SUBJECT: Directorate for Development and Qualification Position on the Final Report of USAAEFA Project No. 82-01, Airworthiness and Flight Characteristics Test (A&FC) of AH-1S with Aircraft General Purpose Dispenser System (AGPDS)

SEE DISTRIBUTION

1. The purpose of this letter is to establish the Directorate for Development and Qualification position on the subject report. The report documents the test results of the subject evaluation and substantiates that the performance and flying qualities of the AH-1S with the prototype M-130 AGPDS installation are not significantly changed from a standard configuration AH-1S. However, relocation or a different orientation of the installation could cause a degradation in performance and/or flying qualities requiring additional testing.

2. This Directorate agrees with the report's conclusions. There were no shortcomings or deficiencies.

FOR THE COMMANDER:

CHARLES C. CRAWFORD, JR. Director of Development and Qualification

INTRODUCTION

BACKGROUND

1. The US Army contracted with TRACOR (the manufacturer) in 1976 to develop an XM130 chaff dispenser installation for the AH-IS. The chaff dispenser was initially mounted at the left wing stores station. This installation resulted in a large amount of chaff being ingested into engine inlet screens and recirculated by the main rotor. A new M130 location near the extreme bottom of the AH-IS vertical stabilizer on the left side was developed and tested on the AH-IS and determined to be effective. The physical size and location of the M130 installation on the AH-IS required that limited performance and stability and control testing be conducted. The US Army Aviation Research and Development Command (AVRADCOM) requested (ref 1, app A) the US Army Aviation Engineering Flight Activity (USAAEFA) conduct an Airworthiness and Flight Characteristics Test (A&FC) of the AH-IS with an M130 Aircraft General Purpose Dispenser System (AGPDS) installed.

TEST OBJECTIVE

2. The objective of this A&FC was to obtain performance and handling qualities data for inclusion in the operator's manual.

DESCRIPTION

3. The production AH-1S is a tandem seat, two-place helicopter with a two-bladed main rotor and a two-bladed Model 212 tractor tail rotor. The helicopter is powered by a Lycoming T53-L-703 turboshaft engine thermodynamically rated at 1800 shaft horsepower (SHP) at sea-level, standard-day conditions and derated by main transmission limit...ons to 1290 SHP for 30 minutes and 1134 SHP for continuous operation. Distinctive features of the helicopter include the narrow fuselage, stub wings with four stores stations, and a flat-plate canopy. A more complete description of the AH-1S is presented in the operator's manual (ref 2, app A) and appendix B.

4. The test aircraft AH-1S (Prod) USA Serial Number 76-22573 was configured with the K747 main rotor blades, two M65 tube-launched, optically-tracked, wire-guided (TOW) missile launchers on each outboard store station and an M159C 19-tube launcher on each of the two inboard store stations, as shown in photo A. Photo B shows the AGPDS installed on the AH-1S.

Photo B. M130 AGPDS Installation

TEST SCOPE

5. The A&FC evaluation was conducted at Edwards Air Force Base, California, from 12 May through 16 June 1982. Thirteen test flights were flown for a total of 12.1 flight hours of which 8.9 hours were productive. Flight restrictions contained in the operator's manual (ref 2, app A) and the airworthiness release (ref 3) were observed. A comparison of handling qualities and performance data with an AH-1S without M130 AGPDS installed (ref 4, app A) was also conducted. Flight conditions are summarized in table 1. ____

TEST METHODOLOGY

6. Established flight test techniques were used (ref 5, app A). Data were recorded by an onboard magnetic tape system. A more detailed instrumentation list is provided in appendix C. The test methods and data analysis methods are briefly described in appendix D. A Handling Qualities Rating Scale (HQRS) (fig. 1, app D) was used to augment pilot comments relative to handling qualities. The aircraft was weighed and the center of gravity (cg) was computed prior to testing. A current airspeed calibration was utilized. Table 1. General Test Conditions¹

RESULTS AND DISCUSSION

GENERAL

7. Level flight performance and handling qualities tests were performed on an AH-1S (Prod) helicopter with an M130 AGPDS installed. The tests were conducted to obtain performance and handling qualities data for inclusion in the operator's manual and to determine the effects of installation of the M130 AGPDS on the AH-1S. There was no apparent effect on power required to maintain level flight. No change in handling qualities was caused by the installation of the M130 AGPDS. No deficiencies or shortcomings attributed to the M130 AGPDS installation were identified.

