AUTOMATIC THRESHOLD DESIGN FOR A

BOUND DOCUMENT SCANNER

by

BILL JAMES STANTON, JR

Captain, United States Air Force

Submitted to the Department of Electrical Engineering and Computer Science August 1982 in partial fulfillment of the requirements for the Degree of Master of Science in Electrical Engineering

ABSTRACT

Research was carried out on an electro-optical bound document scanner using a charge-coupled device (CCD) as a sensing element. The goal was to develop a means whereby the voltage threshold level of the video analog-to-digital converter could be set automatically to provide optimum hard-copy output over a range of lighting conditions and document background colors and qualities. To determine an acceptable component of the analog video signal as a thresholding reference, an extensive study of the signal behavior was conducted over a variety of conditions.

An Automatic Threshold Control (ATC) was designed that exploited the modulation transfer function of the CCD's analog signal. A CALIBRATION PATTERN is superimposed at the left-hand margin of the page being scanned. This pattern contains various discrete spatial frequencies. The threshold voltage is varied automatically until the number of black/white (zero/one) transitions is maximized for the CALIBRATION PATTERN. The threshold voltage producing this maximum number of transitions is equivalent to the threshold required to produce optimum resolution in the scanner hard-copy output. This threshold value is then locked in for the duration of the page being scanned.

System performance using this ATC scheme is excellent. The scanner selects a threshold voltage on a per-page basis that yields acceptable copies. The ATC is able to automatically compensate for various types of paper and changes in lighting conditions due to fluorescent tube deterioration. Slightly less than optimum thresholding may occur about 10 to 15 percent of the time, but this is due to data uncertainty and other shortcomings in the scanner rather than in the ATC scheme. AFIT RESEARCH ASSESSMENT

The purpose of this questionnaire is to ascertain the value and/or contribution of research accomplished by students or faculty of the Air Force Institute of Technology (ATC). It would be greatly appreciated if you would complete the following questionnaire and return it to:

AFIT/NR
Wright-Patterson AFB OH 45433

RESEARCH TITLE: Automatic Threshold Design for a Bound Document Scanner

AUTHOR: Bill James Stanton, Jr.

RESEARCH ASSESSMENT QUESTIONS:

1. Did this research contribute to a current Air Force project?

( ) a. YES ( ) b. NO

2. Do you believe this research topic is significant enough that it would have been researched (or contracted) by your organization or another agency if AFIT had not?

( ) a. YES ( ) b. NO

3. The benefits of AFIT research can often be expressed by the equivalent value that your agency achieved/received by virtue of AFIT performing the research. Can you estimate what this research would have cost if it had been accomplished under contract or if it had been done in-house in terms of manpower and/or dollars?

( ) a. MAN-YEARS ________ ( ) b. $________

4. Often it is not possible to attach equivalent dollar values to research, although the results of the research may, in fact, be important. Whether or not you were able to establish an equivalent value for this research (3. above), what is your estimate of its significance?

( ) a. HIGHLY SIGNIFICANT ( ) b. SIGNIFICANT ( ) c. SLIGHTLY SIGNIFICANT ( ) d. OF NO SIGNIFICANCE

5. AFIT welcomes any further comments you may have on the above questions, or any additional details concerning the current application, future potential, or other value of this research. Please use the bottom part of this questionnaire for your statement(s).

ABSTRACT

Research was carried out on an electro-optical bound document scanner using a charge-coupled device (CCD) as a sensing element. The goal was to develop a means whereby the voltage threshold level of the video analog-to-digital converter could be set automatically to provide optimum hard-copy output over a range of lighting conditions and document background colors and qualities. To determine an acceptable component of the analog video signal as a thresholding reference, an extensive study of the signal behavior was conducted over a variety of conditions.

An Automatic Threshold Control (ATC) was designed that exploited the modulation transfer function of the CCD's analog signal. A CALIBRATION PATTERN is superimposed at the left-hand margin of the page being scanned. This pattern contains various discrete spatial frequencies. The threshold voltage is varied automatically until the number of black/white (zero/one) transitions is maximized for the CALIBRATION PATTERN. The threshold voltage producing this maximum number of transitions is equivalent to the threshold required to produce optimum resolution in the scanner hard-copy output. This threshold value is then locked in for the duration of the page being scanned.

System performance using this ATC scheme is excellent. The scanner selects a threshold voltage on a per-page basis that yields acceptable copies. The ATC is able to automatically compensate for various types of paper and changes in lighting conditions due to fluorescent tube deterioration. Slightly less than optimum thresholding may occur about 10 to 15 percent of the time, but this is due to data uncertainty and other shortcomings in the scanner rather than in the ATC scheme. ACKNOWLEDGEMENTS

I would like to express my sincere appreciation to Professor J. F. Reintjes for his steadfast assistance throughout the course of this research. He promoted an atmosphere of complete academic freedom which was a pleasure to experience. I would also like to mention my deep gratitude to my wife for her unfailing support and patience in the preparation of the manuscript. The task of completing this thesis would have been much more difficult without her contributions.

BIOGRAPHICAL NOTE

B. J. Stanton, a Captain in the U. S. Air Force, is a distinguished graduate of the U. S. Air Force Academy, Class of 1973. As an undergraduate, his work included research in the security of defense communications systems. He completed Undergraduate Pilot Training with top honors in 1974 and Advanced Fighter Training in 1975. He served as an F4D Aircraft Commander and Wing Weapons and Tactics Officer at Royal Air Force Base Woodbridge, England from 1975 to 1978. During that time he participated in joint NATO Force exercises and taught laser weapon tactics. From 1978 to 1981 he served as an AT-38B fighter instructor pilot and academic instructor. His duties included aerial instruction in basic and advanced fighter maneuvers, surface attack tactics, low-level ingress techniques, and various tactical formations. Additionally, he was responsible for significant phases of the surface attack academic curriculum. He is an experienced fighter pilot with 1125 hours of flying time.

SYMBOLS AND ABBREVIATIONS

AC	Alternating Current
ATC	Automatic Threshold Control
CALIBRATION PATTERN	Series of black and white line-pairs of varying thicknesses used to generate a specific analog video waveform for threshold-setting purposes
CCD	Charge Coupled Device
DC	Direct Current
ECP	Experimental Calibration Pattern
EOPS	Electro-Optical Page Scanner; also the mnemonic used to describe the complete F8 software package for the scanner
F8	Designation of the microprocessor used with the scanner for various control functions; complete nomenclature is: Fairchild F8 Formulator
ISE	Image Sensing Element
MTC	Maximum value of VTC obtained from scanning a particular Calibration Pattern
N	Decimal equivalent of the value supplied by the F8 to the Threshold Level Generator to produce a specific threshold voltage
Np	Value of N generating the maximum value of VTC in a given series of samples
Pass	The act of taking seven samples of VTC at N-values that are separated by a fixed step size
Pel Swing	Positive difference between the black and white voltage levels in the analog video signal

Symbols and Abbreviations

QSET	Mnemonic used for the algorithm that picks the optimum threshold value by taking four sets of seven samples per set with each set using a progressively smaller sampling increment of N
R	Reduced range of N-values that have been defined from the results of the previous pass of the algorithm QSET; the reduced range R is that range sampled on the next pass of QSET
RV	Span of values of N producing significant VTC values (where significant is defined as VTC > 1)
S1	Step size used to increment the value of N while taking VTC samples in the first pass of the algorithm QSET; subsequent passes use step sizes labeled in sequence: S2, S3, S4
TLG	Threshold Level Generator
Vref	Output of op amp U3 of the Threshold Level Generator; used as the reference voltage for the 10-bit D-to-A converter
V2	Output of op amp U2 of the Threshold Level Generator; represents the inverted fraction of V2 as determined by the quotient (N/1024)
V0	Voltage output of the Threshold Level Generator
VTC	Video Transition Count: the sum of digitized video black/white transitions encountered in one scan line for a given threshold value

CHAPTER 1

INTRODUCTION

A. PROBLEM STATEMENT

The goal of this research was to refine an existing electro-optical bound document scanner under development in the Laboratory for Information and Decision Systems by reducing the need for manual adjustments. Specifically this involved designing and incorporating a means of automatically setting the voltage threshold level of the video one-bit analog-to-digital converter at a value that would provide optimum quality in the reproduced copy. The subsystem accomplishing this task will be referred to as an Automatic Threshold Control, or ATC in this report. A further objective of the ATC was to provide the scanner with the capacity for automatically compensating for paper color and/or quality and for variations in illumination.

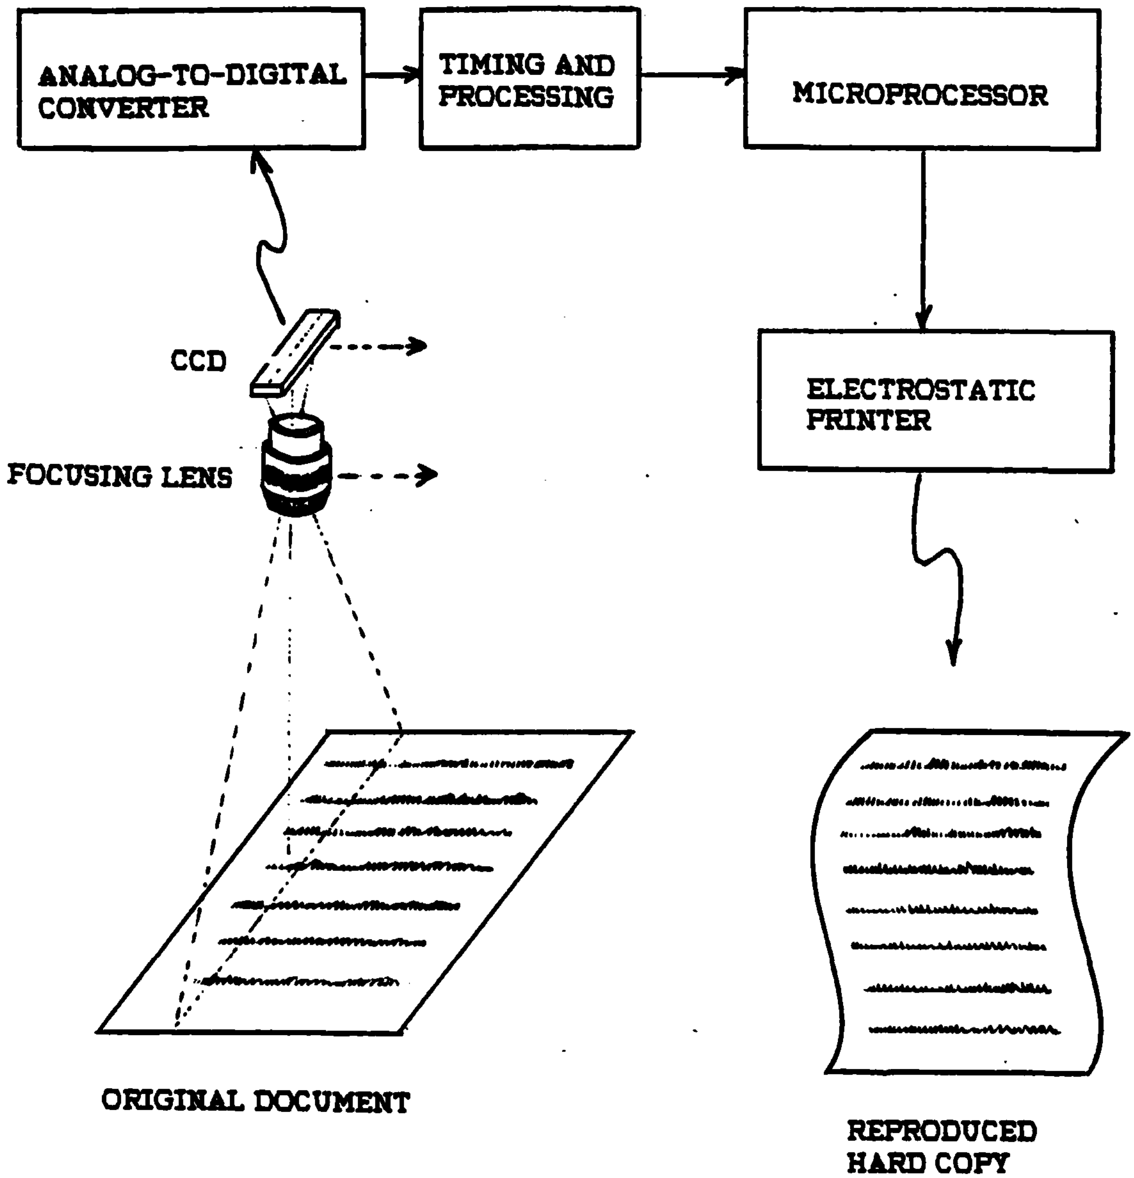
B. PROJECT BACKGROUND

The immediate thrust behind the development of a bound document scanner at the Laboratory for Information and Decision Systems is to improve the interlibrary resource sharing process which now works on a "lending-borrowing" principle. The requirement to physically move either originals or copies from one geographic location to another can take up to two to four weeks from the initial request. On the other hand, the ability to electronically move hard copy material economically would essentially reduce turn-around time to only that required to process the request, locate the document, and transmit the specified pages. Conceivably, turn-around time could be reduced to less than a day, and in many cases less than one hour. In addition, the follow-on applications of such a system in commercial, industrial, and military areas could result in significant increases in efficiency of information management.

The principle of the bound document scanner to which the ATC will be applied is to convert the information content of an 8.5 x 11 inch printed page into 3.6 megabits of digital information through line-by-line scanning. The digital signal can then be compressed for transmission on a 56 kilobit/second data line, such a line representing a tradeoff between transmission cost and per-page transmission time. Copy is produced at the destination by an electrostatic printer.

In the laboratory, scanning is accomplished by a system that uses a Fairchild Charge Coupled Device (CCD) to convert light to analog electrical signals. The CCD consists of a linear array of 2048 image sensing elements (ISEs). The output of each element is proportional to the intensity of light and integration time allowed. One "line" of information is obtained in parallel form and then shifted out of the CCD serially for subsequent processing. The CCD, light source, and focusing lens are mounted on a common structure and physically moved in the second dimension by a phase-locked loop DC motor to provide a raster scan of the entire page.

Several theses have been written concerning the bound document scanner either directly or indirectly. They are listed



SIMPLIFIED BLOCK DIAGRAM OF
THE BOUND DOCUMENT SCANNER

FIGURE 1.1

in Chapter 7, but they also deserve mentioning now for those interested in more extensive background review. Aghamohammadi conducted the original design and fabrication of the bound document scanner. If a working knowledge of the scanner is required, his thesis should be read and thoroughly understood before proceeding. Keverian, while primarily concerned with a parallel project on microfiche scanning, developed hardware interfaces with the F8 microprocessor available in the laboratory. These interfaces are used in the bound document scanner system. Agudelo worked on a document cradle, light non-uniformity, and other problems associated with the existing scanner. Medley accomplished extensive software and hardware modifications to the F8 microprocessor independent of any other projects supported by the F8. His thesis should be reviewed when information concerning current operation of the F8 is required. Vinciguerra studied the feasibility of various data compression schemes for application to document transmission, and Dishop followed this work with further evaluation and design.

C. RESEARCH PLAN

The first phase of this research consisted of analyzing the analog video signal behavior with respect to various light conditions, paper reflectivities, and spatial frequency excitation. The objective was to pinpoint critical variables that would be suitable for obtaining a proper threshold relation. In the second phase, a subsystem was designed and built that would sense the video signal variable and control the voltage threshold level according to the performance of this variable. Finally, the system was evaluated with different lighting conditions, paper colors, and spatial frequency patterns to determine its feasibility.

D. SUMMARY OF RESULTS

An ATC was designed that exploited the modulation transfer function of the CCD as a means for selecting an optimum voltage threshold level. A CALIBRATION PATTERN consisting of several sets of parallel lines is superimposed at the left-hand margin of the page being scanned. This pattern contains various discrete spatial frequencies. The threshold voltage is varied automatically until the number of black/white transitions is maximized for the CALIBRATION PATTERN. The threshold voltage producing this maximum number of transitions is then locked in for the duration of the page being scanned.

System performance using this ATC scheme has been excellent. The scanner now selects a threshold voltage on a per-page basis that yields acceptable copies. The ATC is able to automatically compensate for various types of paper and changes in lighting conditions due to fluorescent tube deterioration. Thresholding errors occur about 10 to 15 percent of the time, but they are due to other shortcomings in the scanner rather than in the ATC scheme. When threshold errors do not occur, the threshold chosen is the best that can be obtained.

E. PREVIEW OF DISCUSSION

Chapter 2 presents an analysis of the analog video waveforms that are derived from the CCD under operational conditions. The results of this analysis are used to develop a conceptual approach to automatic threshold control. Chapter 3 discusses the evaluation of various experimental CALIBRATION PATTERNS to determine the characteristics necessary to produce the desired analog video waveform for thresholding purposes. A practical implementation of tne ATC is developed in Chapter 4, together with considerations that led to the implementation. Chapter 5 contains the development of sampling algorithms that allow the thresholding process to be accomplished in minimum time along with the incorporation of these algorithms into the existing scanner software. Finally the results, conclusions, and recommendations for further research are detailed in Chapter 6.

CHAPTER 2

ANALOG VIDEO SIGNAL ANALYSIS

A. OBJECTIVE

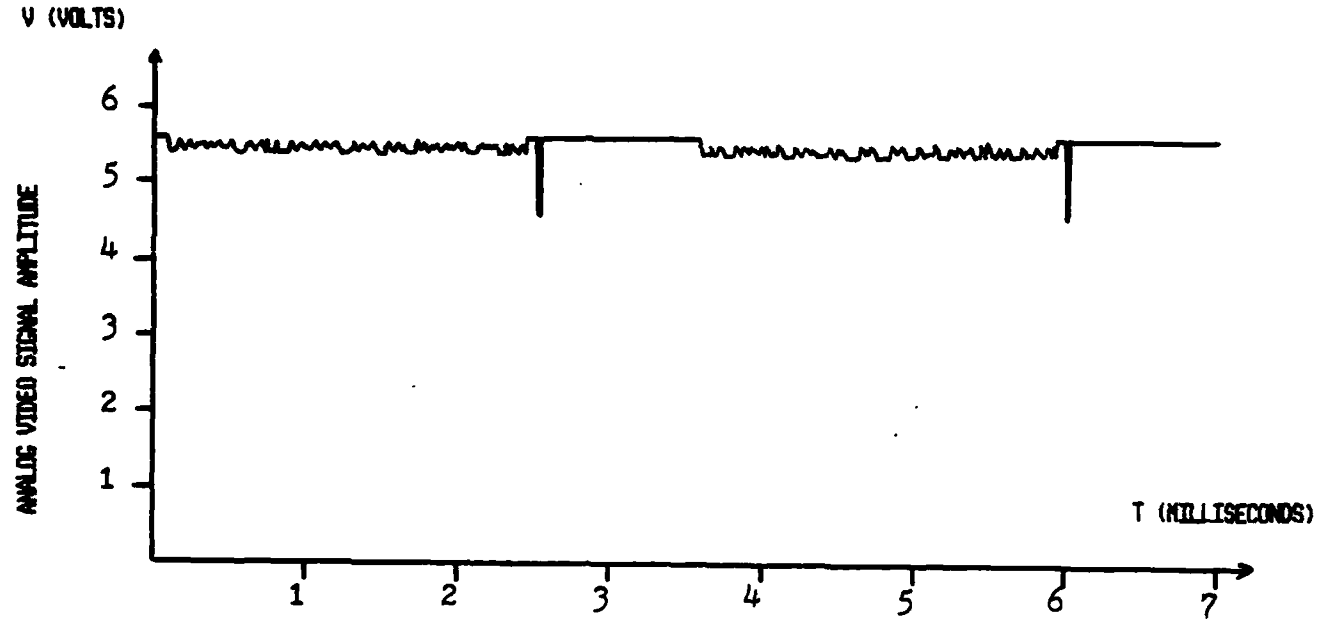
A thorough analysis of the analog video signal derived from the CCD during the line-scanning process was conducted to classify its components and learn its behavior under different conditions. The purpose was to develop a sound basis for selecting a parameter of this signal for use in controlling the voltage threshold level of the A-to-D converter. Ultimately, the analog video signal is dependent on the amount of light reaching the individual image sensing elements (ISEs) of the CCD. Many factors affect the amount of light that the CCD sees, but the relevant factors are those that normally occur in a "user environment", rather than abnormal conditions that could be induced in a "laboratory environment". The factors researched were:

1. Intensity of the light source (1)
2. Color content of the document
3. Spatial-frequency content of the document

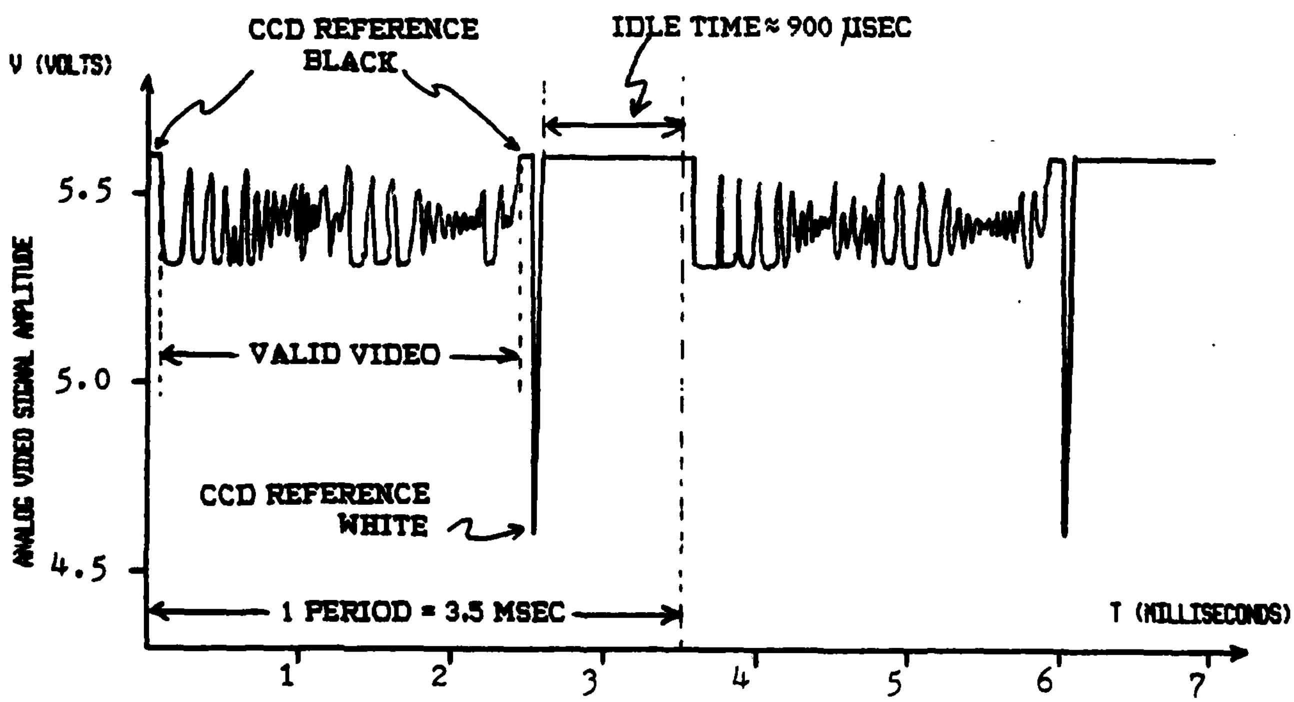
B. FINDINGS

The general configuration of the analog video signal will first be described with reference to Figure 2.1 and the CCD142 data in Appendix A. One period of the signal is equivalent to

(1) Note that the distance between the document and the CCD also affects the amount of light reaching the ISEs. This fact, due to the optics and the geometry of the scanner, gives rise to a light non-uniformity issue which was addressed by Agudelo. Additional information on this subject is included in Chapter 6.



(A) TWO PERIODS OF THE CCD ANALOG VIDEO SIGNAL



(B) EXPANDED SCALE OF AC COMPONENT

FIGURE 2.1

one line of video information. In turn, the period is controlled by the signal, EXTERNAL EXPOSURE (1) which initiates the dump of data from the CCD. The CCD analog data stream for one line is in the following order: black reference level, valid video, black reference level, and white reference level. Once the CCD data dump is complete, there are almost 900 microseconds of idle time to allow for microprocessor command functions. In terms of magnitude, the video information is contained in an AC component obtained by subtracting the instantaneous total analog voltage from a fixed DC component of 5.6 volts. The maximum voltage of 5.6 volts represents absolute black, and negative departures from this maximum result from various light levels absorbed by the CCD ISEs. The CCD typically saturates at 1400 millivolts below absolute black, and the fluorescent lights used as the illumination source provide ample output to drive the CCD to saturation. But in the current design, the focusing lens f-stop is set at 5.6 for depth-of-field considerations. This resulted in the largest white levels observed being 200 to 300 millivolts below black, depending on the condition of the lights. In other words, the existing combination of illumination source and f-stop setting drives the CCD at 14 to 21 percent of its capacity. Valid video information therefore was found in the extreme to reside in the range 5.3 to 5.6 volts and more commonly in the range 5.4 to 5.6 volts. The major issue of setting the proper

(1) Reference Aghamohammadi, Chapter 6 and TIMING AND PROCESSING circuit, Appendix E.

threshold level is finding the value of voltage that is LESS THAN all black voltage values and GREATER THAN all white voltage values. For this purpose, it is important to understand how the black and white video levels react to the factors listed above. First, however, it will be convenient to introduce the term "pel swing," defined as the magnitude of the DIFFERENCE between black and white voltage levels in the video signal. Pel swing is normally measured in millivolts and provides a convenient quantity for expressing the analog signal behavior.

That light intensity has a predictable effect on pel swing was easily demonstrated by varying the f-stop of the focusing lens. A blank piece of white paper was scanned with soft white fluorescent lights providing illumination. Pel swing was measured from absolute black (5.6 volts) to the maximum deviation from absolute black. The results are illustrated in Figure 2.2. Note that f-stops of 2.8 and below saturate the CCD.

The background color of the document being scanned is also an important parameter because in a user environment the scanner will certainly encounter different qualities and textures of white paper and, less commonly, a variety of paper colors. CCD response to paper color and texture at a fixed f-stop of 5.6 was measured experimentally by scanning a blank piece of construction paper of a uniform color and recording the pel swing from absolute black to the maximum deviation. Again, soft white fluorescents were used. These results are shown in Figure 2.3. In a predictable fashion, white and black paper yield the two

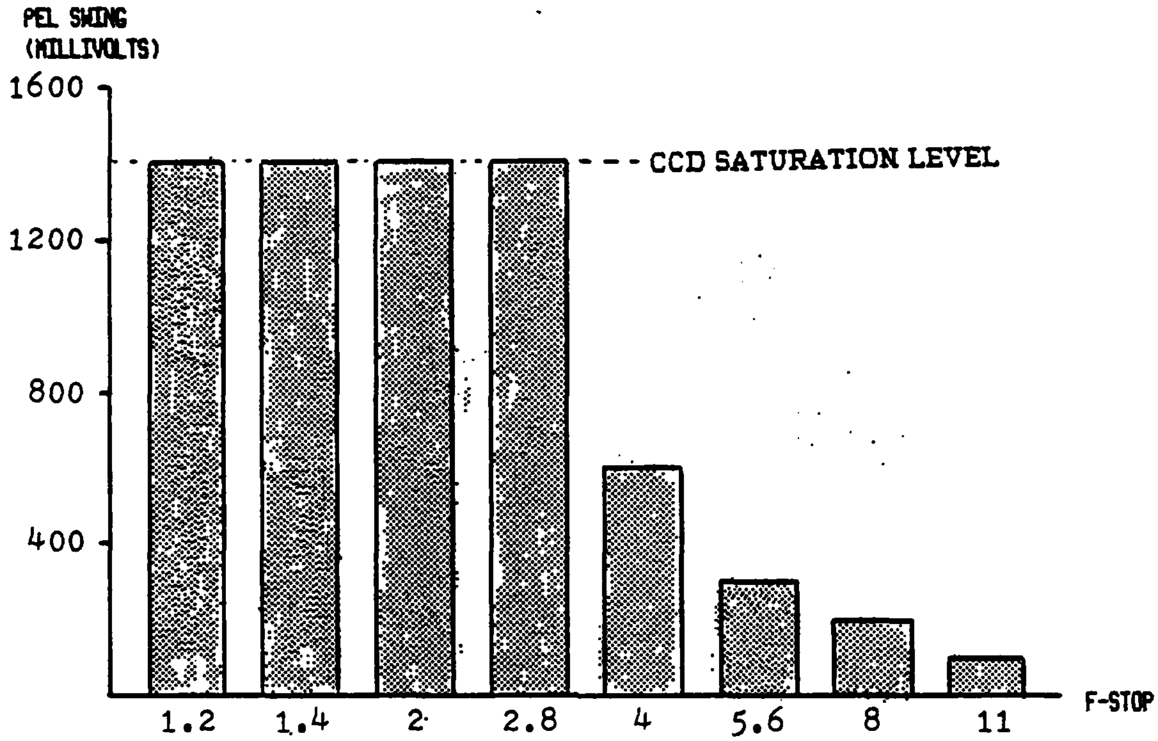


FIGURE 2.2 PEL SWING VERSUS LIGHT INTENSITY AS CONTROLLED BY THE FOCUSING LENS F-STOP

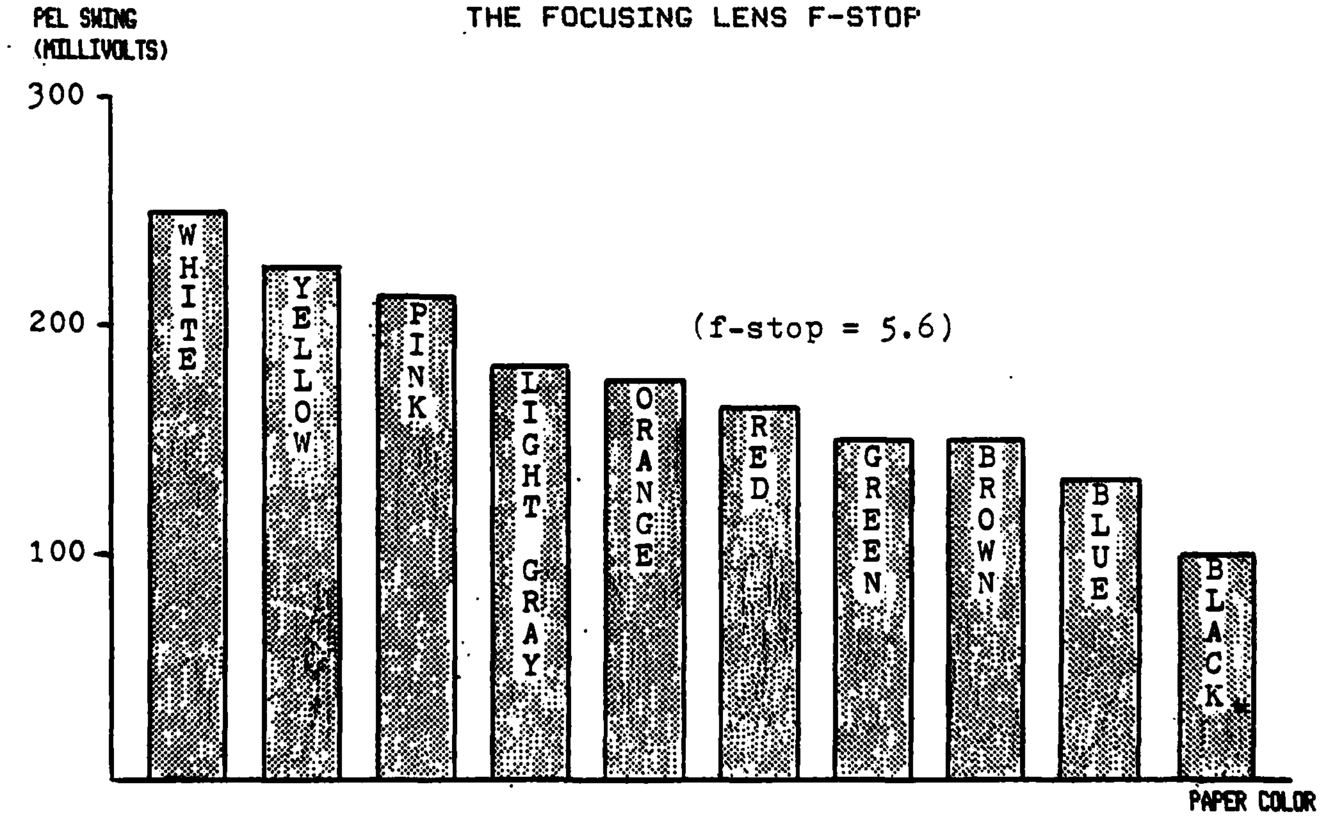

FIGURE 2.3 PEL SWING VERSUS PAPER COLOR

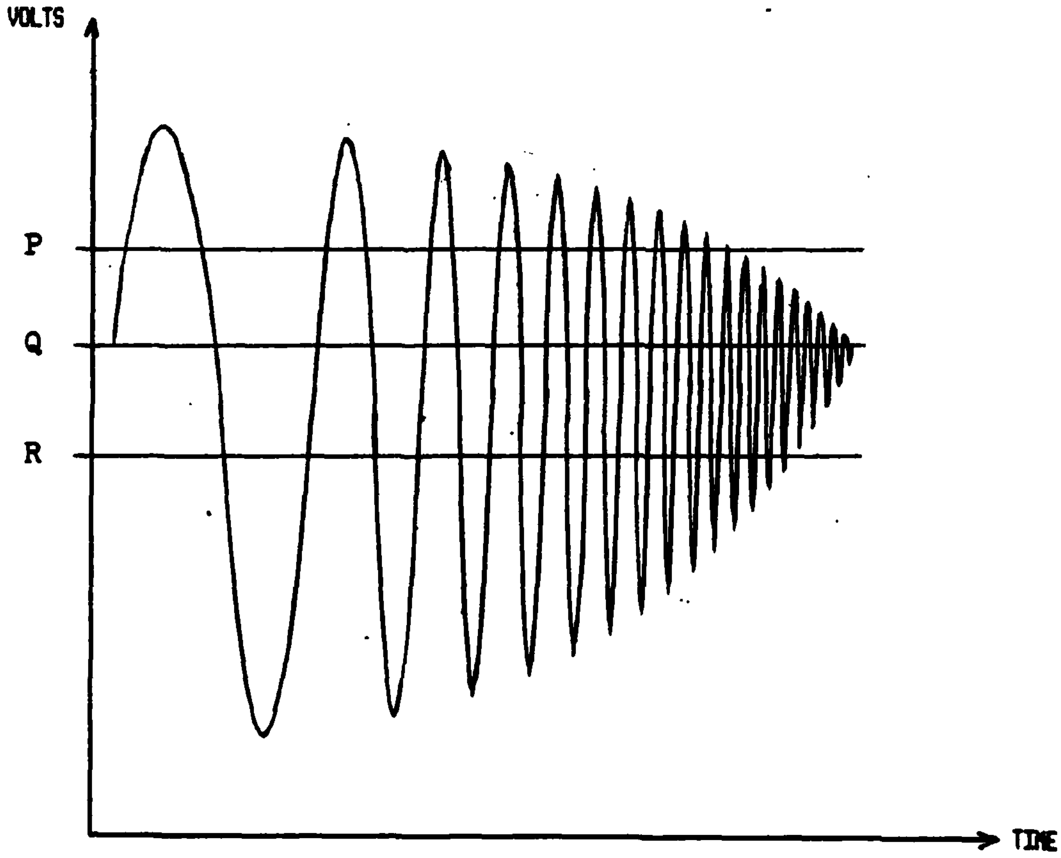
extremes in the range of pel swings. But from a more critical standpoint, one would expect the resulting analog signal from scanning black paper to be very close to absolute black, that is, to yield a very small pel swing. However, this experiment revealed considerable pel swing with black paper. The cause was traced to stray light "leaking" to the CCD ISEs due to a design deficiency in the scanner's optical path. This problem is covered in Chapter 6.

