1. OVERVIEW

This annual report describes the work performed during the first year of a two-year effort. The overall goal of the project is to develop improved techniques for acoustic-phonetic recognition, with eventual application to automatic speech understanding.

Earlier this work on subject has vielded phonetic recognition rates of 60-70%. We estimate that a minimum recognition rate of 80% is needed for a high-performance speech understanding system. We believe that the information needed to achieve the higher recognition accuracy is available in the speech signal. This research is directed towards discovering as many context-sensitive acoustic-phonetic rules as possible to improve the recognition performance.

This first year of research was devoted to three major activities: Speech database generation, computer tool building, and development of acoustic-phonetic rules. Specifically, the following tasks were performed:

- 1. Designed, recorded, digitized and processed a database of speech.
- 2. Converted and extended several large utility programs that had run on the PDP10 to run on the VAX 11/780.
- 3. Implemented spectrogram display programs for the Benson Varian printer and the BBN BitGraph display terminal.
- 4. Examined a selected number of spectrograms and catalogued acoustic-phonetic rules.
- 5. Initiated the development of a set of context-dependent acoustic-phonetic features to distinguish among phonemes with greater accuracy.

ſ

In the following sections, we describe each of these tasks in greater detail.

To aid in our acoustic-phonetic work, a real-time spectrograph display was purchased from Spectraphonics. The real-time spectrograph has been useful in looking at spectrograms and discovering certain acoustic-phonetic properties.

2. DATABASE

2

. .

.

...

To enable us to discover rules for phonetic recognition that are applicable to a wide range of phonetic environments, we designed a large database of sentences. The initial database consists of 110 different sentences. Phonetic transcriptions of the sentences were analyzed statistically to ensure that they represented aphonetic balance similar to that in fluent everyday speech. Appendix 1 contains a list of the 110 sentences. It also indicates the word count and phoneme counts used in the phonetic analysis. Each sentence was recorded by four male speakers. The digitized speech waveforms were then analyzed using our Primary Speech Analysis (PSA) program, which had been converted to run on the VAX computer. The output of the PSA program is a large set of acoustic parameters such as the energy different frequency bands, zero-crossing count, formant in frequencies, etc., for each 10 ms frame. These parameters will be used by the Acoustic-Phonetic Recognition (APR) program that will be developed under this project.

We have just begun to align the phonetic transcription of each of the sentences with the parameters. This will allow us to use the Acoustic-Phonetic Experiment Facility (APEF) to discover more rules and features by looking at all occurrences of any phonetic sequence within the database.

To augment our new database, we have also transferred the phonetically transcribed database that had been used in the ARPA Speech Understanding Research (SUR) Project to the VAX.

3. UTILITY PROGRAMS CONVERTED

Our move from the PDP-10 computer to the VAX-11/780 has necessitated the conversion of all of our utility programs that had been developed over the past several years. The move to the VAX computer was necessary as the VAX system provides both realtime processing capabilities (with the aid of the FPS-AP120B and the DEC LPA-11K systems) and interactive computing on a computer with a large virtual address space. Both of these capabilities are necessary for the efficient performance of our research.

Below we describe the programs that have been transferred (and rewritten when necessary).

3.1 Library

We have, over the years, developed an extensive subroutine library with routines that perform a wide variety of signal processing functions, string manipulation functions, user interaction functions, etc. As a first step to developing programs on the VAX computer, we transferred or rewrote all of the generally useful subroutines in our user library. Appendix 2 contains a list of the routines in the library, with a short description for each.

To make the library more useful, we used the on-line documentation facility provided by the VAX VMS operating system, together with a tree structured documentation file.

.....

Report No. 5239

3.2 RTIME

•

(1

L

This program, which had resided on our PDP-11/40 system and was converted to run on the VAX, is used for real-time signal acquisition and playback, waveform editing, and spectral display. Although the original PDP-11 program and the new VAX program are both in FORTRAN, the program had to be almost completely rewritten due to the differences in I/O, real-time systems, FPS software package, and operating system facilities. The program was also modified to enable recording of large databases with improved user-machine interaction and automatic editing of silences.