LEVEL FLIGHT PERFORMANCE

8. Level flight performance tests were conducted to determine power required and fuel flow as a function of airspeed, gross weight and density altitude. The constant referred gross weight and rotor speed $(W/\delta, N/\sqrt{\theta})$ method was used to obtain data in stablized level flight at incremental airspeeds ranging from approximately 40 knots true airspeed (KTAS) to the maximum airspeed for level flight. Level flight tests were flown at zero sideslip, with the aircraft loaded to a forward cg location at near maximum gross weight. Results of these tests are presented nondimensionally in figures 1 through 3, and dimensionally in figures 4 through 6, appendix E. Baseline data were obtained with the M130 AGPDS removed. The data were compared to level flight performance with M130 installed.

9. Figure A presents a comparison of the AH-1S with and without the M130 installed. The drag effects of the M130 AGPDS were negligible.

HANDLING QUALITIES

Control Positions in Trimmed Forward Flight

10. The control positions of the AH-1S (Prod) in trimmed forward flight were evaluated in conjunction with level flight performance testing. The test results for both M130 installed and removed configurations are presented in figures 7 and 8, appendix E, respectively.

11. During level flight, consistently increasing forward longitudinal control trim positions were required at increasing forward speeds. Trim control position variations with airspeed were

essentially linear, and adequate control margins were available. During level flight from 50 knots calibrated airspeed (KCAS) to 85 KCAS, a noticeable right lateral cyclic (1/2 inch) was required; however, from 85 KCAS to 130 KCAS left lateral cyclic (3/4 inch) was required. Pitch attitude varied from 4 degrees nose down to 10 degrees nose down from 50 KCAS to maximum airspeed for level flight. The control position variation with M130 AGPDS installed or removed was essentially the same.

Static Longitudinal Stability

12. The static longitudinal stability characteristics of the AH-1S were evaluated in level flight with M130 AGPDS installed at the conditions presented in table 1, and data are presented in figures 9 and 10, appendix E. The variation of longitudinal control position and control force with airspeed were essentially linear and indicated weak positive static stability (forward control displacement and an accompanying push force for higher airspeeds). The weak static stability required increased pilot effort to establish and maintain a desired airspeed and resulted in a +3 knot airspeed excursion when trying to maintain 110 KCAS (HQRS +). Pitch attitude varied $\pm 11/2$ degrees from trim and provided weak cues for maintaining desired airspeed. The weak static longitudinal stability with M130 AGPDS installed is essentially unchanged from the standard AH-1S (ref 4, app A).

Static Lateral-Directional Stability

13. Static lateral-directional stability characteristics of the AH-1S were evaluated at the conditions presented in table 1 in level flight, climbs, partial power descents, and autorotations with M130 AGPDS installed and data are presented in figures 11 through 14, appendix E. At all airspeeds tested, the helicopter exhibited positive directional stability (increased left directional control for increase in right sideslip), and positive dihedral effect (increased right lateral control with increased right sideslip). The gradient of directional control position with change in sideslip angle was approximately 1 inch of pedal displacement per 20 degrees of sideslip at 68 KCAS. These gradients became larger at the higher airspeeds tested. Sideforce cues were weak about trim as evidenced by the small change in roll attitude. The static lateral-directional stability characteristics of the AH-1S with the M130 AGPDS installed were essentially unchanged from those of a standard AH-1S (ref 4, app A).