The behavior of the video signal with respect to spatial-frequency content of the information contained on a page is a more complicated issue. As stated above, pel swing has been measured between absolute black and the maximum white level generated by the CCD under blank, monochromatic paper conditions (zero spatial frequency). But with increases in spatial frequency information on the page resulting from alternating black and white lines, signals corresponding to the black level migrate downward away from absolute black, while signals corresponding to the white level migrate upward although not at the same rate. Figure 2.4 illustrates this behavior by showing the CCD response to a series of black lines and white spaces that represent increasing spatial frequency. This phenomenon is due to "crosstalk" between ISEs in the form of hole-electron spillovers. In other words, when one ISE is excited while an adjacent ISE is not excited, there tends to be a certain amount of charge transfer between the two ISEs. The result is less signal output from the principal ISE and a small signal output from adjacent

(A) SERIES OF LINES AND SPACES REPRESENTING INCREASING SPATIAL FREQUENCY



(B) ANALOG VIDEO SIGNAL RESULTING FROM SCANNING LINES IN (A)

FIGURE 2.4

ISEs, and this is exhibited in the modulation transfer function discussed in Appendix A. For the CCD142 in this particular application, a spatial frequency of 100, equivalent to a resolution of 200 lines on the scanned document, will produce the Nyquist rate at the face of the CCD. The Nyquist rate is defined as the spatial frequency that will excite every other ISE in the CCD's linear array. Hence, it is the maximum spatial frequency the CCD is physically capable of resolving. Experimental measurements of pel swing versus spatial frequency are displayed in Figure 2.5. The measurements of black and white level migrations as a function of spatial frequency are presented in Figure 2.6. It is important to understand the relationship among Figures 2.4 to 2.6. First observe the fact that the curves in Figure 2.6 exactly form the envelope of the waveform of Figure 2.4. (1) Also note in Figure 2.6 that the vertical distance between the two curves at a particular spatial frequency is precisely the pel swing generated by that spatial frequency as pictured in Figure 2.5.

The results presented thus far are correct in showing the general trend of analog signal behavior, but the data have limited accuracy for a number of reasons. One reason already cited is the stray light leakage which has the effect of inducing unwanted bias signals. Another reason is the fact that the analog signal contains 30 to 50 millivolts of clocking noise

---

(1) The apparent curving envelope in Figure 2.4 is due to a scaling factor in the computer generation of the waveform.

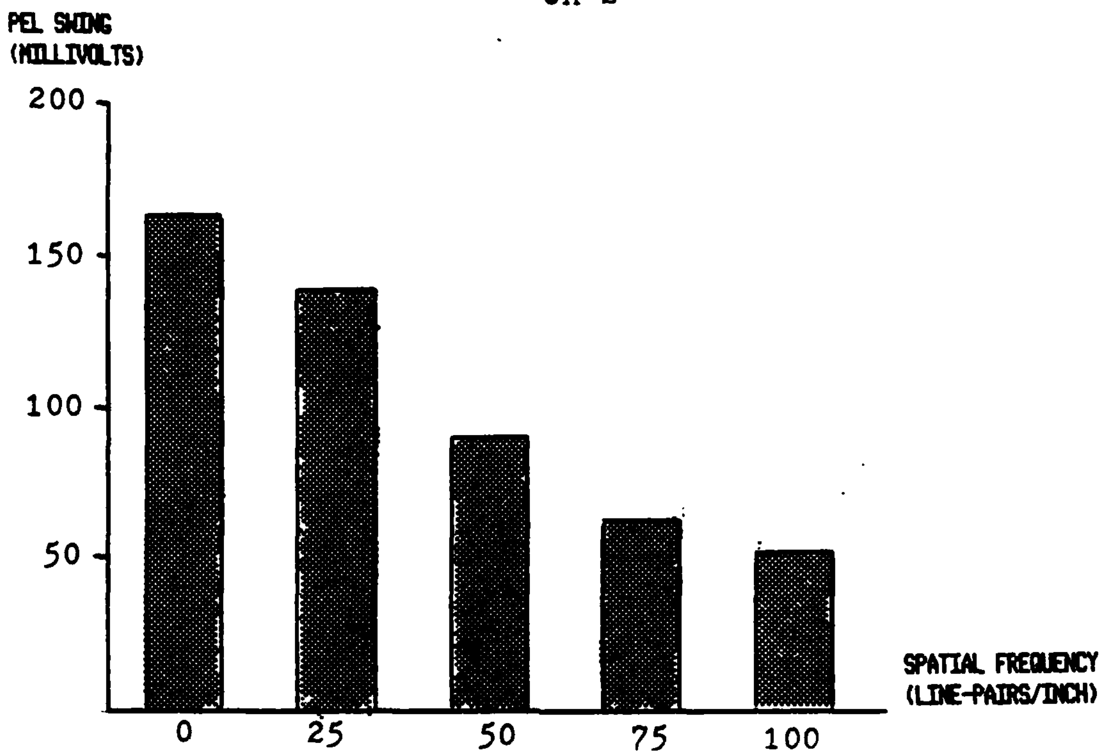


FIGURE 2.5 PEL SWING VERSUS SPATIAL FREQUENCY

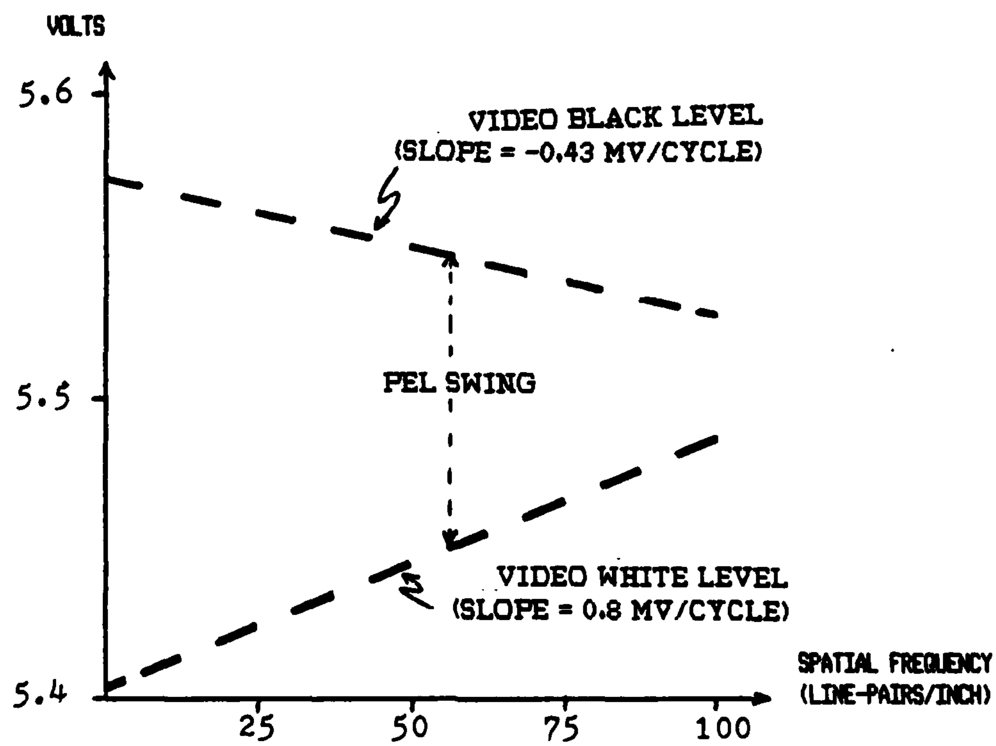

FIGURE 2.6 BLACK AND WHITE ANALOG VIDEO LEVELS VERSUS SPATIAL FREQUENCY

which makes precise measurements extremely difficult to obtain. A third reason stems from the deterioration of fluorescent lights with time, causing slightly different light levels from day to day. Despite these uncertainties, however, adequate information had been obtained at this point to proceed with the ATC design.

C. CHOICE OF PARAMETER FOR THRESHOLD CONTROL

Recall from Chapter 1 that the threshold value being sought is that which will enable the scanner to give the highest quality output possible. Output quality can be measured by "resolution" or the ability to resolve a set of alternating black and white lines of equal width. The more lines/unit length of the ensemble the scanner can resolve, the better will be the quality of the output. Resolution, in turn, is directly related to spatial frequency. Therefore, it can be said that the desired threshold level is one that will digitize all spatial frequencies represented in the analog video signal thereby producing the highest resolution in the output. With the goal now defined as preserving all spatial frequencies as the video signal is digitized, it is logical to exploit the analog video-signal behavior with respect to spatial frequency as the parameter for controlling the threshold. The concept is more easily understood by the following example.

Referring back to Figure 2.4, if one were required to select a threshold voltage that would permit proper digitization of all alternations between black and white, one should choose voltage-level Q as the correct value. Other threshold levels such as P or R would cause loss of the higher spatial-frequency information in the A-to-D conversion process. This leads to a simple algorithm for selecting the optimum threshold, using the particular analog signal of Figure 2.4:

1. Vary the A-to-D threshold voltage through an appropriate range of discrete values.
2. Count the number of zero/one (black/white) transitions at each discrete threshold value.
3. Select the threshold value that resulted in the maximum number of black/white transitions.

It is important to highlight the fact that, for threshold-setting purposes, use of an analog video signal containing linearly increasing spatial frequencies is fundamental to the success of the algorithm. A signal such as this must be obtained by scanning a CALIBRATION PATTERN such as that shown in Figure 2.4(A). Issues concerning choice of a CALIBRATION PATTERN will be discussed in Chapter 3.

D. PARAMETERS REJECTED FOR THRESHOLD CONTROL

Other options that were considered but not chosen for threshold control include:

1. Video white and black levels
2. CCD reference white and black levels
3. Combinations of the above

Use of one of the above parameters would have been in the context of a real-time threshold control scheme; that is, one that would have continuously modified the threshold level based on incoming video information. In general, controlling the threshold level by direct reference to a particular voltage value of the time-varying video signal was explored but rejected due to the complexity involved in extracting the required information from the video signal. The clocking noise in the video signal, relatively long durations of white signal, and the migration of the white and black signal levels toward each other as the spatial frequency of the textual patterns increases, all complicate the task of pinpointing a particular level of video signal. Further complexities arise in selecting a video level or combination of video levels that would provide a stable reference for selecting an optimum threshold value. A relatively simple method of detecting both peak white and black levels of the time-varying video signals and then averaging the two for a correct threshold level was also deemed unfeasible due to the different migration rates (1) of the black and white levels, and due to the video signal normally containing substantially more white information than black information. Finally, using the CCD reference white and black levels was eliminated from consideration because these levels contained no information about light intensity, paper reflectivity, or spatial frequency content of the document.

(1) Note the absolute values of the slopes of the two curves in Figure 2.6 are different.

CHAPTER 3

CALIBRATION PATTERN EVALUATION

As implied in Chapter 2, the term CALIBRATION PATTERN will be used in this thesis to denote a series of parallel black and white lines for forcing the CCD to produce a specific analog video signal for threshold-setting purposes. The design of the ATC calls for the CALIBRATION PATTERN to be located in the left-hand margin of the document being scanned. During a normal scanning sequence, the first lines that the scanner sees would be those of the CALIBRATION PATTERN. Transmission of video information to the printer would be inhibited until the threshold-setting sequence is complete.

Optimally, the CALIBRATION PATTERN should consist of black lines on a transparent surface, thereby allowing the margin of the document being scanned to provide the background. This would permit the analog video signal to be indicative of the characteristics of the paper being scanned, and in this way the threshold setting could be based on the reflectivity and/or color of the paper. On the other hand, using the left margin of the document as the background for the CALIBRATION PATTERN implies that a certain portion of the margin will be unavailable for information content. This was not considered to be a problem since it is highly unlikely there will be a need to transmit a document having no margins. A more critical question, however, is just how much of the margin will be required to support the CALIBRATION PATTERN, or equivalently, how many lines will the ATC require to properly select an optimum threshold level. This issue is addressed Chapter 5.

A. PERFORMANCE REQUIREMENTS

In the selection of a CALIBRATION PATTERN, certain criteria should be followed. First and foremost, the pattern should allow the ATC to select the optimum threshold level, that is, the level that produces the highest resolution in the output. Secondly, the pattern should allow the ATC to produce consistent results; that is, with all inputs constant, the ATC should generate the same threshold level again and again. Thirdly, the pattern characteristics should be invariant to light and/or paper characteristics. And finally, the pattern should be of the proper dimensions in order to fit in the margin of the document.

B. PATTERN COMPOSITION

The discussion thus far has been directed toward the fact that the CALIBRATION PATTERN would consist of a series of parallel lines, and it is easy to see why this would be a logical choice. At the very low spatial frequencies, a series of black lines separated by white spaces of equal width (called line-pairs) produces a square wave in the analog video signal. As the line-pairs become thinner, thus causing the spatial frequency to increase, the black and white analog levels migrate together, and the resulting analog video signal becomes very nearly sinusoidal and extremely predictable. The relationship, illustrated before in Figure 2.4, is re-oriented in Figure 3.1(A)

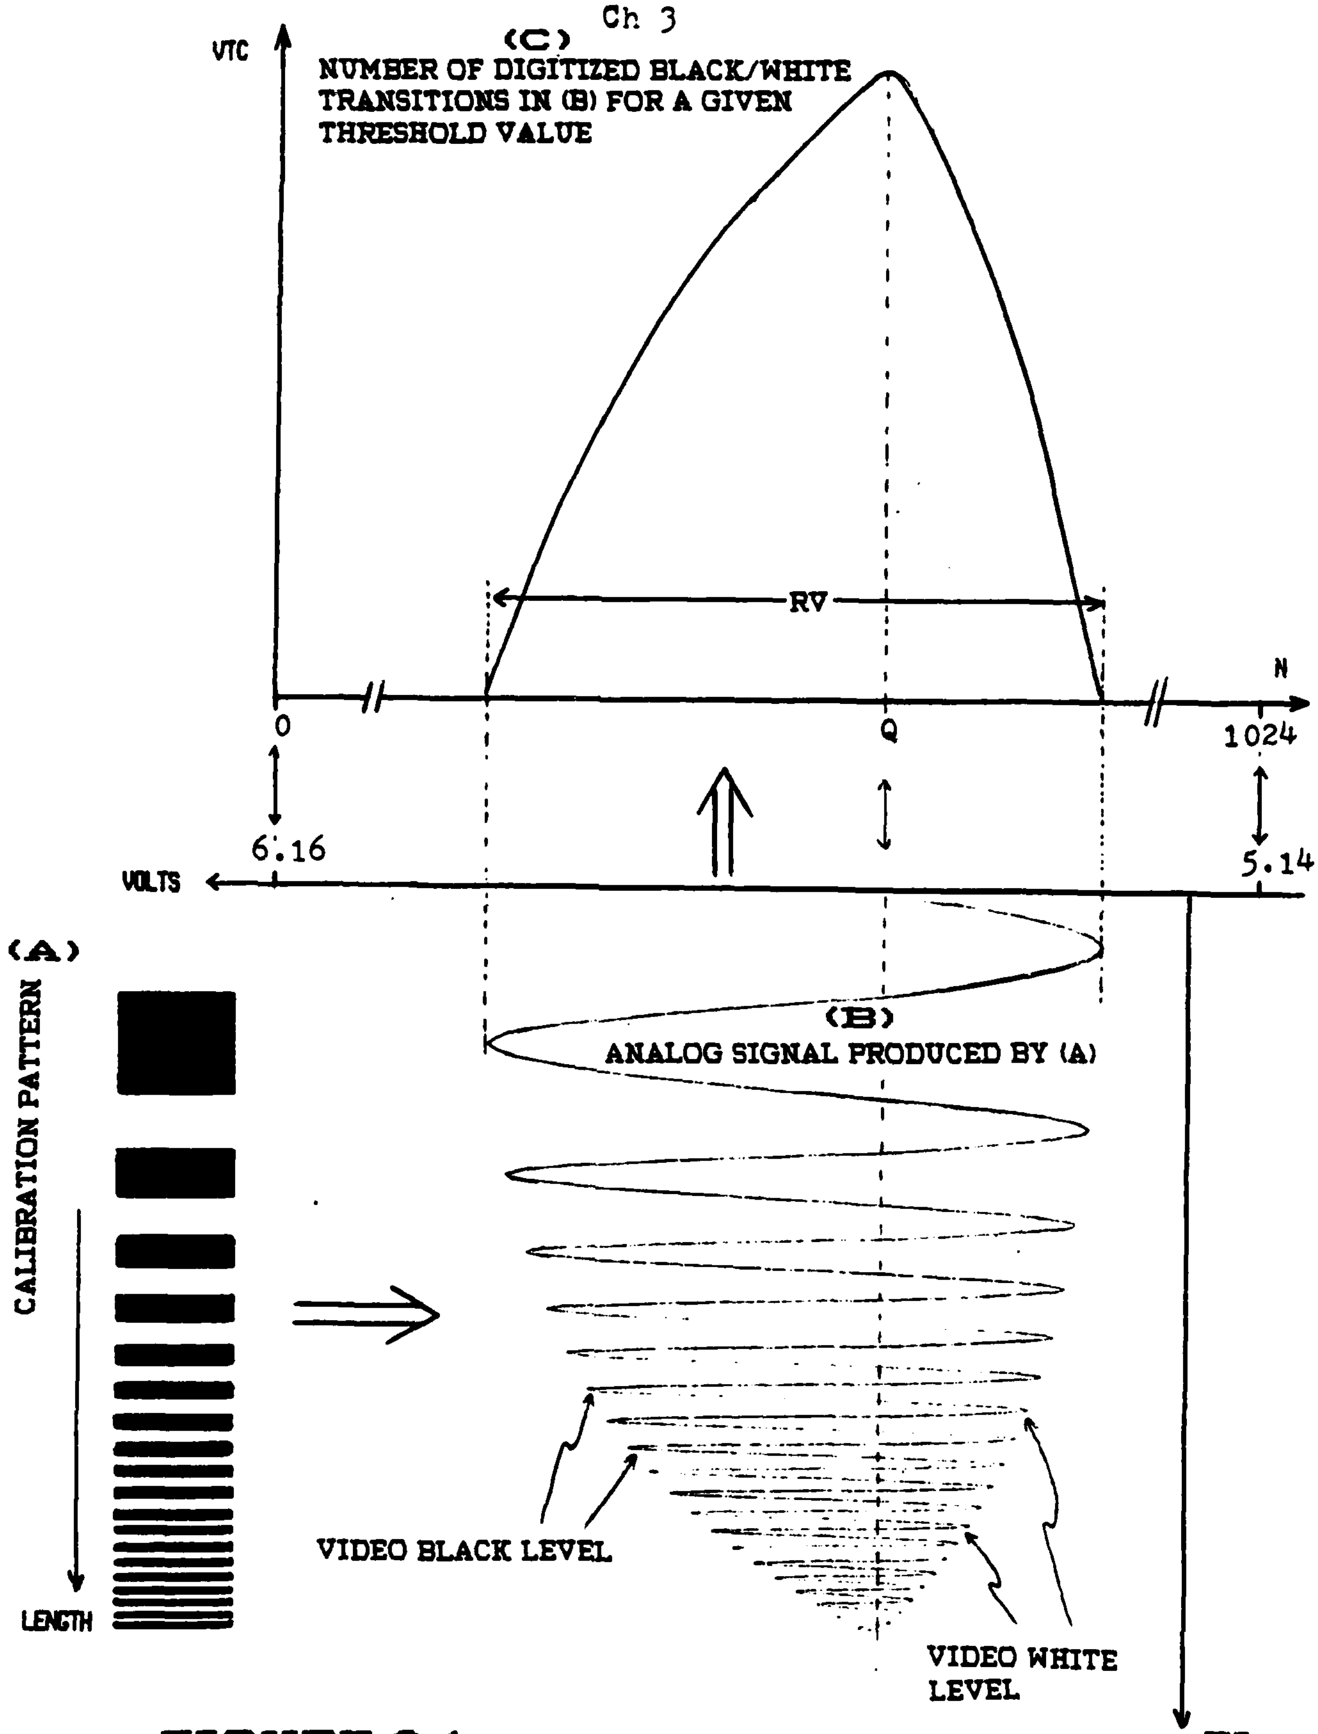

FIGURE 3.1 RELATION AMONG CALIBRATION PATTERN, ANALOG VIDEO SIGNAL, AND VTC-VERSUS-N CURVE

and (B). (1) So given that the CALIBRATION PATTERN will consist of line-pairs, the real question therefore is what spatial frequency or frequencies will be represented by the line-pairs. As mentioned in Chapter 2, the theoretical best choice would be a pattern that equally represented all spatial frequencies up to the CCD Nyquist rate of 100 line-pairs/inch. However it might also be possible that a pattern containing only the Nyquist frequency would be the best choice. It turns out that the very small pel swing generated by the Nyquist rate would be a significant disadvantage to the development of an efficient sampling algorithm. This point is covered in Chapter 5. The object of this phase of research was to ascertain the proper CALIBRATION PATTERN composition by direct evaluation of various candidate patterns. Unfortunately, within the scope of the project, there were relatively few sample patterns available for evaluation. Still much insight was gained with the patterns at hand, and a workable facsimile for a CALIBRATION PATTERN was obtained.

Another important question in CALIBRATION PATTERN composition is, in physical terms: How far along the left margin should the pattern extend? Or in other words, how much of one line of analog video does it take to successfully select the optimum threshold level? The answer, while not simple, can be illustrated fairly easily. Figure 3.2(A) shows the analog video

(1) Disregard Figure 3.1(C) for the present time.

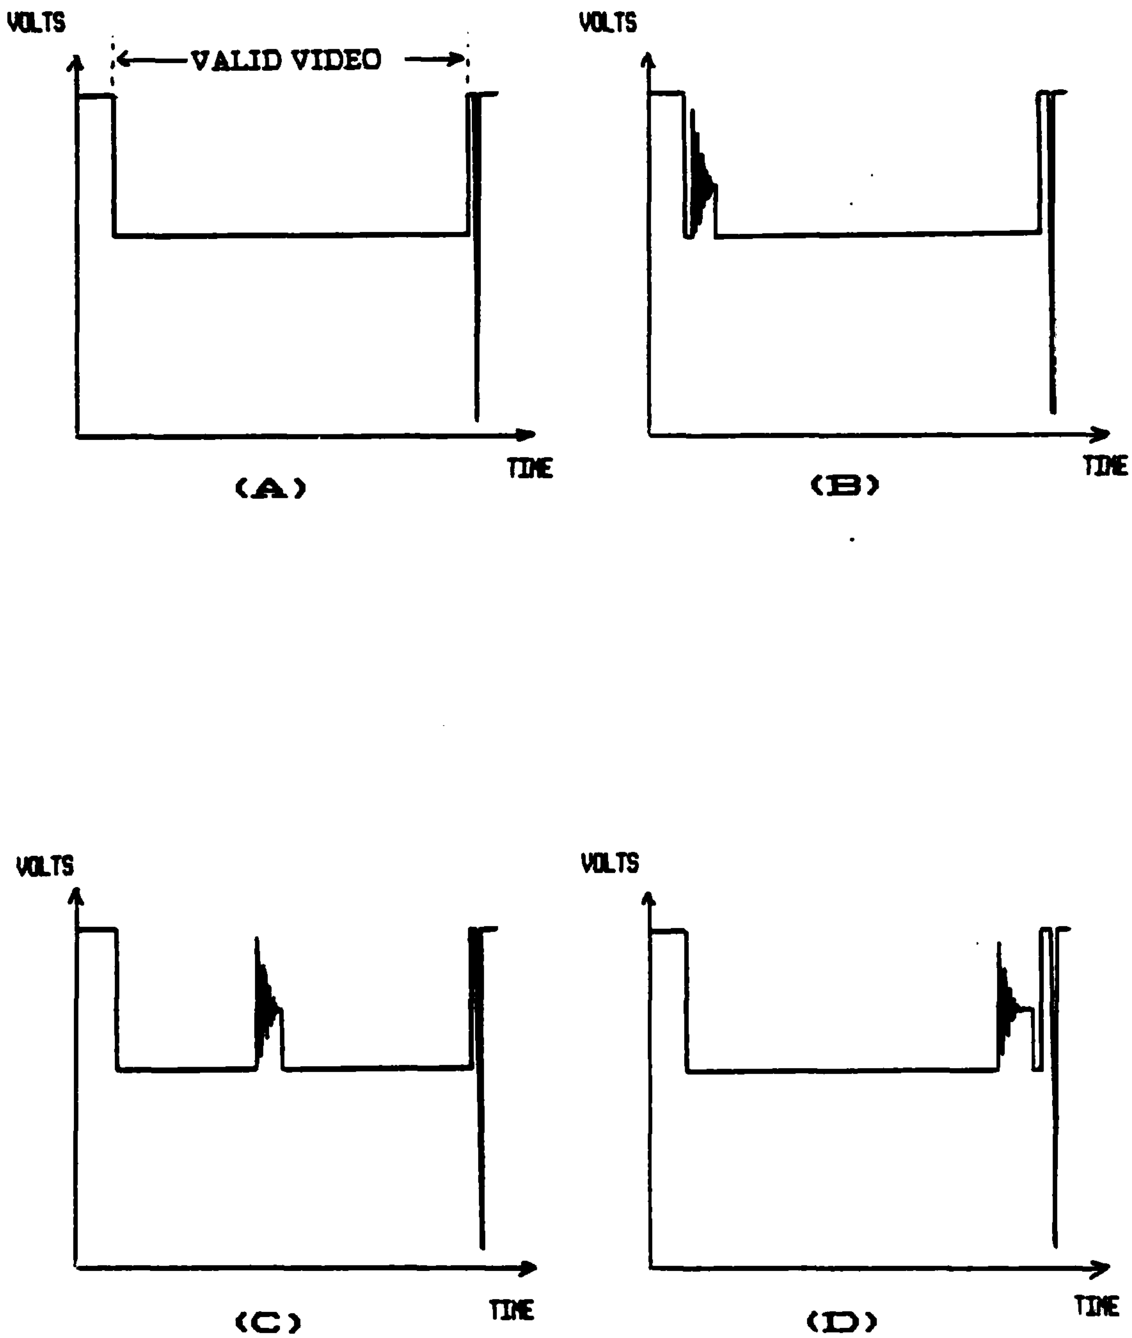

FIGURE 3.2 CALIBRATION PATTERN PLACEMENT EFFECTS ON THE ANALOG VIDEO SIGNAL

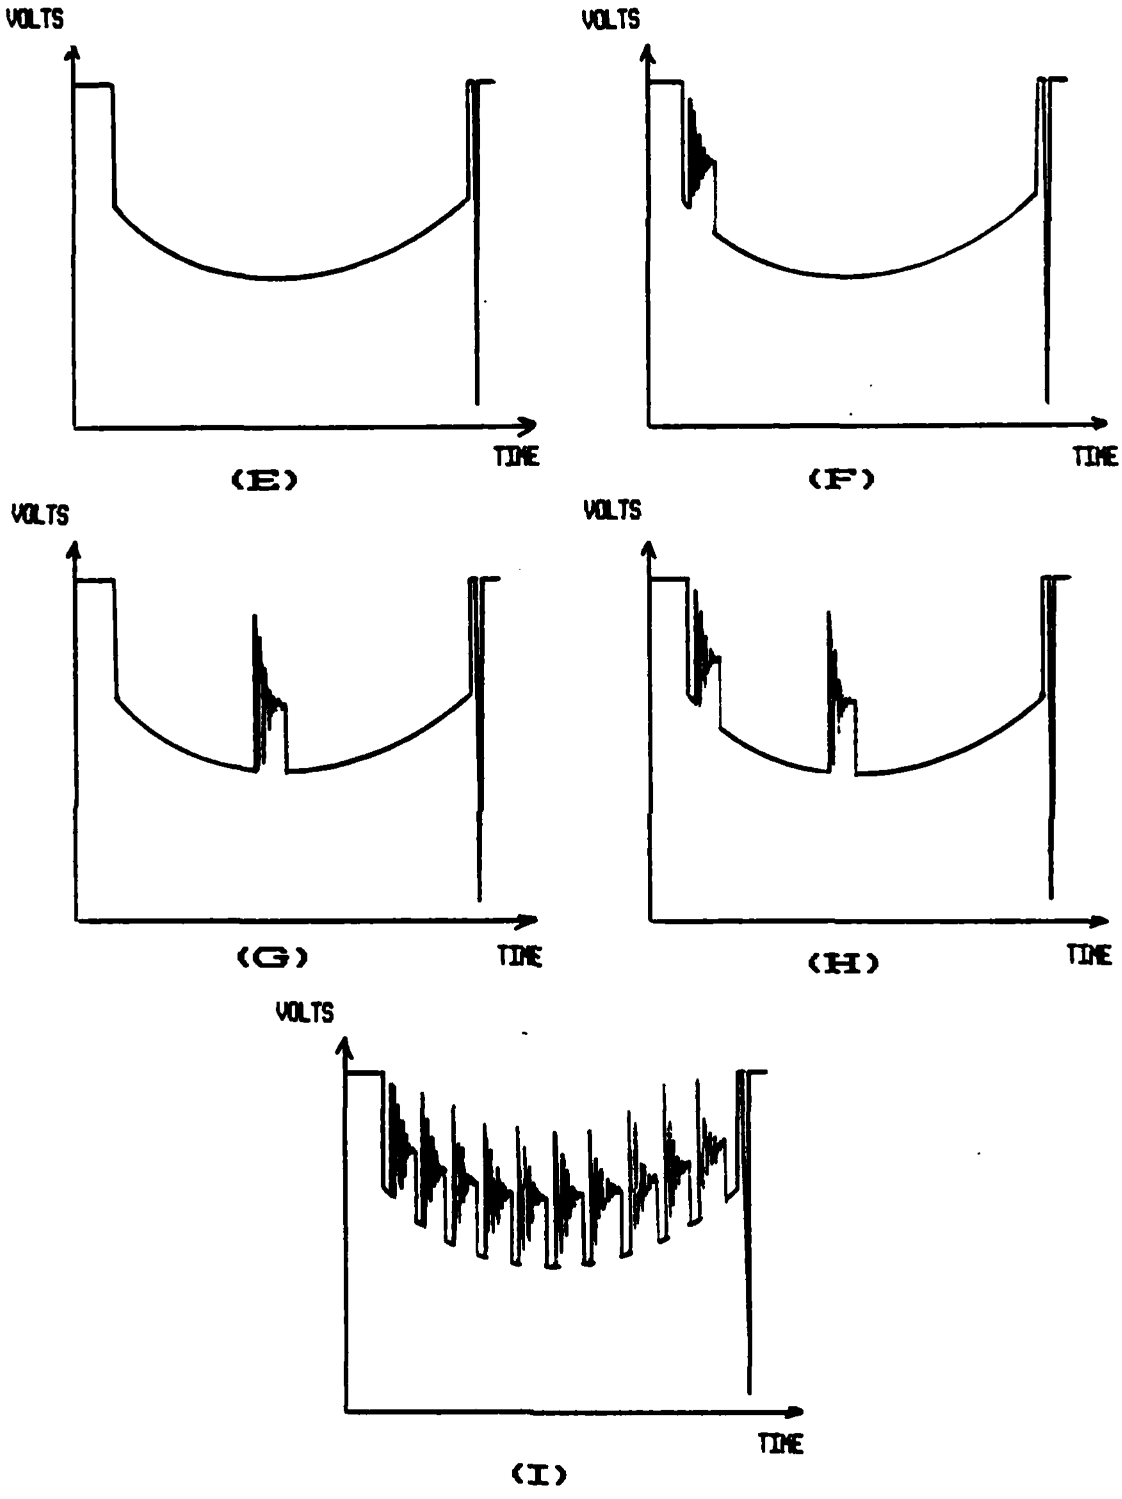

FIGURE 3.2 (CONT.)

signal resulting from scanning a blank white page with perfectly compensated illumination. Under these conditions, the CALIBRATION PATTERN that is superimposed on the white page would only need to be long enough to contain the necessary spatial frequencies, and could be located anywhere along the length of the margin. Figures 3.2(B), (C), and (D) show the analog signal that would result for pattern length of about an inch and placement in the bottom, middle, and top of the margin respectively. Now, for some reason, let us assume the illumination is not uniform over the length of the page, as illustrated in 3.2(E). The threshold level is now sensitive to pattern placement along the length of the margin as shown in 3.2(F) and (G). However, two patterns placed as in 3.2(H) would result in a threshold being chosen somewhere between the levels of 3.2(F) and (G). Realizing that this is indeed a compromise necessitated by less than optimum illumination, it is still a better choice than either extreme. Extrapolating to the limit, it would be necessary to use an entire line of video to get the best average over a line for non-uniform lighting conditions. This line corresponds to the entire left margin and should be filled with repeated CALIBRATION PATTERNs as in 3.2(I).

