## I. INTRODUCTION:

The nitromethyl radical has been postulated to be involved in a number of different phenomena. In a study<sup>1</sup> of nitromethylation of aromatic compounds it was determined that the radical had appreciable electrophilic character. The only products formed were through reactions at the carbon suggesting that it was the more reactive center. Interestingly in the reaction with manganese (III) acetate and nitromethane the authors<sup>1</sup> suggested that it might be the aci form (CH<sub>3</sub>ONO) that underwent oxidation followed by tautomerization.

The radical could be produced in the following reaction:

$$CH_3 + CH_3NO_2 + CH_4 + CH_2NO_2$$

which has been suggested<sup>2</sup> to explain the appearance of methane as a major product in the decomposition of nitromethane. Once formed the nitromethyl radical is believed to effect the thermal decomposition of nitromethane in condensed phase systems<sup>3</sup>. Such systems include propellant ignition and explosive initiation. Nitromethyl radical may even play a role in the chemistry of the upper troposphere through the degradation of nitromethane formed from the possible reaction of  $CH_3$  and  $NO_2^4$ .

Very recently the vibrational spectrum of  $CH_2NO_2$  was reported by Jacox<sup>4</sup> who codeposited F atoms and nitromethane in an Argon matrix at 14 K and analyzed the changes in the IR spectra. Different isotopes of nitromethane were used in the study to help assign the bands.

The beat of formation of gaseous nitromethyl radical has been estimated to be 37.5 kcal/mol.

The ESR spectrum of the nitromethyl radical has been interpreted<sup>6</sup> as supporting a nonplanar geometry. However, the only reported theoretical calculation on  $CH_2NO_2$  was an INDO calculation<sup>7</sup> which predicted a planar structure.

The motivation for this study was not only to gain an understanding of this particular system as a reactive intermediate, but also to view the system as a model for the radicals produced from high energy species such as TNT (1,3,5-trinitrotoulene) where radical intermediates<sup>8</sup> as  $\frac{1}{1}$  or  $\frac{2}{1}$  might occur.

The two valence structures which can be written for planar

1

CH,NO, are:

A theoretical study<sup>9</sup> on radicals of this nature involving structures with comparable energies but inequivalent assignments of  $\pi$  bonds and the lone electron suggest that accurate results require substantial effort to correctly predict their relative energy. Indeed this could be predicted by the sophisticated basis sets needed<sup>10</sup> to predict the states of NO<sub>2</sub>.

## II. OBJECTIVES OF THE RESEARCH EFFORT:

The object of this work was to study the types of radicals that could be generated by thermal or photolytic decomposition of high energy materials. Specifically the radicals produced from polynitrated systems as TNT or HMX. To do this one must determine which is the most economical method that will produce results of sufficient quality or accuracy to answer the particular chemical problem. If empirical methods are not sufficiently accurate and more sophisticated methods too costly, one may ask if there are trends which could still allow the empirical methods to be used predictively with some confidence. The objectives of this study were as follows:

(1) To study the electronic states of the  $CH_2NO_2$  radical with the semiempirical method MNDO to determine the ground state and electronic configuration.

(2) To study the problem using ab initio methods with geometry optimization and correlation.

(3) To determine the extent that other configurations play in determining the properties of the electronic states by using a MCSCF method.

#### III. RESULTS AND DISCUSSION:

The first method used to study the electronic states of  $CH_2wO_2$ was the MNDO method, a semiempirical method based on the NDDO approximation<sup>11</sup> and very successfully parameterized by Dewar and Thiel<sup>12</sup>. All calculations were carried out using the unrestricted SCF formalism.

The heats of formation and geometries for  $C_{2v}$  species are given in Table 1. The most stable state is the planar  ${}^{2}B_{1}$  followed very closely by the staggered  ${}^{2}B_{2}$ . These two states simply correspond to rotation of the singly occupied p orbital on carbon. The other states were obtained by starting with a bond order generated from an orbital guess in which selected orbitals were occupied. During the iteration to self consistency the switched orbital was monitored to insure that it remained occupied. Unfortunately in many instances the wavefunction lost the initial  $C_{2v}$  symmetry and it proved to be impossible to obtain those states.

