin fill, relative levels of seismicity, and potential for surface rupture and related phenomena associated with faulting. These items are discussed here since they could not be readily incorporated into the matrix because of the general lack of Valley specific information or because the unpredictable nature of occurrence of these factors in the suitable areas did not allow Valley comparative analyses.

Environmental considerations are only superficially addressed in the matrix analysis since the data base for applicable environmental factors is insufficient at this time to allow for reasonable Valley analyses. Regional environmental considerations such as inclusions of Valleys into wilderness and other environmentally sensitive areas are addressed in Appendices E, F, and G, principally as reduced suitable area. Further discussions of the potential or probability for withdrawal of lands to wilderness or other protective stature are discussed in Section 2.2.6.

### 2.2.2 CALICHE, SAND DUNES, AND PLAYAS

Caliche is a cementing agent generally occurring near the surface in basin-fill deposits. The presence of caliche cannot be predicted with a high degree of confidence since it is a subsurface phenomena and can be directly observed only in drill holes, open excavations, stream cuts, or stripped areas where upper soil layers have been removed. Factors affecting the degree of caliche cementation and limit and extent of its occurrence in each basin-fill unit include: 1) the composition of rock types in the source area; 2) land surface morphology and runoff characteristics; and 3) a variety of environmental factors including temperature variations, amounts and intensity of rainfall, and wind.

A Valley-by-Valley comparison relating occurrence and degree of caliche cementation could not be accomplished at this time because of the great number of variables that exist for predicting caliche occurrence and because of the relatively small data base noting specific examples. However, since caliche is an important consideration for both construction and nuclear weapons effects of a deployed MX system, some general statements can be made regarding caliche occurrence in all suitable siting areas.

These are:

1. Caliche is present in diffuse or massive forms, or both, in all but the most geologically recent basin-fill deposits. It is most likely to be well-developed in the older (A5o) and intermediate (A5i) alluvial fan deposits, and stream terrace (A2) deposits. It will

36  
L 100

be less prominent in the younger alluvial fans and bajadas (A5y). Caliche is not expected to be significant in recent deposits of stream channels (A1), sand dunes (A3), lake terraces (A2), or playas (A4).

2. The most likely areas for caliche occurrence are those deposits in the suitable Valley areas that are immediately adjacent to the mountain front or near large rock outcroppings. It should be noted that the 100-foot depth to rock exclusion criteria eliminated many of the basin-fill deposits having the highest likelihood of caliche occurrence (i.e., pediment deposits-A6; older alluvial fans-A5o) and probably significantly decreased areas in the subsurface having a high likelihood of deeply buried older calichified basin fill (i.e., fanglomerates).

Valleys in the eastern portion of LBGR, all Valleys in the Gila Bend Group, and Valleys in WSMR have a higher likelihood for occurrence of well-developed caliche than Valleys in the remaining siting areas. This does not indicate a lack of caliche in these other areas, but rather indicates that the caliche present is probably less well-developed.

The presence of large areas covered by playas or sand dunes was considered in the matrix analysis under favorability of geologic conditions but was not considered an exclusion to siting. However, since this category was assigned a small weighting factor (1.0) in the matrix analysis, and since it is possible that

DRAFT

these less favorable conditions could not be given appropriate consideration, the presence of playas or sand dunes merit further discussion.

Playas are common in the suitable Valley areas of NBGR and WSMR and are particularly significant in many Nellis Group Valleys (Drawings 1 and 3). Playas are small and rare in YPG/LBGR, Gila Bend Group Valleys and the White Sands Missile Range Extension area (Drawings 1 and 2). Table 15 lists the total amount of suitable Valley area and percent of the total suitable area that is covered by playa and sand deposits in each of the six siting areas. These data show that the total suitable area in general decreases only slightly in most siting areas if playas are considered unsuitable siting area. However, as much as a 15 percent decrease occurs in the NBGR siting area. The impact on a relative Valley ranking could be significant, particularly with regard to Stonewall Flat and Jakes Valley where playas compose greater than 25 percent of the total suitable Valley area. Sand dune areas have less total impact (Table 15). If sand dunes are to be considered unsuitable areas at some future time, three Valleys could be significantly affected. Tularosa Basin South (New Mexico DoD) and Mohawk-Tule Valley (Arizona DoD) each have more than 30 nm<sup>2</sup> of sand dunes and nearly 65 percent of Cactus Plain (Arizona DoD) is covered by sand dunes.