C. EVALUATION RESULTS

CALIBRATION PATTERN evaluation consisted of two stages: plotting the digital video transition count (VTC) versus threshold level value (N) for all possible threshold values; and running actual copies with the threshold value that yielded the maximum video transition count (MTC). The experimental CALIBRATION PATTERNs (ECPs) evaluated were obtained from the IEEE Std 167A-1975 Facsimile Test Chart whose data are contained in Appendix A. To simplify documentation, the ECPs that were examined are labeled A through F in Figure 3.3. Referring to this figure, ECP A (IEEE Facsimile Test Pattern 9) consists of repetitions of 12 discrete spatial frequencies ranging from 30.5 to 203 line-pairs/inch. ECPs B, C, and D (IEEE Facsimile Test Patterns 5, 4, and 3) are single-frequency patterns containing 48, 25, and 5 line-pairs/inch respectively. ECP E (IEEE Facsimile Test Pattern 19) contains 0.01-inch lines spaced 0.10 inch apart. ECP F is a vertical strip of pseudo-random text taken from the IEEE Facsimile Test Chart and chosen so as to fall in the 50-to-100 line-pairs/inch region of Test Pattern 12. While none of the ECPs precisely satisfy the theoretical criterion of containing all spatial frequencies up to the Nyquist value, it can be predicted that ECP A will exhibit the best performance due to its controlled distribution of discrete spatial frequencies. ECP F was included in the testing to get an idea of the behavior of the VTC curve when scanning a relatively uncontrolled variety of spatial frequencies.

A general plot of a VTC-versus-N curve is illustrated in Figure 3.4. To fully appreciate the information presented on this and similar plots to follow, a few details deserve highlighting. Recall first that the x and y scales represent integers; each unit increase in N corresponds to a decrease of

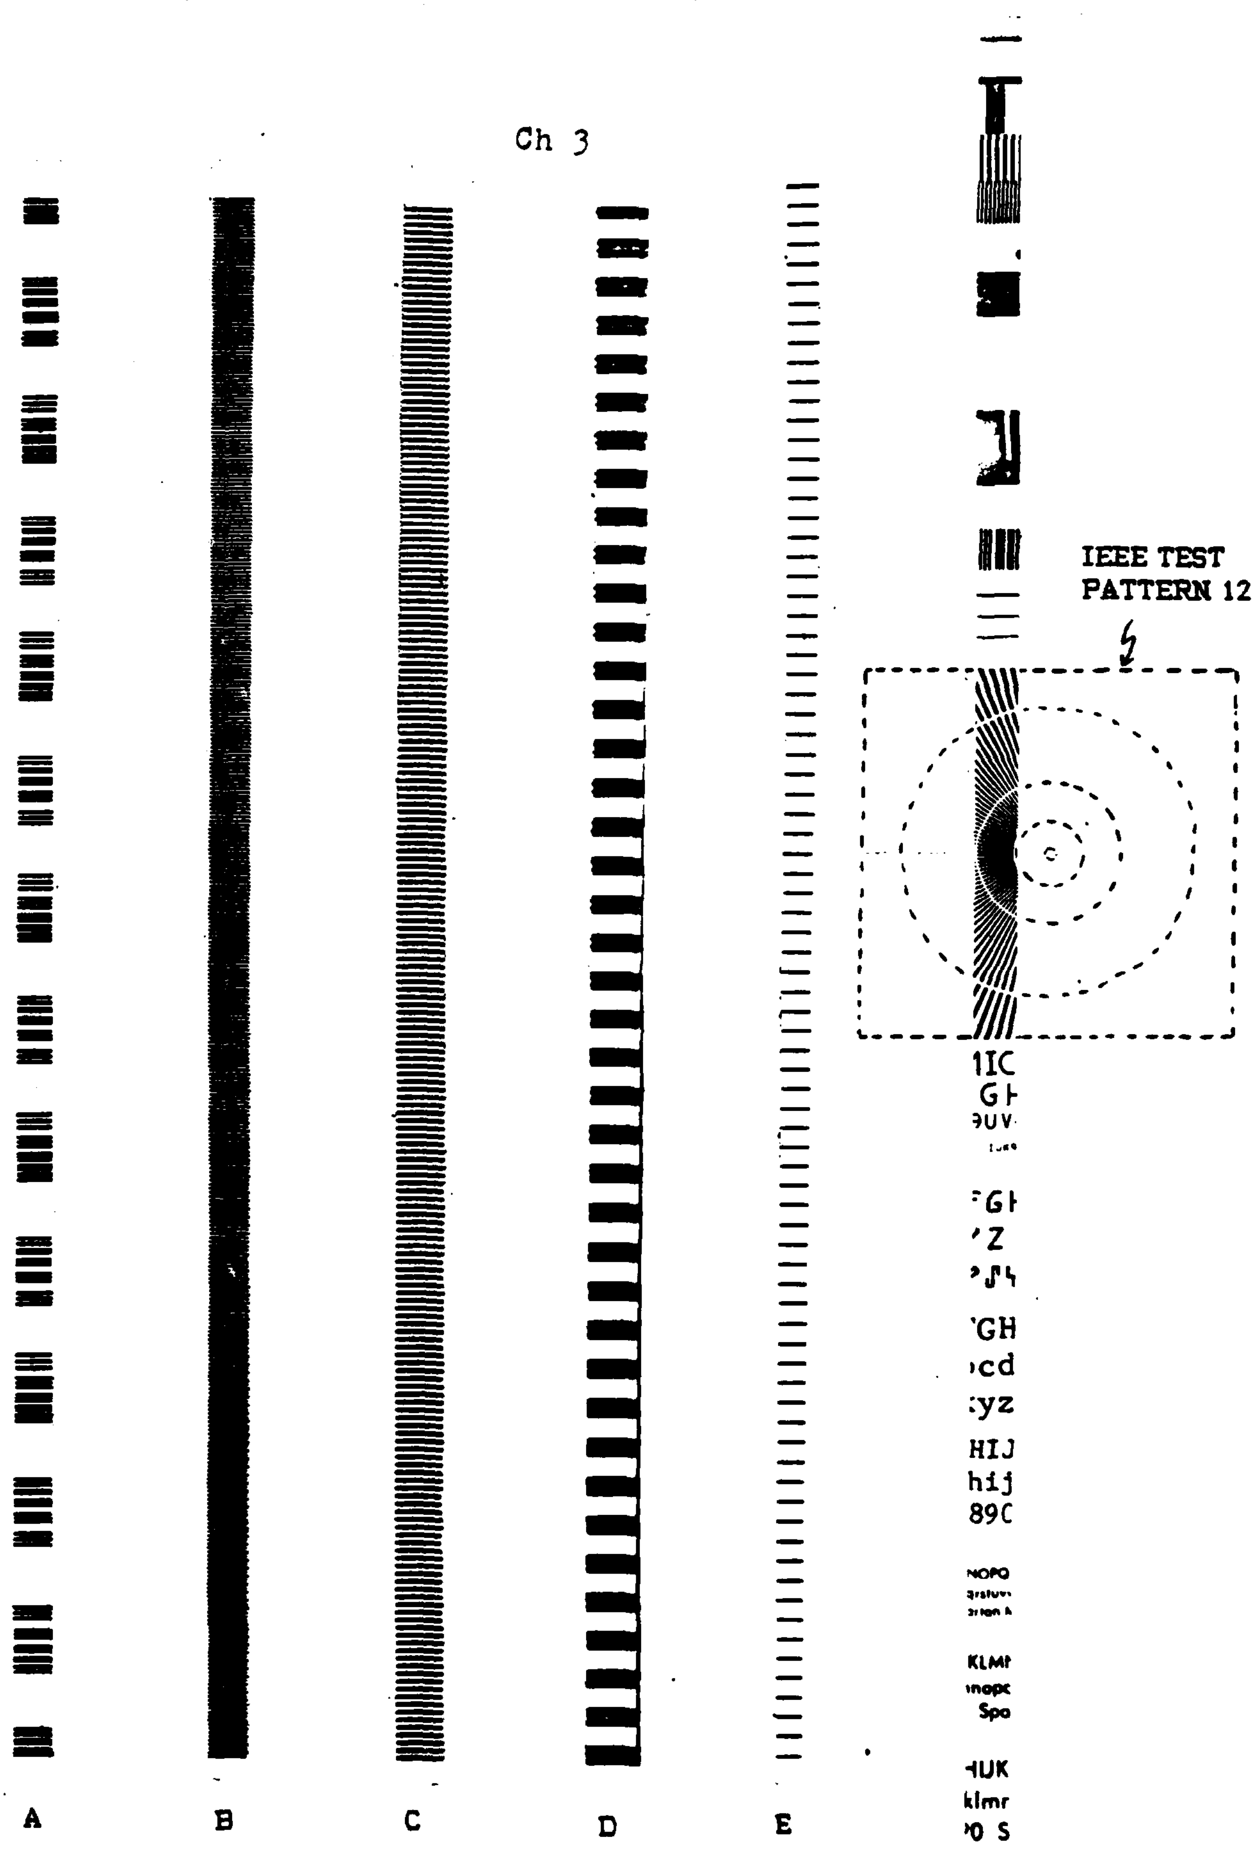

FIGURE 3.3 EXPERIMENTAL CALIBRATION PATTERNS (ECP) OBTAINED FROM IEEE FACSIMILE TEST CHART

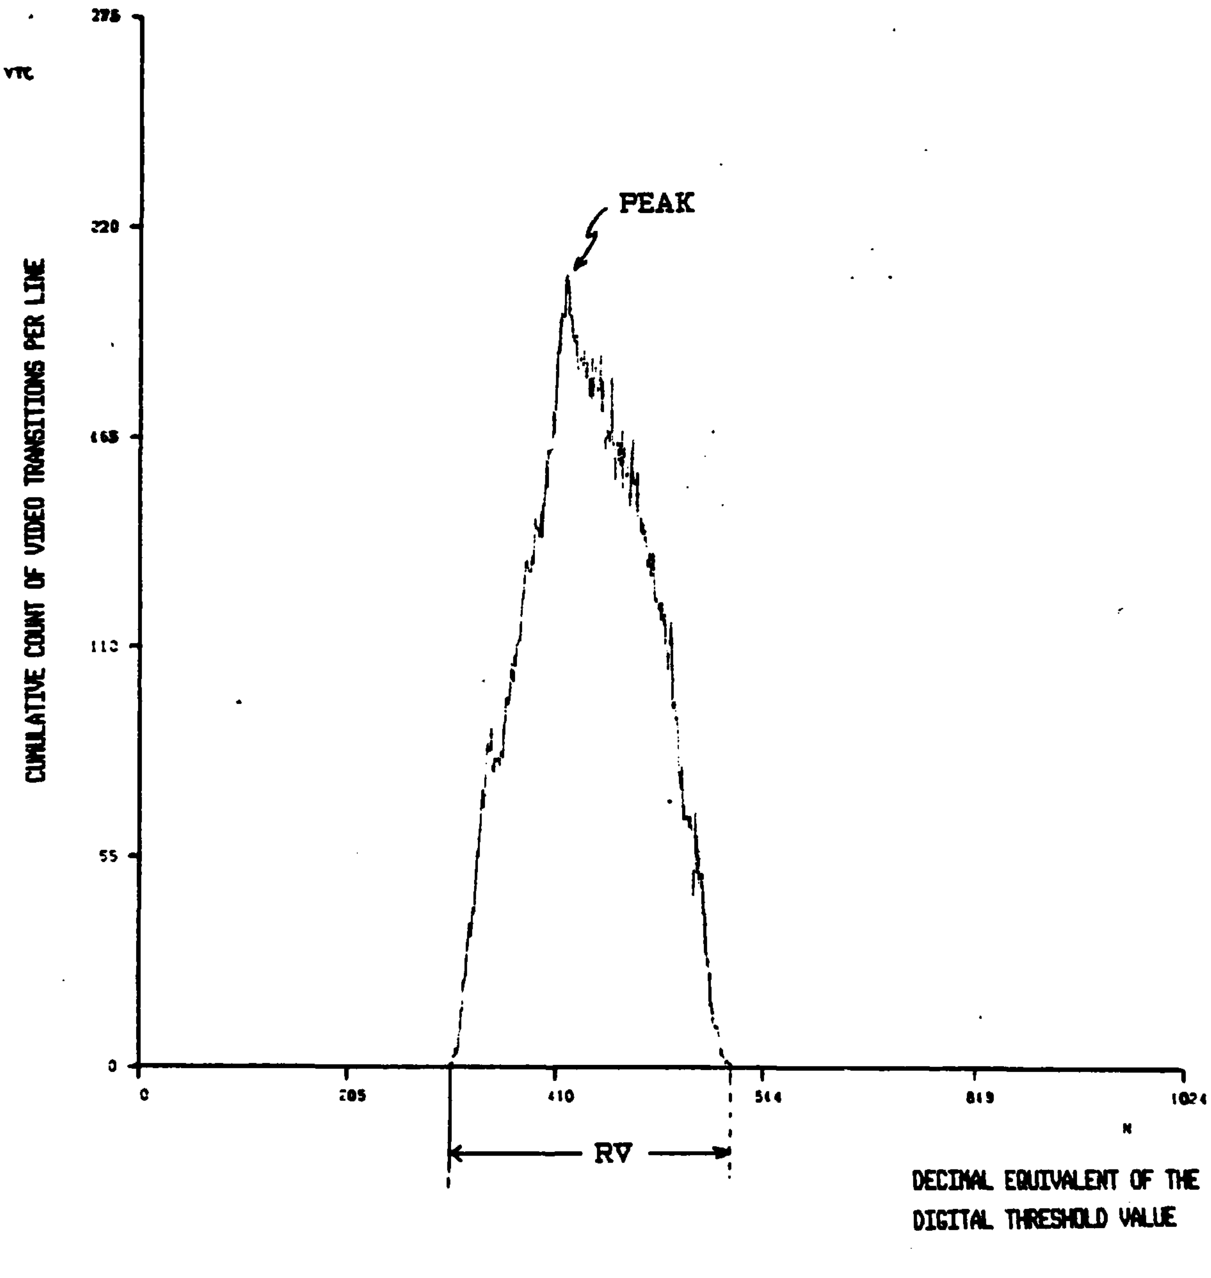

FIGURE 3.4 VTC CURVE PLOTTED OVER THE FULL RANGE OF N

one millivolt in the threshold level, and the dependent variable, VTC, is an accumulation of black/white transitions along one line of video for a given value of N. Although the full range of N is depicted, only a relatively small span contains pertinent information. Therefore, subsequent plots will constrain the N-axis to the span of significant VTC information. It should also become apparent that the span of N containing significant VTC information (subsequently called RV) is directly correlated to pel swing; larger pel swings will result in larger spans of RV, as illustrated by the relationship between parts (B) and (C) of Figure 3.1. This feature will be especially useful when comparing various plots. As for the vertical axis, VTC, it is emphasized that the absolute value, while interesting, is not nearly so significant as where along the horizontal axis the PEAK of VTC occurs. As an example, it is easy to see that ECP B in Figure 3.3 will have a much larger overall VTC than ECP D simply because it provides more black/white transitions per video line. This however does not mean that the peak of ECP B will be easier to detect. Since the idea is to work with digital information, the ATC will be equally capable of detecting a peak with a value of 800 or a peak with a value of 200. The absolute value of the peak is arbitrary. The important information is the value of N that causes the peak, because it is that value of N that the ATC should choose for its optimum threshold. One final property of these plots can best be described by referring to Figure 3.1. When N equals zero, the threshold level is at 6.16

volts, or well above the video signal. As N increases, the voltage threshold level decreases, eventually passing through the span of the analog video signal. On the basis that any portion of the analog video signal below the threshold level is decoded as white, and any portion of the analog signal above the threshold level is decoded as black, it can be seen that, when the threshold voltage lies between 6.16 volts and point Q, a portion of the video transitions to black are being lost. In other words, the digitized video signal contains less black information than it should. Conversely, when the threshold voltage is between point Q and 5.14 volts, the digitized video signal contains less white information than it should. So, when this information is applied to the VTC-versus-N plot in Figure 3.4, the values of N to the left of the VTC peak equate to thresholds that give lighter-than-optimum copy, and values of N to the right of the VTC peak equate to thresholds giving darker-than-optimum copy. This, of course, assumes that the VTC peak is indeed AT the optimum threshold N value. Figure 3.5 illustrates this point by showing scanner reproductions of IEEE Facsimile Test Pattern 12 for incremental increases of N. Note the lack of black information with the smaller values of N followed by lack of white information as N increases beyond optimum.

We are now in a position to intelligently analyze the VTC-versus-N plots for the various ECPs to see if an optimum threshold value is indeed pinpointed by the peak of the VTC

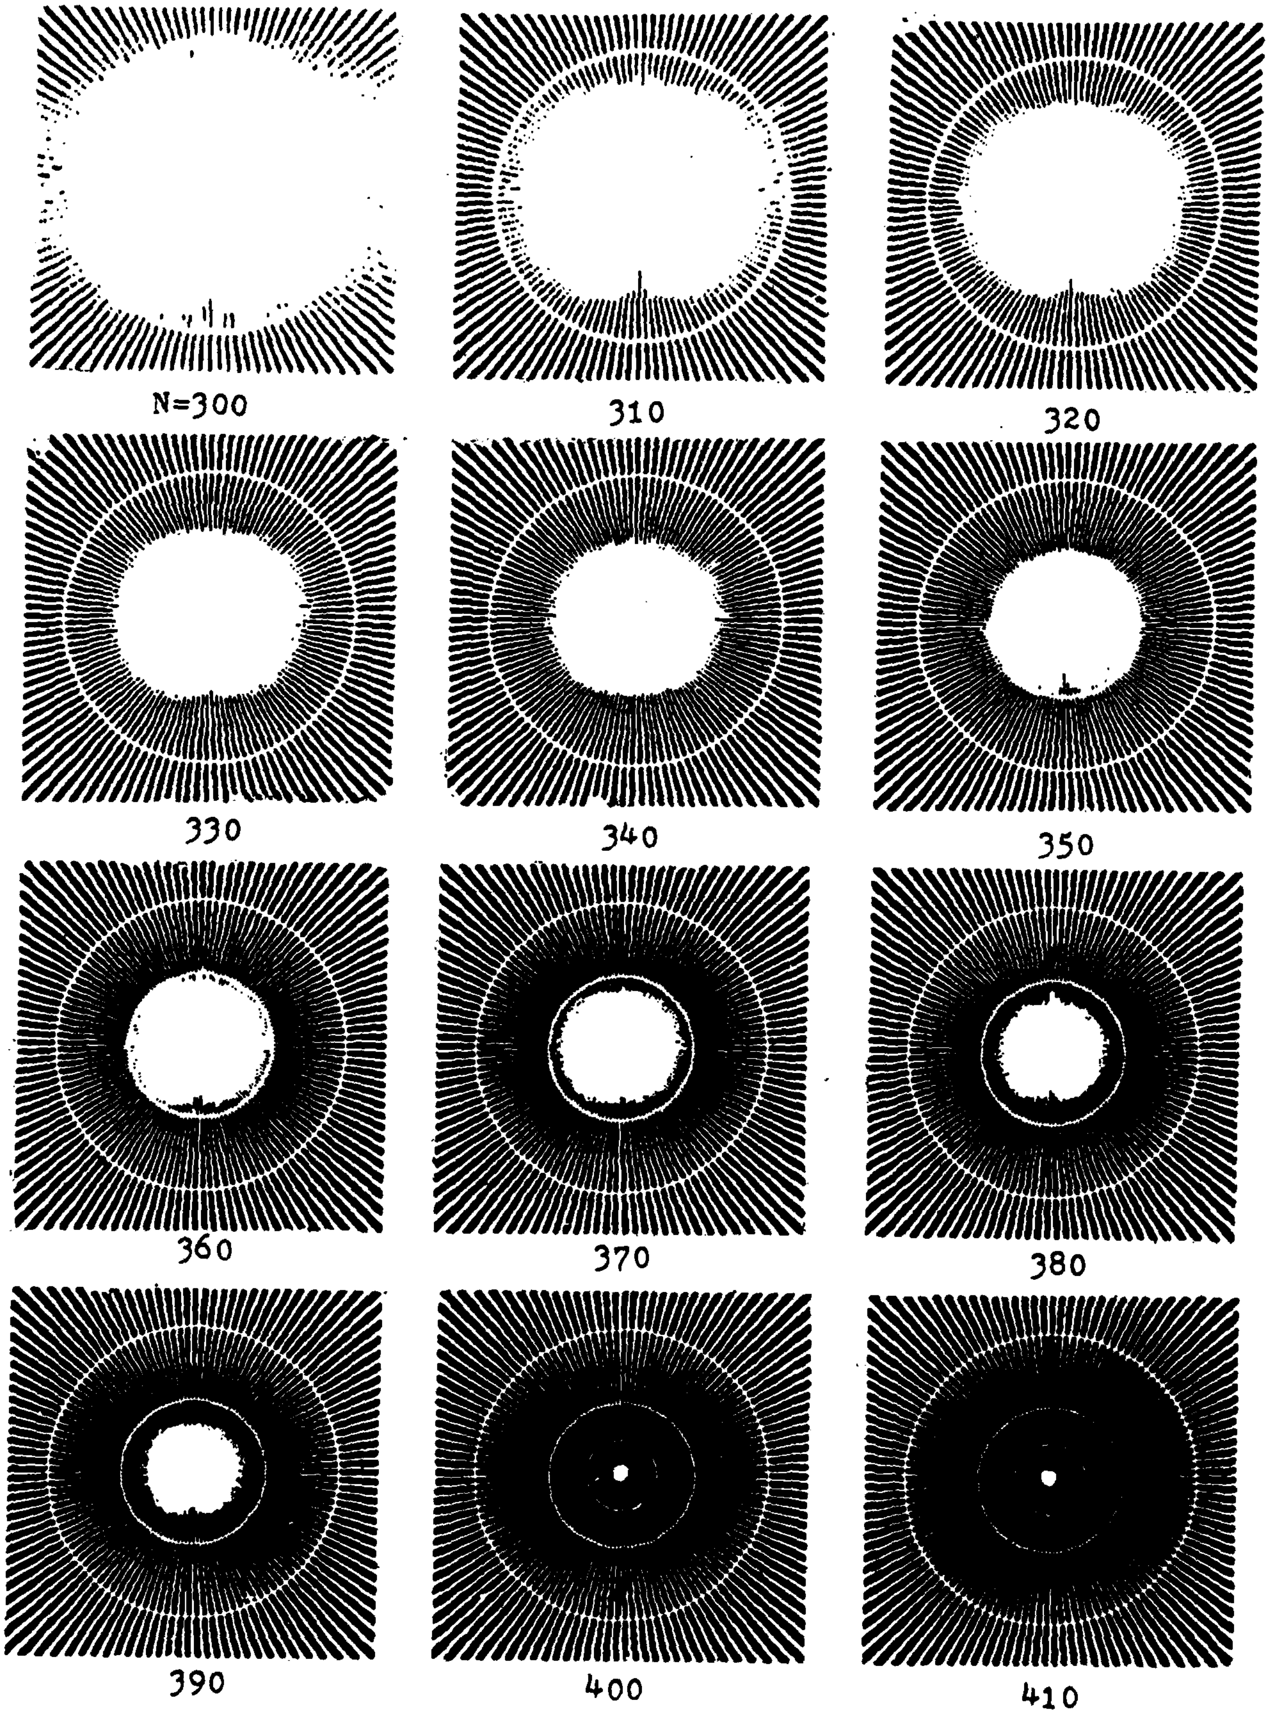

FIGURE 3.5 IEEE TEST PATTERN 12 SCANNED WITH INCREASING VALUES OF N WHICH CORRESPONDS TO DECREASING VALUES OF THRESHOLD VOLTAGE

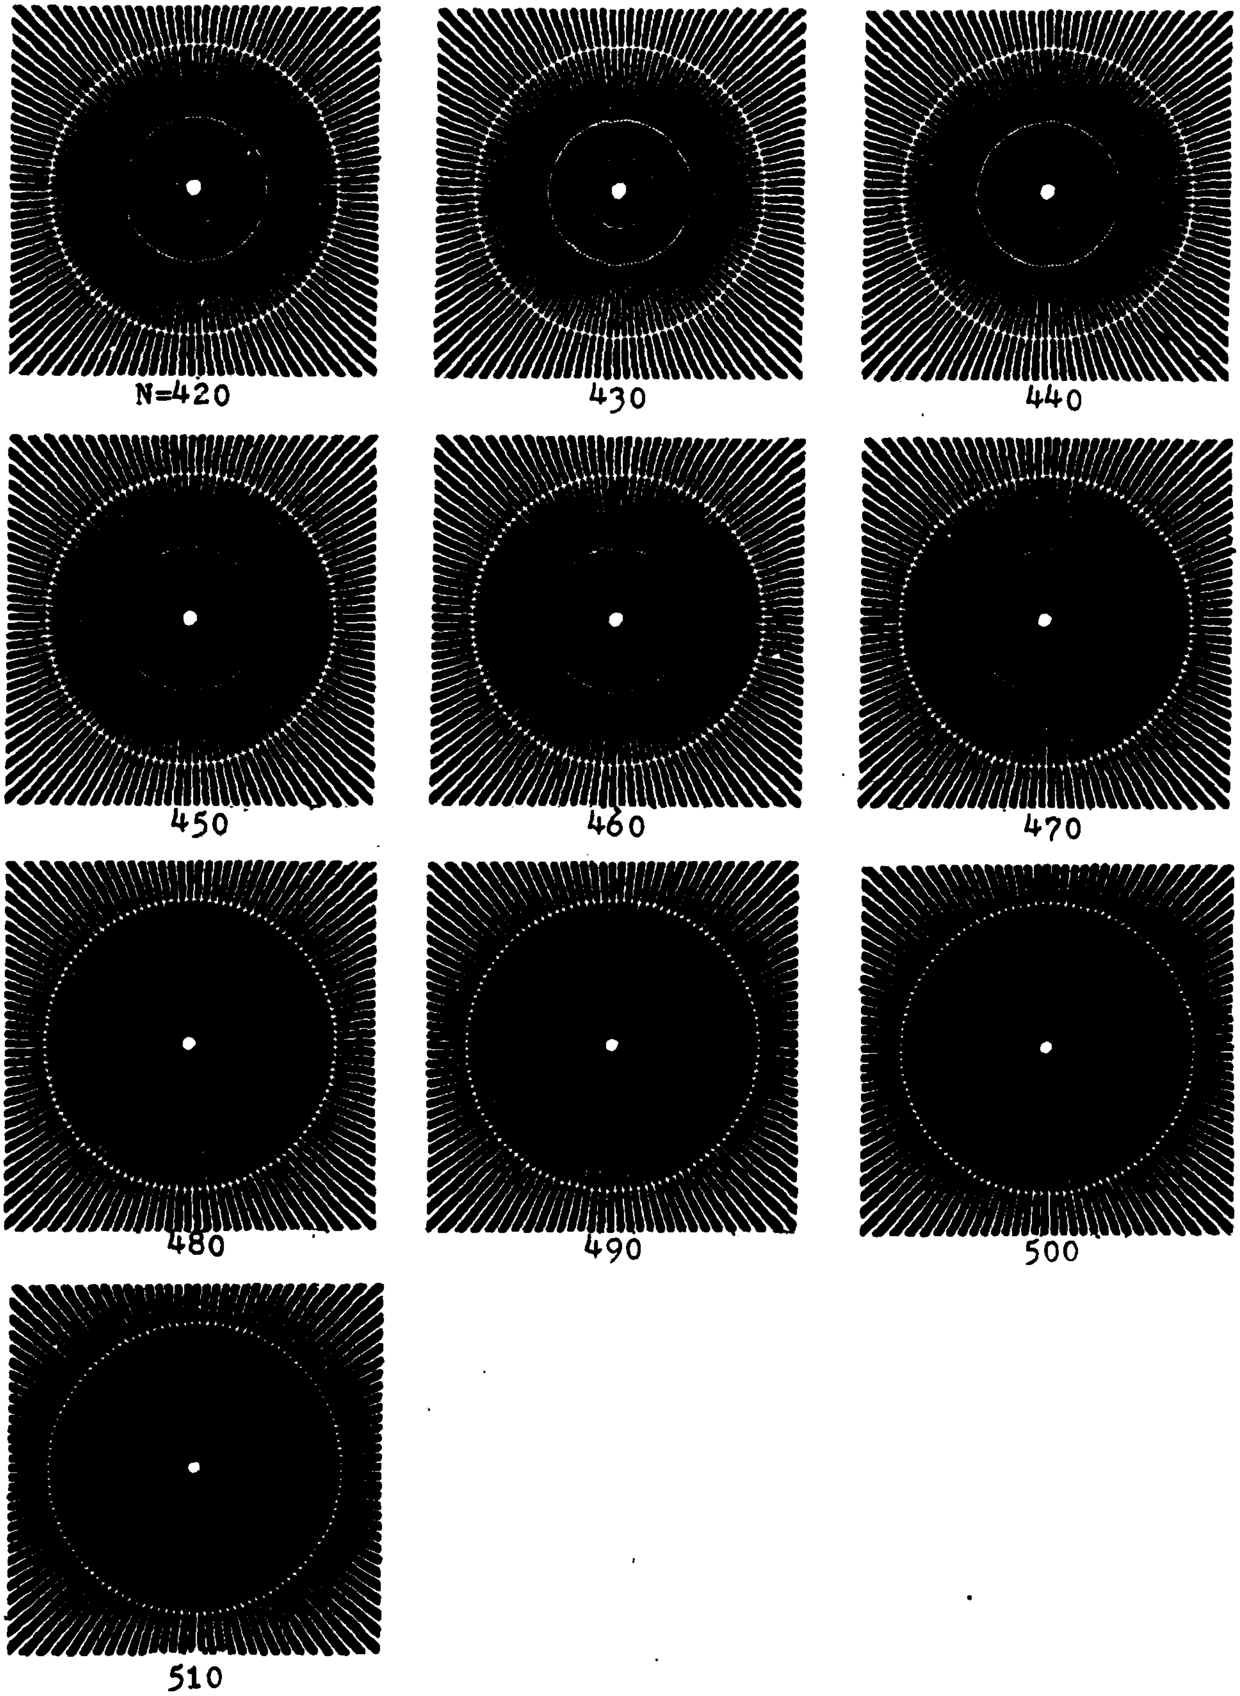

FIGURE 3.5 (CONT.)

curve. Figures 3.6 to 3.12 contain individual plots of the various ECPs. In Figure 3.6(A) ECP A was found to exhibit the desired characteristics required for the ATC. The peak of VTC was well defined and indeed occurred at a value of N that produced optimum hard copy as in Figure 3.6(B). Note that even in the copy in this report, (1) the capital letters in the 4-point type are legible.