One important type of speech database is characterized by large numbers of individual sentences. Extracting these from a previously recorded audio tape is a time consuming and laborious task. Consequently, we implemented a semi-automatic sentence acquisition capability into the RTIME program. In the most commonly used mode of operation, the program is given a list of file names for the output. The program then prompts the user with the name of the file and waits for a carriage return. The speaker types the carriage return, and whenever ready, speaks the sentence. The program automatically detects the beginning and end of speech, plays back the edited waveform, and asks for verification. If verified, it writes out the file and goes on to the next sentence. Otherwise, it allows many other operations such as playing the file again, recording it again, or allowing the user to override the end points chosen by the program.

Report No. 5239

3.3 PSA

P

D

D

The Primary Speech Analysis (PSA) program performs a wide variety of functions. First, it accepts as input a digitized speech waveform, and analyzes it to produce a large set (50) of acoustic parameters. The parameters computed include several energy parameters derived from the LPC spectrum, the formant frequencies (also derived by algorithm from the narrow-bandwidth LPC poles), and other useful parameters such as the z p-crossing count and spectral center of mass. The speech parameters and manual transcriptions produced by this program are the used by the APEF and phonetic recognition programs (described for the speech parameters by the approximation of the several described for the speech parameters by the approximation programs (described for the speech parameters by

The program is capable of displaying the most commonly used parameters using the IMLAC display computer. It also displays a section of the speech waveform and the LPC power spectrum at a time indicated by a cursor. By allowing the simultaneous display of all the available information, the program allows a user to develop intuitions for distinguishing among phonemes. The program is also used for the interactive manual transcription of speech material.

Since PSA consists largely of I/O functions and interactions with the IMLAC display computer, the program had to be completely rewritten. The program had evolved over a period of 10 years, and this was a good opportunity to restructure the many functions in a well-organized manner. The new program was written in FORTRAN-77, which is a block structured language, making this redesign straightforward.

Report No. 5239

3.4 APEF

The Acoustic-Phonetic Experiment Facility (APEF) is a highly interactive system that allows a speech researcher to perform a wide variety of experiments on a large database of continuous speech [1]. This system, which has been used extensively during our previous phonetic research, is essential to the development of a large set of acoustic-phonetic features and rules for recognizing the different phonemes of English.

APEF was written in BCPL on the PDP-10, so it had to be translated to a language that exists on the VAX. Several languages were considered for this translation, including PASCAL, PRAXIS, a subset of ADA, FORTRAN-77, and C. C was chosen since it is, by far, the language that is most similar to BCPL. C has recently become available on VAX VMS systems, and is compatible with all other VMS languages. The translation of 12,000 lines of BCPL code into 15,000 lines of C code has been completed. At present, some of this very large program has been debugged and is operating correctly. However, there are still several essential modules that have not been debugged as yet. This debugging process should be completed during the coming year.

Since this program will be used so extensively in the research under this project, we present below a brief description of its capabilities. The primary use of the program is to examine many occurrences of some set of phonetic phenomena extracted from a large database of continuous speech, and then to

ľ

D

D

examine this data statistically, and develop algorithms for phonetic recognition without the need to incorporate these algorithms in a complete phonetic recognition program. The user first specifies a phonetic context of interest. For example, he might be interested in distinguishing among the unvoiced plosives when followed by vowels or glides. The phonetic context is specified in terms of a sequence of segment descriptions. These descriptions can be given in terms of phonemes, classes of phonemes, or boolean combinations of classes. The program also allows the user to specify the context in terms of the presence or absence of word boundaries, syllable boundaries, different vowel stress levels, or particular words. It also allows for the designation of some of the segments being optional.

Once the phonetic context has been specified, the user enters a procedure that will compute several acoustic-phonetic features. The procedure is given in terms of a list of highlevel routines. The routines include a wide variety (52) of functions for examining acoustic parameters (e.g., average, maximum, minimum, standard deviation, etc.), arithmetic functions (e.g., sum, difference, product, quotient, abs, max, min, etc.), boolean functions (e.g., and, not, or), loops, branches, tests, display functions, and computation of new acoustic parameters from the raw power spectrum.

The user then instructs the program to search the database for occurrences of the specified context. For each occurrence

T

L

found, the procedure is run to compute the desired features. Then, the user is given a variety of ways of examining the data gathered. The program is capable of producing various statistical displays on the IMLAC display processor, giving statistical information for a *pecified feature, and performing pattern recognition experiments on the gathered data to attempt to distinguish among the different phonemes using the features gathered.

The end result is that an initial experiment can be performed in just a few minutes, and easily modified, making it possible to fully investigate a particular phonetic recognition problem in a few hours.

