20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

An important part of development of electronic packages for space use is verification of performance under expected environmental conditions. The system developed at NRL is designed to provide thermal vacuum testing of atomic clocks for use in the Global Positioning System (GPS). It is capable of testing all pertinent clock parameters in a preprogrammed sequence. Test durations from minutes to months may be selected. Real time as well as historical data presentations and reductions are available.

CONTENTS

THERMAL VACUUM TEST FACILITY

1.0 Assembling the Equipment Rack

Equipment Needed:
==========

(does not include interface cards, cables, or software items)

1. 69 7/8 inch Cabinet Rack
2. Sliding Desk Top Shelf
3. Rack Mount Tray
4. Power Strips with at least 15 outlets
5. 9825 Calculator with flexible disk drive, plotter-general I/O-extended I/O, and string-advanced programming ROM's
6. 9878 I/O Expander
7. 9885M Flexible Disk Drive
8. 9885S Flexible Disk Drive
9. 98035 Real Time Clock
10. Racal-Dana Counter
11. Cs Control Box
12. 27V Power Supply
13. Chamber Temperature Controller
14. 436 RF Power Meter
15. 59301 ASCII to Parallel Converter
16. Analog Thermometer Matrix
17. 3455 Digital Voltmeter
18. 3495 Scanner
19. Kepco Bipolar Operational Power Supply
20. 7245 Plotter/Printer

[rack #2 only] 21. 1350 Graphics Translator

[rack #2 only] 22. 1311 Display

ASSEMBLY: This paragraph describes the assembly of the cabinet. Two different versions of the rack can be built. The 1st rack contains items 1-20 from the equipment list above. These items are arranged in the cabinet as shown in figure 1.1. Item 20, the plotter/printer is not rack-mountable, but can be placed on a table top. The 2nd rack contains the items marked [rack #2 only], in addition to items 1-20. The graphics translator and display generate soft-copy lists and plots and are driven by the same software that runs the 1st rack. The equipment does not all fit into rack #2. See figure 1.2. The graphics translator is placed in slot reserved for the calculator in rack #1. The calculator, display, and plotter/printer are placed on a table top.

SELECT CODES and DEVICE ADDRESSES: Each device has its own unique select code and device address. The select code is a single digit from 0 to 9 specified on the bus interface card by adjusting a rotary select switch. The device address is a two digit number from 0 to 31 specified by selecting the appropriate bits on a dip

Manuscript approved September 22, 1983.

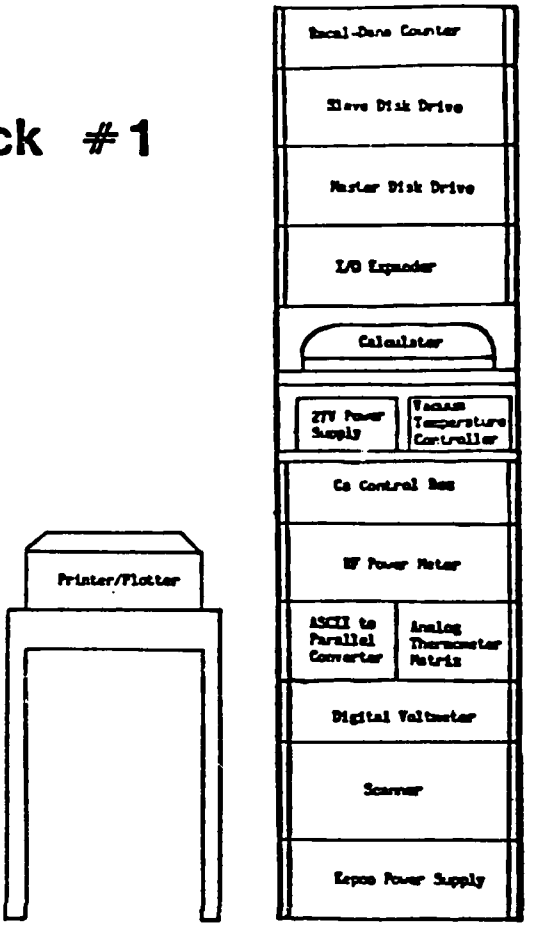

Figure 1.1

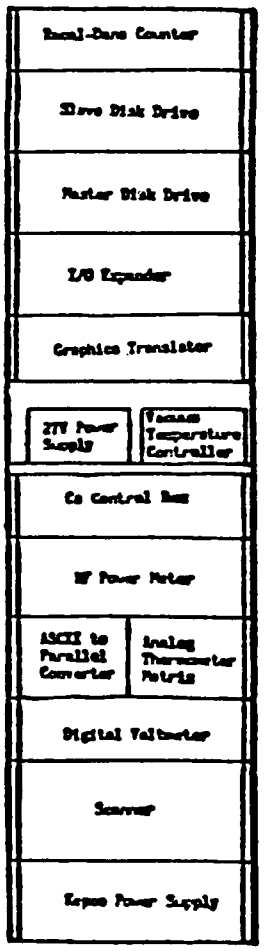
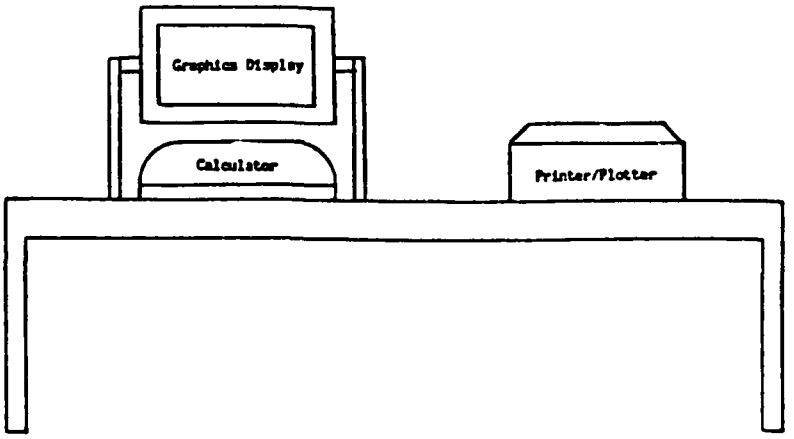