When scanning a single discrete spatial frequency, the analog signal will be very nearly sinusoidal with constant amplitude. For this reason the number of black/white transitions will be constant in the span of significant video information. Accordingly, constant-frequency ECPs B, C, and D in Figure 3.3 produced predictable plateau-type curves. These curves are shown in Figures 3.7 to 3.9. The peaks for some undetermined reason occurred at either end of the plateau region, but intuitively it can be concluded that these peaks were not precipitated by valid video transitions. When hard copy was produced by thresholds based on these peaks, the results were as anticipated: either too light in the cases of ECPs B and C, or too dark in the case of ECP D. A comparison of the VTC plots of these three ECPs in Figure 3.10 provides an interesting manifestation of the

(1) Subsequent scanner outputs in this thesis will be xerox reproductions which fail to do complete justice to the actual scanner hard-copy output. Therefore in some cases, scanner output will only be described rather than included for viewing. Also the reader should be aware that the scanner system digitizes to only one binary level. Hence, gray tones in the IEEE Test Chart are not reproduced as such. The photograph, for example, (IEEE Test Pattern 15) is substantially degraded from the original.

reduction in RV spans with increasing spatial frequency due to smaller pel swings. And with increases in spatial frequency, the VTC curves naturally are higher due to more black/white transitions. The trend exhibited by these curves provides the probable conclusion that if an ECP were available containing the Nyquist frequency of 100 line-pairs/inch, it would most likely produce an impulse-like VTC curve centered around the value of N providing the optimum threshold level.

ECP E in Figure 3.3, due to its constant frequency nature, also yielded a plateau-shaped curve. See Figure 3.11. Its utility was no better than the other discrete-frequency ECPs. On the other hand, ECP F had a definable peak because of the variety of spatial frequencies present (Figure 3.12), but its usefulness was marginal since the actual peak information was occluded by the uncertainty in the data. Therefore, ECP A is obviously the best choice as a CALIBRATION PATTERN for the ATC. Figure 3.13 presents a comparison of all ECP plots as a convenience to the reader.

When the behavior of ECP A plots is analyzed with respect to other variables, further insight is gained to the robustness of its ability to select the optimum threshold value based on the VTC peak. For example, Figure 3.14 shows the behavior of the VTC curve with the loss of one fluorescent light. As expected, less light causes a smaller pel swing which is evidenced by comparing the spans of N in the two curves. Looking more closely, one can see that while the curves begin to rise at almost the same value

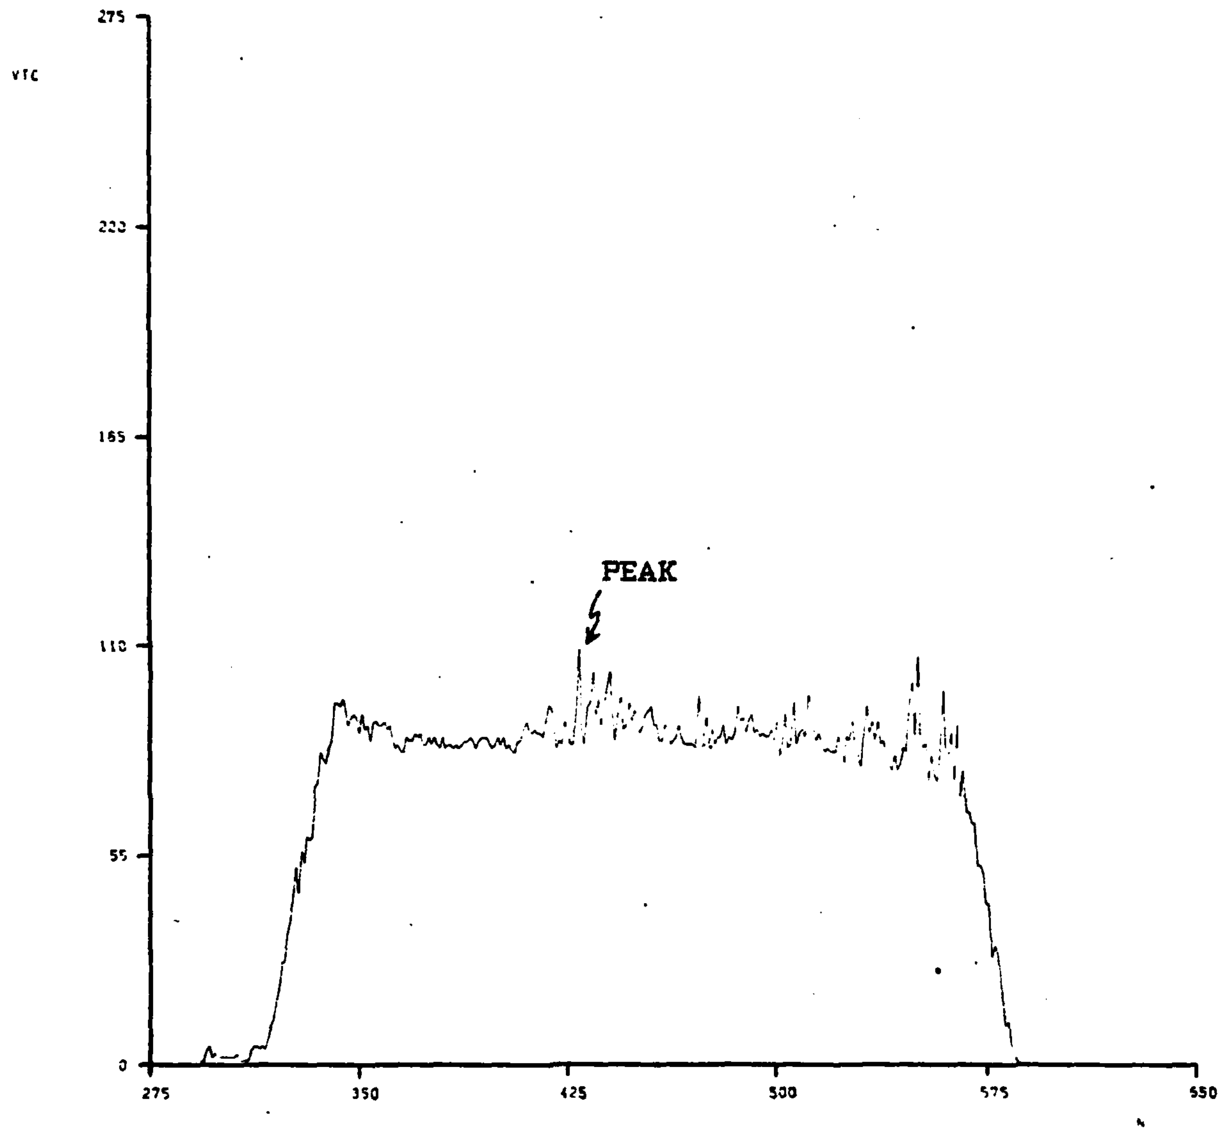

FIGURE 3.11 VTC-VERSUS-N CURVE FOR ECP E

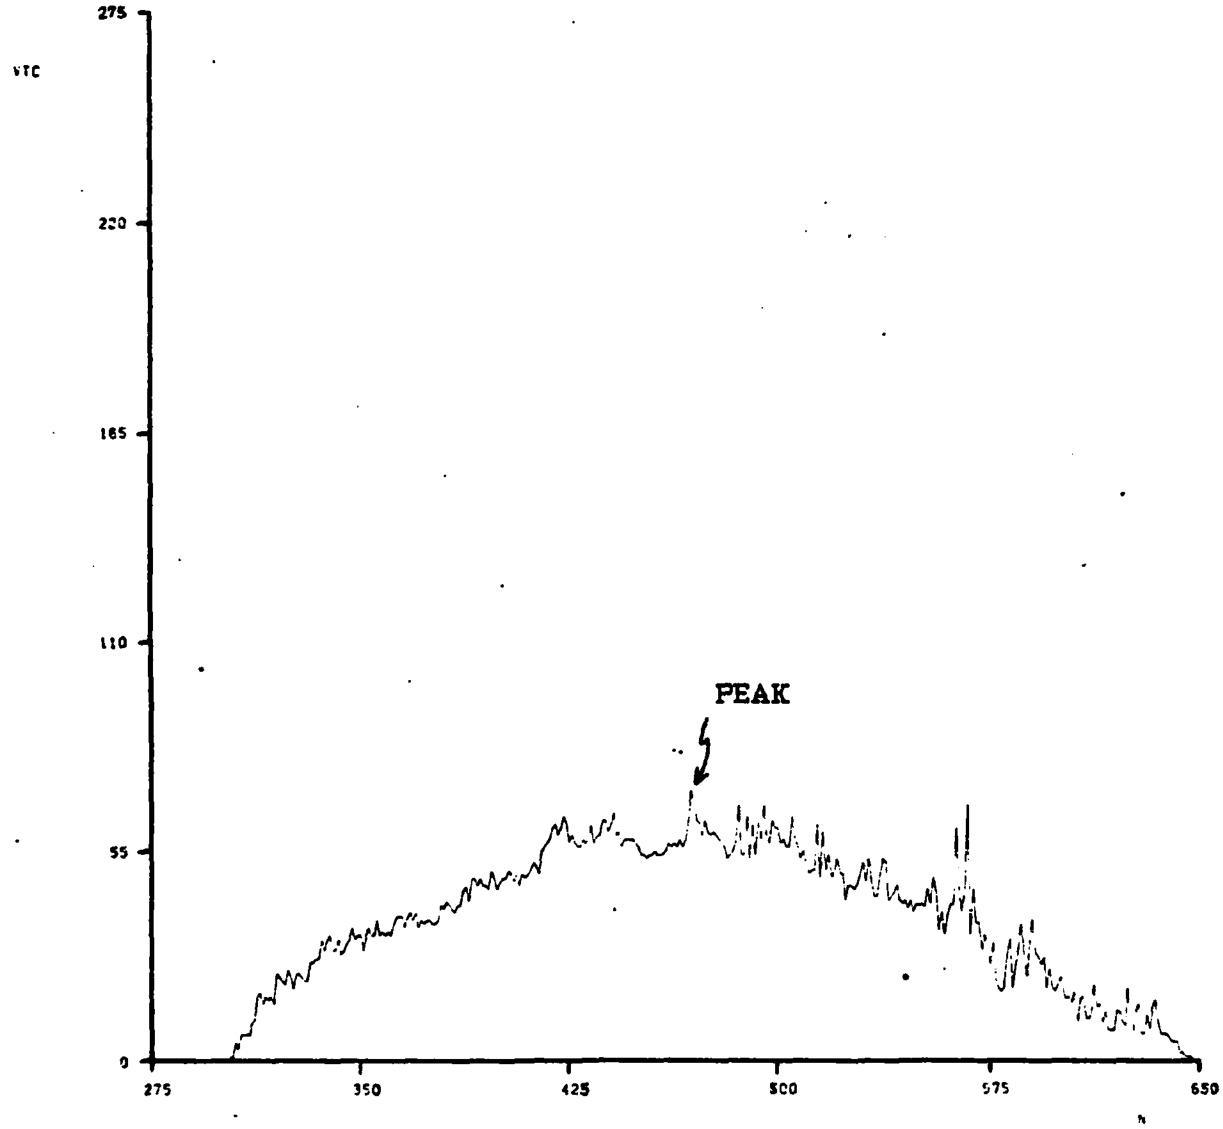

FIGURE 3.12 VTC-VERSUS-N CURVE FOR ECP F

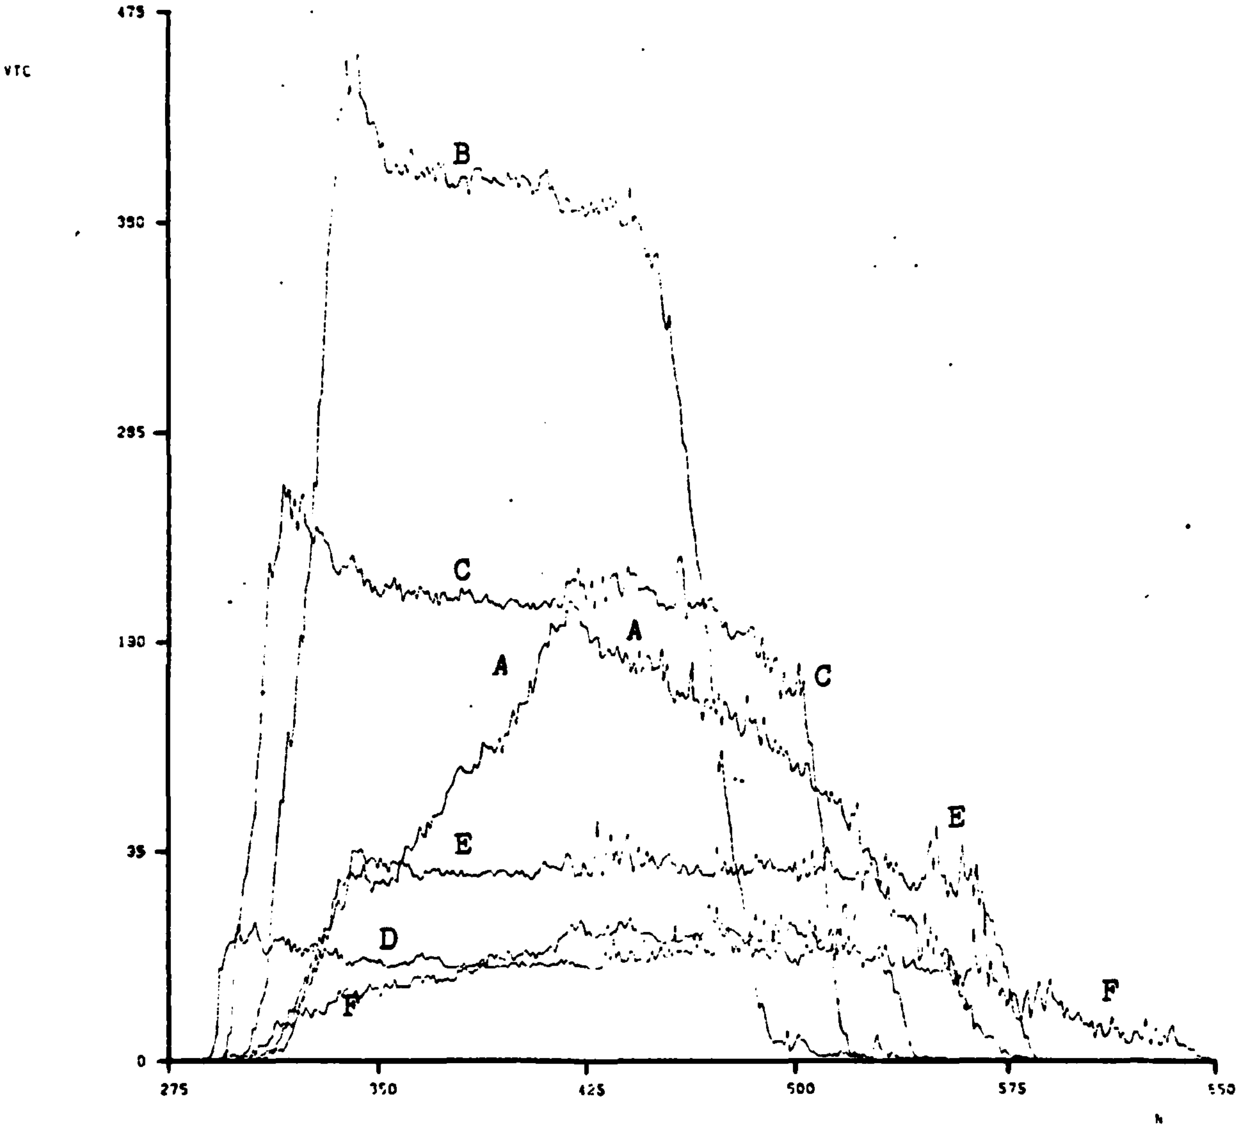

FIGURE 3.13 COMPARISON OF ECFs A THROUGH F

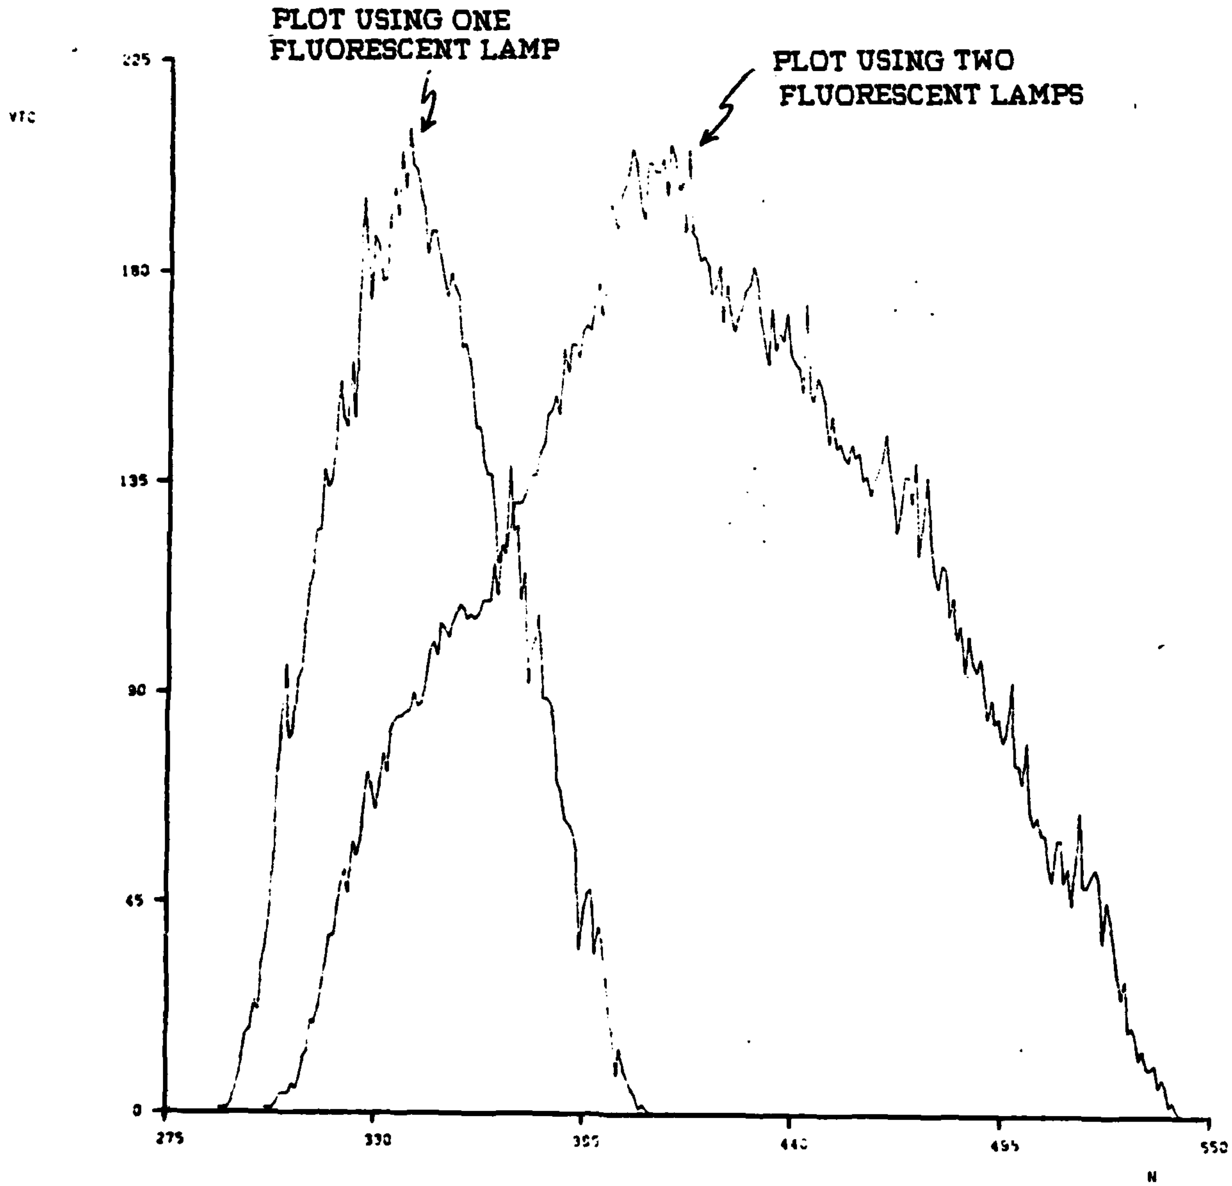

FIGURE 3.14 EFFECT OF ONE FLUORESCENT LAMP VERSUS TWO ON ECP A

of N on the left, they return to zero at much different N-values on the right. The interpretation is thus: In the analog video signal, different amounts of light cause small shifts in the black signal level but large shifts in the white signal level. It can also be seen that of the two curves, the curve resulting from one lamp has the steeper slopes on both sides. This means that an increase in light causes a more dramatic increase in pel swing at the lower spatial frequencies versus the higher spatial frequencies. But by far the most important result is that both curves display an obvious peak; one that will be chosen by the ATC algorithm. The threshold level defined by the two peaks were clearly optimum for the available light, as judged by the quality of hard copy output. (1)

Figure 3.15 illustrates similar effects with different colors of paper. Here the diminishing pel swing and increasing slopes are even more dramatic with the darker colors. As in Figure 3.14, there is a definite shift of the optimum threshold value, but the ATC design will inherently compensate for these shifts and continue to select the threshold providing the best resolution. (2) Figure 3.16 consists of plots using fluorescent lights with various spectral contents. The conclusion is that among the colors examined -- green, cool white, and warm white -- there was not a significant difference in performance, although

(1) Hard-copy samples resulting from single-lamp illumination are contained in Chapter 6.

(2) Scanner output of the IEEE Test Chart on red background is contained in Chapter 6.

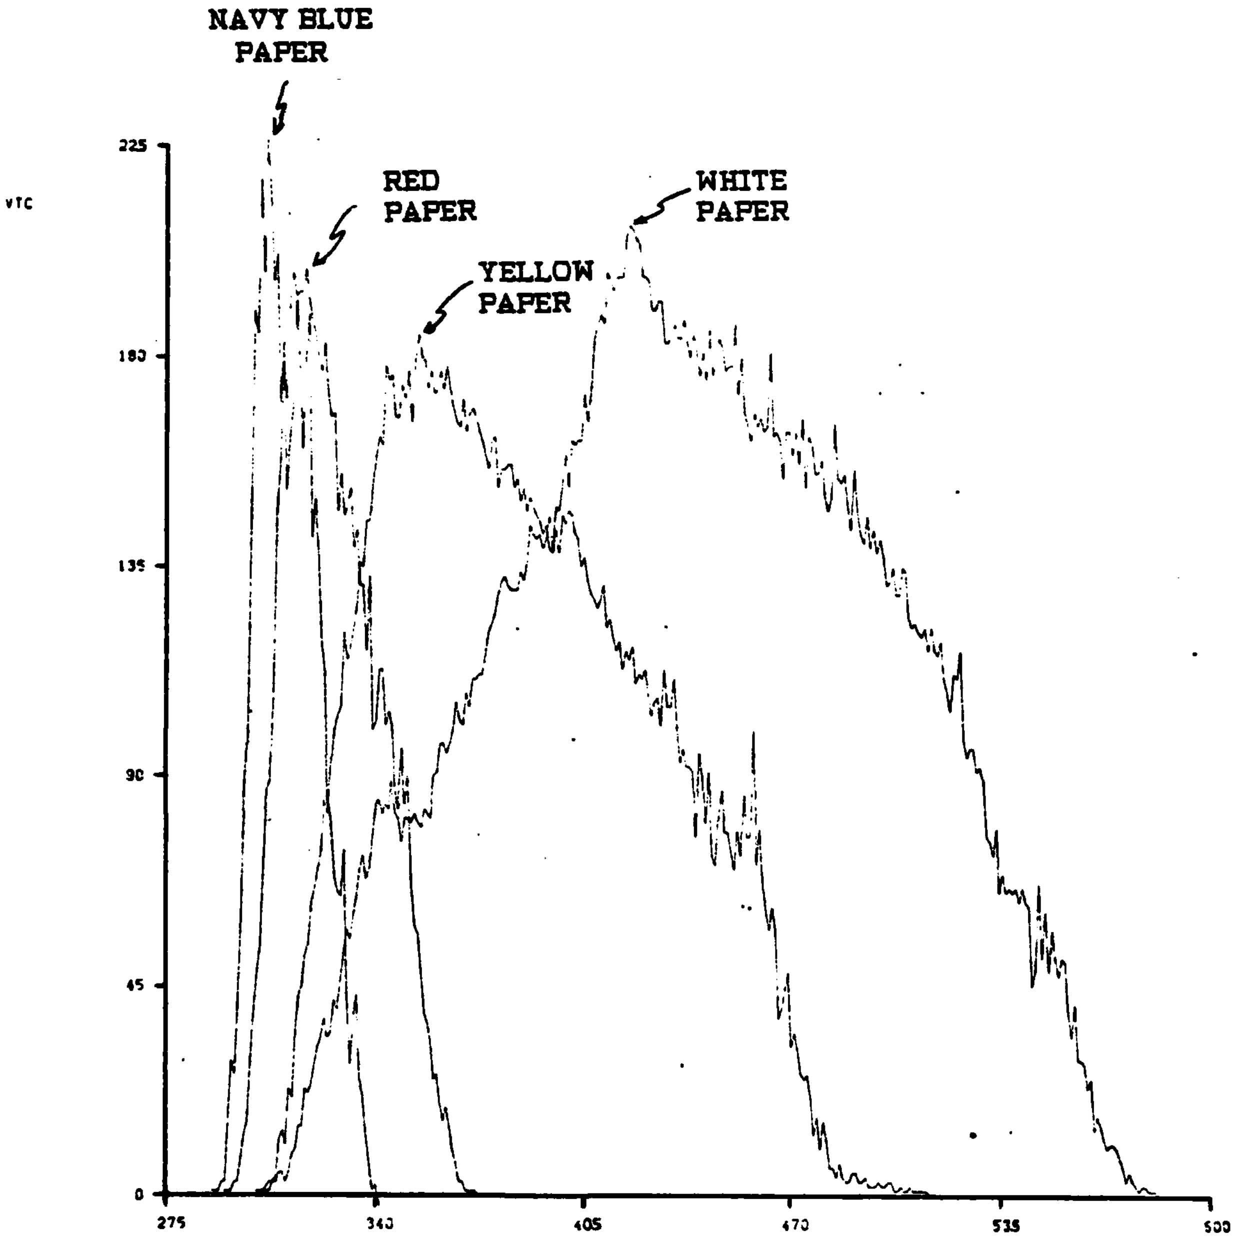

FIGURE 3.15 EFFECT OF DIFFERENT PAPER COLORS ON ECP A

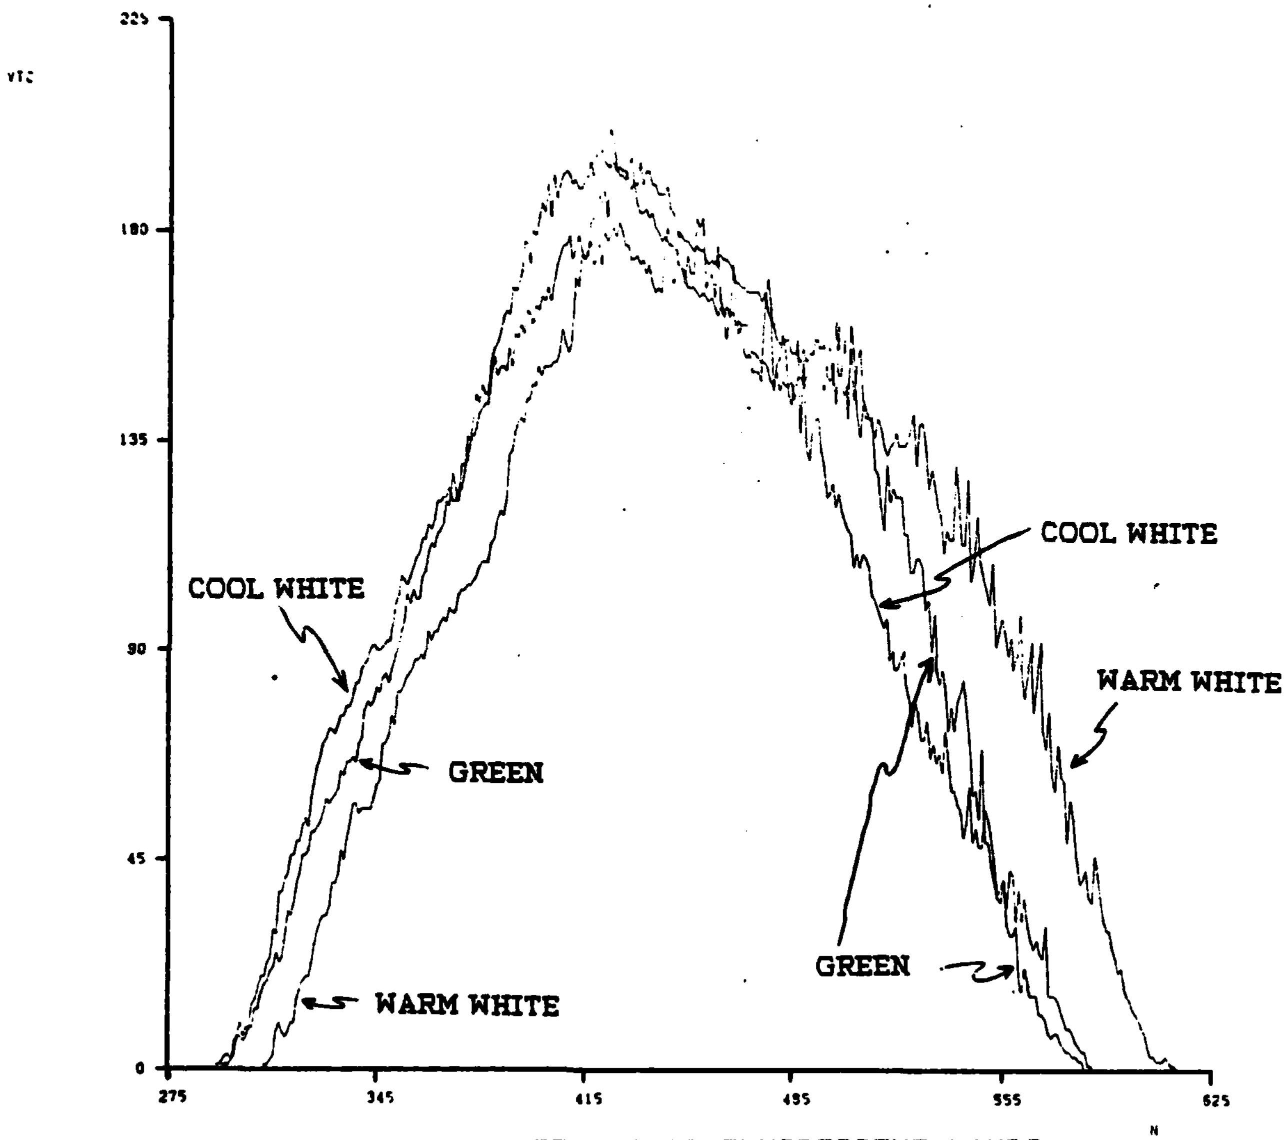

FIGURE 3.16 EFFECT OF FLUORESCENT LAMPS OF DIFFERENT SPECTRAL CONTENT ON ECP A

the warm white bulbs did appear to generate a slightly larger pel swing. On the other hand, Figure 3.17 demonstrates that fluorescent lights experience a certain amount of degradation over their lifetime. Once again the ATC will compensate for this effect. It should be noted that fluorescent lights deteriorate in a non-uniform manner over the length of the tube. Deposits on the inner walls near the filaments at either end cause excessive degradations in light emission at the ends, resulting in precisely the analog waveform illustrated in Figure 3.2(E).