The planar  ${}^{2}A_{2}$  solution was found to be 18.3 kcal/mol higher in energy than the planar  ${}^{2}B_{1}$  state. Roughly, these two states correspond to valence structures 3 and 4. The unrestricted solution obtained for  ${}^{2}A_{1}$  was characterized by three singly occupied orbitals; a b<sub>2</sub> and a<sub>2</sub> orbital of alpha spin and a b<sub>1</sub> orbital of beta spin.

The assumption of  $C_{2v}$  symmetry for  $CH_2NO_2$  radical seems intuitively obvious but due to the interaction of closely related electronic state this assumption may be wrong. It has previously been noted <sup>10a,b</sup> that under certain conditions electronic states in  $C_{2v}$ symmetry may mix by an asymmetric distortion and lead to a lower energy in C\_ symmetry. The conditions which must be met are:

1) the two states in  $C_{2v}$  symmetry must transform as the same irreducible representation in the  $C_{a}$  point group;

2) there must be a surface crossing at some nearby C<sub>2v</sub> geometry;

3) the leading configurations must differ by only one spin orbital.

The  ${}^{2}A_{1}$  and  ${}^{2}B_{2}$  states of NO<sub>2</sub> meet the above conditions and it is found that an asymmetric distortion does lead to a lower energy.

If we look at the  $C_{2v}$  point group table we see that the  $C_{2v}$  symmetry can be reduced to  $C_s$  by the loss of the sigma (yz) plane or the sigma (xz) plane (5)

If the xz symmetry plane is lost then the  $A_2$  and  $B_1$  states transform as A" while  $A_1$  and  $B_2$  states transform as A'. If the yz symmetry plane is lost then  $A_2$  and  $B_2$  transform as A" while the  $A_1$  and  $B_1$  transform as A'.

The MNDO wavefunctions were tested for stability under  $C_s$  distortions and the results are presented in Table 2 and 3.

Table 1 MNDO Heats of Formation (kcal/mol) and Geometries<sup>a</sup> of  $CH_2NO_2$  radicals in  $C_{2v}$  symmetry

State	ΔHf	CN	NO	СН	ONH	HCN
<sup>2</sup> <sup>b</sup>	35.2	1.476	1.214	1.084	119.3	118.3
$^{2}A_{2}^{b}$	53.5	1.414	1.266	1.084	122.3	119.0
${}^{2}B_{2}^{\overline{c}}$	35.6	1.482	1.219	1.082	119.4	117.6
$^{2}A_{1}^{\tilde{c},d}$	63.1	1.454	1.264	1.084	121.5	118.2

a) Distances are given in Angstroms and angles are given in degrees.

b) Planar geometry.

c) Staggered geometry.

d) The  ${}^{2}A_{1}$  state has  $b_{2}$ ,  $a_{2}$ , and  $b_{1}$  orbitals singly occupied.

Table 2 MNDO Heats of Formation (kcal/mol) on distortion from  $C_{2v}$  Symmetry to C Symmetry

Element of	Symmetry	Symmetry		_
symmetry kept	in C <sub>2v</sub>	in C <sub>s</sub>	∆H <sup>a</sup> f	∆ <sup>H</sup> f
sigma(yz)	$^{2}A_{2}, ^{2}B_{1}$	<sup>2</sup> A" 33.	8 <sup>c</sup> (1.4)	71.0
	${}^{2}_{A_{1}}, {}^{2}_{B_{2}}$	<sup>2</sup> A'	-	đ

sigma(xz)

a) Planar geometry. Number in parenthesis refers to lowering in kcal/mol with respect to the lower of the two  $C_{2v}$  states.

b) Staggered geometry. Number in parenthesis refers to lowering in kcal/mol with respect to the lower of the two  $C_{2v}$  states.

c) The wavefunction exhibited only  $C_1$  symmetry.

d) A distortion from  $C_{2v}$  symmetry was not energetically favorable.