rack #2

Figure 1.2



switch. The dip switch is usually located on the back panel of an instrument, but sometimes is placed on a board and is accessible only by taking the cover off. Three different buses are used in this system. Each bus requires its own slot in the I/O expander box. The 98035 HP-IB interface is set to SC 7, the 98032 opt 085 disk interface is set to SC 8, and the 98035 real time clock, which requires its own slot, is set to SC 9. All the instruments which communicate with the calculator, except the clock and disk drives, talk over the HP-IB. The device addresses for each instrument are listed in table I. Although the RF power meter is a bus-compatible instrument, it is not placed on the bus. Rather, the recorder output on the back panel is sampled by the voltmeter. The master disk drive is set to drive 0 by a rotary select switch on the back panel of the instrument. The slave disk drive is set to drive 1.

Table I: Select Codes and Device Addresses

9	-	-	98035 Real Time Clock	-

2.0 Wiring the Interconnections

AC POWER: Connect AC power cords from the back of each instrument to the power strip. Connect the power strips together so that only one line runs out to the wall outlet. Plug the 27V power supply into the duplex power outlet on the front panel of the vacuum chamber.

BUS CONNECTIONS: Plug the I/O expander card into one of the three calculator slots. Cover the other two slots with plastic inserts, if possible. Plug the 98032, 98034, and 98035 cards into any of the I/O expander slots. Connect the other end of the 98032 to the master disc drive. Lock it into place by sliding the clip to the right. Connect the master disk to the slave disk by attaching the special mating cable. Both connectors on the slave disk are identical, so either one can be used. This cable also locks into place at each end. Connect the other end of the 98034 to the counter. Now attach the other instruments listed in table I, with a select code of 7, to the bus with short HP-IB cables. Be aware of creating bus loops. Do not connect the RF power meter to the bus.

INSIDE THE CHAMBER: Five lines must be connected inside the chamber. The 1st line runs from a 37-pin Deutsch connector attached to the chamber bulkhead, to the analog thermometer matrix receptacle box mounted on the chamber base plate. The 2nd cable has a 37-pin Duetsch bulkhead connector on one end, and divides into two separate lines at the other end, which are each terminated by Bendix connectors. These terminals are attached to their mates on the Cs clock. The 3rd line is a coaxial cable. It runs from a bulkhead BNC connector on one end, to the SMA RF output port on the Cs clock at the other end. The 4th and 5th leads supply power to the thermoelectric device (TED). Select wire sufficient to carry 5A without heating. These two wires each have BNC terminations at one end for connecting to the bulkhead feed-throughs, and are attached at the other end to a 9-pin amphenol female connector, pins 2 and 4. The amphenol connector mates with a male connector wired to the TED.

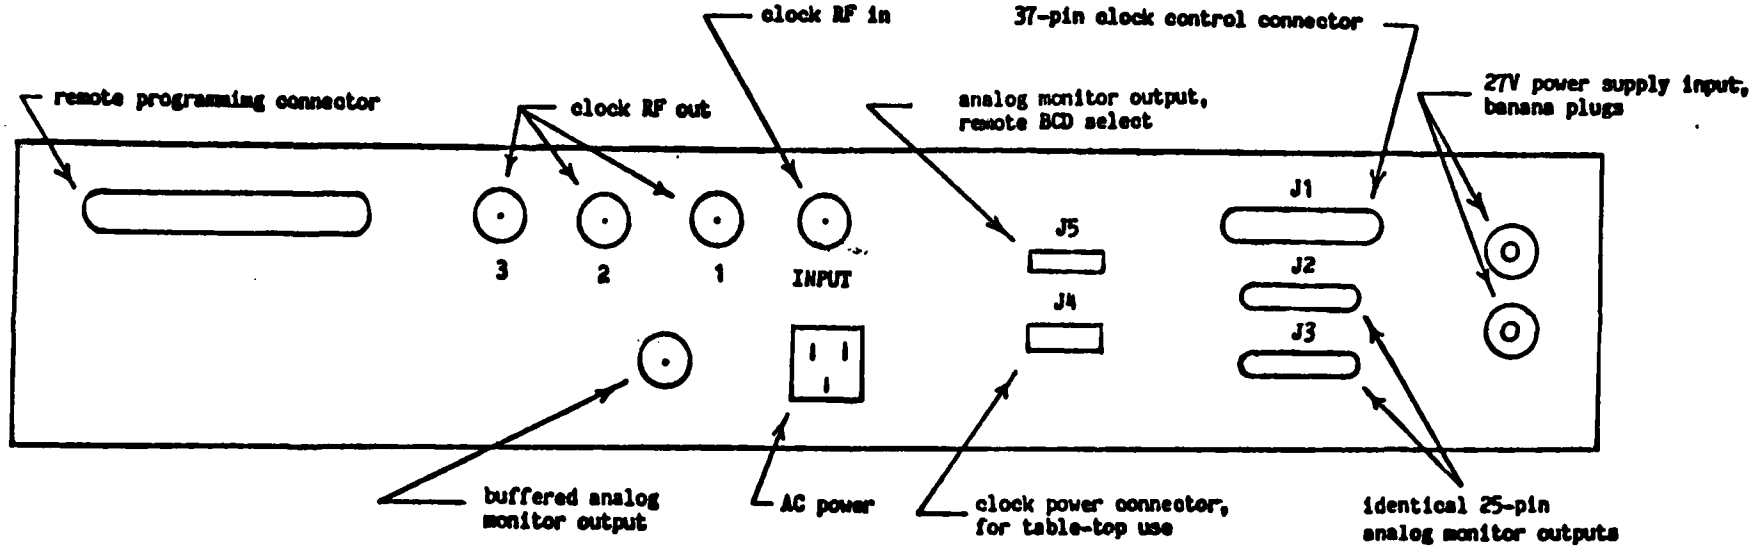
OUTSIDE THE CHAMBER: The 5 lines from above are brought through the bulkhead and connected to appropriate devices. The 1st cable is about 15' long, has a 37-pin Deutsch connector at one end and 10 3-conductor phone plugs at the other end. Attach the Deutsch connector to the 37-pin port which feeds through to the receptacle box. The phone plugs at the other end of the cable are numbered 0 through 9. Each of them mates with a phone jack on the back of the thermometer box. The 2nd cable is also about 15' long, has a 37-pin Deutsch connector at one end and a 37-pin amphenol male connector at the other end. Attach the Deutsch connector to the bulkhead feed-through port that mates with the clock cable on the inside. Attach the other end to the 37-pin connector on the back of the Cs control box. The 3rd cable, a segment of coax, runs