As one final point, note that the curves contain a small degree of uncertainty rather than being smooth. It is hypothesized that the jitter is caused at least in part by the clocking noise in the scanner circuitry. Another cause could be power supply fluctuations producing minor deviations in the output of the circuitry generating the threshold voltage. The important conclusion is that while the general shape of the VTC curve is stable, individual plots will differ by some small amount as illustrated in Figure 3.18, which shows several runs taken under identical conditions. In this instance, extreme care was taken to insure all inputs remained constant, and yet there was still a small degree of inconsistency in the plots taken. The uncertainty that is present is by no means a barrier to the proper operation of the ATC, but the reader must be aware that the DEGREE of uncertainty in the VTC curve will have an effect on ATC performance especially with respect to the VTC sampling activities detailed in Chapter 5.

CHAPTER 4

AUTOMATIC THRESHOLD CONTROL (ATC) DESIGN

A. ATC BLOCK DESCRIPTION

In terms of Chapter 3, the goal is now to design the necessary hardware to expeditiously pinpoint the threshold value, N, that generates the maximum number of black/white transitions. With the CALIBRATION PATTERN producing the desired analog signal, the THRESHOLD CONTROL UNIT (Figure 4.1) commands the THRESHOLD LEVEL GENERATOR to set a series of tentative threshold values for the A-to-D CONVERTER. The number of black/white transitions produced by each threshold value is summed by the VIDEO COUNTERS, and the sum, VTC, is correlated by the THRESHOLD CONTROL UNIT. Once all threshold values in the series have been tested, the THRESHOLD CONTROL UNIT locks in the threshold value that produced the maximum number of black/white transitions.

B. CHOICES FOR IMPLEMENTATION

Because of its availability and inclusion in the existing scanner, it was a logical decision to use the F8 microprocessor as the THRESHOLD CONTROL UNIT and to design a digital-to-analog circuit as the THRESHOLD LEVEL GENERATOR. The VIDEO COUNTERS provided a natural interface to the F8, but modifications in the video A-to-D section were required to upgrade the digital video signal to the quality required for accurate counting. The actual design details are covered in the next section.

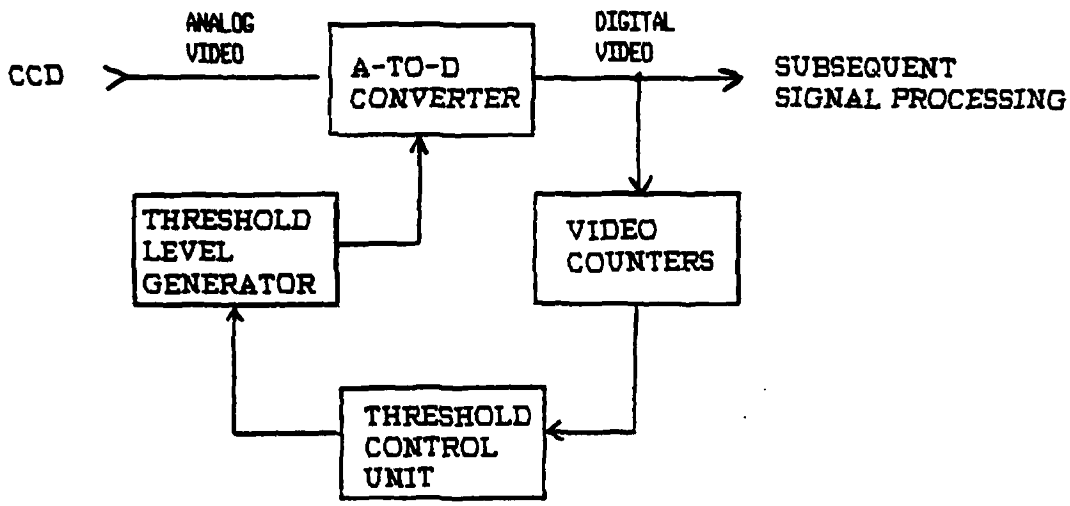

FIGURE 4.1 AUTOMATIC THRESHOLD CONTROL BLOCK DIAGRAM

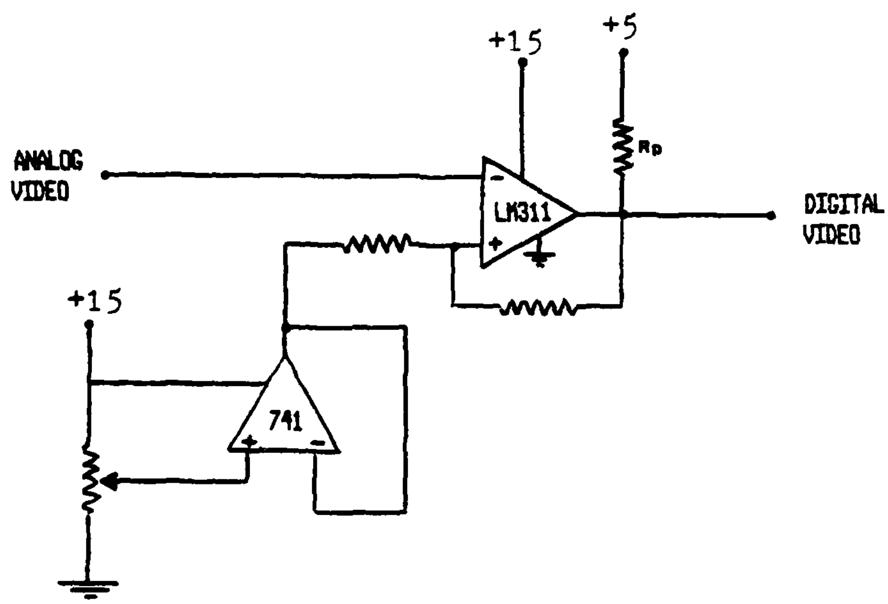

FIGURE 4.2 ORIGINAL VIDEO A-TO-D CONVERTER AND THRESHOLD LEVEL GENERATOR

C. CIRCUIT MODIFICATIONS

1. DIGITAL THRESHOLD LEVEL GENERATOR (TLG)

The existing scanner used a potentiometer buffered by a unity-gain 741 operational amplifier for manually setting the threshold level. See Figure 4.2. This circuit, which included an LM311 comparator as the A-to-D converter, was located on the TIMING & PROCESSING circuit board. It was removed entirely and is documented in Appendix E. A primary theme in the design of the new TLG was flexibility. That is, the circuit was constructed in such a way to allow for future alterations in voltage ranges and sensitivity for experimental purposes. The first consideration was the voltage range of the threshold level. In Chapter 2, it was found that the video information was within a span of 5.3 to 5.6 volts. Changes in the video signal were of the order of 10 to 300 millivolts. Therefore, the TLG had to be able to resolve millivolts in the 5.3 to 5.6-volt range. A 10-bit (1024-step) D-to-A converter was selected which would give a sensitivity of less than a millivolt/digital step over a range of one volt. Additional circuitry had to be added to the D-to-A converter to provide the necessary DC offset. Refer to Figure 4.3. The TLG consists of U1 through U6 with U4 providing the threshold output voltage, VO. U1 is an AD7533 D-to-A converter using an R-2R ladder network described in Appendix A, and U2 is a 741 operational amplifier used as a unity-gain buffer. The output of U2 is given as:

$$V2 = -Vref(N/1024) \qquad (1)$$

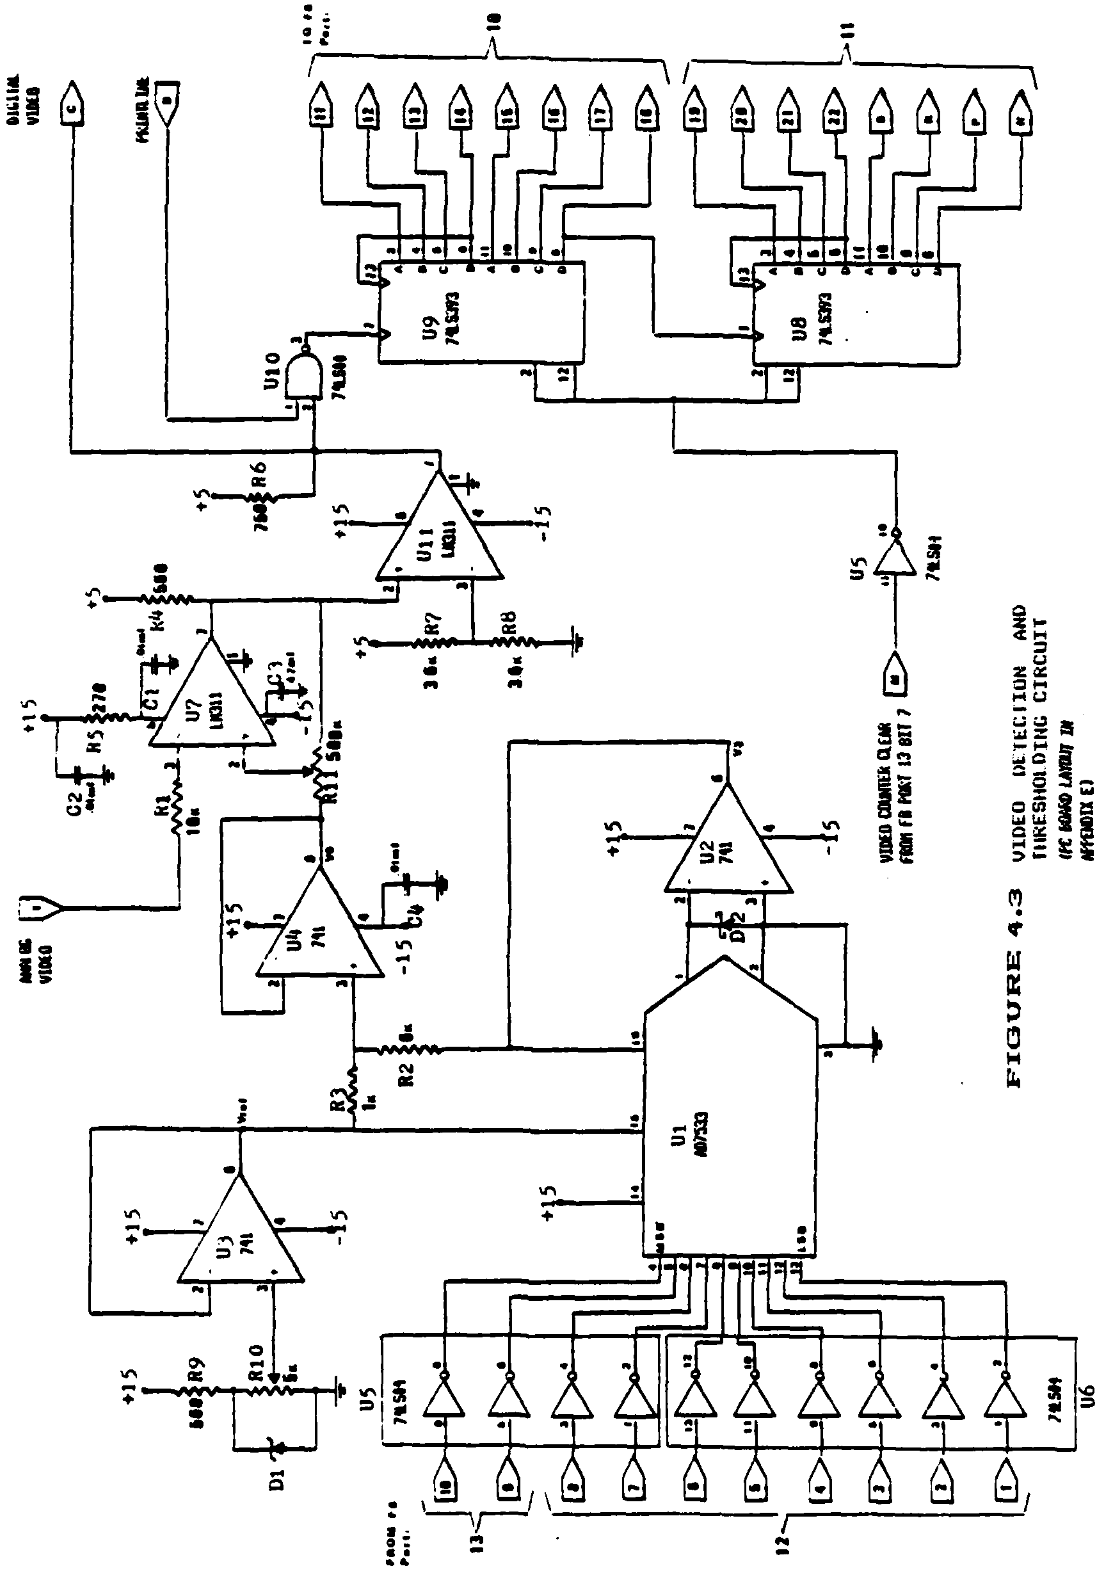

FIGURE 4.3 VIDEO DETECTION AND THRESHOLDING CIRCUIT
(PC BOARD LAYOUT IN APPENDIX E)

where N is the decimal equivalent of the 10-bit binary input from the F8 to U1 through pins 4 through 13, and Vref is controlled by R10 and buffered with unity-gain op amp U3. Since op amp U4 is also a unity-gain buffer, V0 can be expressed as a function of the voltage division between Vref and V2:

$$V0 = \frac{(R3 \times V2) + (R2 \times Vref)}{(R2 + R3)} \qquad (2)$$

Eliminating V2, we have:

$$VO = Vref\left[\left(\frac{R2}{R2+R3}\right) - \left(\frac{R3}{R2+R3}\right)\left(\frac{D}{1024}\right)\right] \qquad (3)$$

Therefore, resistors R2, R3, and R10 control the width and placement of the range of the TLG. From Equation (3), a particular range (VOmin to VOmax) for the TLG can be established with the following procedure:

1. Determine values of V0min and V0max.
2. Arbitrarily select a nominal value for R2 in the range 1K to 10K ohms.
3. Calculate R3 for the R2-R3 voltage divider by:
   R3 = R2(1 - (VOmin/VOmax))
4. Calculate Vref by: Vref = (2 x VOmax) - VOmin
5. Set Vref by adjusting R10.

As an alternative, the graphs implementing Equation (3) in Figures 4.4 and 4.5 can be used as an aid to the calculations. The voltage range of the TLG used for this report was 5.14 to 6.16 volts giving a sensitivity of 1 millivolt/digital step. This choice is realistic and makes the results of the other

3. TRAVEL LEFT TO READ VALUE OF V_{ref}

FIGURE 4.5 GRAPH FOR CALCULATING V_{ref} OF TLG chapters particularly simple to interpret.

2. VIDEO A-TO-D DESIGN

Referring again to the scanner's original video A-to-D circuit in Figure 4.2, the response of this circuit to the highest spatial frequencies was found to be rather slow (3.03 microseconds) due to the size of the pull-up resistor, Rp. While this was adequate for the existing design and in fact helped prevent clock noise feed-through, it was found that the performance was inadequate as a clocking input to the VIDEO COUNTERS. Therefore in the re-design of the video A-to-D circuit, Rp was changed to 560 Ohms giving a rise time of 332 nanoseconds. This allowed the circuit to more faithfully digitize the spatial frequencies up to the Nyquist rate. This feature was essential so the VIDEO COUNTERS could record the black/white transitions of all the spatial frequencies. Unfortunately with the smaller Rp, unwanted clock noise was now passing through the one-stage comparator circuit, which would have been disastrous for the VIDEO COUNTERS. Therefore a second LM311 with a constant threshold of 2.5 volts was cascaded with the first LM311 to effectively bar the clock noise from triggering spurious counts in the VIDEO COUNTERS. The revised video A-to-D circuit consists of comparators U7 and U11 in Figure 4.3.

3. DIGITAL VIDEO COUNTER STAGES

The VIDEO COUNTERS, consisting of U8 and U9 in Figure 4.3, were rather simple to implement once the digital video signal had been upgraded. Dual, 4-bit, binary, asynchronous counters served the purpose adequately, making 16 bits available with minimal hardware. As a precaution, the digital video is gated to the counters by the signal PRINTLINE to insure only valid video transitions are recorded.

4. F8 HARDWARE INTERFACE REQUIREMENTS

To use the F8 as the THRESHOLD CONTROL UNIT, I/O ports had to be made available for data transfer. The existing ports (4, 5, 8, and 9) were already being used for scanner coordination with the hard and soft copy printing devices. (1) The threshold control requirements could have been implemented through these ports, but it would have taken considerable multiplexing and hardware design. Fortunately the research completed by Medley (2) included the addition of four new I/O ports (10, 11, 12, and 13) to the F8 system. So the only requirement to make these I/O ports available for use was to complete the wiring to a compatible connector. Details are contained in Appendix E.

5. COMBINED THEORY OF OPERATION

During the period that the optimum threshold is being sought, the circuitry of Figure 4.3 operates in the following manner. A value of N generated by the THRESHOLD CONTROL UNIT (F8) is applied to pins 4 through 13 of U1. The voltage threshold value V0 is obtained from the division between Vref and V2 by resistors R2 and R3. The voltage threshold level, with the

(1) See Aghamohammadi, Chapter 7.

(2) Reference Chapter 7.

degree of hysteresis controlled by R11, is applied to the non-inverting input of U7 while the analog video signal from the CCD is applied to the inverting input. The digitized video is then fed through a non-inverting comparator stage provided by U11 with threshold fixed at 2.5 volts to help remove digitized clock noise. The clean digital video is then gated by PRINTLINE through U10 into cascaded counters U9 and U8. For a given line of video, the number of black/white transitions in the digital video signal can be read from the counters to ports 10 and 11 of the F8. Once the optimum threshold has been found, the value is loaded to ports 12 and 13 and valid digitized video passes off the board via pin C for synchronization and hard-copy printing. The outputs of U8 and U9 are now ignored.

6. SCANNER CIRCUIT BOARD RELOCATIONS

During the course of this project, inter-circuit interference due to clocking noise and physical separation of several critical circuit boards degraded system performance to the extent that several circuit boards had to be moved in order to shorten the connections containing critical signals. These relocations are documented in Appendix E.

CHAPTER 5

SAMPLING ALGORITHMS

In this chapter, the procedures for finding the VTC peak are discussed in detail. The purpose of this phase of research was to design a method whereby the THRESHOLD CONTROL UNIT could, in the most efficient manner possible, search the entire range of possible threshold values, [N = 0 to N = 1024], and find that value of N corresponding to the peak of the video transition count, VTC. The major constraint on this design was to keep the algoritnm simple enough to be easily implemented on the F8 microprocessor. At one extreme, the algorithm could entail stepping through every value of N and doing a simple comparison of the present value of VTC and the maximum preceding value of VTC (called MTC) to find the VTC peak. In fact this method was used in gathering the data for Chapter 3. The obvious drawback, however, in implementing this procedure in an operational scanner system is the fact that, since each sample requires one scan line of video, a total of 1024 video lines would have to be dedicated to thresholding. With the scanner on the move, that means the CALIBRATION PATTERN would need to be over five inches wide! One can immediately see a way to decrease the number of video lines by recognizing that only a certain span of N (labeled RV in Chapter 3) contains significant VTC information worth sampling.

(1) Recall from Figure 3.1 that when N = 0, the voltage threshold level is greater than the analog video signal which prevents any digital encoding of the video information. VTC therefore is zero until the threshold encounters the span of significant analog

(1) Since the analog video information generally covers a span of 200 to 300 millivolts, and each incremental change in N equates to a one-millivolt shift in the threshold level, the total number of video lines required could be reduced to around 200 to 300. The width of the CALIBRATION PATTERN now must be 1 to 1.5 inches which is still unacceptably large. At the same time the range of N sampled is dangerously small, which would limit the ATC's ability to adapt to drastic changes. So the research centered on finding a feasible algorithm that could cover the largest range of N in the least number of samples. The algorithm explored for implementation with the ATC is detailed below.

A. SUCCESSIVE APPROXIMATION

Under the assumption that the VTC-versus-N curve to be sampled is relatively smooth and has the general shape of Figure 3.1(C), a fairly straightforward approach can be used to pinpoint the VTC peak. When the automatic thresholding sequence is initiated, the idea is to start with a large step size (increments) for N and take a small number of VTC samples over the entire range of N, [0 to 1024]. This will be called the first pass. Since keeping the step size a binary multiple greatly simplifies programming, the initial step size, S1, was chosen as 128. Referring to Figure 5.1, we see that this divides the range [0 to 1024] into eight segments. For reasons that will soon

---

signal. VTC will again be zero once the threshold level is less than the smallest value of the analog signal.

become apparent, the end points, N = 0 and N = 1024, are ignored, and seven samples of VTC are taken beginning at N = 128. For those samples, the value of N giving the maximum VTC, called Np, becomes the middle of a new range, R, to be sampled with the end points defined as (Np-S1) and (Np+S1), as shown in Figure 5.2. Note that R = 2 x S1. The new range R is now divided into eight segments by using a new step size, S2, which turns out to be equal to S1/4. Again end points are ignored and seven samples are taken at the points shown in Figure 5.2. (1) Repeating the procedure to the limit, it can be seen from Figures 5.3 and 5.4 that a total of four passes or 28 video lines are required to pinpoint the VTC peak within one millivolt. With each video line being 0.05 inch wide, the procedure requires 0.14 inch of CALIBRATION PATTERN to find the optimum threshold value. This width is considered to be acceptable in the context of the amount of margin of the original document required for threshold-setting purposes.

The complete algorithm summarizing the above procedure is flowcharted in Figure 5.5. Block 1 initializes the necessary registers for the overall algorithm, and Block 2 initializes the video line counter for each new pass of 7 video lines. Blocks 3

---

(1) Notice that in this case, the end points were sampled in the first pass and therefore do not need to be re-sampled in the second pass. Although the discarded endpoints of the second pass (N = 256 and N = 512) do not provide an exact analogy to the discarded endpoints of the first pass (N = 0 and N = 1024), it is still easy to see that excluding N = 0 and N = 1024 does not preclude the segments [0 to 128] or [896 to 1024] from being sampled in a subsequent pass if necessary. In this manner, each pass consists of identical procedures.

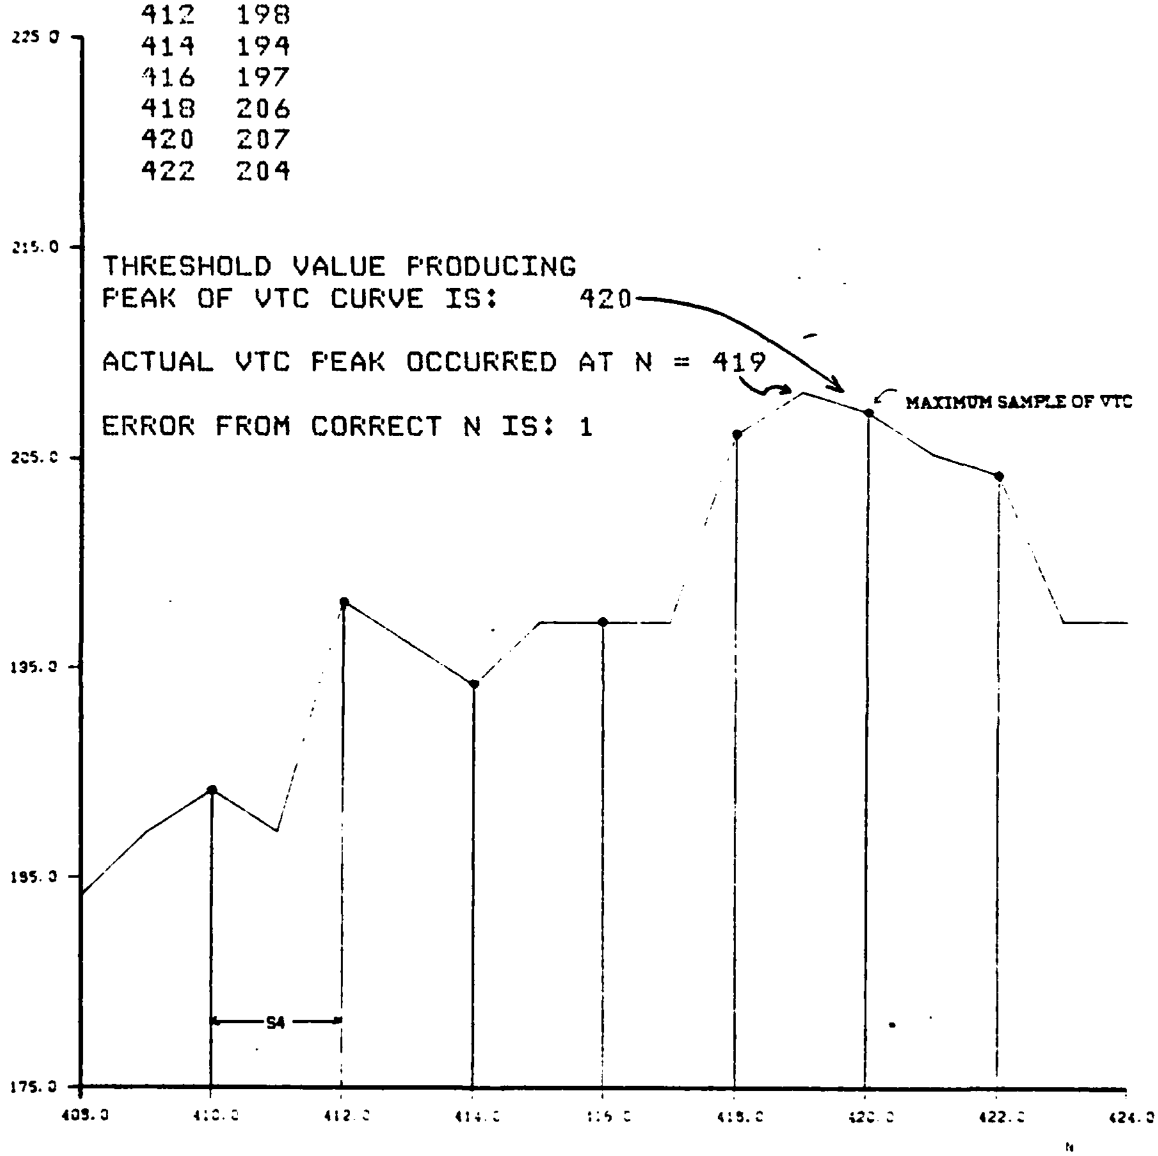

FIGURE 5.4 FOURTH PASS OF ATC SAMPLING ALGORITHM QSET1

through 7 are executed for every line of video. In Block 3 the VIDEO COUNTERS of Figure 4.1 are set to zero, and in Block 4, N is incremented by the existing step size. When PRINTLINE goes active signifying valid video is being transmitted, the digital black/white transitions are counted in Block 5. (1) At the end of the video line, the number of black/white transitions obtained is subtracted from the previous maximum number of transitions. If the result is negative, this means that the VTC just obtained is greater than any VTC previously obtained. Therefore this value of VTC is retained in MTC as the new maximum transition count encountered thus far, and the value of N producing this maximum VTC is also saved. Block 7 counts the number of video lines taken in a particular pass, and the flow is transferred back to Block 3 until the 7 lines of one pass have been completed. For each new pass, Block 8 adjusts the starting value of N for the new range to be sampled, alters the step size, and keeps track of the number of passes executed. At the end of the fourth pass, Block 9 loads the N value that produced the overall maximum VTC into the Threshold Level Generator. This threshold value is used for the entirety of the page being scanned. The algorithm as presented is called QSET1, and computer simulations of QSET1 on actual VTC curves are detailed in Appendix C.

(1) It is important in understanding the sequencing and timing of the algorithm that Block 5 is the only block that is executed during the transmission of valid video information as depicted in Figure 2.1(B). All remaining blocks are executed in the relatively short time gap between successive video lines.