Dynamic Stability

14. Lateral-directional short-term response (figs. 15 through 21, app E) was evaluated during level flight, climbs, descents and autorotations at the conditions shown in table 1. The aircraft was flown with stablity and control augmentation system (SCAS) ON. Short-term response characteristics for directional controls were evaluated following single-axis, 1/2 second, 1 inch pulse inputs and during 1 inch control doublets. Following the inputs all controls were held fixed until the motion subsided.

15. A lateral-directional oscillation (dutch roll) was the principle aircraft response following pedal pulses and doublets. An easily excitable 3 second period oscillation occurred for all control inputs and damped out within 6 to 8 seconds. The lateral directional short-term response of the AH-1S with M130 AGPDS installed appears to be unchanged from the standard AH-1S (ref 4, app A).

Simulated Engine Failures

16. Sudden engine failures were simulated by trimming the aircraft at the test condition and abruptly closing the throttle to the flight-idle position. The flight controls were held fixed until the minimum transient rotor speed of 91 percent was approached or until 2 seconds had elapsed. The delay in moving the controls was to simulate the normal delay in pilot reaction time following an actual engine failure. A typical time history of the test is presented in figure 22, appendix E.

17. The response of the AH-1S following simulated sudden engine failure in level flight was characterized by rapid rotor speed decay, moderate left yaw, and slight left roll. The aircraft response to sudden engine failure was unaffected by the addition of the M130 AGPDS installation.

CONCLUSIONS

18. Installation of the M130 AGPDS on the AH-1S caused negligible effect on power required for level flight. No significant changes in handling qualities were found as a result of the installation of the M130 AGPDS. No deficiencies or shortcomings related to the M130 AGPDS were identified.

RECOMMENDATION

.

19. The following note should be added to the AH-1S operator's manual:

NOTE

The AH-1S (Prod) performance and handling qualities remain unchanged with the M130 AGPDS installed at fuselage station 490.8.

APPENDIX B. AIRCRAFT DESCRIPTION

GENERAL

1. The test helicopter, S/N 76-22573, was a production AH-1S with the K747 main rotor blades installed. Wing stores configuration for all tests were two-M65 tube launched, optically tracked, wire guided (TOW) launchers on each of the outboard wing stores stations and one 19-tube M159C launcher pod on each of the inboard wing stores stations.

MAIN ROTOR BLADES

2. The K747 main rotor blades utilize a multicell filament wound fiberglass spar, a nomex honeycomb core afterbody, and a Kevlar trailing edge spline, all enclosed by fiberglass skin. At the inboard end, checkplates carry loads to an aluminum adapter which is attached to the hub with a pin.

3. The K747 blade airfoil shape is based on a family of airfolls developed by Boeing Vertol. The airfoil shape varies from blade tip to root as follows:

r/R(Blade Radius Station)

Airfoil Design

From tip to 0.85K747 8% thick Boeing Vertol VR-8From 0.85 to 0.67Linear transition to 12% thick VR-7From 0.67 to 0.2512% thick Boeing Vertol VR-7From 0.25 to 0.18Gradual buildup to 25%
thick by cheekplates

ENGINE AND TRANSMISSION/TAIL ROTOR DRIVE

4. The T53-L-703 turboshaft engine is installed in the AH-1S (Prod) helicopter. This engine employs a two-stage, axial-flow free power turbine; a separate two-stage, axial flow turbine driving a five stage axial and one stage centrifugal compressor; variable inlet guide vanes; and an external annular combustor. A 3.2105:1 reduction gear box located in the air inlet housing reduces power turbine speed to a nominal output shaft speed of 6600 RPM at 100 percent N₂. The engine reduction gear box is limited to 1175 foot-pounds (ft-1b) torque for 30 minutes and 1110 ft-1b torque for continuous operation. A T₇ interstage turbine temperature sensor harness measures interstage turbine temperature on the cockpit instruments.