# Table 3 MNDO Geometries<sup>a</sup>

of CH<sub>2</sub>NO<sub>2</sub> radicals in C<sub>5</sub> symmetry

Geometry	ΔHf	CN	NO	СН	ONC	HCN	Dihedral
<u>6</u>	33.8	1.466	1.221	1.083	120.5	118.3	
			1.227	1.083	119.1	118.5	
<u>6a</u>	61.6	1.465	1.268	1.084	118.0	120.2	72.8
				1.082		116.4	
<u>7</u>	71.0	1.452	1.226	1.084	125.3	118.0	88.9
			1.306		116.6		

a) When two values for a variable are given, the first value corresponds to the bond distance or bond angle on the side of the CN bond denoted 'a' in figures 6, 6a, and 7 while the second value corresponds to the side denoted 'b'.

The global minimum was a distorted planar structure <u>6</u> but since the wavefunction did not possess  $C_s$  symmetry, the state could not be definitively assigned. Although the staggered  ${}^{2}A_{2}$  and  ${}^{2}B_{1}$ solutions could not be found, the MNDO value of 71.0 kcal/mol for the heat of formation of the distorted structure <u>6a</u> is a lower bound for the lower of the  $C_{2v}$  states. When the sigma (yz) plane of symmetry is lost the  ${}^{2}A_{1}$  and  ${}^{2}B_{1}$  states interact and lead to a  ${}^{2}A'$ state <u>7</u> 1.5 kcal/mol lower in energy than the  ${}^{2}A_{1}$  state.

-5

Since the relative energies of NO<sub>2</sub> and related compounds are particularly sensitive to the basis set 10, ab initio calculations system<sup>13</sup>. Geometries CH2NO2 were performed on the were completely optimized within either the  $C_{2v}$  or  $C_s$  point group using the 3-21G basis<sup>14</sup> and single point calculations were then made including correlation at the UMP3 level<sup>15</sup>. The energies relative to the staggered  ${}^{2}B_{2}$  are presented in Table 4, absolute energies in Table 5, and geometries in Table 6. From Table 4 one can determine that the  ${}^{2}A_{2} - {}^{2}B_{1}$  (planar) separations calculated at the UHF/3-21G, UHF/6-31G, UMP2/6-31G, and UMP3/6-31G are respectively; -17.7, -4.6, 49.4, and 31.0 kcal/mol. This compares to the MNDO value of 18.3 kcal/mol from Table 1.

a) See Table 3 and Figure 6.

b) The geometries for the two perpendicular states of  ${}^{2}A_{2}$  symmetries differ in the orbital occupancy. The first entry was obtained with 3 open shells, and the second with one open shell(see text).

c) See Table 3 and Figure 8.

The rotational barrier of planar  ${}^{2}B_{1}$  to staggered  ${}^{2}B_{2}$ i 8 fairly insensitive to the level of calculation (7-9 kcal/mol). The rotational barrier of planar  ${}^{2}A_{2}$  to staggered  ${}^{2}A_{2}$  is also insensitive to correlation if the same configuration is used. The barrier at the UHF/6-31G level is 79.6 kcal/mol compared to 86.1 kcal/mol at the UMP3/6-31G level. The high barrier reflects the multiple bond character of C-N bond. At the the single determinant level, however, the  $[8a_1^2b_1^25b_2^2]1a_2^1$  configuration leads to a higher energy than the  $[7a_1^22b_1^21a_2^24b_2^2]8a_1^{1}3b_1^{1}5b_2^{1}$  configuration<sup>16</sup>. The energy difference between the two solutions varied from 10-30 kcal/mol depending on level of calculation (see Table 4).

Of course the true  ${}^{2}A_{2}$  staggered state will be some linear combination of these two states plus other configurations of the correct symmetry. The proper treatment of such states must be based on either an MCSCF approach or a full configuration interaction approach.