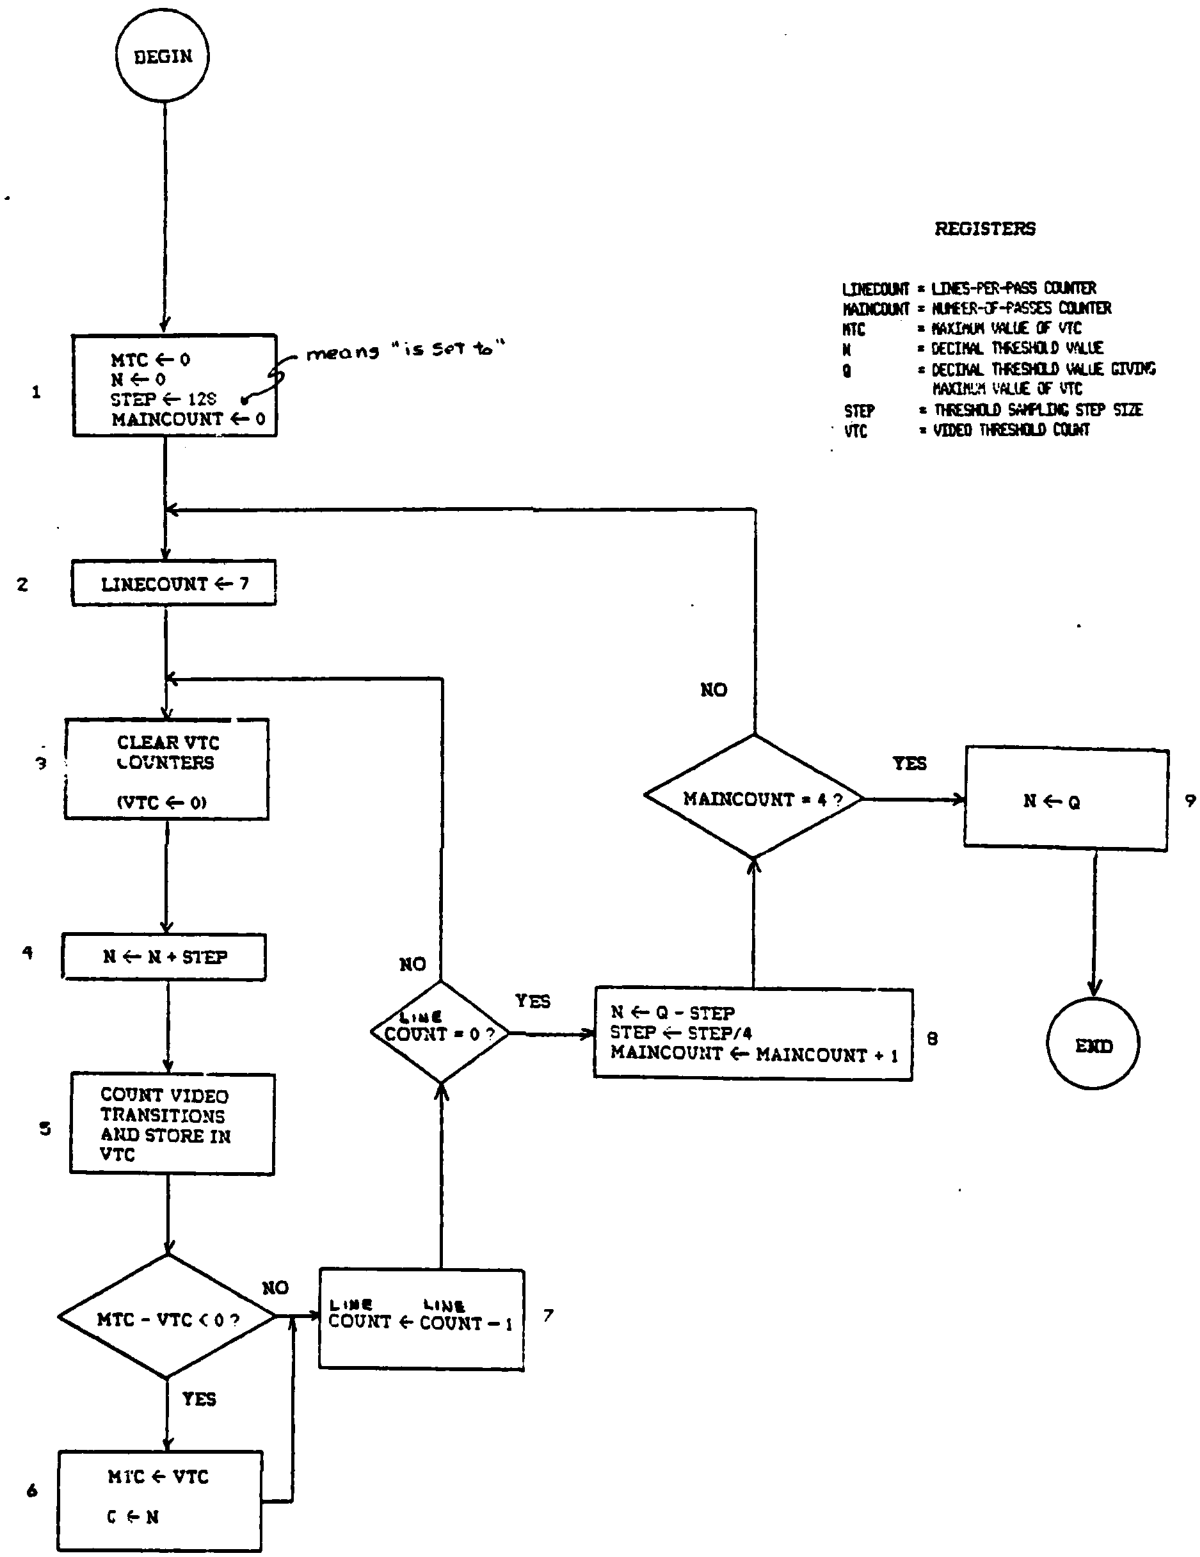

FIGURE 5.5 FLOWCHART OF QSET1 ALGORITHM

B. SAMPLING CONSIDERATIONS

Of prime importance in utilizing a sampling technique such as QSET1 is proper consideration of the initial step size, S1. Specifically, if the range of valid VTC information, RV, is less than S1, then it is possible for all valid VTC information to reside between samples of the first pass as in Figure 5.6. The only instances where the range RV was found to be less than 128 using ECP A were with one-lamp illumination and with the darker paper colors: orange, red, green, brown, and blue. (Remember that f-stop = 5.6 was used throughout the research.) Still, in these cases, the algorithm has the potential of breaking down in its search for the VTC maximum. (1)

The three alternatives to solving the problem of dealing with a small span of VTC information are to either change the voltage range of the TLG, implement a different sampling algorithm, or modify the parameters of the QSET1 algorithm. To maintain a basis for reference throughout this research, the TLG voltage range was not altered although in practice this might be the most reasonable solution. Different sampling algorithms were also considered but rejected due to the additional programming complexity involved. Therefore due to the simplicity of implementation with a microprocessor, the latter alternative was

(1) It should now be clear why a single-frequency CALIBRATION PATTERN at the Nyquist rate is not a good choice as implied in Chapter 3. The resultant impulse-like VTC curve having a very small RV would require a prohibitively small initial step size, S1, to detect.

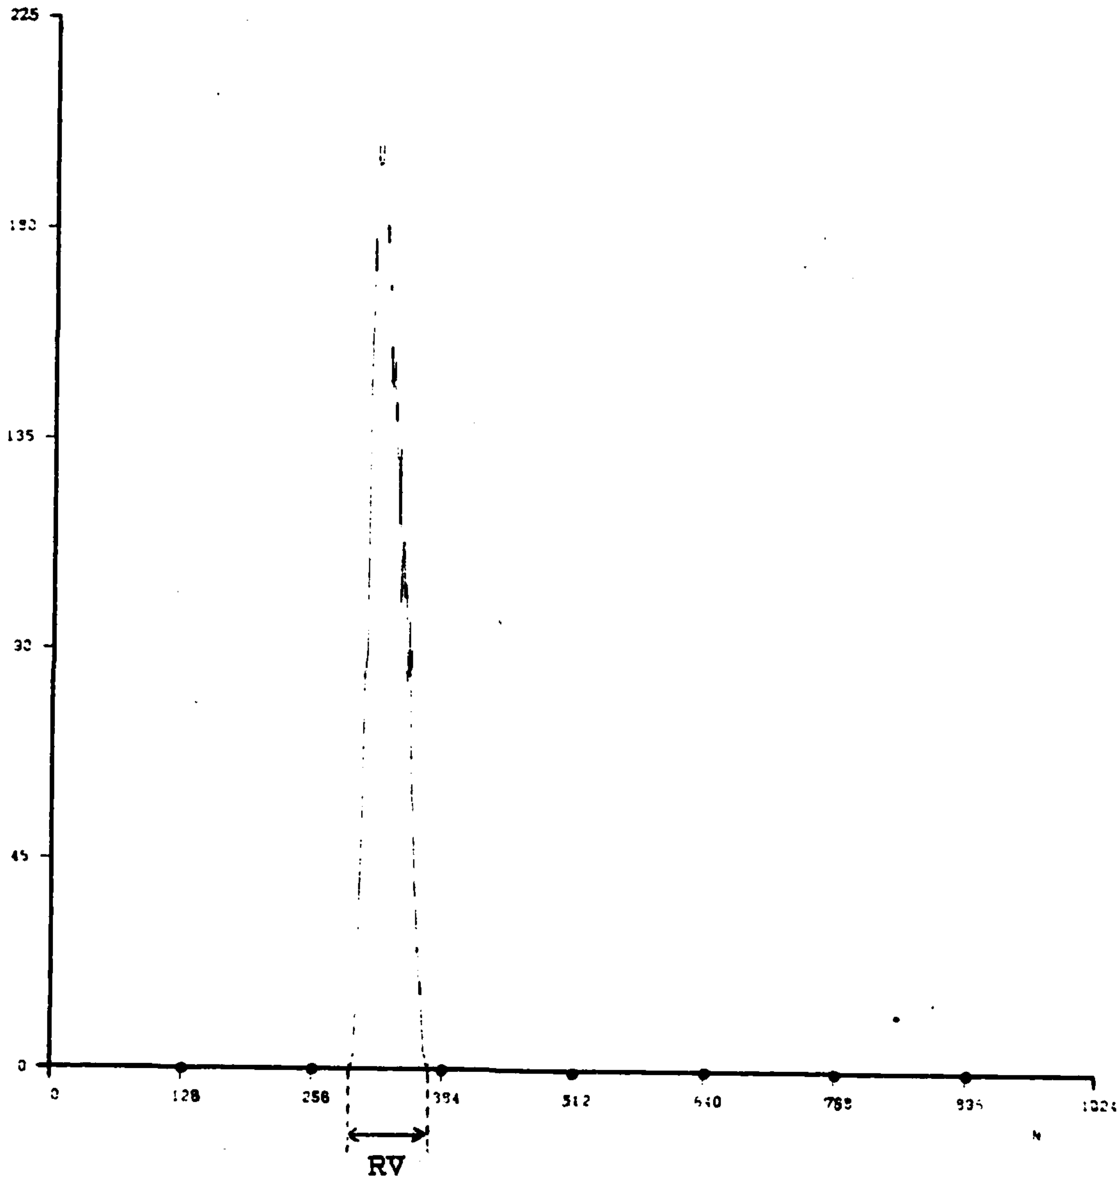

FIGURE 5.6 VTC CURVE PRODUCED FROM SCANNING ECP A ON A RED BACKGROUND. (VTC CURVE IS NEVER FOUND BY QSET1 BECAUSE RV FALLS BETWEEN SAMPLES

preferred for rectifying the problem. Working within the framework of QSET1, the challenge becomes one of decreasing the initial step size, S1, with minimal penalties. Of all experimental observations using ECP A, the smallest span of N over which all VTC values were generated was RV = 67, resulting from navy blue paper. So one possibility is to choose S1 = 64, dividing the range [0 to 1024] into 16 segments, and collecting 15 samples on the first pass. Maintaining 15 samples on subsequent passes results in three passes required in all, or 45 lines of video to set the optimum threshold. Subsequent step sizes would be obtained by dividing by 8:

$$S2 = S1/8 = 8$$
$$S3 = S2/8 = 1$$

Another possibility is to choose S1 = 64 but only collect 7 samples per pass as QSET1 prescribes. This requires the initial sampling range to be cut from 1024 to 512 samples. Maintaining 7 samples per pass results in four passes, or a total of 28 video lines required. Subsequent step sizes are obtained as in QSET1:

$$S2 = S1/4 = 16$$
$$S3 = S2/4 = 4$$
$$S4 = S3/4 = 1$$

In an effort to preserve the small number of video lines used by QSET1, the latter option was chosen. The major compromise was the halving of the overall range of N to be sampled. The impact of this compromise was minimized by using the knowledge of the behavior of the analog video signal to select the starting and ending values of the sampling range as N = 128 and N = 640.

Implemented in the algorithm, QSET2, these choices produced robust performance throughout the range of abnormal paper colors and lighting conditions. The flowchart for QSET2 is identical to that of QSET1 in Figure 5.5 except for Block 1 which becomes:

```
MTC ← 0
N ← 128
STEP ← 64
MAINCOUNT ← 0
```

Another sampling consideration deals with the performance of the QSET algorithm with VTC curves having peaks that are less well-defined. The primary factor that can cause an obscuration of the actual VTC peak is the uncertainty discussed in Chapter 3 and depicted in Figure 3.18. As long as the degree of uncertainty is relatively small, as is the case with ECP A in Figure 3.6(A), the algorithm is quite successful in locating the peak. But if the uncertainty is a significant component of the VTC curve as in Figure 3.12, the results of the algorithm search are not as consistent; the final N value produced by the algorithm becomes more a function of how the samples fall along the VTC curve. These effects are covered more extensively in Appendix C.

C. INCORPORATION WITH SCANNER PRINT SEQUENCE

Once the QSET algorithm was perfected, the next step consisted of adding the necessary software to the F8 program, EOPS (electro-optical page scanner). Since all pertinent F8 source codes are contained in Appendix B, the discussion here will be restricted to the block level. Figure 5.7 is a

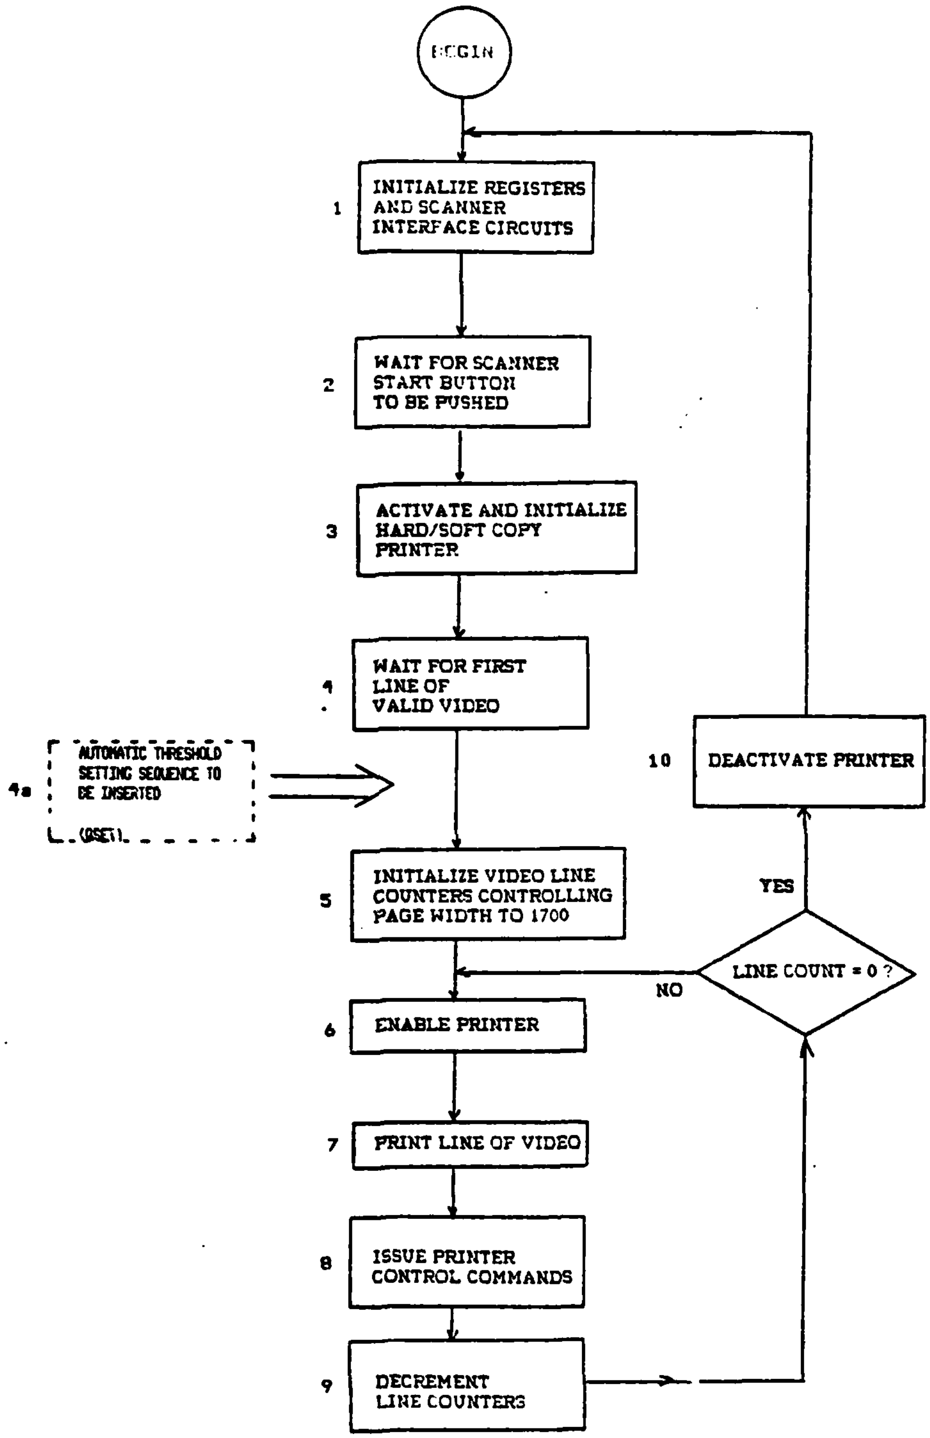

FIGURE 5.7 SIMPLIFIED FLOWCHART OF EXISTING F8 SOFTWARE (EOPS) FOR THE SCANNER

simplified flowchart of the existing scanner algorithm. As stated in Chapter 3, placement of the CALIBRATION PATTERN in the left-most margin allows the first lines of video to provide the necessary information for threshold-setting purposes. Therefore it was necessary for the ATC sequence to be located between Blocks 4 and 5 of Figure 5.7 in order to catch the first lines of valid video. This configuration also turned out to be the most advantageous in terms of software modifications required. With Block 4a included in the flow, the sequence of scanning a document now becomes:

1. After positioning the document, the operator pushes the scanner start button.
2. A start-up delay of just over 1.5 seconds is initiated which allows the fluorescent lights to preheat and the phase-locked loop motor control to stabilize. This delay is accomplished by counting a preset number of pulses generated by the phase-locked loop rate-feedback wheel. Video information is ignored during this time because of the status of the signal PRINTLINE.
3. At the termination of the start-up delay, PRINTLINE goes active, signalling that valid video is now available.
4. The automatic threshold-setting sequence begins and uses 28 video lines to establish the optimum threshold level.
5. Once the optimum threshold is locked in, the VIDEO LINE COUNTERS are set to 1700, giving a page width of 8.5 inches (200 lines/inch).
6. As the video lines are shot, they are printed in real time with the F8 providing the necessary pacing for the printer.
7. When 1700 lines have been read, the printer is shut down automatically, and the F8 software resets. The scanner mechanical assembly is retracted to its starting point upon activation of a limit switch beyond the right-most margin.

For future research purposes, two new versions of EOPS were produced. EOPS1, containing QSET1, provides ATC that samples the entire range of N, [0 to 1024]. EOPS2, containing QSET2, provides ATC that samples the range of N, [128 to 640].

Additional user-oriented features added to EOPS1 and EOPS2 are detailed in Appendix B.

CHAPTER 6

CONCLUSIONS AND RECOMMENDATIONS

A. GENERAL RESULTS

The performance of the scanner with automatic threshold control was considered to be excellent, especially in the context of proving the validity of the ATC concept that was developed. Xerox copies of scanner printouts are contained in this chapter, and if degradation due to xeroxing is ignored, the results are very good. Figures 6.1 to 6.5 represent consecutive scanner outputs of the same image with the automatically-chosen threshold value noted. Due to the uncertainty discussed in Chapter 3, each threshold value is somewhat different. Still, it can be seen that every copy possesses a high degree of quality, thereby demonstrating the consistency of the ATC. Observe, for example, the legibility of the 6-point type at the lower left of each reproduction of the IEEE Test Chart. Microscopic inspection of these scanner outputs revealed resolutions very close to 200 lines/inch.

Figures 6.6 to 6.8 were produced with EOPS2 and only one fluorescent light providing illumination. Even under the degraded lighting conditions, the ATC was able to select the optimum threshold and produce a very acceptable output. Again note the 6-point type in Figure 6.7 is quite readable.

Figure 6.9 is the result of scanning a transparency of the IEEE Facsimile Test Chart with red paper as a background. Again the threshold level chosen was considered the best possible under

these conditions. This was by far the most demanding test of the ATC because total pel swing of the analog signal was less than 80 millivolts and the threshold level obtained still produced legible copy.

Figures 6.10 to 6.13 represent other document selections for evaluating the Automatic Threshold Control from a subjective standpoint. Figure 6.10 needs no comment, but Figures 6.11 and 6.12 represent fairly difficult text for scanner reproduction. Notice the excellent scanner performance with these documents. The original used to produce Figure 6.13 was a magazine advertisement with a very dark brown background and white print. Although the graphics cannot be interpreted, a majority of the print is legible.

A few points should be discussed concerning the actual limitations of the scanner/printer combination when evaluating the scanner's output. The first point concerns the observed resolution capability of the system. Although the scanner can detect resolutions up to 200 lines/inch, (1) the electrostatic printer used to produce hard copy will not faithfully reproduce this resolution due to the overlapping stylii. As illustrated in Figure 6.14, a resolution of 200 lines/inch will actually have more black than white resulting in a small amount of degradation in the output. Patterns approaching 200 lines/inch will appear

(1) Recall that resolution is measured in lines/inch while spatial frequency is measured in line-pairs/inch. This means there is a 2-to-1 correlation between resolution and spatial frequency. Therefore the CCD Nyquist rate theoretically can produce a resolution of 200 lines/inch.

The Federal Reserve Board could, if it chose, somewhat ease the pain of more business failures by flooding the financial system with money. We do not believe that they will choose this course. The nation has come a long way in winding down inflationary expectations and the Fed is unlikely to give up the fight now. We believe they understand that a critical weapon in the battle against inflation is the reintroduction of "risk" into the economic system. Excessive monetary growth and assured corporate bail-outs do not encourage prudent business planning. Rather, it fosters the immoderate use of borrowed funds and the belief that, in the long run, the ability to raise prices will subsequently justify buying extra inventory or paying excessive wage demands. If the Fed sticks to its guns, business will have to learn how to operate with a totally different philosophy. For some, the lesson will be learned too late.

What else can we look for? Certainly, capital spending plans will continue to be pared back. The latest McGraw-Hill survey of capital spending plans for 1982 pointed to a 3.9% dollar increase, representing a 4 1/2% decline in actual physical outlays. Six months ago, spending plans called for a 1982 advance of 9.6%. Commerce Department surveys have also suggested a scaling back of capital spending intentions. We think the process still has further to go. We expect capital spending to be the weakest sector of the economy until well into 1983 and perhaps for even longer if the economy "triple dips" in early 1983 as we think possible.

Operating expenses also get cut back when profits are under pressure. The unemployment rate may not have topped out yet although we suspect it doesn't have too much further to go. Wage "givebacks" have characterized labor negotiations in the depressed cyclical industries. Over the next few months we expect the business media to be rife with stories about white collar layoffs and executive salary cuts. Goodrich, for example, recently announced that its top management would take a 15% salary cut while other executives and salaried employees making more than $20,000 a year would take reductions ranging from 5% to 10%.

We also look for a continuation in the surge of dividend cuts as corporations scramble to retain cash. According to Standard & Poor's, through the first 4 months of 1982, 158 companies decreased or omitted their dividend payments, more than twice the number of companies who took similar action last year. In recent months, dividend casualties included such companies as Inland and Republic Steel, Reynolds Metals, Sun Electric, Champion International, Harnischfeger and Manville. Another source of corporate cash is the sale of assets. Dome Petroleum and Inco, among others, have recently announced such plans. Chrysler and International Harvester, of course, have sold off large and profitable divisions. More such moves will follow.

We have painted a rather grim picture of the financial strains on the economy. The reliquefication process is far from complete, a factor which will serve to slow the recovery process. Thus, for this and other reasons, our investment posture with regard to equities has been selective and opportunistic within a generally cautious framework. Companies with sound balance sheets and well-assured prospects of unit growth could do surprisingly well in a restrictive economic environment. Moreover, during uncertain times, some stocks get down to extraordinarily attractive prices in terms of their

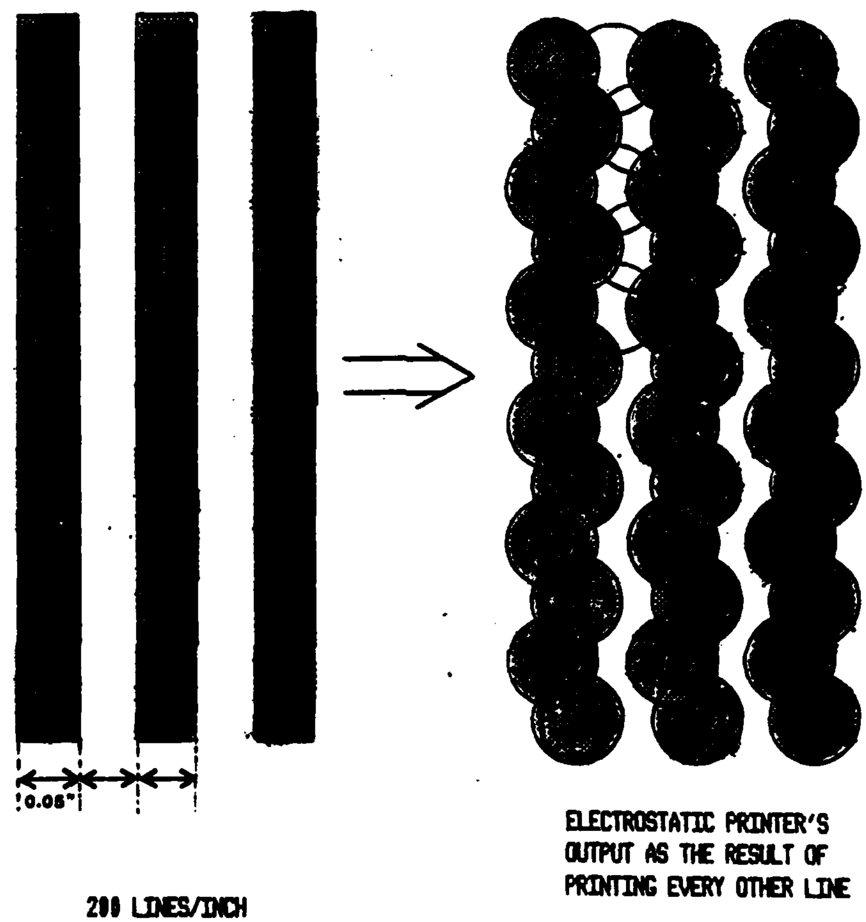

FIGURE 6.14 MAGNIFIED VIEW OF ELECTRO-STATIC PRINTER'S REPRODUCTION OF THE NYQUIST FREQUENCY

to have less white content than they should. This characteristic should be kept in mind when evaluating the resolution of the scanner output with the IEEE Facsimile Test Chart.

The next point deals with the hysteresis included in the video A-to-D converter as an additional measure to prevent clock noise feed-through. The hysteresis was experimentally set at a level that allows all spatial frequencies to be digitized under normal lighting conditions and pastel paper colors. However when abnormal conditions reduce the magnitude of the analog video signal, the pel swing from the highest spatial frequencies are too small to overcome the hysteresis barrier. This effect can be most easily seen with IEEE Test Pattern 12 in Figures 6.6 to 6.9. Distortion due to hysteresis is characterized by a "streaked" or "filled-in" appearance at the affected spatial frequencies.

The last point pertains to the effect of non-uniform illumination. As established in Chapter 3, the ATC will average any light irregularities and select the threshold level giving the highest resolution over the largest portion of the page. This feature of the ATC can be viewed in Figures 6.11 and 6.12. These two copies were produced with fluorescent tubes that had become blackened on the ends due to wear and tear. The ATC still reproduces a majority of the page faithfully with only the bottom of Figure 6.11 and top of Figure 6.12 being degraded because of insufficient light.

B. CONCLUSIONS

In summary, the method produced from this research for automatically selecting the voltage threshold level proved to be successful. The advantages of the ATC are many. First, substantial savings in time, energy, and resources are realized over manual threshold control. Second, the threshold level produced by the ATC is more accurate than one selected by subjective evaluation. Third, the scanner with ATC requires less skills of the user. Fourth, the scanner can automatically respond to a large variety of paper reflectivities and colors. Fifth, light non-uniformities due to deterioration of the fluorescent lamps are automatically compensated. And last, the scanner is able to continue operating automatically with the failure of one fluorescent lamp. On the other hand, a minor disadvantage observed was that the operator must take greater care in placing a document into scanning position to insure the left margin provides background for the CALIBRATION PATTERN.

There are a few critical issues to the proper operation of the ATC that merit discussion. First, it is crucial that the scanner is able to start transmitting video at the same precise physical point for every page. Before ATC incorporation, minor deviations in start position would have hardly been noticeable. But with the need to "see" a narrow CALIBRATION PATTERN in the first few lines, it is now mandatory that the scanner starts reading lines in exactly the same place every time. Inconsistency in the starting position can be offset to a certain extent by widening the CALIBRATION PATTERN, and this measure was taken by using ECP A which is 0.219 inch wide whereas only 0.140 inch is actually needed. Still a small measure of inaccuracy was observed during research that sporadically caused the CALIBRATION PATTERN to be missed either partially or completely. This resulted in either thresholding errors or a portion of the CALIBRATION PATTERN being printed in the output (called pattern feed-through). This issue will be covered in more detail in the next section.

While established in Chapter 3, another critical issue that deserves repeating is the importance of the design of the CALIBRATION PATTERN itself. The pattern must produce a VTC curve spanning a reasonable amount of N values and producing a clearly definable peak that occurs at the value of N resulting in detection of the highest spatial frequencies. Additionally the CALIBRATION PATTERN should cover the length of the page and have each spatial frequency evenly distributed along its length so that light non-uniformity effects can be minimized.

The other issue that needs review is that of the sampling algorithm design. Not only is it important to maintain a simple scheme due to limitations of the F8 microprocessor, but it is also fundamental to remember that there are less than 900 microseconds available for threshold data processing between video lines. (1) In other words, any algorithm chosen must be able to execute on the F8 in less than 900 microseconds per video

(1) See Figure 2.1.

line. The other point is that as long as the threshold sequence is executed with the scanner in motion, the number of video lines used must be kept to a minimum to preclude the CALIBRATION PATTERN from taking excessive margin space.

C. AREAS FOR FURTHER RESEARCH

1. PHYSICAL POSITIONING ACCURACY

As mentioned earlier, the first line of video in a scan sequence is not necessarily taken from the same physical point each time. It is believed that this was a major cause of thresholding errors encountered during evaluation. To understand the problem, the mechanical sequence must first be studied in Figure 6.15. Once the start button is pushed, the first line of valid video will be transmitted after a preset number of pulses from the phase-locked loop rate-feedback wheel have been counted. Theoretically this should define a very precise distance since the wheel is physically mounted on the lead screw and generates 100 pulses per revolution. It is suspected that errors are being introduced by one or both of the following: either the counters in Block 7, Figure 6.15 are being misloaded by spurious noise, or the mechanical assembly is not coming to rest in exactly the same place each time in Block 8 due to tolerance of the left-most limit switch. This issue should be explored with the purpose of eliminating thresholding errors.