5. The main transmission has a 1290 shaft horsepower (SHP) limit for 30 minutes and a 1134 SHP limit for continuous operation at a rotor speed of 324 RPM (100 percent N_R). The aircraft is further limited to 88 percent torque above 100 knots indicated airspeed (KIAS). The tail rotor drive system has a 260 SHP transient limit for 4 seconds and a 187 SHP limit for continuous operation.

PRINCIPAL DIMENSIONS AND GENERAL DATA

6. The principal dimensions and general data concerning the AH-1S (Prod) helicopters are as follows:

Overall Dimensions

Length,	rotor turning	53	feet,	1	inch
Height,	tail rotor vertical	13	feet,	9	inches
Length,	rotors removed	44	feet,	7	inches

Weight and Balance

7. The aircraft weight, longitudinal center of gravity (CG) location and lateral CG location were determined prior to testing. A fuel cell calibration was also performed prior to testing. All weighings were accomplished with instrumentation installed without external stores or chin turret weapon installed.

APPENDIX C. INSTRUMENTATION

1. In addition to the standard aircraft instruments, calibrated instruments were displayed on the pilot and gunner cockpit panels. Data were obtained from cockpit instruments and from the test instrumentation system. The test instrumentation system was installed, calibrated, and maintained by USAAEFA personnel. All test instrumentation parameters are encoded pulse code modulation (PCM) and recorded on magnetic tape aboard the test aircraft. Sideslip vane, angle-of-attack vane, total temperature sensor, and pivoting pitot-static head are located on a test boom extending 89 inches from the nose of the aircraft.

2. The parameters recorded on magnetic tape are:

PCM Parameters

Time code Event Record number Main rotor speed Fuel used Engine fuel flow rate Engine gas producer speed Engine power turbine speed Airspeed (boom system) Airspeed (ship's system) Altitude (boom system) Altitude (ship's system) Total air temperature Angle of attack Angle of sideslip Engine torque Engine exhaust gas temperature Control positions Longitudinal Lateral Directional Collective Throttle Aircraft attitudes Pitch Ro11 Aircraft angular rates Pitch Ro11 Yaw Main rotor shaft torque Main rotor blade angle

3. The parameters displayed in the cockpit are:

Copilot Panel

Pressure altitude (boom system) Airspeed (boom system) Main rotor speed Engine torque Engine gas producer speed Total air temperature Fuel used Time code display Data system control

APPENDIX D. TEST TECHNIQUES AND DATA ANALYSIS METHODS

GENERAL

1. Established test techniques and data analysis methods were used in the handling qualities tests. Descriptions of the test techniques are contained in this appendix. The Handling Qualities Rating Scale, presented in figure 1, was used to augment pilot comments relative to handling qualities. All test flights were conducted with zero sideslip trim condition.

WEIGHT AND BALANCE

2. The aircraft weight, longitudinal CG location, and lateral CG location were determined prior to testing. The weighing was accomplished with instrumentation installed. The aircraft was ballasted as necessary to achieve the desired takeoff gross weight and CG.

Level Flight Performance

Ср

3. Helicopter performance test data were generalized by use of nondimensional coefficients. The purpose of this generalization was to accurately interpolate performance at aircraft gross weight/ambient air condition combinations not specifically tested. The following coefficients were used:

a. Coefficient of power (Cp):

=
$$\frac{SHP \times 550}{\rho A (\Omega R)^3}$$

b. Coefficient of thrust (C_T) :

$$C_{\rm T} = \frac{GW}{\rho A(\Omega R)^2}$$

c. Advance ratio (μ):

 ΩR

d. Advancing tip mach number (M_{TIP}):

$$M_{\rm TIP} = \frac{1.6878 \ V_{\rm T} + \Omega R}{a}$$

Where:

SHP = Engine output shaft horsepower 550 = Conversion factor (ft-lb/sec/shp) $\rho = \text{Air density (lb-sec²/ft⁴)}$ A = Main rotor disc area (ft²) $\Omega = \text{Main rotor angular velocity (rad/sec)}$ R = Main rotor radius GW = Gross weight (lb) 1.6878 = Conversion factor (ft/sec/kt) $V_T = \text{True airspeed (kt)}$ a = Speed of sound (ft/sec)For N_R = 324 RPM $\Omega = 33.93$