from the RF feed-through BNC on the chamber bulkhead, to the input BNC on the back of the Cs control box. The 4th and 5th lines have to be the same gauge as used inside. Run them from the appropriate BNC feed-throughs to the terminal strip pins on the back of the Kepco power supply labeled OUT and COM.

COUNTER CONNECTIONS and SWITCH SETTINGS: The counter compares the clock under test with the in-house reference oscillator. It does this by measuring the time interval between comparable points on the two waveforms. By analyzing how time interval changes as a function of time, frequency stability can be determined. First connect a coaxial cable from one of the three Cs control box BNC output ports to the BNC connector on the back of the counter labeled 'A'. Then run a cable from room 204 containing the 10.23 MHz reference into the BNC connector labeled 'B'. Set the gate select switch to NORM. All other connectors should be left blank, unless an external reference is used.

Cs CONTROL BOX CONNECTIONS: Not all of the connectors on the back of the Cs control box are used. See figure 2.1 for connector locations. To begin, turn on the 27V power supply and adjust the output to 27V. Turn it off, and connect the minus side to ground. Connect the power supply terminals to the Cs control box with 2 banana plug wires, (+) to red and (-) to black. Connect the 15' Cs clock cable to J1. Connect the special scanner cable, which has a 25-pin amphenol connector at one end and 25 lines terminated in amp lugs at the other end, to J2. See SCANNER CONNECTIONS for instructions in wiring that cable to the scanner. Connect J3 to the MASDAT system in room 204 using the special cables that have been run for that purpose. Leave J4 and J5 blank. Feed the RF output of the clock into the BNC labeled 'INPUT' with a coaxial cable that runs from the appropriate feed-through on the chamber bulkhead. The BNC's labeled '1', '2', and '3' are the output terminals of a power splitter. Send one up to channel A on the back of the counter, one to the MASDAT system in room 204, and one to the power sensor attached to the RF power meter. The buffered analog output and remote programming connectors are not used.

CHAMBER TEMPERATURE CONTROLLER CONNECTIONS: The temperature controller works by producing a floating voltage equivalent to the voltage a type J thermocouple would develop at the setpoint temperature. This voltage is compared in the Honeywell controller with a voltage generated by the base plate thermocouple. The difference is used to select heating or cooling mode. Connect a short length of cable terminated by two 50-pin male HP connectors from the back of the vacuum chamber temperature controller to the J1 connector on the back of the ASCII to Parallel converter. Attach a cable from the phone jack to terminals 13 and 14 on the back of the Honeywell controller. The center lead of the phone plug, corresponding to the tip, connects to terminal 14. The middle of the phone plug connects to terminal 13. The phone plug ground lead, the section in contact with the chasis, is not used.



cesium control box, back panel

Figure 2.1

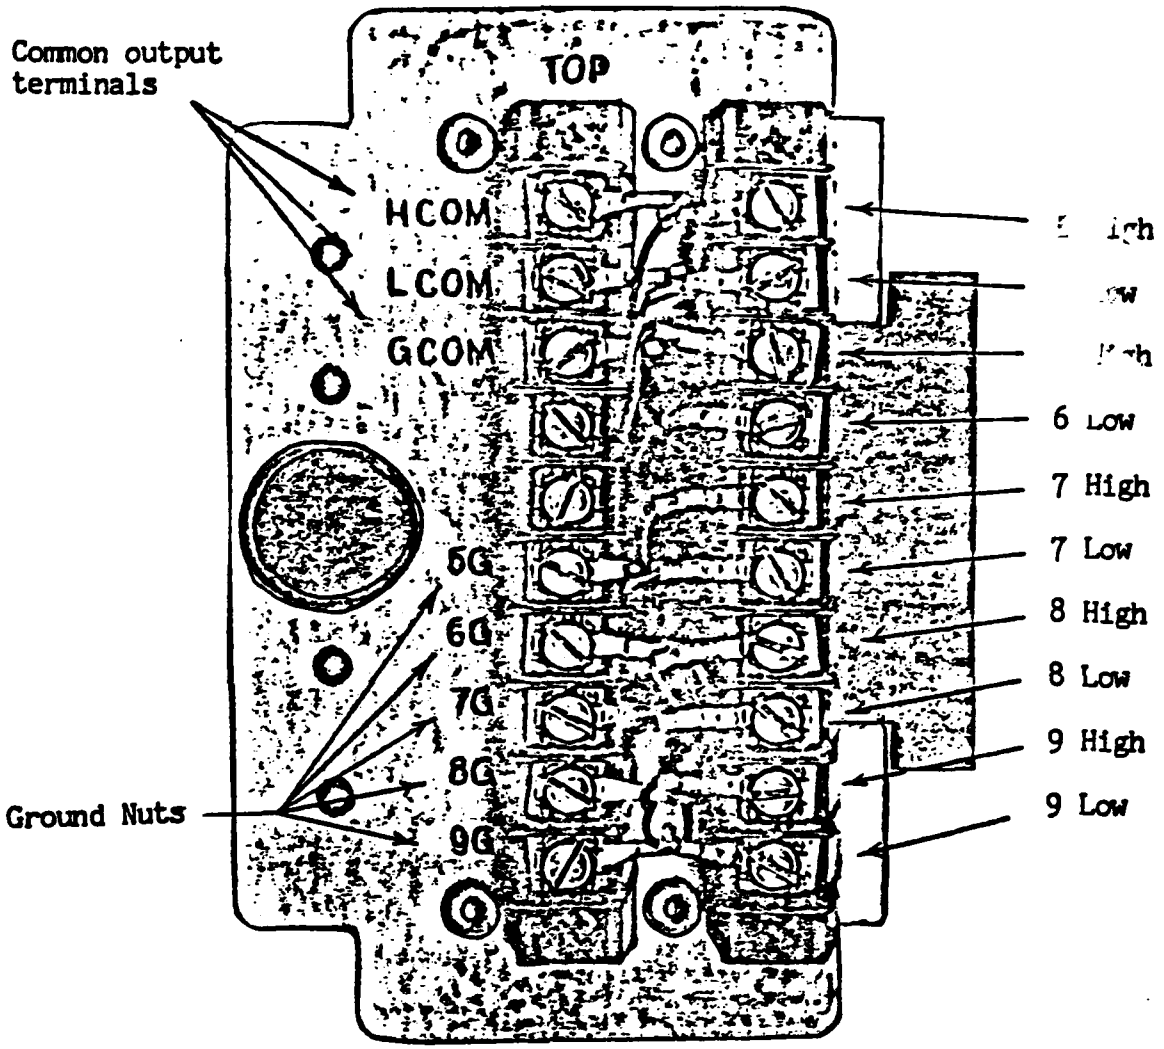
RF POWER METER CONNECTIONS AND SETTINGS: An HP 8481 Power Sensor probe must be connected to the power meter. If the power has a rear terminal sensor input for this probe, use it. Otherwise, connect the probe to the front panel. The end of the sensor should be attached to one of the three RF output ports on the Cs control box. Direct the recorder output on the back of the power meter to scanner channel #26. The HP bus and RF blanking connections are not used. Set the front panel controls to dBm mode and 100% cal function.