As seen in Table 6 the CN bond length of the planar  ${}^{2}B_{1}$  states elongates 0.05 Å upon twisting to the staggered  ${}^{2}B_{2}$  state. This suggests that the 6.7 kcal/mol required for rotation (UMP3/6-31G) may be due either to elimination of conjugation in the planar structure or increased repulsion of the electron in the singly occupied orbital with the oxygen atoms in the staggered structure.

It must be remembered that this is not an electronic transition between states but rather a conformational change. The states  ${}^{2}B_{1}$  and  ${}^{2}B_{2}$  are antisymmetric with respect to  $C_{2}$  rotation while A<sub>2</sub> state is symmetric.

In the former case a rotation will split the  ${}^{2}B_{1}$  and  ${}^{2}B_{2}$ planar states into  $1^{2}A^{"}$  and  $2^{2}A^{"}$  which may interact. The rotation continues until at 180 degrees the states become noninteracting with new designations of  ${}^{2}B_{2}$  and  ${}^{2}B_{1}$ . The interaction could lead to a weak minimum for the lower state or a slight maximum in the higher state. However in this paper rotational barrier refers to the energy difference in the two  $C_{2v}$  electronic states. For  ${}^{2}A_{2}$ rotation the same applies to the interaction of  ${}^{2}A_{2}$  and  ${}^{2}A_{1}$  as  $1^{2}A^{'}$  and  $2^{2}A^{'}$ . In this case the energy separation between the two states makes mixing unlikely.

The shortest CN bond occurs in the planar  ${}^{2}B_{2}$  state, 0.10 Å shorter than the CN bond in the planar  ${}^{2}A_{2}$  state  $\underline{4}$  whose valence structure can be drawn with a double bond. The shorter CN bond is due to removing an electron (with respect to the  ${}^{2}A_{2}$  configuration) from the CN antibonding 5b<sub>2</sub> orbital and putting it in the CN bonding 1a<sub>2</sub> orbital. The loss of a electron from the 5b<sub>2</sub> orbital also causes the CNO bond angle to increase about 6 degrees when compared to the planar  ${}^{2}A_{2}$  geometry.

The spin squared values for the 3-21G wavefunctions are given in Table 6. The only states which approach the ideal 0.75 value (S(S+1)) are the planar  ${}^{2}B_{1}$  state and the staggered  ${}^{2}B_{2}$  state. In these states the extra alpha spin electron is almost completely localized in a p orbital perpendicular to the CH<sub>2</sub> plane. The other states indicate a large amount of spin polarization where alpha and beta spins localize in different regions of the molecule. This gives some indication that a restricted program must use additional configurations to achieve the same result.

It was found that the 3-21G optimized geometries are unstable with respect to distortions from  $C_{2v}$ . The results are also presented in Table 4, 5, and 6. The distortions and energy changes are larger than found for MNDO. When correlation is used the distortion becomes unfavorable.

A perturbational correlation treatment such as the UMP3 method becomes ineffective when the single Hartree-Fock configuration is not the dominant configuration in the wavefunction. Since it is known that there are several configurations of the same symmetry and of comparable energy, a MCSCF treatment was used to continue the study. The program ALIS<sup>17</sup> developed by Klaus Ruedenberg and coworkers and sponsored by the U.S. Department of Energy was used to determined MCSCF energies and wavefunctions.

In order to 'feel out' the potential surface and determine which configurations were important for the different states MCSCF calculations were made using a STO-3G basis<sup>18</sup>. In all calculations reported below the 3-21G geometries were used<sup>19</sup>. It was later -confirmed that the largest contribution to the wavefunction was the configuration used to generate the geometry. It can be argued that using geometries optimized with a single configuration might 'favor' that configuration in a MCSCF scheme, however the extra expense of optimizing at this level was not feasible. MCSCF calculations were performed on the two staggered  $^{2}A_{2}$  states obtained at the 3-21G level (vide supra) using different configurations. For the geometry obtained with 3 open shells, the leading contribution (one space orbital with two spin functions) also contained the 3 open shells  $(a_1, b_1, b_2)$  and accounted for 63% of the wavefunction. For the geometry obtained with one open shell (a,), the same configuration accounted for 49% of the wavefunction.