### 2.2.3 GRAIN-SIZE DISTRIBUTION

Grain size distribution of the basin fill is only indirectly considered in the matrix analysis. Significant accumulations of very coarse- or very fine-grained basin fill could affect

38  
 DRAFT

Table 15  
 Percent of Sand Dune and Playa Deposits

Siting Area	Suitable Area (nm <sup>2</sup> )	Area Covered By (nm <sup>2</sup> )		% Area Covered By	
		Playa	Sand Dunes	Playa	Sand Dunes
YPG/LBGR	2132	1	176	0	8
Gila Bend Group	1801	0	40	0	2
NBGR	1218	186	2	15	0
Nellis Group	4074	215	40	5	1
WSMR/FBMR	668	17	38	3	6
WSMR Extension	112	0	8	0	7

DRAFT

construction and the hardness of the deployed system. Since accurate ratios of coarse- to fine-grained units could not be calculated for the basin fill in individual Valleys, only general statements can be made. Grain sizes of basin-fill deposits within the suitable portions of the Valleys will be highly variable depending upon a multitude of geologic, geomorphic, topographic and climatic conditions in individual Valleys. In most instances, the larger grain sizes occur near the mountain front as part of talus accumulations or the apex portions of alluvial fans. These deposits have been excluded or significantly decreased in the suitable Valley area by the 100-foot depth to rock contour. This contour was plotted approximately 1000 to 2500 feet basinward of the mountain front or rock/pediment occurrences. Large accumulations of fine-grained deposits are not common in the Arizona siting region but are quite numerous in the Nevada and New Mexico siting region due to the presence of significant playa deposits.

#### 2.2.4 SURFACE FAULTING

Capable or potentially capable faults are those which may cause ground rupture and surface displacement. Although capable or potentially capable faults were not identified as excluding criteria for determining suitable area, they could become important when considering the vulnerability of a deployed system. Displacements of a few to tens of feet can occur along a capable fault. In addition, movement of small to large blocks in the vicinity of the fault can also occur,

DRAFT<sup>40</sup>

causing differential movement, cracking and slumping of the ground surface jeopardizing the stability and the hardness of structures built upon or across such features. Numerous such faults occur within the Nellis Group siting area and NBGR. Fewer faults are present in YPG/LBGR and WSMR/FBMR and no significant occurrences are known in the Gila Bend Group or White Sands Extension study area.

#### 2.2.5 SEISMICITY

Seismicity and ground shaking are of lesser importance since the design specifications of the system more than likely will compensate for projected levels of seismicity. All siting areas lie close to potential sources of earthquakes. Low levels of seismicity (infrequent occurrences of earthquakes greater than  $M = 4.0$  on the Richter Scale) characterize WSMR/FBMR, eastern LBGR, eastern NBGR, all of the Gila Bend Group and southern and eastern parts of the Nellis Group. Moderate to high levels of seismicity prevail in western YPG/LBGR, central NBGR, and central and northern portions of the Nellis Group. No significant zones of seismicity affect the White Sands Extension area.