ANALOG THERMOMETER MATRIX CONNECTIONS: The analog thermometer matrix accepts a BCD digit from the ASCII to Parallel converter, relays the leads of one of ten input thermistors into a thermometer, and sends the output voltage into one of ten lines for recording by the voltmeter. Connect the plugs numbered 0 through 9 on the thermometer cable to the proper phone jacks on the back of the thermometer box. Next, connect the 9-pin amphenol connector on the thermometer to connector J2 on the ASCII to Parallel converter. A special cable has been made for this purpose. Finally, connect the 15-pin amphenol connector on the thermometer to the 4th scanner decade with another special cable made for this purpose. The end of this cable contains 11 wires terminated in amp lugs. Pin #1 on the thermometer connects to scanner channel #30, pin #2 to 31 ..., pin #10 to 39. Pin #11 connects to the common low on the scanner decade. The 4th scanner decade is dedicated to temperature measurements.

ASCII TO PARALLEL CONVERTER CONNECTIONS: The ASCII to Parallel box is dedicated to controlling both the vacuum chamber temperature and the analog thermometer matrix. The 1st 10 digits of any word sent to the ASCII box exit connector J1. The temperature controller uses 2 1/2 of these digits plus a sign bit. The two boxes are connected together by a 50-wire cable terminated in male HP connectors. The 2nd 10 digits sent to the ASCII box exit connector J2. The analog thermometer matrix uses 1 digit. The ASCII box and thermometer are connected together by a special cable that has a 50-pin male HP connector at one end, and a 9-pin female amphenol connector at the other end.