The steps taken to obtain the MCSCF energy<sup>20</sup> are given below. An initial guess of orbitals is made by doing a restricted open shell calculation. For the STO-3G basis the energy normally converged but

for the 6-31G basis the energy diverged. In the latter case it was necessary to stop the SCF at the point of divergence and orbital improvement was made at the expense of extra MCSCF microiterations. few intuitive limited MCSCF was performed with a Next а configurations. Using this wavefunction a CI in a larger space (approximately 500 Spin Adapted Antisymmeterized Products) was made to determine which configurations made substantial contributions to the wavefunction. These configurations were then used in another MCSCF calculation with the CI orbitals as the initial guess. The process repeated until the MCSCF and CI had the same dominant Was configurations and until no configuration in the CI which was not included in the MCSCF contributed 1% or more to the wavefunction. The final MCSCF was carried out with between 5 and 11 spin adapted configurations. This provides an approximation to the full 500 configuration MCSCF as the most important configurations have been iteratively selected.

The MCSCF/STO-3G results are presented in Table 7. The first column represents the restricted open shell energies while the second column gives the MCSCF energy with the number of configurations in parenthesis and the per cent contribution of the most important configuration. The third column gives the CI energy with the number of spin adapted configurations in parenthesis (8 orbitals and 7 electrons in  $C_{2v}$  symmetry). It has been pointed out that in some cases carrying out a calculation in  $C_{2v}$  symmetry may lead to a higher energy than if only  $C_s$  symmetry were used, but in the calculations<sup>10a,b</sup> for NO<sub>2</sub> it was found that the  $C_{2v}$  solution was the same as the  $C_s$  solution. For this reason plus economics, the  $C_{2v}$  point group was used when possible.

Relative energies are presented in Table 9. In contrast to MNDO and ab initio results, the planar  ${}^{2}A_{2}$  state is predicted to be the most stable of the  $C_{2v}$  states followed by the planar  ${}^{2}B_{1}$  state 8.0 kcal/mol higher. The rotational barrier for the  ${}^{2}B_{1}$  to  ${}^{2}B_{2}$  conformational change is 18.6 kcal/mol, considerablely higher than the MNDO (0.4 kcal/mol) or the UMP3/6-31G (6.7 kcal/mol) barrier. The barrier for the rotation of the  ${}^{2}A_{2}$  state (45.1 kcal/mol) is larger than the UMP3/6-31G value (51.1 kcal/mol).

a) Largest contribution from a single configuration in the MCSCF wavefunction.

b) Largest contribution from a single configuration in the CI which was not optimized in the MCSCF wavefunction.

The STO-3G minimal basis set is known to be inferior to the near double zeta quality 6-31G basis set<sup>21</sup>. For this reason the calculations were repeated with the larger basis set. It was felt that most of the important configurations would already be identified from the STO-3G basis allowing rapid convergence to the most important configurations in the expanded basis.

The absolute energies for the MCSCF/6-31G calculations are presented in Table 8 and the relative energies are presented in Table 9. The restricted open shell energies are not given as the SCF diverged. The percent contribution of the single largest contributing configuration clearly indicates that a single determinant cannot be adequate. The <sup>2</sup> B<sub>2</sub> planar <sup>2</sup>B<sub>1</sub> and staggered configuration states have one comprising approximately

State MCSCF/STO-3G +CI

90% of the wavefunction. These corresponds to one electron in a p orbital perpendicular to the  $CH_2$  plane and are the same states that produced 'normal' S<sup>2</sup> values. Even for these two states the orbitals occupations showed a significant population of a 'virtual' orbital. In Figure 8 and 9 the nonbonding oxygen b<sub>2</sub> orbital contained 1.8 electrons while the antibonding (bonding across oxygen) contained 0.2 electrons.