#### 2.2.6 PROPOSED WILDERNESS AREAS AND OTHER ENVIRONMENTALLY SENSITIVE AREAS

Both the Cabeza Prieta Game Range, Arizona, and the Desert National Wildlife area, Nevada, have had Final Environmental Statements submitted evaluating these areas for wilderness withdrawal. An extension of 79,000 acres to the Cabeza Prieta to the west is presently under consideration. If approved,

DRAFT

this extension would also be included in the proposed Cabeza Prieta Wilderness area. Since these areas may contain minerals vital to the national interest, the President of the United States deferred action (as of June 1974) on granting wilderness status to these areas until an adequate mineral survey has been completed. If the Cabeza Prieta and Desert National Wildlife area are approved for incorporation into the National Wilderness Preservation System, it is likely that a joint-use status with an MX land mobile system would be difficult and probably impossible. An area that is environmentally sensitive, but which is not a proposed inclusion into the National Wilderness Preservation system is the Nevada Wild Horse Range. It is presently entirely within the NBGR on public land under Air Force control. The wild horses are protected by the Free-Roaming Horse and Burro Act of 1971, and probably could not co-exist with the MX system, particularly during construction phases. It is for these reasons that dual rankings (including and excluding areas within these proposed wilderness and environmentally sensitive areas) were performed in the matrix analysis. However, as of the date of this report, the Cabeza Prieta, Nevada Wild Horse Range, and the Desert National Wildlife Refuge are not recognized exclusions. Valleys potentially affected by these areas and total suitable area are shown in Table 16.

DESERT  
DESERT

TABLE 16

Valleys Potentially Affected by Proposed  
Wilderness and Environmentally Sensitive Areas

Environmentally Sensitive Area	Affected Valley	Suitable Area (nm <sup>2</sup> )	Suitable Area (nm <sup>2</sup> ) Excluding Sensitive Areas
Cabeza Prieta* (Arizona)	3. Growler/Childs (DoD)	413	220
	7. Lechuguilla (DoD)	172	140
	9. Mohawk/Tule (DoD)	521	271
	11. San Cristobal (DoD)	275	230
Desert National Wildlife Area (Nevada)	25. Emigrant (DoD)	191	135
	26. Frenchman Flat (DoD)	62	35
	33. Tikaboo (DoD)	70	29
	40. Coyote Spring/ Kane Spring (BLM)	276	209
	45. Indian Spring (BLM)	52	11
	59. Three Lakes (BLM)	19	0
Nevada Wild Horse Range	60. Tikaboo (BLM)	229	144
	24. Cactus Flat (DoD)	201	188
	27. Gold Flat (DoD)	108	132
	29. Kawich (DoD)	113	0

\* The proposed extension would also affect a small portion of Yuma Desert (Valley No. 14).

DRAFT

### 3.0 CONCLUSIONS AND RECOMMENDATIONS

#### 3.1 CONCLUSIONS

Over 70 percent of all Arizona BLM, Arizona DoD, and Nevada BLM Valleys have final scores in the upper 50 percent of all Valleys (Matrix Analysis, Table 6). Nevada DoD and New Mexico BLM and DoD Valley Final Scores are predominantly in the lower 50 percent.

Seventy-four percent (7423 nm<sup>2</sup>) of all suitable Valley area is in the upper 50 percent; of this total, 30 percent (2248 nm<sup>2</sup>) is DoD land, most of which 76 percent (1715 nm<sup>2</sup>) is in Arizona. Eighty-eight percent of this Arizona DoD land is present in LBGR.

If the proposed areas within the Cabeza Prieta and Desert National Wildlife Ranges are incorporated into the Wilderness Preservation system (Section 2.2.6, Table 12), then 29 percent (520 nm<sup>2</sup>) of the suitable area in LBGR, five percent (212 nm<sup>2</sup>) in the Nellis Group, and ten percent (124 nm<sup>2</sup>) of the NBGR would be affected. Although the Nevada Wild Horse Range (Nevada DoD) is not eligible for wilderness status, the area has been informally designated as a protected range for the wild horses. This protective status could be incompatible with MX deployment schemes. Exclusion of the Wild Horse Range would result in a further 13 percent reduction (162 nm<sup>2</sup>) of suitable area in NBGR.