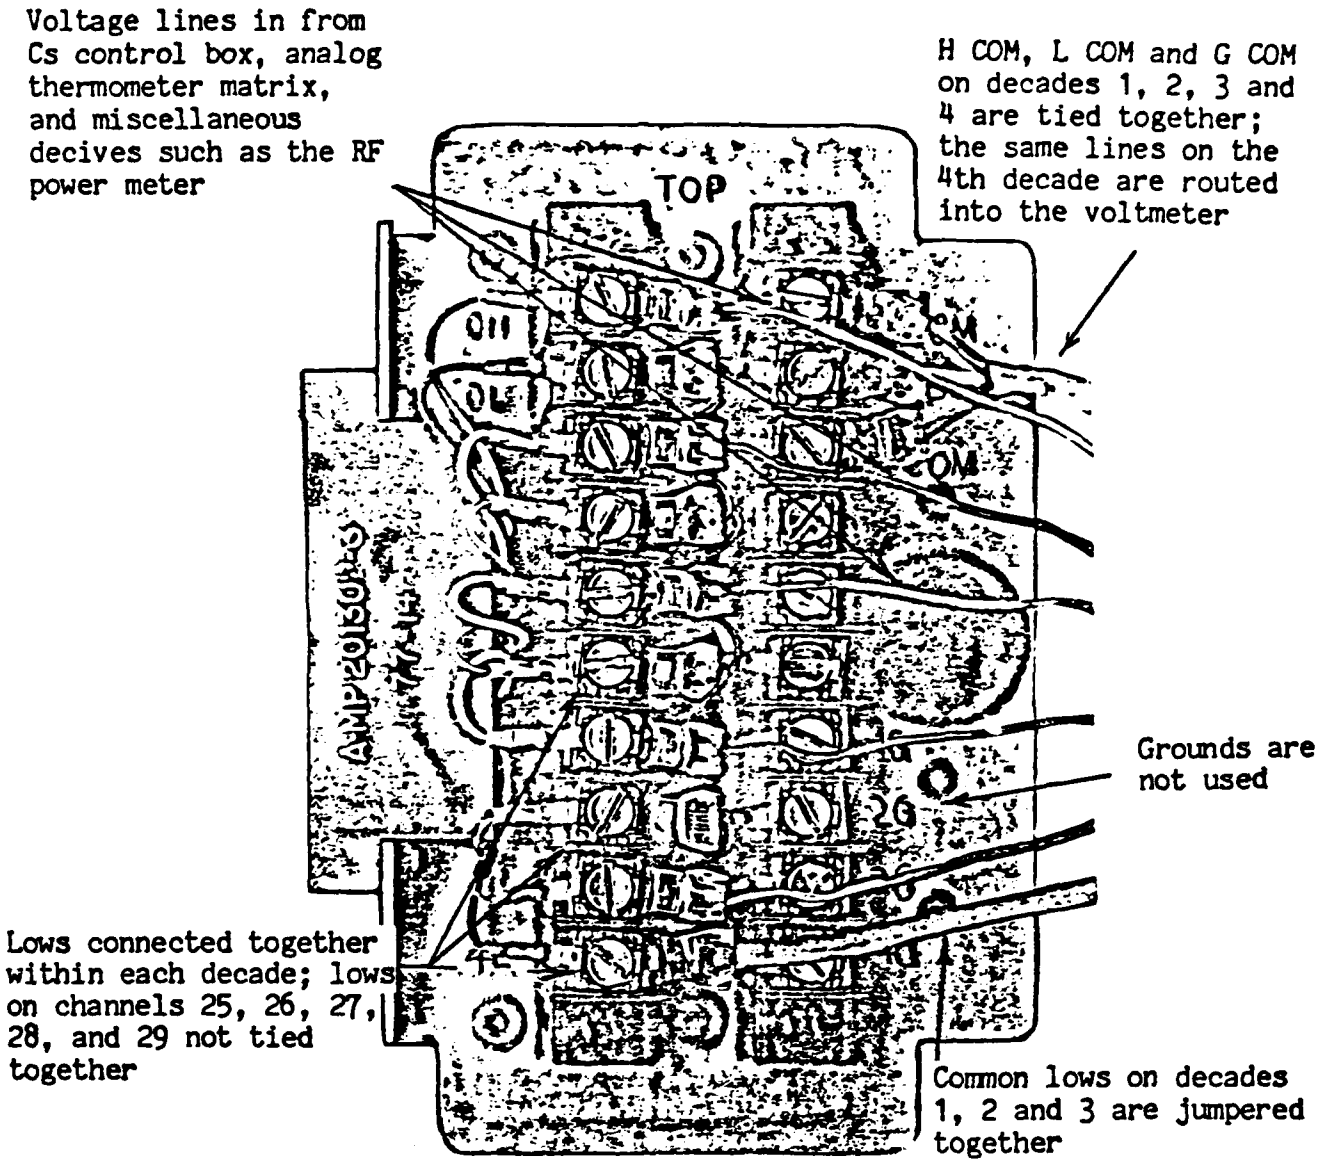
VOLTMETER CONNECTIONS and SWITCH SETTINGS: There are 5 banana plug connectors on the back of the voltmeter. The 2 on the left, under the 4 wire ohm label, are not used. HI connects to H COM on scanner decade #4. LOW connects to L COM, and GUARD connects to G COM. Special 3-wire cables with banana plugs at one end and amp lugs at the other end have been constructed for this purpose. Set the rear panel input select switch to REAR.

SCANNER CONNECTIONS: The scanner accepts 40 analog voltage signals on its four 10-terminal connector cards; and channels these signals into the digital voltmeter under calculator control. An example of an unwired scanner terminal card is shown in figure 2.2. Each scanner card has 10 High, 10 Low and 10 Ground connections. In addition each card has two Common High, Common Low



scanner card without connections

Figure 2.2



scanner card with connections

Figure 2.3

and Common Ground output connections. The terminals are numbered 0 through 9. The card which plugs into the scanner slot farthest to the right has a ten's digit of 0. The next one over is 1, the one after that 2, and the last card 3. Therefore, the scanner channels are numbered 0 through 39. When the calculator selects channel 12, for example, the 3rd set of relays on the 2nd decade is closed.

The 1st 25 relays, numbered 0-24, are reserved for the Cs clock monitors. A special cable has been constructed with a 25-pin female amphenol connector at one end, and 25 wires terminated in amp lugs at the other end. The amphenol connector plugs into connector J2 on the Cs control box. The 25 amp lugs are wired to the High side of the 1st 25 channels on the 1st 2 1/2 scanner cards. Pin #1 connects to channel 0, pin #2 to channel 1, ... pin #11 to channel 10, ... pin #25 to channel 24. The Low sides of the 1st 25 channels are all tied together. To establish continuity between the Low coming out of the Cs control box and the Low on the scanner cards, place a jumper between channel 12 High and channel 12 Low. Pin #13 coming out of the Cs control box is analog ground.

The last 10 relays, numbered 30-39, are reserved for temperature measurements. Channel 30 measures the temperature of the thermistor plugged into jack 0 of the thermometer receptacle box located inside the chamber. Channel 31 measures the temperature on thermistor #1, ... channel 39 measures the temperature on thermistor #9. A special 11-wire cable has been made for the purpose, with a 15-pin female amphenol connector at one end and amp lugs at the other end. Pin #1 connects to channel 30, pin #2 connects to channel 31, ... pin #10 to channel 39. All the Lows on the 4th decade should be jumpered together. Do not connect the Lows on channels 30-39 to the Lows on channels 0-24.

The remaining 5 channels, 25-29, are available for additional recordings. The following devices will generally be connected: temperature offset from pins 16 (low) and 17 (high) on the back of the Honeywell controller into channel 25; the RF power meter recorder output into channel 26; and the ionization gauge recorder output, if available, into channel 27.