3.5 IMLAC Display Interface

The IMLAC display interfaces that had been developed on the PDP10 were reworked so that the VAX could communicate with the IMLAC in the same ways as the PDP10. This conversion included the special purpose IMLAC programs used by RTIME (SPECI2), which supports the scrolled waveform display and two spectrum displays. The PSA program also uses a special purpose IMLAC display program (PSAI), which allows the simultaneous display of 14 speech parameters, a power spectrum, and a section of a speech waveform. It also includes several 2-way interactions between the host computer and the IMLAC computer, controlled by various knobs and switches connected to the IMLAC. Finally, we brought up the

L

١

general purpose display package, IMSYS, that is used by APEF and other programs.

4. DISPLAY PROGRAMS

We have developed several display programs for the VAX computer. These display programs fall into two categories:

1. Spectrogram Displays

2. Speech Parameter Displays

We have developed a spectrogram display program that produces a hardcopy display of a spectrogram on the Benson Varian printer, which is connected to the VAX computer. This program uses the FPS for the signal processing and image processing necessary to produce a pleasing visual display. We have also developed a version of the program that produces a spectrogram on the BBN BitGraph terminal. These interactive programs are intended to complement the capabilities of the Spectraphonics Real-Time Spectrograph. In particular, the new programs also allow the display of several acoustic parameters adjacent to the spectrogram, on the same time scale, using the PARPLOT program

The PARPLOT program was developed to make hardcopy displays of the speech parameters (computed by PSA) on the Benson Varian printer. These parameter displays are scaled such that they are compatible with the spectrogram displays. The program allows the user to specify, in an interactive way, which parameters are to be plotted, and with what scales. These hardcopy plots will be used to help design the acoustic-phonetic recognition algorithms.

5. ACOUSTIC-PHONETIC RULES/FEATURES

One of the primary research tasks performed this year was to develop context-dependent acoustic-phonetic rules for distinguishing among phonemes with greater accuracy than previously possible. For each class of phonemes, we began by examining spectrograms of those phonemes in different contexts. The Spectraphonics was particularly useful for this process, since it allowed us to generate spectrograms for a phoneme in many contexts with a minimum of effort. An important source of ideas for useful features was obtained from our interactions with the research group at MIT. When an idea was mentioned, we were able to verify it quickly, using the spectraphonics. Most often, the rules developed from looking at spectrograms are qualitative in nature, and are also based on a very small number of samples. Therefore, we then used APEF to develop specific quantitative rules and tested them on a large database.

While the VAX version of APEF is being translated and debugged, we have been using the PDP-10 version of the program with our old database of labeled speech to continue to find rules and features that are useful for acoustic-phonetic recognition. The rules that we are developing are of the type that would be appropriate for addition to the Acoustic-Phonetic Recognition (APR) program that is also being written. Most of the effort with APEF, however, has been directed towards finding features that are most useful for distinguishing among phonemes that are

within certain classes. We have found that it is possible to distinguish among particular phonemes within a class (for example among the three nasal phonemes, or the three unvoiced plosive phonemes) with 80%-90% accuracy. This accuracy is achieved by searching for features that are fairly independent of the phonetic context (adjacent phonemes), and also by considering separate phonetic contexts where appropriate.

Typically, the features are made independent of the phonetic context by normalizing them by some measurement made during the adjacent phoneme. For example, one strong cue to the identity of a nasal is the direction of the formant transitions in the preceding vowel. The second and third formants tend to drop preceding an [M], rise preceding an [N], and come together preceding and [NX]. However, the actual amount and direction of the transition depends on the previous vowel. Figure 1 shows density distributions of the derivative of F3 in the two frames preceding an [M] or an [N]. (The figures shown were produced by the APEF program and transferred directly from the IMLAC screen to the Benson-Varian printer plotter.) As can be seen, the overlap in the distributions for the two phonemes is quite large, making this (commonly quoted) feature quite useless. However, by normalizing the amount of formant change by the measured formant frequencies in the middle of the vowel, the transitions are made much more useful in distinguishing among the nasals, without having to know exactly what the preceding vowel was. Figure 2 shows density distributions of the adjusted derivative values.

D

Report No. 5239

C

I.