 $\Omega R = 746.442$ $(\Omega R)^2 = 557176.28$ $(\Omega R)^3 = 415900007.$

4. Engine output SHP was determined from the engine torque pressure. Torque pressure as a function of engine torque output of the engine was obtained from the engine manufacturer's test cell calibration. Shaft horsepower was determined by the following equation:

$$SHP = \frac{2\pi \times N_p \times T_q}{33,000}$$

Where:

N_p = Engine output speed (RPM) T_q = Engine output shaft torque (ft-1b) 33,000 = Conversion factor (ft-1b/min/shp)

SHP = Shaft horsepower

5. Each level flight performance flight was designed to obtain one curve of Cp versus μ at a constant value of C_T. The flight technique was to stabilize at zero sideslip at incremental airspeeds from approximately 40 KIAS to the maximum attainable. At each airspeed, torque, altitude, airspeed, and rotor speed were held constant for at least 1 minute prior to recording data. Altitude was increased between data points as a function of fuel burnoff in order to maintain a constant ratio of gross weight to air pressure ratio (W/ δ). Also, rotor speed (N) was varied as a function of ambient air temperature in order to maintain a constant ratio of rotor speed to square root of the air temperature ratio (N/ $\sqrt{\theta}$). The reason for maintaining constant N/ $\sqrt{\theta}$ was to minimize the difference in compressibility effects between flights. Target N/ $\sqrt{\theta}$ was 324 RPM for all level flight performance tests.

6. The C_p versus μ curves were cross plotted as C_p versus C_T with lines of constant μ . From these curves level flight performance at any combination of gross weight, rotor speed, pressure altitude, and air temperature can be determined.

7. Specific range was calculated using measured values of $V_{\rm T}$ and fuel flow as follows:

$$NAMPP = \frac{V_T}{W_f}$$

Where:

NAMPP = Specific range (nautical air miles per pound of fuel)

 V_T = True airspeed (kt)

 W_f = Fuel flow (1b/hr)

Control Positions in Trimmed Forward Flight

8. Control positions in trimmed forward flight at zero sideslip were determined by stabilizing the helicopter on a constant heading and airspeed. Data were recorded on magnetic tape. Control positions were plotted as a function of calibrated airspeed.

Static Longitudinal Stability

Ī

9. Static longitudinal stability was evaluated in level, climbing, and autorotational flight. The aircraft was trimmed at the desired trim airspeed. With collective fixed, the aircraft was stabilized at approximately 5-knot increments +20 knots from trim airspeed, allowing altitude, rate of climb, or rate of descent to vary as necessary. Control positions and airspeeds were recorded on magnetic tape. The control positions were then plotted as a function of calibrated airspeed.

Static Lateral-Directional Stability

10. This test was conducted using the steady-heading sideslip method and was accomplished by establishing a trimmed flight condition and then stabilizing at sideslip angles, in 5-degree increments, to the limit of the flight envelope or until full control deflection was reached, whichever occurred first. Collective control position was fixed at the trim value and altitude was allowed to vary. The trim airspeed and desired heading were maintained. All pertinent parameters were recorded on magnetic tape. The static directional stability, dihedral effect, and side-force characteristics of the aircraft were evaluated by plotting the variation of control position and aircraft attitude as a function of sideslip angle.

Dynamic Stability

11. Dynamic stability tests were conducted to evaluate the shortperiod response characteristics of the aircraft. Short-period characteristics were evaluated to determine aircraft response to sudden wind gusts. Short period response characteristics were simulated by rapidly displacing the cyclic control approximately one inch, holding the input for 0.5 second, then rapidly returning the control to the trim position while recording the resulting aircraft responses on magnetic tape. Lateral-directional shorttera response was further evaluated by directional control doublets.