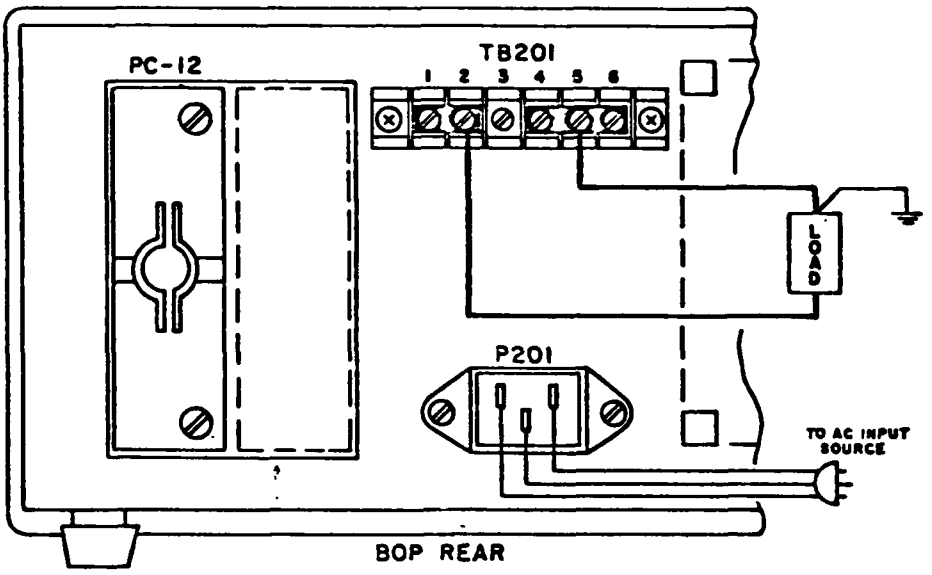
H COM, L COM and G COM on each of the 4 decades should be connected together as shown in figure 2.3. The same terminals on the 4th decade must be connected to the HI, LOW and GUARD inputs on the back of the voltmeter. A special 3-wire cable has been made for this purpose, with amp lug terminations at one end and banana plug terminations at the other end. The names and functions of each of the channels are assigned during a software initialization routine.

KEPCO POWER SUPPLY CONNECTIONS: The Kepco power supply is a bipolar 36V @ 12A, HP-IB programmable device. It is used to drive current through the thermoelectric device. In order to use the rear terminal strip, the front panel error sensing links must be removed. Short rear terminals 1 and 2 together; and 4, 5 and 6

together, as shown in figure 2.4. Connect the TED leads to terminals 2 and 5.

PLOTTER/PRINTER SETTINGS: Set the dip switch on the rear of the plotter/printer to: ERROR BEEP, 8 LPI, 8 BIT, METRIC and 9872.

CONNECTIONS TO ROOM 204: The clock RF output and analog voltages go out to the MASDAT system in room 204. A 10.23 MHz clock reference signal comes in. The RF output signal comes out of a BNC on the back of the Cs control box. The analog voltages come from connector J3 on the Cs control box. The 10.23 MHz clock reference signal is applied to channel 3 on the counter.



NOTE: FRONT SENSING LINKS MUST BE REMOVED. REAR SENSING LINKS MUST BE CONNECTED AS SHOWN.

bipolar operational power supply

Figure 2.4

3.0 Instrument Startup and Checkout

Before starting a test, the following steps should be taken to insure that each device is calibrated, receiving the appropriate signals, and operating properly.

MOUNTING THE CLOCK: Bolt the bottom of the clock to the upper plate of the TED. Bolt the lower plate of the TED to the base plate of the chamber. Connect the 9-pin male amphenol connector on the TED to its mating connector inside the chamber. Attach the RF output, power, and analog voltage monitor lines to the 3 ports on the front of the clock.

27V POWER SUPPLY: The AC power cord should be plugged into the duplex power outlet on the front panel of the chamber. If the foreline pressure is low enough, duplex power will come on when the push-button next to the outlet is pressed. If duplex power will not come on, plug the AC power cord temporarily into a wall outlet. Disconnect the banana plugs from the power supply and turn it on. Adjust the output to 27V. Turn the power supply off. Reconnect the banana plugs and return the AC power cord to the duplex power outlet. Set the red trip-point needle on the foreline pressure gauge to 100 millitorr.

Cs CONTROL BOX: Check for proper connections from the back of the Cs control box to the clock, counter, RF power meter, and MASCAT system. Turn the 27V power supply on. Refer to the manufacturer-supplied documentation for starting the clock. The procedure varies from manufacturer to manufacturer, and from model to model. Check the voltage monitors to see whether they are within manufacturer-specified limits. Before roughing the vacuum system, be sure to disconnect power from the clock.

COUNTER CHECKOUT: With the clock powered up, check the frequency on channel A by setting the appropriate counter keyboard switches to NORM and SEP, and pressing the key labeled 'FA'. If the display does not show the correct clock frequency, something is wrong. Check the signal coming over from the in-house reference standard in room 204 by temporarily switching that cable from channel B into channel A. Display the frequency by pressing FA. The two signals should have the same frequency. Return the clock signal to channel A and the reference signal to channel B.

REAL TIME CLOCK CHECKOUT: To load the correct time into the Real Time Clock enter:

```
wrt 9, "SMM,DD,HH,MM,SS"      <execute>
```

where MM,DD ... SS are the month, day, hour, minute and second. To read the clock enter:

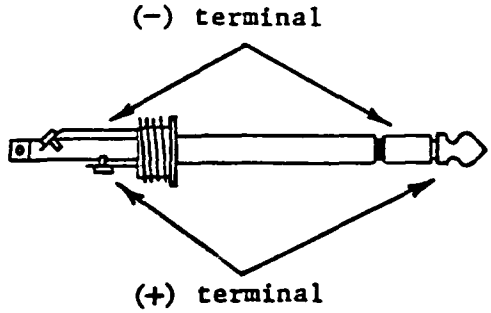
```
dim T$[14]                     <execute>
```

```
wrt 9, "R"                    <execute>
red 9, T$                     <execute>
dsp T$                        <execute>
```

If the calculator hangs up while reading the clock, check the connection of the clock to the I/O expander box. Wait a few minutes and try again. If the problem persists, replace the clock card with a new one.