As can be seen, the overlap between the distributions has been substantially decreased. A similar effect is shown for the derivative of F2 in Figures 3 and 4. While each of these features is not sufficient to separate the nasals with high accuracy, taken together with other useful features, the phoneme recognition can be quite high. Figure 5 shows the results of an APEF experiment using four features to distinguish among the three nasals. The cases considered included all the nasals preceded by any vowels. There were a total of 339 such nasals in the database. In addition to the two adjusted formant derivatives, the average F2 and F3 during the nasal were used as features. The resulting performance was 87% correct on the first choice, and 98% on the second choice. The confusion matrix for the first choice is shown at the bottom of the figure.

Figure 6 shows the improvement in performance when using context-dependent features, and when considering the phoneme context in the decision. The first set of results shows that the accuracy when using the unnormalized derivatives and averages is 84%. Using the adjusted derivatives increases the performance to 87%. Finally, we considered adding another feature - the F2-F3 distance in the frame before the nasal. This distance should be small for [NX] and larger for the other nasals. As shown, the performance actually decreases to 86%, due to the fact that this formant distance can also be affected considerably by the preceding vowel. Consequently, we considered the cases of nasals preceded vowels with close F2-F3 by those distance

([IY,EY,AY,OW,OY,AW,ER,AXR]) separately from all other vowels. As shown, the performance in these two cases when considered separately increased to 92% and 90% respectively. This recognition performance among the nasals is quite high, compared to results reported in the literature, and compared to results previously obtained by us.

We have shown that by performing the recognition under separate hypotheses for the context, the separation of phonemes within a class can be improved significantly. Although the APR program cannot reliably determine the phonetic context, the word matching component in the speech recognition system has available the complete spelling of any word being hypothesized by the rest of the system. It can then use only the scores assigned under the correct hypothesis for the context. This same logic also applies to a program trying to determine the phonetic identity of a sentence (e.g., a phonetic vocoder), since when evaluating any phoneme hypothesis, the program can take into account the previous phonemes in the theory under consideration.

Ż

| 29 | How much was budgeted for travel in the second guarter? |
|----|---|
| 30 | When is the next progress report due in Washington? |
| 31 | Plot one function immediately above the other. |
| 32 | Isn't there some other way to show the structure in the data? |
| 33 | Indent alternate lines in this paragraph. |
| 34 | Show me all the expenses approved so far. |
| 35 | How many purchase orders are outstanding? |
| 36 | Why has his trip report not been submitted? |
| 37 | Are there any other late trip reports? |
| 38 | Can we close the books on the project's first phase now? |
| 39 | The RFP contained a detailed work statement. |
| 40 | Who do we have free to work on this task? |
| 41 | Reschedule the remainder of the tasks as well. |
| 42 | Who's project manager for this effort? |
| 43 | Did the accounting system screw up again? |
| 44 | Has a critical path analysis been done for this job? |
| 45 | Which jobs are furthest behind schedule? |
| 46 | Arrange a meeting of all task managers for Tuesday. |
| 47 | Have the replacement parts been delivered yet? |
| 48 | Top management will have to decide on that question. |
| 49 | The system crash destroyed most of our records. |
| 50 | Were the records archived, and could we retrieve them? |
| 51 | You'd better consult a lawyer about our liability. |
| 52 | Print up a financial summary sheet. |
| 53 | Can't we avoid an overrun on the rest of the tasks? |
| 54 | Print the last four messages. |
| 55 | Is there any mail in my box? |
| 56 | Show me message seventy two. |

- 57 Delete the first twenty eight messages.
- 58 Send message fifty seven to everyone in the group.
- 59 Clear the screen.

C

- 60 Open my mail file.
- 61 Archive all deleted messages.
- 62 What messages have I had from ISI this year?
- 63 Print a draft of this chapter.
- 64 How many pages still need editing?
- 65 Who at BBN is working on VLSI?
- 66 Where and when is the ARPA review meeting?
- 67 Close this file.
- 68 A hundred and thirty one pages is too long.
- 69 Tell Dwayne we don't anticipate a cost overrun.
- 70 Who's on vacation now?
- 71 Who deleted the backup files?
- 72 There's room for five more lines in the footnote.
- 73 Is there a concept called "Mailing Address," or something close?
- 74 What concepts have roles with role-names like "Nickname?"
- 75 Show me the generic concept called "Employee."
- 76 I can't fit a new label below it.
- 77 Could you move it up?
- 78 Now make an individual employee concept.
- 79 The first name is "Gordon," and the last name is "Hook."
- 80 His Social Security number is 2 5 4, 3 6, 7 9 zero 8.
- 81 Is there a role on employee called "Retirement Fund?"
- 82 How about a role called "Pension Program," or "Pension Plan?"
- 83 I'd like to see the structure below "Employee Benefits."
- 84 Empty the screen and save the current display.