2. CALIBRATION PATTERN

Since this research was conducted with a limited number of available ECPs, a specially designed CALIBRATION PATTERN should

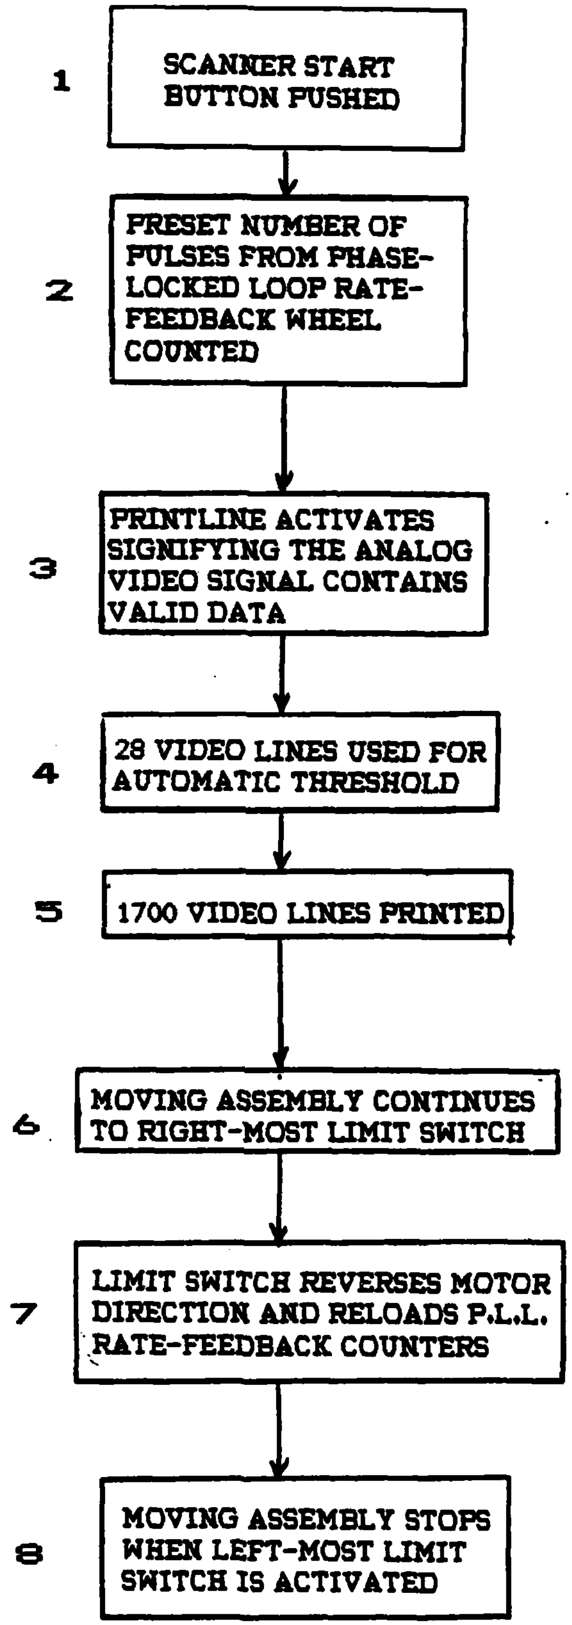

FIGURE 6.15 SCANNER MECHANICAL MOVEMENT SEQUENCE

now be fabricated for use with an operational scanner. Although ECP A works, each frequency burst has only seven discrete spatial frequencies that the CCD can detect; the other five spatial frequencies are above the Nyquist rate and therefore contribute nothing. Additionally, 50% of ECP A has no spatial frequency content whatsoever. In view of this, I suggest designing a CALIBRATION PATTERN specially tailored to the needs of the ATC. Two possible frequency-burst designs are: one with more discrete frequencies, and one containing a linearly increasing set of spatial frequencies. Each burst should be about one inch long and repeated along the length of the page. This effort will not improve the ATC's choice of threshold level since the optimum has already been achieved, but on the other hand, it could further enhance the ATC's robustness under abnormal conditions. Once the operational CALIBRATION PATTERN design has been completed, the pattern itself should be permanently etched into the glass face of the scanner. For expediency in this research, a transparency of ECP A was taped into position to serve the purpose of a CALIBRATION PATTERN.

3. ADJUSTABLE DARKNESS CONTROL

The ATC is designed to select the threshold that will give the most black/white transitions which in turn produces an output that gives equal priority to black and white information. During evaluation however, it was found that, from a subjective standpoint, copies were sometimes more pleasing if the threshold was shifted to slightly blacker than optimum. In this way, portions of fine print (smaller than 6 point) having spatial frequencies above Nyquist tended to be more readable. The compromise involved the loss of some white information in the form of black fill-in, but this was not a major detraction. Therefore I suggest adding a control whereby the user could bias the threshold to lighter or darker than optimum, depending on the specific need. This could most easily be accomplished by using a multi-position multi-wafer switch configured to feed various 8-bit binary numbers to an F8 I/O part. At the end of the threshold-setting sequence, the F8 would alter the optimum threshold level by the value selected by the user.

4. INK COLOR

Due to time constraints, this research focused only on documents having black print. It is predictable that on a white background, colors of ink other than black will produce a smaller pel swing, but it is unclear what colors of print will not be detected with the threshold level set by the ATC. Future experimentation in this area will better define the capabilities and limitations of the scanner system.

5. SCANNER ILLUMINATION DESIGN

A number of issues concerning the scanner's light source were encountered during the course of this research. (1) First of all, a problem was noted with the light start-up at the beginning of the page-scanning sequence. Either one or both

(1) The reader should refer to Aghamohammadi and Agudelo as necessary for background concerning the existing design.

lights failed to illuminate approximately 30 to 40 percent of the time. Start-up failures were more prevalent with:

a. new tubes
b. very old tubes
c. green tubes in general

Secondly, a fairly rapid deterioration at the end of the tubes (1) caused significant non-uniform illumination to occur over the lifetime of the tube. The results of this were seen in Figures 6.11 and 6.12. Thirdly, a significant amount of light leakage (2) into the CCD shifted the analog black level away from absolute black and thereby reduced the effective contrast of the document being scanned.

In view of these difficulties, I suggest that a thorough re-evaluation of the existing illumination design be conducted. This is not necessarily a suggestion to abandon fluorescent tubes for some other type of lamp. On the contrary, there are many advantages of fluorescent lighting to warrant further investigation on obtaining the desired performance with them. One possible source of aggravation for the fluorescent tubes could be the DC drive currently used. While the original idea was to avoid "flicker" problems, it may be a reason for the rapid deterioration and inconsistent start-ups. One alternative is to evaluate the feasibility of using a high-frequency AC drive and incorporating a quarter-wave phase shift between the two tubes.

(1) As discussed in Chapter 3.

(2) As discussed in Chapter 1.

The problem concerning the light leakage can be eliminated by adding a light-proof shroud between the face of the CCD and the focusing lens.

6. SCANNER START BUTTON

Throughout this project, it was noted that the scanner start button was not adequately resistant to various forms of interference. This problem was commonly manifested by the scanner going through one or more uncommanded page-scanning cycles immediately upon completion of a user-initiated page-scanning cycle. Additionally, the scanner would cycle through at least one page-scanning sequence when power was first applied to the system. Although this is not a disabling problem, it is a nuisance that should be corrected before the scanner is placed in a user environment for operational evaluation.

APPENDIX A

MANUFACTURER'S TECHNICAL DATA

This appendix contains technical data extracts of pertinent items and components used during the course of this research. This material is included for convenience as reference to support the discussion in the body of this report, and is not meant in any way to serve as a complete set of data. Readers desiring more information should refer to the manufacturers' publications.

FAIRCHILD
A Schlumberger Company

CCD

CCD122/142

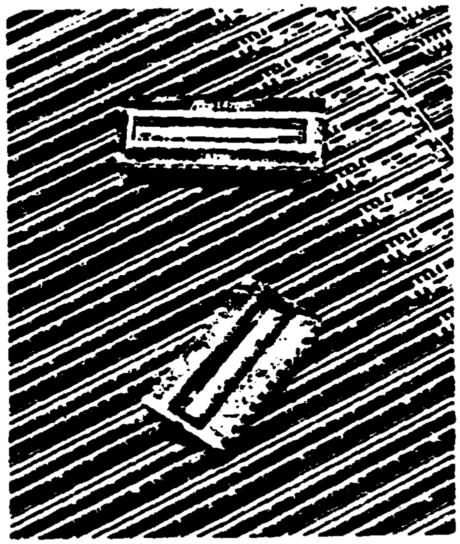
1728/2048-ELEMENT LINEAR IMAGE SENSOR
FAIRCHILD CHARGE COUPLED DEVICE

GENERAL DESCRIPTION—The CCD122 and CCD142 are monolithic 1728 and 2048-element line image sensors, respectively. The devices are designed for page scanning applications including facsimile, optical character recognition and other imaging applications which require high resolution and high sensitivity.

The 1728 sensing elements of the CCD122 provide a 200-line per inch resolution across an 8-1/2 inch page adopted as an international facsimile standard. The 2048 sensing elements of the CCD142 provide an 8-line per millimeter resolution across a 256 millimeter page adopted as the Japanese facsimile standard.

The CCD122 and the CCD142 have overall improved performance compared with the CCD121H including higher sensitivity, an enhanced blue response and a lower dark signal. The devices also incorporate on-chip clock driver circuitry.

The photoelement size is 13 μ (0.51 mils) by 13 μ (0.51 mils) on 13 μ (0.51 mils) centers. The devices are manufactured using Fairchild advanced charge-coupled device n-channel Isoplanar buried-channel technology.



- ENHANCED SPECTRAL RESPONSE (PARTICULARLY IN THE BLUE REGION)
- LOW DARK SIGNAL
- HIGH RESPONSIVITY
- ON-CHIP CLOCK DRIVERS
- DYNAMIC RANGE TYPICAL: 2500:1
- OVER 1V PEAK-TO-PEAK OUTPUT
- DARK AND WHITE REFERENCES CONTAINED IN A SAMPLED-AND-HELD OUTPUT

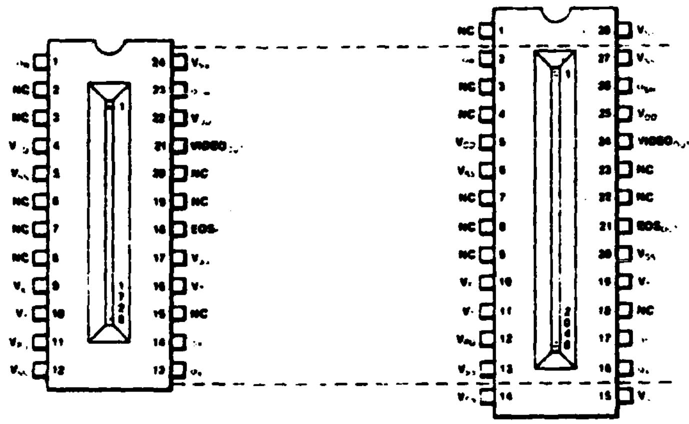
CCD122/142

CONNECTION DIAGRAM
DIP (TOP VIEW)



CCD122 CCD142

FUNCTIONAL DESCRIPTION—The CCD122/142 consists of the following functional elements illustrated in the Block Diagram:

Image Sensor Elements — A line of 1728/2048 image sensor elements separated by diffused channel stops and covered by a silicon dioxide surface passivation layer. Image photons pass through the transparent silicon dioxide layer and are absorbed in the single crystal silicon creating hole-electron pairs. The photon generated electrons are accumulated in the photosites. The amount of charge accumulated in each photosite is a linear function of the incident illumination intensity and the integration period. The output signal will vary in an analog manner from a thermally generated noise background at zero illumination to a maximum at saturation under bright illumination.

Transfer Gate — Gate structure adjacent to the line of image sensor elements. The charge-packets accumulated in the image sensor elements are transferred out via the transfer gate to the transport registers whenever the transfer gate voltage goes HIGH. Alternate charge-packets are transferred to the analog transport shift registers. The transfer gate also controls the exposure time for the sensing elements and permits entry of charge to the End-Of-Scan (EOS) shift registers creating the end-of-scan waveform.

Four 879/1639-Bit Analog Shift Registers — Two on each side of the line of image sensor elements and separated from it by the transfer gate. The two inside resisters, called the transport shift registers, are used to move the image generated charge-packets delivered by the transfer gate serially to the charge-detector/amplifier. The complementary phase relationship of the last elements of the two transport shift registers provides for alternate delivery of charge-packets to establish the original serial sequence of the line of video in the output circuit. The outer two registers serve to deliver the end-of-scan waveform and reduce peripheral electron noise in the inner shift registers.

Gated Charge-Detector/Amplifier — Charge-packets are transported to a precharged diode whose potential changes linearly in response to the quantity of the signal charge delivered. This potential is applied to the gate of an n-channel MOS transistor producing a signal which passes through the sample-and-hold gate to the output at $VIDEO_{OUT}$. The sample-and-hold gate is a switching MOS transistor in the output amplifier that allows the output to be delivered as a sampled-and-held waveform. A reset transistor is driven by the Reset Clock (ϕ_R) and recharges the charge-detector diode capacitance before the arrival of each new signal charge-packet from the transport registers.

Clock Driver Circuitry — Allows the CCD122/142 to be operated using only three external clocks, (1) a Reset Clock signal which controls the integrated output signal amplifier, (2) a square wave Transport Clock which operates at half the reset clock frequency and controls the readout rate of video data from the sensor, and (3) a Transfer Clock pulse which controls exposure time of the sensor. The external clocks should be able to supply TTL level power.

Dark and White Reference Circuitry — Four additional sensing elements at both ends of the 1728/2048 array are covered by opaque metalization. They provide a dark (no illumination) signal reference which is delivered at both ends of the line of video ouptut representing the illuminated 1728/2048 sensor elements (labelled "D" in the block diagram). Also included at one end of the 1728/2048 sense element array is a white signal reference level generator which likewise provides a reference in the output signal (labelled "W" in the block diagram). These reference levels are useful as inputs to external DC restoration and/or automatic gain control circuitry.

DEFINITION OF TERMS:

Charge-Coupled Device — A charge-coupled device is a semiconductor device in which finite isolated charge-packets are transported from one position in the semiconductor to an adjacent position by sequential clocking of an array of gates. The charge-packets are minority carriers with respect to the semiconductor substrate.

Transfer Clock ϕ_X — The voltage waveform applied to the transfer gate to move the accumulated charge from the image sensor elements to the CCD transport shift registers.

Transport Clock ϕ_T — The clock applied to the gates of the CCD transport shift registers to move the charge-packets received from the image sensor elements to the gated charge-detector/amplifier.

Gated Charge-Detector/Amplifier — The output circuit of the CCD122/142 which receives the charge-packets from the CCD transport shift registers and provides a signal voltage proportional to the size of each charge-packet received. Before each new charge-packet is sensed, a reset clock returns the charge-detector voltage to a fixed base level.

Reset Clock ϕ_R — The voltage waveform required to reset the voltage on the charge-detector.

Sample-and-Hold Clock ϕ_{SH} — An internally supplied voltage waveform applied to the sample-and-hold gate in the amplifier to create a continuous sampled video signal at the output. The sample-and-hold feature can be defeated by connecting ϕ_{SH} to V_{DD}.

Dark Reference — Video output level generated from sensing elements covered with opaque metalization providing a reference voltage equivalent to device operation in the dark. Permits use of external dc restoration circuitry.

White Reference — Video output level generated by on-chip circuitry providing a reference voltage permitting external automatic gain control circuitry to be used. The reference voltage is produced by charge-injection under the control of the electrical input bias voltage (V_{EI}). The amplitude of the reference is typically 70% of the saturation output voltage.

Isolation Cell — A site on-chip producing an element in the video output that serves as a buffer between valid video data and dark and white reference signals. The output from an isolation cell contains no valid video information and should be ignored.

Dynamic Range — The saturation exposure divided by the peak-to-peak noise equivalent exposure. (This does not take into account any dark signal components.) Dynamic range is sometimes defined in terms of rms noise. To compare the two definitions a factor of four to six is generally appropriate in that peak-to-peak noise is approximately equal to four to six times rms noise.

Peak-to-Peak Noise Equivalent Exposure — The exposure level which gives an output signal equal to the peak-to-peak noise level at the output in the dark.

Saturation Exposure — The minimum exposure level that will produce a saturated output signal. Exposure is equal to the light intensity times the photosite integration time.

Charge Transfer Efficiency — Percentage of valid charge information that is transferred between each successive stage of the transport registers.

Spectral Response Range — The spectral band in which the response per unit of radiant power is more than 10% of the peak response.

Responsivity — The output signal voltage per unit exposure for a specified spectral type of radiation. Responsivity equals output voltage divided by exposure level.

Dark Signal — The output signal in the dark caused by thermally generated electrons which is a linear function of integration time and highly sensitive to temperature. (See accompanying photos for details of defintion.)

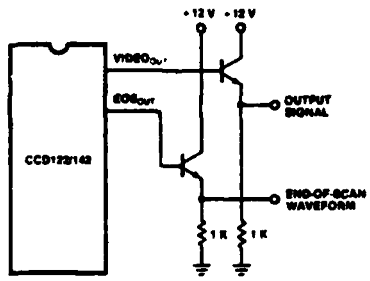
Total Photoresponse Non-Uniformity — The difference of the response levels between the most and least sensitive elements under uniform illumination. (See accompanying photos for details of definition.)

Saturation Output Voltage — The maximum usable signal output voltage, measured from the zero reference level. (See timing diagram.) Any photoelement whose video output < saturation output voltage has an in-spec charge transfer efficiency (CTE). CTE will be below the specification if the video output ≥ saturation output voltage.

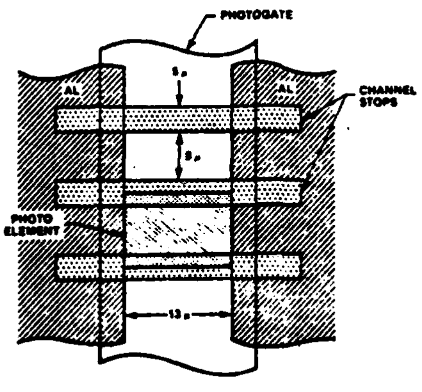
Integration Time — *The time interval between the falling edges of any two successive transfer* pulses ϕX as shown in the timing diagram. The integration time is the time allowed for the photosites to collect charge.

Pixel — Picture element (photosite).

TEST LOAD CONFIGURATION



PHOTOELEMENT DIMENSIONS



All dimensions are typical values

ABSOLUTE MAXIMUM RATINGS (Above which useful life may be impaired)

Storage Temperature		−25°C to +125°C
Operating Temperature (See curves)		−25°C to +70°C
CCD122:	Pins 1, 4, 9, 10, 11, 13, 14, 16, 22, 23	−0.3 V to 15 V
	Pins 5, 12, 17, 24	0 V
	Pins 2, 3, 6, 7, 8, 15, 18, 19, 20, 21	NC
CCD142:	Pins 2, 5, 10, 11, 12, 16, 17, 19, 25, 26	−0.3 V to 15 V
	Pins 6, 13, 14, 15, 20, 27, 28	0 V
	Pins 1, 3, 4, 7, 8, 9, 18, 21, 22, 23, 24	NC

CAUTION NOTE: These devices ha[illegible] limited built-in gate protection. It is recommended that static discharge be controlled and minimized. Care must be take[illegible] to avoid shorting pins $V_{IDEOOUT}$ and EOS_{OUT} to V_{SS} or V_{DD} during operation of the devices. Shorting these pins temporari[illegible] to V_{SS} or V_{DD} may destroy the output amplifiers.

DS	Dark Signal					
	DC Component		5	15	mV	Notes 13, 14
	Low Frequency Component		5	10	mV	Notes 13, 14
SPDSNU	Single-pixel DS Non-uniformity		20	40	mV	Notes 13, 15
R	Responsivity	2.0	3.5	5.0	Volts per $\mu J/cm^2$	Note 17
V_{SAT}	Saturation Output Voltage	800	1400	1600	mV	Note 18

*All PRNU Measurements taken at a 700 mV output level using an f/2.8 lens and excluded the outputs from the first and last elements of the array. The "f" number is defined as the distance from the lens to the array divided by the diameter of the lens aperture. As the f number increases, the resulting more highly columnated light causes the package window aberrations to dominate and increase PRNU. A lower f number results in less columnated light causing device photosite blemishes to dominate the PRNU.

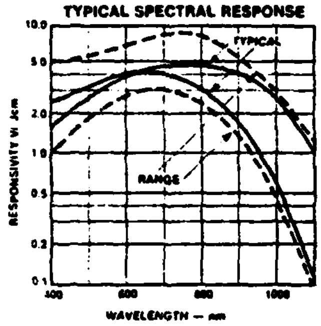
NOTES:

1. T_P is defined as the package temperature.
2. V_T should be equal to (1/2) $V_{\phi TH}$.
3. V_{EI} is used to generate the end-of-scan output and the white reference output. These two signals can be eliminated by connecting V_{EI} to a voltage level equal to $V_{\phi XH}$ + 5 V.
4. Negative transients on any clock pin going below 0.0 V may cause charge-injection which results in an increase of apparent DS.
5. $C_{\phi T}$ = 700 pF
6. $C_{\phi X}$ = 300 pF
7. $C_{\phi R}$ = 5 pF
8. Minimum clock frequency is limited by increase in dark signal.
9. Dynamic range is defined as VSAT/peak-to-peak (temporal) or VSAT/rms noise.
10. 1 $\mu J/cm^2$ = 0.02 fcs at 2854°K, 1 fcs = 50 $\mu J/cm^2$ at 2854°K
11. SE for 2854°K for light without 3.0 mm thick Corning 1-75 IR-absorbing filter is typically 0.8 $\mu J/cm^2$.
12. CTE is the measurement for a one-stage transfer.
13. See photographs for DS definitions.
14. Dark signal component approximately doubles for every 5°C increase in T_P.
15. Each SPDSNU is measured from the DS level adjacent to the base of the SPDSNU. The SPDSNU approximately doubles for every 8°C increase in T_P.
16. See photographs for PRNU definitions.
17. Responsivity for 2854°K light source without 3.0 mm thick Corning 1-75 IR-absorbing filter is typically 2 V per $\mu J/cm^2$.
18. See test load configurations.

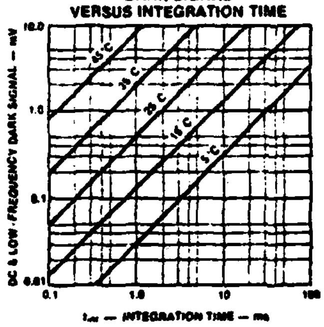
CCD122/142

TYPICAL PERFORMANCE CURVES

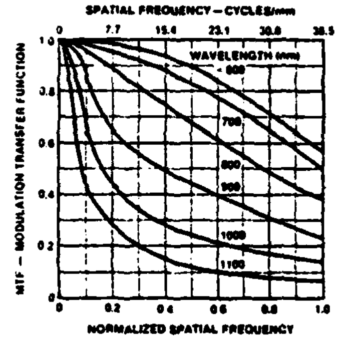
TYPICAL SPECTRAL RESPONSE



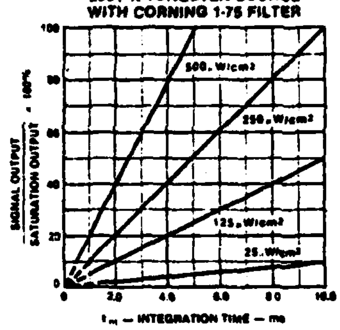
DC AND LOW-FREQUENCY DARK SIGNAL VERSUS INTEGRATION TIME



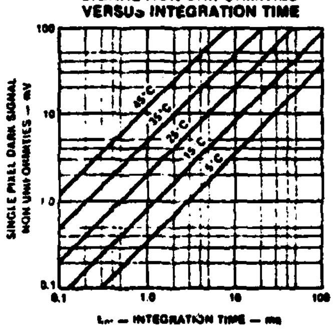
MODULATION TRANSFER FUNCTIONS FOR NARROW BAND ILLUMINATION SOURCES



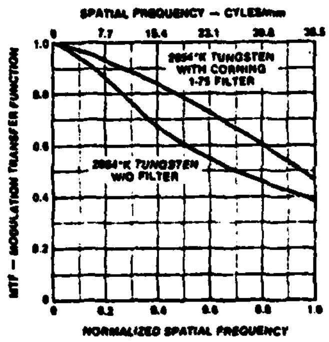
OUTPUT SIGNAL LEVEL VERSUS INTEGRATION TIME 2854°K TUNGSTEN SOURCE WITH CORNING 1-75 FILTER



SINGLE-PIXEL DARK SIGNAL NON-UNIFORMITIES VERSUS INTEGRATION TIME

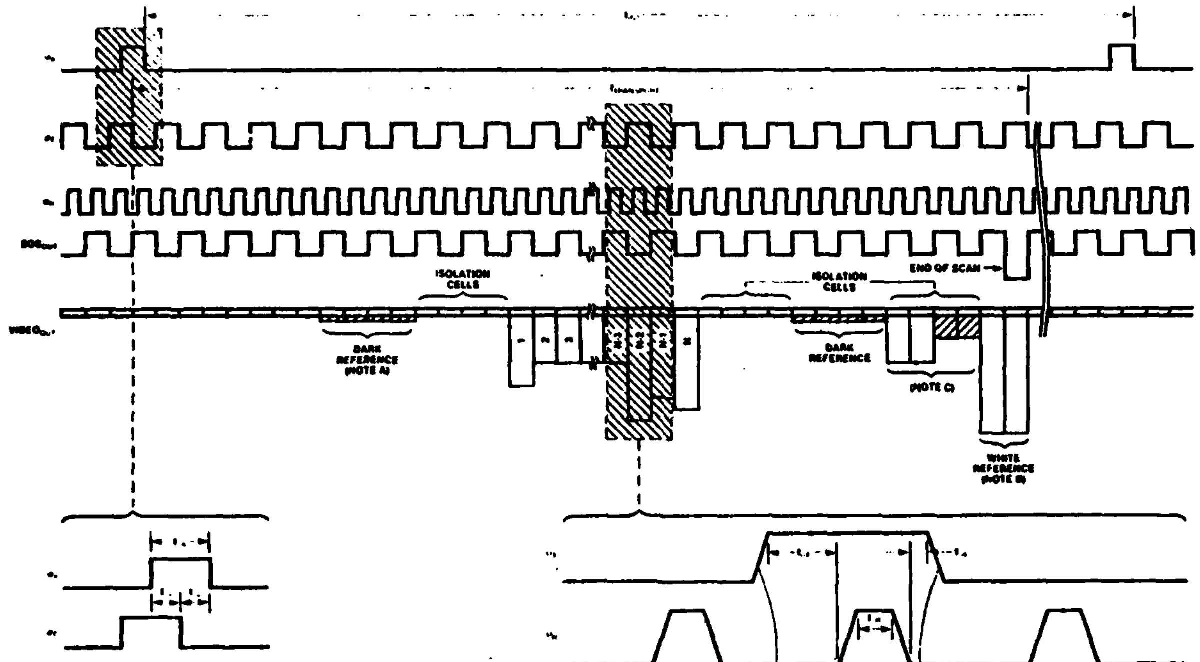


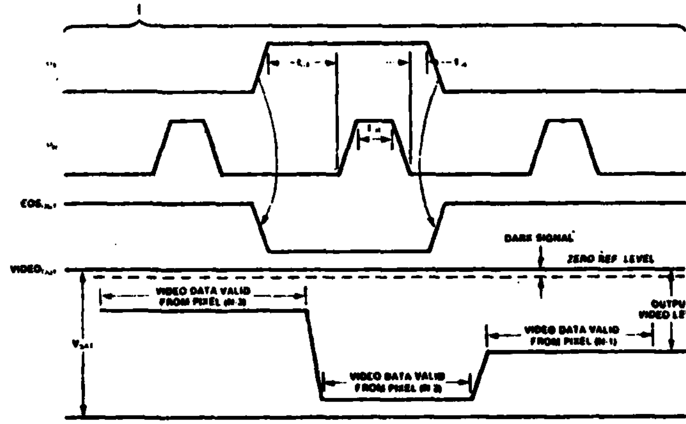
MODULATION TRANSFER FUNCTIONS FOR TWO BROADBAND ILLUMINATION SOURCES



The Corning 1-75 filter has the following typical transmittance spectral characteristic: >85% at <600 nm, 80% at 700 nm, 30% at 800 nm, 5% at 900 nm and <2% at >1000 nm.

TIMING DIAGRAM DRIVE SIGNALS





Timing requirements for transfer pulse ϕ_X (Note D). A ϕ_X pulse must straddle a ϕ_T transition as shown.

$t\phi_X > 200$ ns $t_{e1} > 100$ ns $t\phi_2 > 100$ ns

Timing requirements for reset pulse ϕ_R (Note D)

$t\phi_R > 40$ ns $t_{e3} > 350$ ns $t\phi_4 > 120$ ns

NOTES:

A. The first and last elements of the dark reference signal output may not contain a valid representation of that signal.

B. White reference cell output signals will be approximately equal in height.

C. These isolation cells may contain output signals as part of their buffer function. These signals should be disregarded.

D. Recommended rise and fall times for all clocks are that they are ≥ 20 ns.

IEEE Std 167A-1980
Facsimile Test Chart

Pattern Descriptions

The pattern number given in the following description may be identified from Figure 1. This chart is designed for scanning in either direction, horizontally across the page.

IEEE Std 167-1966, Test Procedure for Facsimile was based on previous issues of the IEEE Test Chart.

Patterns 1 and 2. 96 lines per inch (3.78 lines per millimeter) consisting of 48 dark and 48 light lines, substantially equal in width. In pattern 1, the black corresponds approximately to step 2 and gray to step 7 of pattern 8. In pattern 2, white represents paper white and gray to approximately step 11. These patterns are intended for generating low-modulation high-frequency signals at both ends of the density scale— useful for testing modulation characteristics at edges of band in a frequency shift system.

Patterns 3, 4, and 5. Vertical bar patterns at 10, 50, and 96 lines per inch (0.394, 1.97, and 3.78 lines per millimeter) of substantially equal width — useful for square-wave testing at several keying frequencies.

Pattern 6. A continuous density wedge designed so that at equal intervals of distance across the page, the variation in reflectance will be roughly equally perceptible to the eye. Reading left-to-right across the page, the relative reflection density values at the heavy dots are approximately as shown in Table 1. Pattern 6 is useful for cases where intermediate reflection densities are needed between the steps in Patterns 7 and 8.

Table 1
Pattern 6 Density Values

Dot	1	2	3	4	5	6	7
Density	1.95	1.75	1.23	0.73	0.38	0.14	0.08

Patterns 7 and 8. Reversed step tablets of 15 steps with reflection densities corresponding the approximately equal perceptibility modified to provide smaller low density increments. Consistent with conventional practice, paper white is understood to be equal to 0.00 in density (approximately 0.07 on an absolute scale). For patterns 7 and 8 the relative reflection densities are shown in Tables 2 and 3 respectively.

These patterns will assist in appraising gradient and absolute scale. They are useful for checking half-tone characteristics. Reversed sequences are used since the dynamic halftone characteristics may differ for a rising density or a falling density scale.

Pattern 9. National Bureau of Standards (NBS) type repeating tri-bar resolution test pattern. Twelve complete sets of three-line patterns are repeated across the sheet. Alternate groups are of different line spacing. Density values are shown in Table 4. This pattern is useful for checking definition.

Pattern 10. Rectangle with 45° diagonal marks at each corner — useful for checking index of cooperation, skew, and paper-feed error.

Patterns 11 and 17. White wedge on black background and black wedge on white background, 0.07 in (1.78 mm) to zero — useful for checking single-line definition.

Pattern 12. W. and L. E. Gurley type Pestrecov Star pattern. Outer circle 50, second circle 100, and third circle 200 lines per inch (1.97, 3.94, and 7.87 lines per millimeter).