CHAMBER TEMPERATURE CONTROLLER and HONEYWELL CONTROLLER, CALIBRATION and CHECKOUT: Before doing anything in this section, turn the chamber Thermal Control off (push-button on the front panel of the chamber). To calibrate the chamber temperature controller, remove the top cover and locate the trim pot. Disconnect the plone plug from the phone jack on the rear of the box, and put an empty phone plug, with plastic cover removed, back in its place. Connect a coaxial cable with aligator clip leads from the digital voltmeter to the two terminals of the phone plug as shown in figure 3.1. Set the voltmeter for front panel operation.

Figure 3.1:



phone plug

Turn the temperature controller on. The largest number the D/A converter in the controller can accept is 1111111111 binary, or 3FF hexadecimal. On the calculator enter:

```
wrt 707, "+000"               <execute>
```

This should produce an output of 0.000 mV. Next enter:

```
wrt 707, "+3FF"               <execute>
```

Adjust the trim pot until the output is 8.000 mV. As a quick check that everything is working, enter:

```
wrt 707, "-3FF"               <execute>
```

Now the output should be -8.000 mV. Reconnect the phone plug and replace the cover.

Loosen the case lock screw on the Honeywell controller and slide the box out far enough to reach the LOCAL/REMOTE switch. Place the Honeywell in LOCAL mode. With the chamber Thermal Control still off, turn the dial clockwise and counterclockwise, and watch the red alarm light come on and off. The red light comes on whenever the chamber temperature is outside a narrow setpoint temperature range. Adjust the HI and LOW alarm screws on the side of the Honeywell until the red light comes on at the +2 and -2 percent deviation points (one tic mark off center on the controller dial). Place the honeywell controller in remote. Push the case back in and tighten the case lock screw. On the calculator enter:

wrt 707, "+3FF" <execute>

The red temperature offset indicator needle on the Honeywell controller should peg to the left. Then enter:

wrt 707, "-3FF" <execute>

which should make the needle peg to the right. If this does not happen, check the connection from the temperature controller to the Honeywell controller. Before a test is run, turn the chamber Thermal Control on.

SCANNER and VOLTMETER CHECKOUT: Before starting this section, check the wiring and set the rear panel input selector switch on the voltmeter to REAR.

1) Cs CONTROL BOX signals - turn the clock on. On the calculator enter:

   wrt 709, "C00E" <execute>

   This command opens all scanner channels and closes channel 0. Verify that channel 0 displays a value appropriate for Supply V. Now enter:

   wrt 709, "C01E" <execute>

   to close channel 1. Verify that channel 1 displays a value appropriate for Supply I. Continue this procedure for all 10-12 channels in use. It may be helpful to obtain a printer listing of the INIT file as an aid to the identification of each of the channels.

2) HONEYWELL CONTROLLER signal - the deviation recorder output of the Honeywell controller is connected to channel 25. The output signal is a +/- 1V dc signal proportional to deviation from setpoint. Enter:

   wrt 709, "C25E" <execute>

   and check the output by turning the Honeywell dial to

deflect the error needle.

3) RF POWER METER signal - the recorder output on the power meter is connected to channel 26 of the scanner. The output signal is +1.000V dc full scale for the range selected. With the clock on, enter:

```
wrt 709, "C26E"                    <execute>
```

and verify that the output power is in the appropriate range.

4) IONIZATION GAUGE signal - if the ionization gauge on the vacuum chamber control panel has a recorder output, it should be connected to channel 27. Output is +2V full scale. Logarithmic changes in pressure produce linear changes in voltage. To test the output of the gauge, the chamber must be pumped down, and the ion tube turned on. Enter:

```
wrt 709, "C27E"                    <execute>
```

and check the output voltage.

5) ANALOG THERMOMETER MATRIX signals - Before proceeding with this section, turn the Thermal Control, on the chamber control panel, off. The analog thermometer expects to receive a non-complemented BCD character from 0 to 9. The ASCII to Parallel box is output-formatted to generate complementary hexadecimal. To write a 0 to the thermometer, an 'F' must be sent to the ASCII box in column 11. To write a 1, an 'E' must be sent, and so on. To write a 9, the character '6' must be sent. The transforming function is: hex(15 - the channel # desired). If a thermometer jack is left empty, and that channel is selected, an output voltage of -.51 mV will be displayed. Otherwise, the displayed voltage should equal the temperature at the thermistor divided by 100. To check thermistor 0, enter on the calculator:

```
wrt 707, "F0000000000"             <execute>
wrt 709, "C30E"                    <execute>
```

The first line selects thermistor 0, and the second line channels the output voltage of the thermometer into the voltmeter. To check thermistor 1, enter:

```
wrt 707, "E0000000000"             <execute>
wrt 709, "C31E"                    <execute>
```

and so on, decrementing the 1st character in the wrt 707 statement, and incrementing the 3rd digit in the wrt 709 statement, with each increment in channel number. To

check the last thermistor, enter:

```
wrt 707, "60000000000"        <execute>
wrt 709, "C395"               <execute>
```

With each channel selected, check the appropriateness of the number displayed on the voltmeter.

KEPCO BIPOLAR POWER SUPPLY and THERMOELECTRIC DEVICE CHECKOUT: Words written to the Kepco power supply are 6 characters long, formatted as follows: CMMMLL, where C is a mode command from 0 to 7, MMM is the output select, and LL is a limit. The system uses the Kepco in High Current mode which provides +/- 12 A full scale. The command for positive polarity is C=4, and for negative polarity, C=5. MMM ranges from 000 to 999. 000 corresponds to 0 Amps output, 999 corresponds to 12 Amps output. Each increment of 083 to MMM adds 1 A of output current. In current mode the device is voltage limited. The system prevents the current from going above 4 Amps. But as a safety precaution, the device is voltage limited to a value corresponding to about 5 Amps. LL ranges from 0, which corresponds to 0 V, to 99, which corresponds to 36 V. LL is always set to 60 (about 22 V).

