20. ABSTRACT (Continue on reverse side if necessary and identify by block number) → During the NRL Remote Sensing Experiment in the Phelps Bank Region ($40^{\circ} 50' N$, $69^{\circ} 20' W$) precision depth recorder data were collected during the ten days the USNS HAYES operated there. This data was averaged over 15 minute intervals and contoured. This report presents the contours of maximum, minimum and average depth and tabulates the data sorted into $10'$ by $10'$ tessera in the region 40° to $41^{\circ} N$ and 69° to $70^{\circ} W$ and sorted into $1'$ by $1'$ tessera within 10 nautical miles of Phelps Bank. The occurrence of sand ridges is also reported.

BATHYMETRIC DATA AND ANALYSIS
FOR THE NRL REMOTE SENSING EXPERIMENT:
PHELPS BANK, JULY 1982

1. INTRODUCTION

→ The NRL (Naval Research Laboratory) Remote Sensing Experiment was carried out in and around Phelps Bank (about 40 miles south - southeast of Nantucket Island) during July, 1982. The exercise was the pilot experiment in a program to examine how and why ocean surface expressions of bathymetric features are sometimes manifest. The specific expressions of interest occur in several types of radar images of the ocean surface. The most interest is in SAR (synthetic aperture radar) images since they appear to be most sensitive to the surface bathymetric signatures; and historically these signatures were first observed in SAR imagery.

The exercise involved a surface ship (USNS HAYES) and several aircraft. The HAYES collected Meteorological, Oceanographic and Bathymetric data in the operational area. Since this exercise was concerned with bathymetric effects, the precision depth recorder (PDR) system on the HAYES was continually run while in the area bounded by $40^{\circ}10'N$ and $41^{\circ}N$, and $69^{\circ}10'W$ and $70^{\circ}W$. The maximum concentration of data was in the area $40^{\circ}40'N$ to $41^{\circ}N$ and $69^{\circ}10'$ to $69^{\circ}40'W$. This report describes the data, the instrumentation, its method of collection, and finally presents the data in graphical and tabular form.

The data here covers a relatively large area. The same PDR data was more densely scanned in the immediate vicinity of Phelps Bank and plotted in Gordon and Greenewalt (1982). ←

Manuscript approved January 6, 1983.

2. INSTRUMENTATION

To obtain the bathymetric data, precision depth recorders (PDRs), Loran C navigation systems and an HP (Hewlett-Packard) 1000 series computer were used.

The USNS HAYES utilizes two sonar systems in conjunction with the PDRs. The first system is an EDO Western, Model 248E, solid state transiever set for wide beam at 3.5 kilohertz, a Model 240 head, a 10 kilowatt booster, and a Raytheon LSR-1811 Line Scan Recorder. The second system uses an identical transceiver set at 16 kilohertz, a Model 202 head, and an identical Line Scan Recorder. These systems were installed only one month prior to the experiment and were calibrated to compensate for the draft of the ship. The sonar systems were operated both separately and simultaneously with accuracy within 1 meter of depth.

The Raytheon LSR-1811 Line Scan Recorders were set with a sweep rate of 0.25 seconds per line, and a paper feed of 150 lines per inch. The feed mechanism is accurate to within 0.02 percent. The recorders are calibrated with a sound speed of 1500 m/sec; a typical value for the operational area was 1490 m/sec. Thus, errors in depth due to this factor are about .6%, or less than .5 m.

The navigational data was provided by two Northstar 7000 Loran C systems; the ship's position was determined as a function of Greenwich Mean Time (GMT). This system is accurate to within 200 yards. The Loran data was logged and converted by the HP computer. The navigation was updated once per minute and averaged over 15 minute intervals.

3. METHODOLOGY

Unfortunately, the bathymetric records could not be interfaced to the computer, so the bathymetric had to be read by hand and then manually merged with the navigation file.

Based on the sweep speed and paper feed rate of the Line Scan Recorder, the paper advanced 96 inches per hour. It was decided to average the bathymetry over 15 minute intervals since this was the averaging interval for the other data collected. The time (GMT) of each data record is the end of the averaging interval. Generally in the Phelps Bank area, the HAYES was under way with a speed less than 5 kts, so each 15 minute average is in effect a spatial average of about one nautical mile or less. Within a 15 minute period, the maximum, minimum, and average depths were recorded. Also noted was the presence of sand ridges.

Care was taken to ensure that any apparent change in the displacement rate of the paper¹ would be compensated for. On several occasions, the displacement rate was determined by measuring the distance between two known points in time.

Finally, the data collected was tabulated and placed into a computer file. Once in the file, the data was used to create contour maps of the average, maximum, and minimum depths in the Phelps Bank area. The data was also sorted into latitude and longitude bins.

No correction was made to the depths for sea surface elevation changes due to tidal motion. The closest station to the operational area listed in the Tide Table (1982) is Davis Bank ($41^{\circ}08'N$, $69^{\circ}39'W$). There the

¹ The apparent paper displacement rate variation was caused by occasional inaccurate time marks on the PDR chart.

spring tidal range is 0.5 m and the mean tide level change is less than 0.2 m. These amplitudes are smaller than the error in the depth data.

4. BATHYMETRIC CONTOURS AND DATA

The 804 bathymetric records are contoured in Figs. 1, 2 and 3. Fig 1 is the field of average depth, Fig 2 is the maximum depth and Fig 3 is the minimum depth in meters per each 15 minute interval; the contour interval is 5 meters. The shallowest depth reported on the NOAA U.S. East Coast Fisheries Chart, 1:220,000 (No. 13203) was 10-1/2 m at 40°48'N, 69°21'W. Two other depth minima of 13 m are reported at 40°49'N, 69°21'W and 40°51'N, 69°21'W, whereas we found 16 m at 40°48.62'N, 60°20.81'W. Another minimum of 17 m was measured at 40°50.66'N, 69°21.08'W. We made no attempt to perform a systematic survey and actually locate the depth minima, whereas the NOAA charts do report the shallowest depths observed at mean low water.

The contouring routine used fits a minimum curvature surface to the data and then grids coordinates on this surface for plotting purposes (the grid points are indicated on the average depth map). There is some scatter in the data. For example, one 1' by 1' tessera contains 21 data points. The average depth in this tessera ranges from 27 to 39 m. These data are plotted on the map in Fig. 4. Note that even though the data spread in the tessera is 12 m, the data is consistent within ± 1 m.

All the data is tabulated in Appendix A and B. The time at the end of the 15 minute period (DTG in Julian day and GMT); location; average, maximum and minimum depths in meters; and the occurrence of sand ridges (1) are listed. Appendix A divides the area from 40°N to 41°N and 69°W to 70°W into 10' by 10' tessera. Appendix B covers the area 40°45'N to 40°55'N

and $69^{\circ}15'W$ to $69^{\circ}25'W$ subdivided into 1' by 1' tessera. This latter area completely encompasses the Phelps Bank/Asia Rip area.

A summary of the data distribution by latitude and longitude and the fraction of observations which contain sand ridges are given in Table 1. The upper number is the sand ridge fraction and the lower number the total observations in that tessera.

5. ACKNOWLEDGEMENTS

Several support personnel at the Naval Research Laboratory contributed to this report, and their help is gratefully acknowledged. Jack Ostrander, Code 5004, for navigation assistance and help in contouring the data; Lee Huston, Code 5004, for assistance and maintenance of the PDR system; and Chuck McMath, Code 5003, for implementing the contouring algorithm.