This suggests that there may be some stabilization through pi overlap of the oxygen p orbitals.

The MCSCF/6-31G plus CI lead to a predicted staggered  ${}^{2}B_{2}$ C<sub>2v</sub> ground state for the nitromethyl radical. This is different from each of the previous methods. The planar  ${}^{2}B_{1}$  state is 7.8 kcal/mol less stable and the planar  ${}^{2}A_{2}$  state is 13.1 kcal/mol above the staggered  ${}^{2}B_{2}$  state. The difference between the  ${}^{2}A_{2}$ states is 72.3 kcal/mol which is almost identical to the STO-3G difference and greater than that predicted by UMP3/6-31G.

The relative energies have not converged with respect to increasing the sophistication of the basis set. Therefore it is premature to give the definitive electronic state ordering. In particular polarization functions as well as a more complete CI may make significant contributions to the relative energies.

Another possible influence on relative energies could be distortions from  $C_{2v}$ . This was found to be favorable in the MNDO approximation and at the UHF/3-21G and UHF/6-31G levels (though not at the UMP2/6-31G or UMP3/6-31G levels). In order to see if the planar  ${}^{2}A_{2}$  and  ${}^{2}B_{1}$  states might interact upon loss of the sigma (xz) plane (vide supra), MCSCF calculations were carried out on the planar  ${}^{2}A_{2}$  state at the  ${}^{2}B_{1}$  geometry and on the  ${}^{2}B_{1}$  state at the  ${}^{2}A_{2}$  geometry. The results shown in Figure 10 (see Table 8 for absolute energies) indicate that a crossing must occur somewhere between the two geometries along a  $C_{2v}$  reaction coordinate.

A MCSCF calculation was carried out on the distorted  $C_{2w}$ 

. Jean

geometry optimized with the UHF/3-21G basis (see Table 6). The results given in Table 8 and 9 indicate that the distortion is favorable and yields a  ${}^{2}A''$  state 14.6 kcal/mol more stable than the planar  ${}^{2}B_{1}$  state. This is 6.8 kcal/mol more stable than the staggered  ${}^{2}B_{2}$  and thus becomes the ground state. It would be important to precisely determine the  $C_{g}$  minimum before structural predictions are made as the UHF/3-21G optimized geometry may not be accurate, but it is felt that such optimization would not qualitatively change this result.

Figure 10. Illustration of  $C_{2v}$  Energy Crossing with the MCSCF calculations at the four labeled points.

S. St.

#### RECOMMENDATIONS

On the basis of the above study the following recommendations can be made:

(1) That single determinant methods for the nitromethyl radical may neglect important contributions to the wavefunction and must be used with some caution in making structural and energetic predictions.

(2) That semi-empirical and ab initio methods provide similar qualitative predictions, however it is more difficult to obtain different electronic states with the MNDO method.

(3) That distortions from  $C_{2v}$  symmetry must be considered when states differing by only one spin orbital cross at some  $C_{2v}$  geometry.

(4) That unrestricted ab initio results without correlation probably overestimate such distortions.

(5) That a similar study be undertaken at the ab initio level for the radicals derived from 1-nitropropene which may be a more realistic model for the radicals produced from TNT.

(6) That in order to study the decomposition mechanism for nitromethane the reaction pathway from the nitromethyl radical to  $CH_2$  plus NO<sub>2</sub> and to  $CH_2O$  plus NO be studied.

### ACKNOWLEDGEMENTS

I would like to thank the Air Force Office of Scientific Research for the opportunity to carry out research at their facilities. Financial support for the Summer Faculty Research Program Fellowship was administered through the Southeastern Center for Electrical Engineering Education. The hospitality shown by the members of the Frank J. Seiler Research Laboratory was greatly appreciated. In particular I would like to acknowledge helpful conversations with Capt. Larry P. Davis and Dr. Almon G. Turner.

The MCSCF program was provided by the Ames Laboratory, Iowa State University, Ames, Iowa. Stephen T. Elbert also provided technical assistance.