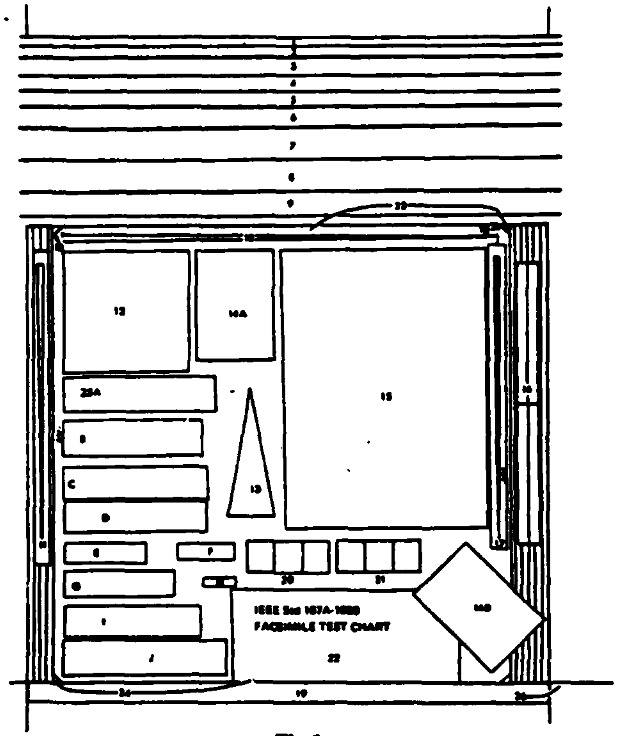


Fig 1
Pattern Arrangement

Pattern 13. Truncated fan-type multiple-line test pattern. Calibrated in lines per inch—useful for checking multiple-line definition along scanning line, envelope delay distortion, and ringing.

Patterns 14A and 14B. NBS type Microcopy Resolution test pattern. Numerals indicate the number of cycles (one black plus one white line) per millimeter (that is, line pairs)—useful in checking high definition systems.

Pattern 15. Photograph with detail in highlight and shadow. The limiting densities of the photograph approximate those of test patterns 7 and 8.

Pattern 16. Vertical gray steps with relative reflection densities of approximately 0.95 and 0.27 — useful in testing rising and falling transient characteristics and level variations.

Pattern 18. Horizontal "V" pattern with 0.13 in (3.3 mm) opening. Number of scanning line crossings of both lines, multiplied by 7.7 will equal number of lines per inch (multiply by 0.3 for number of lines per millimeter).

Pattern 19. "Fence" pattern with 0.01 in (0.254 mm) lines 0.10 in (2.54 mm) apart—useful for checking jitter and measuring available line length.

Patterns 20 and 21. Halftone dot screens. Reproduced in approximately 10, 50 and 90 percent black, left to right and at 65 dots per inch (2.56 dots per millimeter) at a 45° angle for pattern 20, and 120 dots per inch (4.72 dots per millimeter) for pattern 21.

Pattern 22. Title and credit box. Three sizes of Times Roman type font.

Patterns 23 and 24. Fiducial dots forming a 3, 4, 5 right triangle—useful for indicating the presence of skew by comparing the hypotenuse of the two patterns.

Pattern 25. Type faces as indicated—useful for checking readability.

Pattern 26. Extension lines to permit measurement of available line and useful length of copy.

Table 2
Pattern 7 Density Test

ANALOG DEVICES

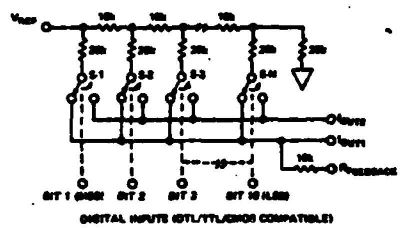
CMOS Low Cost 10-Bit Multiplying DAC

AD7533

FEATURES
Lowest Cost 10-Bit DAC
Low Cost AD7520 Replacement
Linearity: 1/2, 1 or 2LSB
Low Power Dissipation
Full Four-Quadrant Multiplying DAC
CMOS/TTL Direct Interface
Latch Free (Protection Schottky not Required)
End-Point Linearity

APPLICATIONS
Digitally Controlled Attenuators
Programmable Gain Amplifiers
Function Generation
Linear Automatic Gain Control

AD7533 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION
The AD7533 is a low cost 10-bit 4-quadrant multiplying DAC manufactured using an advanced thin-film-on-monolithic-CMOS wafer fabrication process.

Pin and function equivalent to the industry standard AD7520, *the AD7533 is recommended as a lower cost alternative for* old AD7520 sockets or new 10-bit DAC designs.

AD7533 application flexibility is demonstrated by its ability to interface to TTL or CMOS, operate on +5V to +15V power, and provide proper binary scaling for reference inputs of either positive or negative polarity.

PACKAGE IDENTIFICATION[1]
Suffix D: Ceramic DIP – (D16B)
Suffix N: Plastic DIP – (N16B)

[1] See Section 20 for package outline information.

Output Voltage (pin 1, pin 2) . . . . −0.3V to V_{DD}
Power Dissipation (Package)
Plastic (Suffix N)
To +70°C. 670mW
Derates above +70°C by . . . . .8.3mW/°C
Ceramic (Suffix D)
To +70°C. 450mW
Derates above +75°C by . . . . .6mW/°C
Operating Temperature Range
Commercial (JN, KN, LN versions). . . . . 0 to +70°C
Industrial (AD, BD, CD versions) . . . . −25°C to +85°C
Military (SD, TD, UD versions) . . . . −55°C to +125°C
Storage Temperature . . . . −65°C to +150°C
Lead Temperature (Soldering, 10 seconds). . . . . +300°C

CAUTION:

1. ESD sensitive device. The digital control inputs are Zener protected; however, permanent damage may occur on unconnected devices subjected to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts.
2. Do not apply voltages lower than ground or higher than V_{DD} to any pin except V_{REF} (pin 15) and R_{FB} (pin 16).

TERMINOLOGY

RELATIVE ACCURACY: Relative accuracy or end-point nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for ideal zero and full scale and is expressed in % or ppm of full-scale range or (sub) multiples of 1LSB.

RESOLUTION: Value of the LSB. For example, a unipolar converter with n bits has a resolution of (2^{-n}) (V_{REF}). A bipolar converter of n bits has a resolution of $[2^{-(n-1)}]$ $[V_{REF}]$. Resolution in no way implies linearity.

SETTLING TIME: Time required for the output function of the DAC to settle to within 1/2 LSB for a given digital input stimulus, i.e., 0 to Full Scale.

GAIN ERROR: Gain error or full-scale error is a measure of the output error between an ideal DAC and the actual device output.

FEEDTHROUGH ERROR: Error caused by capacitive coupling from V_{REF} to output with all switches OFF.

OUTPUT CAPACITANCE: Capacity from I_{OUT1} and I_{OUT2} terminals to ground.

OUTPUT LEAKAGE CURRENT: Current which appears on I_{OUT1} terminal with all digital inputs LOW or on I_{OUT2} terminal when all inputs are HIGH.

CIRCUIT DESCRIPTION

GENERAL CIRCUIT INFORMATION

The AD7533, a 10-bit multiplying D/A converter, consists of a highly stable thin film R-2R ladder and ten CMOS current switches on a monolithic chip. Most applications require the addition of only an output operational amplifier and a voltage or current reference.

The simplified D/A circuit is shown in Figure 1. An inverted R-2R ladder structure is used – that is, the binarily weighted currents are switched between the I_{OUT1} and I_{OUT2} bus lines, thus maintaining a constant current in each ladder leg independent of the switch state.

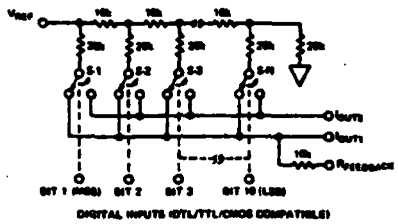

Figure 1. AD7533 Functional Diagram

One of the CMOS current switches is shown in Figure 2. The geometries of devices 1, 2 and 3 are optimized to make the digital control inputs DTL/TTL/CMOS compatible over the full military temperature range. The input stage drives two inverters (devices 4, 5, 6 and 7) which in turn drive the two output N-channels. The "ON" resistances of the switches are binarily sealed so the voltage drop across each switch is the same. For example, switch 1 of Figure 2 was designed for an "ON" resistance of 20 ohms, switch 2 for 40 ohms and so on. For a 10V reference input, the current through switch 1 is 0.5mA, the current through switch 2 is 0.25mA, and so on, thus maintaining a constant 10mV drop across each switch. It is essential that each switch voltage drop be equal if the binarily weighted current division property of the ladder is to be maintained.

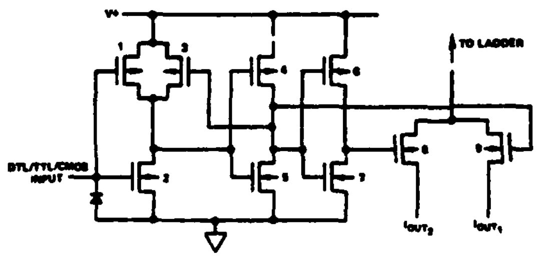

Figure 2. CMOS Switch

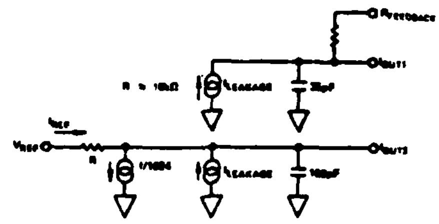

Figure 3. AD7533 Equivalent Circuit – All Digital Inputs Lo

EQUIVALENT CIRCUIT ANALYSIS

The equivalent circuits for all digital inputs high and all digi inputs low are shown in Figures 3 and 4. In Figure 3 with all digital inputs low, the reference current is switched to I_{OUT2}. The current source $I_{LEAKAGE}$ is composed of surface and junction leakages to the substrate while the $\frac{I}{1024}$ curre source represents a constant 1-bit current drain through the termination resistor on the R-2R ladder. The "ON" capacita of the output N channel switch is 100pF, as shown on the I_{OUT2} terminal. The "OFF" switch capacitance is 35pF, as shown on the I_{OUT1} terminal. Analysis of the circuit for all digital inputs high, as shown in Figure 4, is similar to Figure 3, however, the "ON" switches are now on terminal I_{OUT1}, hence the 100pF at that terminal.

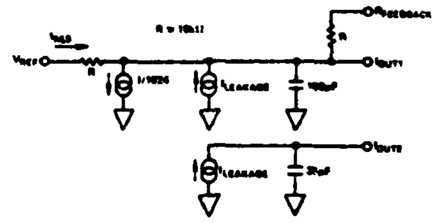

Figure 4. AD7533 Equivalent Circuit – All Digital Inputs High

positive logic: High input to clear resets all four outputs low

description

Each of these monolithic circuits contains eight master-slave flip-flops and additional gating to implement two individual four-bit counters in a single package. The '390 and 'LS390 incorporate dual divide-by-two and divide-by-five counters, which can be used to implement cycle lengths equal to any whole and/or cumulative multiples of 2 and/or 5 up to divide-by-100. When connected as a bi-quinary counter, the separate divide-by-two circuit can be used to provide symmetry (a square wave) at the final output stage. The '393 and 'LS393 each comprise two independent four-bit binary counters each having a clear and a clock input. N-bit binary counters can be implemented with each package providing the capability of divide-by-256. The '390, 'LS390, '393, and 'LS393 have parallel outputs from each counter stage so that any submultiple of the input count frequency is available for system-timing signals.

Series 54 and Series 54LS circuits are characterized for operation over the full military temperature range of −55°C to 125°C; Series 74 and Series 74LS circuits are characterized for operation from 0°C to 70°C.

APPENDIX B

F8 MICROPROCESSOR SOFTWARE

This appendix contains the source codes for the F8 developed in conjunction with the design of the Automatic Threshold Control for the scanner. Assembly listings and linking information for each software module are included. The floppy disc HELP file describing the software package is also included to serve as an overview.

```
*------------------------------------------------------------*
  THIS IS THE MAIN DESCRIPTOR FILE FOR THIS DISK.
  IT DESCRIBES THE PROGRAMS ON IT AND HOW TO USE THEM.
*------------------------------------------------------------*
```

PROGRAMS MODIFIED AND DEBUGGED
BY
CAPT B. J. STANTON, JUNE 82.

***** USER INFORMATION *****

THE F8 PROVIDES THRESHOLD AND PRINTER CONTROL FOR THE ELECTRO-OPTICAL PAGE SCANNER (EOPS). THE SOFTWARE IS IN A VARIETY OF FORMS DESIGNATED BY THE FILE ATTRIBUTE:

'00' IS A TEXT FILE SUCH AS THIS ONE OR ONE CONTAINING UNASSEMBLED SOURCE CODE.

'10' IS AN OBJECT CODE FILE THAT CAN BE LOADED AND/OR LINKED, DEPENDING ON THE NATURE OF THE SOFTWARE.

'30' IS A CORE IMAGE FILE THAT (WHEN LOCATED ON DISK DRIVE 0) IS LOADED AND EXECUTED AS A SYSTEM-LEVEL COMMAND WHEN THE FILENAME IS ENTERED.

'40' IS AN EXECUTIVE FILE FOR FACILITATING VARIOUS FILE OPERATIONS.

THE FILES EOPS1,30:1 AND EOPS2,30:1 ARE COMPLETE SOFTWARE PACKAGES. EOPS1 AND EOPS2 ARE DISTINGUISHED BY THEIR THRESHOLD SAMPLING ALGORITHMS. EOPS1 HAS AN INITIAL STEP SIZE (S1) OF 128 AND SAMPLES THE ENTIRE RANGE 8 N (0 TO 1024). EOPS2 HAS AN INITIAL STEP SIZE OF 64 AND SAMPLES THE RANGE OF N (128 TO 640). TO USE EITHER OF THESE PACKAGES, FIRST INSURE THE DESIRED PACKAGE IS LOADED ONTO DISK DRIVE 0. YOU MAY WANT TO MAKE A COPY OF ONE OF THESE FILES ON DRIVE 0 BY EXECUTING A COMMAND SUCH AS:

```
COPY FILE EOPS1,30:1
```

TO PUT THE F8 INTO THE EOPS MODE, CALL THE APPROPRIATE SOFTWARE PACKAGE BY TYPING ITS NAME:

```
EOPS1
```

ONCE THE SOFTWARE IS LOADED AND RUNNING, USER CONTROL IS PROVIDED THROUGH THE 'SENSE' SWITCHES ON THE FRONT PANEL OF THE F8. THE FUNCTIONS ARE:

SENSE #	DOWN	UP
4	NORMAL OPERATION	RETURN TO DOS4
5	NORMAL PAGE	INFINITE LINES
6	AUTOMATIC THRESHOLD	THRESHOLD FREEZE
7	SOFT COPY	HARD COPY

SENSE 4 IS USED TO EXIT EOPS MODE AND RETURN CONTROL OF THE F8 TO THE ZENITH KEYBOARD. (CAUTION: THIS SWITCH MUST BE DOWN WHEN ENTERING EOPS; OTHERWISE AN IMMEDIATE JUMP BACK TO THE OPERATING SYSTEM WILL OCCUR.

SENSE 5 IS USED FOR CALIBRATION AND CAUSES THE LINE COUNTER TO BE DISABLED SO THAT, WITH THE SCANNER IN '[illegible] MODE' THE SOFTWARE WILL CONTINUE TO ACCEPT AN INFINITE STREAM OF LINES WITHOUT ENDING THE PAGE. WHEN SENSE 5 IS RETURNED TO TO THE DOWN POSITION THE SOFTWARE IMMEDIATELY EXECUTES THE END OF PAGE SEQUENCE AND RESETS.

SENSE 6 IS USED FOR CONTROL OF THE AUTOMATIC THRESHOLD FEATURE. IN AUTOMATIC THRESHOLD MODE, 28 LINES OF THE LEADING MARGIN CONTAINING THE TEST PATTERN ARE SAMPLED TO OBTAIN THE OPTIMUM THRESHOLD FOR EXISTING CONDITIONS. THE VALUE OF THE SELECTED THRESHOLD IS DISPLAYED ON THE SCREEN IN HEX. IN THRESHOLD FREEZE MODES, THE LAST THRESHOLD SET BY THE SOFTWARE IS RETAINED AND DISPLAYED ON THE SCREEN. NOTE: IF THE THRESHOLD IS ALTERED FROM THE FRONT PANEL OR BY OTHER DEBUGGING MEANS, THE MESSAGE TO THE SCREEN WILL NOT REFLECT THE ALTERATION.

SENSE 7 SELF EXPLANATORY.

EOPS IS IN TURN COMPOSED OF SMALLER LINKABLE SOFTWARE PACKAGES. THESE MODULES ARE DESCRIBED BELOW:

MAIN4 ------ MAIN CALLING PROGRAM, VERSION 4

THIS MODULE CONTAINS THE MAINLINE ROUTINES OF EOPS AND THEREFORE MUST BE AT THE BEGINNING LINK. IT CONTAINS ALL INITIALIZATIONS, SENSE SWITCH CONTROLS, LINE COUNTERS, COMMAND TRANSMISSIONS, CRT SCREEN PROMPTS, AND ATC CALLS. IT ALSO INITIALIZES THE SAMPLING ALGORITHM, QSET, THEREBY CONTROLLING SAMPLING RANGE AND INITIAL STEP SIZE (31).

FSTLN ----- FIRST LINE

THIS SUBROUTINE POLLS THE SIGNAL CALLED 'PRINTLINE' WHICH IS PRESENT ON INPUT PORT 4 IN THE LEAST SIGNIFICANT BIT POSITION. THE PROGRAM IS DESIGNED TO DETECT A RISING TRANSITION OF THE INPUT SIGNAL. THIS IS ACCOMPLISHED BY LOOPING UNTIL THE SIGNAL IS FALSE AND THEN LOOPING UNTIL IT IS TRUE. WHEN THIS PROGRAM RETURNS, THE TRANSITION WILL HAVE JUST OCCURRED. THE SOFTWARE IS DESIGNED TO TAKE INTO ACCOUNT THE INVERSION THAT TAKES PLACE THROUGH THE F8 I/O PORT. THEREFORE THIS MODULE ACTUALLY SENSES A DOWNWARD TRANSITION OF THE SIGNAL 'PRINTLINE' IN THE SCANNER. THE GOAL IS TO CATCH THIS DOWNWARD TRANSITION WHICH SIGNALS THE END OF A LINE OF VIDEO INFORMATION.

ENDLN ----- END OF LINE

THIS SUBROUTINE IS A SLIGHTLY MORE COMPLEX VERSION OF FSTLN. IT ALSO DETECTS A FALLING TRANSITION OF 'PRINTLINE' HOWEVER, IT IS DESIGNED TO WAIT FOR THIS TRANSISTION FOR 10 MS. THIS FEATURE WAS INCLUDED TO PREVENT THE SOFTWARE FROM GETTING HUNG UP AND OUT OF SYNC IF THE SCANNER SHOULD EITHER STOP IN MIDPAGE OR PRODUCE A FALSE START. IN THE EVENT THAT THIS SUBROUTINE MUST WAIT MORE THAN 10 MS, IT SETS THE LINE COUNTER TO THE LAST LINE SO THAT WHEN THE RETURN TO THE MAIN PROGRAM OCCURS, THE LAST LINE CONDITION WILL BE INVOKED AND THE SOFTWARE WILL RESET. SHOULD IT BE NECESSARY TO HAVE THE SCANNER FROZEN IN MIDPAGE AND STILL HAVE THE SOFTWARE OPERATING SYNCRONOUSLY WITH THE SCANNER (FOR ALIGNMENT ETC.), SENSE SWITCH 5 SHOULD BE USED.

XMITS ----- TRANSMIT COMMAND

THIS IS THE SIMPLEST OF ALL THE SUBROUTINES. IT IS THE ONE WHICH ACTUALLY SENDS THE COMMANDS TO THE PRINTER OR THE TEKTRONICS DISPLAY. IT EXPECTS THE COMMAND CHANNEL IN THE INTERFACE BOARD TO HAVE ALREADY BEEN OPENED AND THE COMMAND FOR TRANSMISSION TO BE STORED IN REGISTER 9.

QSET ----- QUICK THRESHOLD SAMPLING ALGORITHM

THIS MODULE SAMPLES THE RANGE OF THRESHOLD VALUES BY USING PROGRESSIVELY SMALLER AND SMALLER STEP SIZES. EACH TIME QSET IS CALLED, THE EXISTING STEP SIZE WILL BE USED FOR SEVEN SAMPLES AND WILL THEN BE DIVIDED BY FOUR BEFORE CONTROL IS RETURNED TO THE MAIN CALLING PROGRAM. WITH EACH VALUE OF N, VTC IS COMPARED TO THE PREVIOUS MAXIMUM VTC (MTC). THE VALUE OF N PRODUCING THE OVERALL MAXIMUM VALUE OF VTC IS STORED FOR EITHER THE NEXT INVOCATION OF QSET OR FOR THE MAIN CALLING PROGRAM TO LOAD INTO PORTS 12 AND 13 AS THE OPTIMUM THRESHOLD VALUE FOR THE PAGE TO BE SCANNED.

********************** EXAMPLES **************************

SHOULD IT BE NECESSARY TO REASSEMBLE AND RELINK THE EOPS SOFTWARE PACKAGE, THE FOLLOWING SEQUENCE OF COMMANDS WILL PRODUCE THIS RESULT:

```
ASM MAIN4,00:1 TO MAIN4,10:1 NOLIST ERRS
ASM FSTLN,00:1 TO FSTLN,10:1 NOLIST ERRS
ASM ENDLN,00:1 TO ENDLN,10:1 NOLIST ERRS
ASM XMITS,00:1 TO XMITS,10:1 NOLIST ERRS
ASM QSET ,00:1 TO QSET ,10:1 NOLIST ERRS

LINK 1 CLEAR ORG 0 MAIN4,10:1
LINK 1 FSTLN,10:1
LINK 1 ENDLN,10:1
LINK 1 XMITS,10:1
LINK 1 QSET ,10:1
```

THE SOFTWARE IS NOW LOADED IN RAM AND READY FOR EXECUTION EITHER FROM THE FRONT PANEL OR BY USING THE F8 DEBUG SOFTWARE.
SHOULD IT BE NECESSARY TO CREATE A FILE FROM THE ABOVE MODULES THAT CAN BE LOADED WITH A SINGLE COMMAND, THE FOLLOWING COMMANDS CAN BE USED:

```
ASS DO VDISK FILENAME,10:1
DUMP 0000-0255
```

THIS PACKAGE WILL BE STORED ON DISK, AND CAN BE LOADED INTO RAM AT ANY TIME BY THE COMMAND:

```
LOAD FILENAME,10:1
```

TO EXECUTE THE PROGRAM LOADED IN THIS MANNER, USE THE F8 FRONT PANEL:

```
HALT
```

```
CLEAR DISPLAY
LD ADDRESS
RUN
```

IF THE USER WISHES TO HAVE A FILE WHICH LOADS AND ALSO AUTOMATICALLY EXECUTES FROM THE SYSTEM DISK, IN PLACE OF THE ABOVE EXAMPLE, THESE FOLLOWING COMMANDS CAN BE EXECUTED:

```
CCI FILENAME,30:1 C000-0255
COPY FILE FILENAME,30:1
```

THIS LAST COMMAND PLACES A COPY OF THE CORE IMAGE ON THE SYSTEM DISK WHERE IS WILL BE FOUND BY THE OPERATING SYSTEM IN RESPONSE TO THE USER TYPING 'FILENAME', SINCE THE SYSTEM LOOKS FOR LOAD-AND-EXECUTE FILES ON DRIVE 0 WHERE THE SYSTEM DISK USUALLY RESIDES.

IT MUST BE NOTED THAT THESE COMMANDS TO CREATE NEW COPIES OF THE OPERATING PROGRAMS MUST BE EXECUTED IMMEDIATELY FOLLOWING THE LINKING OPERATION SINCE SOME OF THE OTHER FDOS PROGRAMS (LIKE THE ASSEMBLER AND THE EDITOR) OBSCURE THE LOWER ADDRESSES OF THE MEMORY WHERE THE SCANNER PROGRAMS ARE LOADED.

ON THIS DISK THE FILES EOPS1,30:1 AND EOPS2,30:1 ARE AUTOMATIC LOAD-AND-EXECUTE FILES WHICH CAN BE COPIED TO A DISK IN DRIVE 0 FOR IMMEDIATE USE.

FOR FURTHER INFORMATION CONCERNING THE OPERATION OF THE F8 AND ITS OPERATING SYSTEM FDOS, CONSULT THE USERS MANUALS SUPPLIED WITH THE SYSTEM.

APPENDIX C

COMPUTER SIMULATIONS

These simulations use the APL programs QSET1 and QSET2 on the following page to emulate the flowchart of Figure 5.5. The VTC data used in the simulations were taken with the scanner and F8 under operational conditions as noted in Table C.1. Therefore the simulated performance accurately represents the actual behavior of QSET when implemented with the F8 and incorporated with the normal page-scanning sequence.

A few details deserve special attention as one examines these simulations. First, the smallest step size of QSET1 is S4 = 2 whereas the smallest step size of QSET2 is S4 = 1. In other words, QSET1 is fundamentally limited to only being able to pinpoint Np (the value of N producing the peak of the VTC curve, MTC) within an error of one millivolt. For this reason, errors of one millivolt with QSET1 are ignored when comparing QSET1 to QSET2 in Table C.3. Next, errors in the value of N are signed. If QSET produced an N-value less than the actual value of Np, then the error is negative (^), and if the QSET result is greater than the actual value of Np, then the error is positive. However, it is more significant to ignore the sign and evaluate the MAGNITUDE of the QSET error since this will reveal information on how far QSET "misses" the actual VTC peak, or equivalently, how far from optimum the threshold will be set due to sampling error. Finally it is important to understand that the QSET algorithm was designed to find the peak of a relatively smooth discrete curve with only one obvious maximum. But some of the data sets used in the simulations have much different characteristics, and it is instructive to note the behavior of the QSET algorithm in these situations.

The VTC data sets can be grouped into three general categories: (I) data sets using ECP A under normal conditions; (II) data sets using ECP A under abnormal conditions; and (III) data sets using other ECPs under normal conditions. Table C.2 lists the data sets belonging to each group, and Table C.3 summarizes the results of the simulation data. Although the data base is relatively small due to time constraints in this research, a few significant trends can still be identified. Notice first that the performance of both QSET1 and QSET2 are identical for Category I data sets. Looking at the individual simulations reveals that the same errors occurred mainly due to similar multiples in the samples taken. Also, the largest error occurred with data set A6232 which had an abnormal shape. And in general, it is important to realize that sampling errors are a product of the uncertainty in the VTC curve itself.

The performance with Category II data is a perfect example of the problem discussed in Chapter 5 concerning the occasion when the range of significant VTC information (RV) is smaller than the initial step size (S1). By examining the QSET1 simulations with data sets A606A and A606D, it can be seen that the algorithm will "freeze" on the initial sample because no significant VTC data is ever encountered. Recall however that

QSET2 was designed to overcome this specific problem, and as noted in the simulation results, its performance is excellent.

QSET evaluations with Category III data sets are more for example of the dependence of the algorithm on a properly shaped VTC curve. As discussed in Chapter 3, the CALIBRATION PATTERN must produce a VTC curve whose peak is at the value of N giving the optimum resolution in the scanner's output. While both algorithms faithfully locate the peaks in data sets B6062, C6062, and D6062, remember that these data sets are generated from constant-frequency ECPs that give erroneous VTC maximums. The large sampling errors occurring with data sets E6062 and F6062 are due to the significant ambiguities present in these VTC curves. Therefore it can be seen that ATC performance in general will be extremely unpredictable when scanning anything other than the proper CALIBRATION PATTERN.

APPENDIX D

DATA SET TRANSFER AND PLOTTING

The purpose of this appendix is to document the procedure for gathering VTC-versus-N data and transferring it to the Multics Computing System for analysis. Included are the source codes and explanations for the software used with the F8 microprocessor and with the Multics Graphics System.

To analyze the VTC curve for a particular set of conditions, the first step is to prepare the scanner for gathering a data set by loading and running the software package PLOT4 with Sense Switches 4, 5, and 6 in the DOWN position. (The Sense Switches are located on the front panel of the F8). With the Experimental Calibration Pattern (ECP) ready, the scanner start button should be pressed to initiate the page-scanning sequence. Once the moving assembly is approximately mid-page, the scanner should be frozen in position with the Crossfeed-Motor Pause Switch. Now, by referencing the shape of the analog video signal with an oscilloscope, the ECP to be scanned can be placed into position. VTC data are taken and stored in the F8 RAM memory when Sense 5 is placed to the UP position. Since PLOT4 gathers VTC data for every value of N from N = 0 to N = 768, it will take about three seconds from the time Sense 5 is activated until all data have been stored. The status of the lights on the front panel of the F8 will indicate when data transfer is complete. (Note that it is a simple software modification to alter the sampling range of

N if necessary.) At this point, if one is satisfied with the conditions under which the data was taken, Sense 4 can be placed UP which will terminate the PLOT4 routine. Otherwise PLOT4 can be recycled by first placing Sense 5 DOWN and then momentarily placing Sense 6 UP and then DOWN.

By resetting PLOT4, this enables the user to overwrite the original set of data with new data.

The next step is to enter the F8 DEBUG program to gain access to the data set that is now stored in RAM. The data buffer begins at memory location 0100(HEX), but significant data normally starts between 0500(HEX) and 0600(HEX). The data can be examined in BYTE form by using the DIM (display memory) command described in the F8 manuals. Values of N and VTC each require two bytes, and N-VTC data pairs are stored consecutively. As an example, data displayed by the command, DIM 0910-0A7F are shown in Figure D.1. To minimize the amount of storage and Multics computer time required, the bounds of significant VTC data should be ascertained before transferring any information out of RAM.

With the bounds of the data determined, the next step is to write the data into an F8 disk file for permanent storage and ease of manipulation. While still in the DEBUG program, the following sequence of commands will accomplish this:

```
MON
ASS CR WDISK <filename>,00:1
DEBUG
DIM <starting RAM address>-<ending RAM address>
MON
ASS CR ZTO
```

The data set is now in the form of an ASCII file on disk. To transfer the data to the Multics System, the following commands must be added to the file by the XEDIT editor. Before the data, include these lines:

```
&version 2
&trace off
&attach
apl -ttp ASCII
input2
```

After the data, include these lines:

```
stop
&detach
&quit
```

The disk file should now appear like the example in Figure D.2.

The F8 program, MULTX, is used to transfer the disk file to a Multics storage segment via dial-up link. Since the data set is now set up as an exec file, the Multics segment name must have the .ec suffix, e.g. filename.ec. With the data in a segment, any of a number of options can be employed to convert the data from its ASCII format to a usable decimal equivalent. However, this author used APL language for data manipulations. The procedure therefore continues as such: An APL workspace named CONTINUE must be already established and contain as a minimum the functions INPUT2 and CONVERT whose listings and explanations are included in this appendix. With these prerequisites met, execute the data set segment with the Multics command,

```
ec filename
```

A terminal prompt message will indicate when data transfer is complete. Multics is now in the APL ASCII mode and the proper conventions must be followed. To complete the data conversion, select an appropriate variable name for the data set and invoke the function, CONVERT:

```
VARIABLENAME <- CONVERT
```

VARIABLENAME becomes a two-dimensional array with each row representing an X-Y (or N-VTC) data pair. The various APL functions described in the remainder of this appendix can now be used to operate on the data as necessary. One note of caution concerning the plotting functions should be observed. ALWAYS link and unlink the Multics Graphics I/O at the Multics Command level, NEVER while within the APL mode. The commands to do this are,

```
setup_graphics      (sg)
remove_graphics     (rg)
```

The syntax associated with these commands should be reviewed in the Multics Users Manuals as necessary.

APPENDIX E

MODIFIED SCANNER CIRCUITS

This Appendix contains the documentation for all changes made to the scanner circuitry along with the pin connections for the new F8 I/O ports 10 through 13 (hex). The THRESHOLD LEVEL GENERATOR (TLG), Video A-to-D Converter, and VIDEO COUNTERS are located on the VIDEO DETECTION AND THRESHOLDING board. The old Video A-to-D Converter and manual threshold circuit were removed from the TIMING AND PROCESSING board.

Although no additional circuits were changed, it is also noted here that during the course of this project, severe clocking interference necessitated the relocation of several circuit boards that use the high-frequency clock signal generated on the CCD board. Specifically, the following boards were mounted on the top of the mechanical moving assembly of the scanner to minimize the lengths of the leads carrying clocking signals:

1. SYNCHRONIZED LINE-FREQUENCY GENERATOR
2. F8 INTERFACE BOARD NUMBER 4
3. TIMING AND PROCESSING
4. VIDEO DETECTION AND THRESHOLDING