- 85 What's the book say on old age benefits?
- 86 Is it a dollar amount?
- 87 Set the value of old age benefits to twenty five thousand dollars.
- 88 Can you display just the role-set?
- 89 O.K., use the old role.
- 90 No, change that.
- 91 Display the role-set and the old role.
- 92 Now I need some figures on overhead and IR&D.
- 93 I'd like to see the representation of "Companies."
- 94 Thanks.

Ŋ

1

- 95 Now show me the concept for "Persons."
- 96 I need your help on layout decisions.
- 97 Change the role-name to "Residence."
- 98 Could you put the role-value map here.
- 99 Redefine this concept to include individuation.
- 100 Insert a telephone number of 6 4 3, 6 6 3 8.
- 101 That should read twelve thousand and three, not eleven thousand.
- 102 Make that forty nine hundred.
- 103 There should be seventeen entries.
- 104 Twenty K sounds about right.
- 105 Order some more Form fourteen seventy threes.
- 106 Type up six copies of the abstract.
- 107 A block is two fifty six words, right?
- 108 Change this entry to eight thousand.
- 109 Would you put this box to this side.
- 110 Interchange these two tables.

GENERAL_INFORMATION

<u>_</u>

IG-bit integers, and should therefore always he read into and written from INTEGER*2 arrays (the default in VMS Fortran is INTEGER*4). All arguments, parameters, and variables indicated below to be 'integer' (and not specifically labelled INTEGER*2) should be assumed INTEGER*4. sequential Waveform files (header and data) consist of

11-XVA Jo Returned status codes are Fortran status codes For JOPENWAV and J. OSEWAV (see page 7-2 of V. Fortran Users' Guide); 0 => success. Returned status endes are RMS status codes for all other functions; .true. => success

0-1

HEADER INFORMATION

BBN SAMPLED DATA FILE HEADER FORMAT (256 16-bit words)

This describes the BBN ILS-compatible Sampled Data File Header Format

The complete ILS header format is given in: The complete ILS header format is given in: ILS Programming Guide - Summary of ILS Subroutines (Version 3.0), October 1, 1980, Signal Technology, Inc., Santa Barbara, Calif. (document does not have unique page numbers - see approx page 16) The header is defined to be 256 16-bit (INTEGHA2) words long,

mediately in front of the consecutive data samples, were very of the sample formal. Normal unpacked data (See 'IFRMAT' below for data sample formal. Normal unpacked data sample formal. Sored one per 16-bit (INTEGER2) word, right justified, sign extended.) a order for ILS routines to interact with this 256-word header. ILS routine 'ILS' must be modified: 'NCWFU' must be initialized to 256 MoCivations for increasing the header length from 64 to 256 words are as follows:

with no danger of future ILS use of currently unused words 4 additional words of BBN header format can be ulilized in 1-64 range. 2

2) Header length of 256 allows higher sampling rate (according to DACS User Manual (page A2FIL-45)), since buffer boundaries will coincide with (256-word) block boundaries. In the table below, the 256 words are referenced as 1-256, and are assumed input into an INTEGER*2 array of length 256.

KField 3/31/81

| DESCRIPTION | | (unused) Number of sampled data blocks | (256 16-bit words per block) in file (unused) | Flag set to SO if samples are 8-bit, log quantization - Flag is O if 12-bit | samples, stored one per 16-bit word, |

SIGNAL_PROCESSING

PREAUT

Sowree: DRAL: [SPERCH.L.I.BRARY]FREAUT.FOR. Sowree: DRAL: [SPERCH.L.I.BRARY]FREAUT.FOR. Subpregram Definition: SUBROUTINE PREART (RIN, ROUT, NIN, BFREQ, SFREQ) ROUTINE TO PREARPHASIZE SIGNAL IN THE AUTOCORRELATION DOMAIN. Fortran Subroutine

Additional informuliăn available:

FULL DESCRIPTION

SIGNAL_PROCESSING

SPEC

Source: DRAT: (SPEECH.LIBRARYISPEC.FOR. Subrogram Definition: SUBROUTINE SPECCLOG2N, NSANP, S.SP, WORK) COMPUTES POWER SPECTRUM OF A REAL SIGNAL Fortran Subroutine

Additional information available:

FULL DESCRIPTION

SIGNAL_PROCESSING

VTI,

FROM A SET OF FORMANT USED THE WAKITA-ZUE METHOD. Source: DRAT: (SPI-FCH. LIBRARY) VTL. FOR. Subprogram Definition: SUBROUTINE VTL.(F, B, NFORN, XL., FSL.) ESTIMATES THE VOCAL TRACT LENGTH FREQUENCIES AND HALF-BANDAIDTIES. Fortran Subroutine

Additional information available:

FULL DESCRIPTION

SIGNAL_PROCESSING

ZCROSS

Fortran Subroutine

Source: DRAT: (SPEECH.LIBRARY)ZCROSS.FOR. Source: DRAT: (SPEECH.LIBRARY)ZCROSS.FOR. Subprogram Definition: Subprogram Definition: Subprogram Definition: Subprogram Definition: Subprogram Definition: CHIS NOUTINE ZCROSS(ISIG, NSO) THIS NOUTINE ZCROSS(ISIG, NSO) THIS NOUTINE ZCROSS(ISIG, NSO) OVER A GIVEN INTERVAL. FOR A ZERO-CROSSING, THE SIGNAL NUST OVER A GIVEN INTERVAL. FOR A ZERO-CROSSING, THE SIGNAL NUST CROSS ZERO (1.E., NOT JUST -1,0,-1).

Additional information available:

SIGNAL_PROCESSING

CSVIIdZ

Fortron Subroutine Source: DRAT: (SPEECH. LJBRARYJZPHAS3. FOR. Subprogram Definition: SUBROUTINE ZFHAS3 (XIN. XOUT, N. CENTER) THREE POINT ZERO-PHASE FILTER.

Additional information available:

FULL DESCRIPTION

STRING_PROCESSING

ADDDINSTR

Fortran Subrouline Source: DRAT:(STFE)CH.L.JBRARYIADDDIRSTR.FOR. Subprogram Definition: Subprogram Definition: Subrouline ADDDIRSTR(filename, new_dir_string) Subrouline to add a directory name string to a filename string

Additional information available:

FULL, DESCRIPTION

STRING_PROCESSING

ADDEXTSTR

Fortram Subroutias Source: DRAT: (SPEECH.L.DBRARY)ADDEXTSTR.FOR. Source: DRAT: (SPEECH.L.D. Subprogram Definition: Subprogram Definition: Subprogram Definition: Fortram subroutine to append an extention string onto a Fortram subroutine to append an extention string onto a filename string.

Additional information available:

FULL DESCRIPTION

STRING_PROCESSING

AFFINUSTIK

Fortran Subroutine Source: DRAL: (SPERCH.LIBRARY)APPENDSTR.FON. Subprogram Definition: Subprogram Definition: Subprodutine APPENDSTR(hase_string.oppend_string) Appends "append_string" to "base_string.

Additional information available:

FULL DESCRIPTION

STRING_PROCESSING

CHARCOUNT

Fortran Integer Function Source: DRAT: ESPERATION LARKYTCOUNT. FOR. Subprogram Definition: integer function CHARCOUNT(string) Fortran function to count the number of characters in a string.

Additional information available:

FULL DESCRIPTION

STRING_PROCESSING

CIIGDIRSTR

Fortran Subroutine Source: DRAI:ISPEECH.J.IBRARYICHGDIRSTR.FOR. Subprogram Definition: subroutine CHGDIRSTR(filename,new_dir_string) Fortran subroutine to change the directory of a filename string.

Additional information available:

FULL DESCRIPTION

STRING_PROCESSING

CHGEXTSTR

Fortras Subrouline Source: DRA1:1SPEECH.LIBRARYJCHGEXTSTR.FOR. Subprogram Definition: Subprogram Definition: Subrouline CHGEXTSTR(filename, new ext_string) Fortran subrouline which deletes the present extention of a filename and substitutes a new one.

Additional information available:

FULL DESCRIPTION

STRING_PROCESSING

CIIGF ILSTR

Fortran Subrouline Source: DRAI: ISPECH.LIBRARYJCHGFHLSTR.FOR. Subprogram Definition: Subprogram Definition: Fortran subrouline to change the "name" portion of a filename string to a new name.