Exclusion of Wildlife Ranges does not affect the Final Score ranking of any BLM Valleys (Appendix G). It does, however,

44

affect the ranking of individual DoD Valleys (Appendix F). However, none of the final scores change sufficiently to move a Valley from the upper 50 percent to the lower 50 percent.

When DoD Lands (Appendix F) and BLM Lands (Appendix G) are ranked separately, additional conclusions can be drawn.

Arizona DoD Valleys within LBGR score highest in the ranking, with Final Scores in the upper 50 percent for all Valleys in the group. YPG and NBGR rank about evenly with scores ranging from the upper 25 percent to the lower 25 percent.

In the BLM rankings the Arizona BLM Valleys generally score higher than the Nevada BLM Valleys, with all Arizona Valleys except La Posa Plain (18) and Cactus Plain (16) ranking in the upper 50 percent on the Final Score rankings. Eleven Nevada Valley Final Scores fall in the upper 50 percent, 16 fall in the lower 50 percent.

Playa areas (see Drawings 1, 2, and 3) have not been excluded from the suitable area totals in this report. Suitable areas containing playas have, however, received lower scores because of the presence of playas. If playa or sand areas are excluded from consideration, suitable areas will be reduced accordingly.

Additional iterations of the Matrix Analysis using different sets of weighting factors have been produced, but are not included with this report. When weighting factors are changed, the rankings are, of course, changed accordingly. For example,

45  
SECRET

to place more emphasis on ownership in BLM areas, the weighting factor for Column H was increased from 1.0 to 3.0 and the weighting factors for Columns A and B were each reduced by 1.0. Using these weighting factors, the BLM Valleys in Arizona were effected the most with Harquahala Plain (17) dropping in numerical rank (w) from 6th to 40th, McMullen (19) dropping from 18th to 50th, Palomas/Hyder (21) from 9th to 25th and Ranegras Plain (22) from 3rd to 18th. BLM Valleys in Nevada were also effected, but not to this degree. Tikaboo Valley (60) dropped from 31st to 51st, Monitor (49) from 34th to 47th, Emigrant (25) from 35th to 51st, and Coyote Spring/Kane Spring (40) from 41st to 59th. Other Arizona and Nevada BLM Valleys had drops of smaller magnitude, while some had a slight increase in rank.

In general, the DoD Valleys rose in numerical rank, although Valleys such as Cactus Flat (24) and Yucca Flat (34) dropped significantly in numerical rank, due to conflicting non-BLM, non-DoD federal control of Valleys within NBGR.

3.2 RECOMMENDATIONS

The New Mexico siting region has less total suitable area (780 nm<sup>2</sup>) than necessary for deployment of one wing (1500 nm<sup>2</sup>, assumed). For this reason, it should be eliminated from present consideration as a viable siting area (region).

Suitable Valley areas presently included within the Cabeza Prieta Game Refuge, Desert National Wildlife Range and Nevada Wild Horse Range should be eliminated from present considerations for siting. The boundaries of these Wildlife Ranges are shown on Figure 3.

Valleys with considerable playa and sand dune deposits should be considered low priority suitable area and should be incorporated only if additional area is needed. Playa areas are indicated on Drawings 1, 2, and 3.

The Arizona and Nevada siting regions are recommended for Phase 1 and 2 studies. Table 17 summarizes the areas considering DoD Lands only, BLM Land only, and combined DoD/BLM Lands.

TABLE 17  
Preferred Ranking of Siting Areas  
for Phase 1 and 2 Geotechnical Studies

<u>DoD Only</u>	<u>BLM Only</u>	<u>Combined DoD/BLM</u>
LBGR (1)	Nellis Group (1)	Gila Bend Group and YPG (2)
NBGR (2)	Gila Bend Group (2)	Nellis Group and NBGR (3)

Individual core Valleys within each of these rankings should be selected with additional land added to make up the area for the necessary deployment scheme. Valleys which score in the upper ten percent are considered to be prime candidates for core Valleys.