Additional information available:

FULL, DESCRIPTION

STRING_PROCESSING

CONFLEX

C

Z

Furtran Legient Function Source: DRAI: ISPERTIL, I, BRARYICONFIRM, FOR, Subprogram Definition: Logical function CONFIRM (prompt_string) Fortran Logical function which prompts SYS\$INPUT (normally the user's terminal) and accepts a single character as input. A default prompt is supplied if the prompt string contains no characters. Returns true. for (cr), (esc), Y(cr) or T(cr). Returns false, for N(cr) or F(cr).

Addilional information available:

FULL DESCRIPTION

STRING_PROCESSING

DELDIRSTR

Fortran Subrouline Source: URAL: [SPEECH.LIBRARYIDELDIRSTR.FOR. Sources URAL: [SPEECH.LIBRARYIDELDIRSTR.FOR. Subprogram Definition: Subroutine DELDIRSTR(filename) Fortran subroutine to delete the directory name portion of a Fortran subroutine to delete the directory name string (logical filename string. Any legal VNS directory name string (logical names, subdirectories, none, etc.) is allowed.

Additional information available:

FULL DESCRIPTION

STRING_PROCESSING

DELEXTSTR

Fortran Subroutine Source: URAL:[SPERCH.LI.BRARY]DELEXTSTR.FOR. Subprogram Definition: Subprogram Definition: Subproutine UELEXTSTR(filename) Fortran subroutine which deletes the extention from a filename Fortran subroutine which deletes the file name and extention string. The delimeter "." between the file name and extention is also deleted.

Additional information available:

FULL DESCRIPTION

STRING_FROCESSING

FILENAME

Fortran Character Function Source: DRAI: [SPEECH.LIBRARY]FILENAME.FOR. Subprogram Definition: Subprogram Definition: Character1(1) function FILENAME(prompl_string) Fortran character function designed to prompt a user program Fortran character function designed to prompt a user program for a filename string. It searches for the specified file, and

PROMPT

7

Source: Dum. Definition: Subprogram Definition: subroutine PDONUT(prompt_string) Fortram subroutine which types "prompt_string" on SYS\$OUTPUT, Fortram subroutine which types "prompt_string" on SYS\$OUTPUT, fortram subroutine which types "prompt_string" on SYS\$OUTPUT, Type-out. Usefut for prompting a user program for data. Typically, "prompt_string" will be a literal string in "...tation marks. Type-out begins on the current line. Sources: DRAT: ISPERCH. LIBRARY IPROMPT. FOR. Fortran Subrouting

FULL DESCRIPTION

STRING_PROCESSING

PROMPTR

Source: DRAI: [SPEECH.LIBRARYIPROMPTR.FOR. Sobrogram Definition: Subroutine PROMPTR(prompt_string) Fortran subroutine which Types "prompt_string" on SYS\$OUTPUT Fortran subroutine which Types "prompt_string" on SYS\$OUTPUT for prompting a user program for data. Typically, "prompt_string" will be a literal string in quotation marks' Type-out begins on the current line. Fortran Subrouline

Additionnl information available:

FULL DESCRIPTION

STRING_PROCESSING

RCIIAR

character'i function RCHAR(prompt_string) character'i function which Types a prompt string to SYS\$OUTPUT (normally the user's terminal) and reads n single character from SYS\$INPUT (normally the user's terminal). Fortran Character Function Source: DRAI: (SPEECH. LIBKARY) RCHAR.FOR. Subprogram Definition:

Additional information available:

FULL DESCRIPTION

STRING_PROCESSING

RSTRING

Fortran Character Function Source: DRA1: [SPFECH.L.DBRARY]RSTRING.FOR. Subprogram Definition: character*(*) function RSTRING(prompt_string)

Fortran character function to type a prompt string to SYS*OUTPUT and then read a string from SYS*INPUT.

Additional information available:

FULL DESCRIPTION

STRING_PROCESSING

UPPERCIIAR

Fortran Character Function Source: DRA1: [SPEECU.LIBRARY]UPPERCHAR.FOR. Subprogram Definition: Subprogram Definition: character*1 function UPPERCHAR(input_character) Fortran function to convert a single character to upper-case. Fortran function to convert a single character to upper-case. If already upper-case, character is returned unchanged.

Additional information available:

FULL DESCRIPTION

STRING_PROCESSING

UPPERSTR

Fortran Subroutine Source DRAL: (SPEECH.LIBRARY)UPPERSTR.FOR. Subprogram Definition: Subprogram Definition: Fortran subroutine to change each character in a string to uppercase.

Additional information available:

FULL DESCRIPTION