Check the wiring to the TED and enter:

```
wrt 701, "416660"             <execute>
```

The output should indicate +2 Amps. With this polarity, the upper plate of the TED should heat. If, instead, it cools, turn the Kepco off and interchange the lead wires attached to the outside ports on the chamber bulkhead. Turn the Kepco back on and repeat the process. To cool the TED, enter:

```
wrt 701, "516660"             <execute>
```

Never send more than 4 Amps current to the TED (MMM=333).

4.0 Hardware Configuration

The Thermal Vacuum Test Facility is a calculator-controlled, automatic data collection system capable of controlling the thermal environment within a vacuum chamber. The calculator communicates directly with a peripheral I/O expander as shown in figure 4.1. The I/O expander controls 3 buses, each with a unique select code. The general purpose interface bus (GPIB), to which most of the instruments are connected, is assigned a select code of 7. The two disk drives are on a separate bus with a select code of 8. The real time clock occupies another bus slot, with a select code of 9. Instruments on the GPIB are assigned a unique device address from 0-31. The system operates according to a multiple interrupt scheme. Data collection has the highest priority. TED control has the next highest priority. On-line data reduction programs have the lowest priority.

Temperature is controlled, both at the level of the chamber base plate, and at the level of the TED. The chamber temperature controller programs the Honeywell controller to set the base plate temperature to whatever value is desired. Oscillations in base plate range from 3-10 degrees C, depending on the setpoint temperature chosen. The Kepco power supply fine-tunes the temperature to within 3 tenths of a degree C, eliminating the effect of base plate error. The TED can support a temperature gradient of 15 degrees C.

Figure 4.1

5.0 Software Configuration

There are two programs a user should be familiar with. The first is INIT, a program that edits initialization files containing temperature control, scanner control, and measurement interval data. INIT is stored on the system disk, loaded in drive 0. To run INIT, enter:

```
drive 0                    <execute>
get "INIT"                 <execute>
                           <run>
```

A flow diagram showing the questions prompted by INIT is shown in figure 5.1. INIT, like many programs in the system, requests a binary cassette tape labeled the 'Softcopy Graphics Library'. This tape contains programs for facilitating output to the graphics translator. Insert the tape into the cassette drive and press <cont>.

Two data files are maintained by the system. They are: INIT.D and INIT.V. The 1st is a default initialization file containing standard settings as shown in figure 5.2. INIT.D can be edited, if necessary, but it would be wise not to change it. The other file, INIT.V, is a variable initialization file for tests which require non-default conditions. INIT.V should be updated each time the requirements of a test change.

To edit one of the initialization files, enter 'I' to the prompt, 'Initialize, List, Gather, or End'. Flow is directed through 3 program segments as shown in figure 5.1: temperature control, scanner control, and measurement interval. Prompts should be answered with YES or NO unless otherwise stated. Entering 'Y', for example, to the prompt 'delete temperature setpoints' will enter the user into a subroutine that allows for selective deletion of temperature setpoints.

To list the contents of an initialization file, enter 'L' to the prompt, 'Initialize, List, Gather, or End'. The program will prompt for screen or printer. Enter 'S' for screen only if the graphics translator and display are on the system [rack #2].

Entering 'G' to 'Initialize, List, Gather, or End' will call the program GATHER into calculator memory, and start its execution. Entering 'E' will end INIT.

GATHER is the system's data collection program. It resides in calculator memory whenever a test is running. GATHER can be requested in INIT, or it can be run by entering:

```
drive 0                    <execute>
get "GATHER"               <execute>
```

INIT.D default initialization file

Figure 5.2

<run>

A flow diagram for GATHER is shown in figure 5.3. GATHER requests the Softcopy Graphics Library tape, asks for the initialization file to use. When the calculator prompts for a test start date, entering <cont> will cause the current date and time to be loaded. An end date must be specified.

The POWER FAIL TAPE is a special cassette tape that remains in the cassette drive whenever a test is running. The tape contains two files. The 1st is a program file containing the program REBOOT. The second is a short data file. Whenever power is turned on, the calculator attempts to load and run a program from file 0 of the cassette tape. When REBOOT is loaded after a power failure, it resets all of the devices in the system, restarts the interrupt cycles, and loads in the memory file MEMORY. MEMORY contains an exact image of calculator memory at the time it was saved. The memory file is resaved each time data is collected. To create a POWER FAIL TAPE, load a blank cassette tape into the cassette drive and enter:

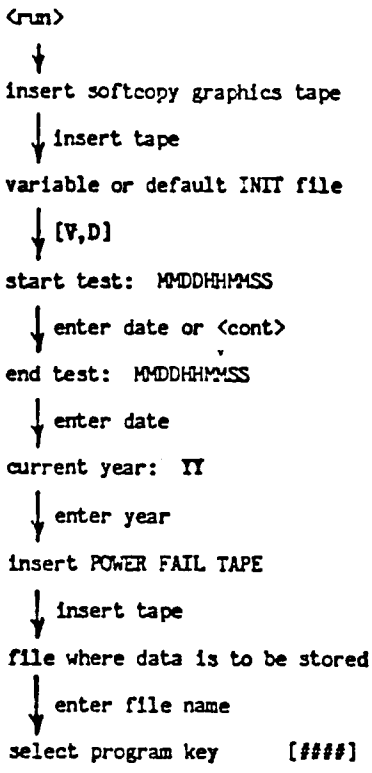
```
ert 0                          <execute>
rew                            <execute>
mrk 1, 2000                    <execute>
mrk 1, 100                     <execute>
drive 0                        <execute>
get "REBOOT"                   <execute>
rcf 0                          <execute>
```

Be sure to label the tape, 'POWER FAIL'.

After loading the POWER FAIL TAPE, the calculator requests a data file name. File names are 6 characters or less. A very common error is to attempt opening a file for which there is not enough disk space. If this operation produces 'error 08' (insufficient storage space on disk), correct it by killing unnecessary data files, going to a new data disk, or shortening the time interval of the test so that not as much data is collected. Once GATHER is successfully running it displays, 'select special function key [####]' where #### is the number of measurement cycles remaining.

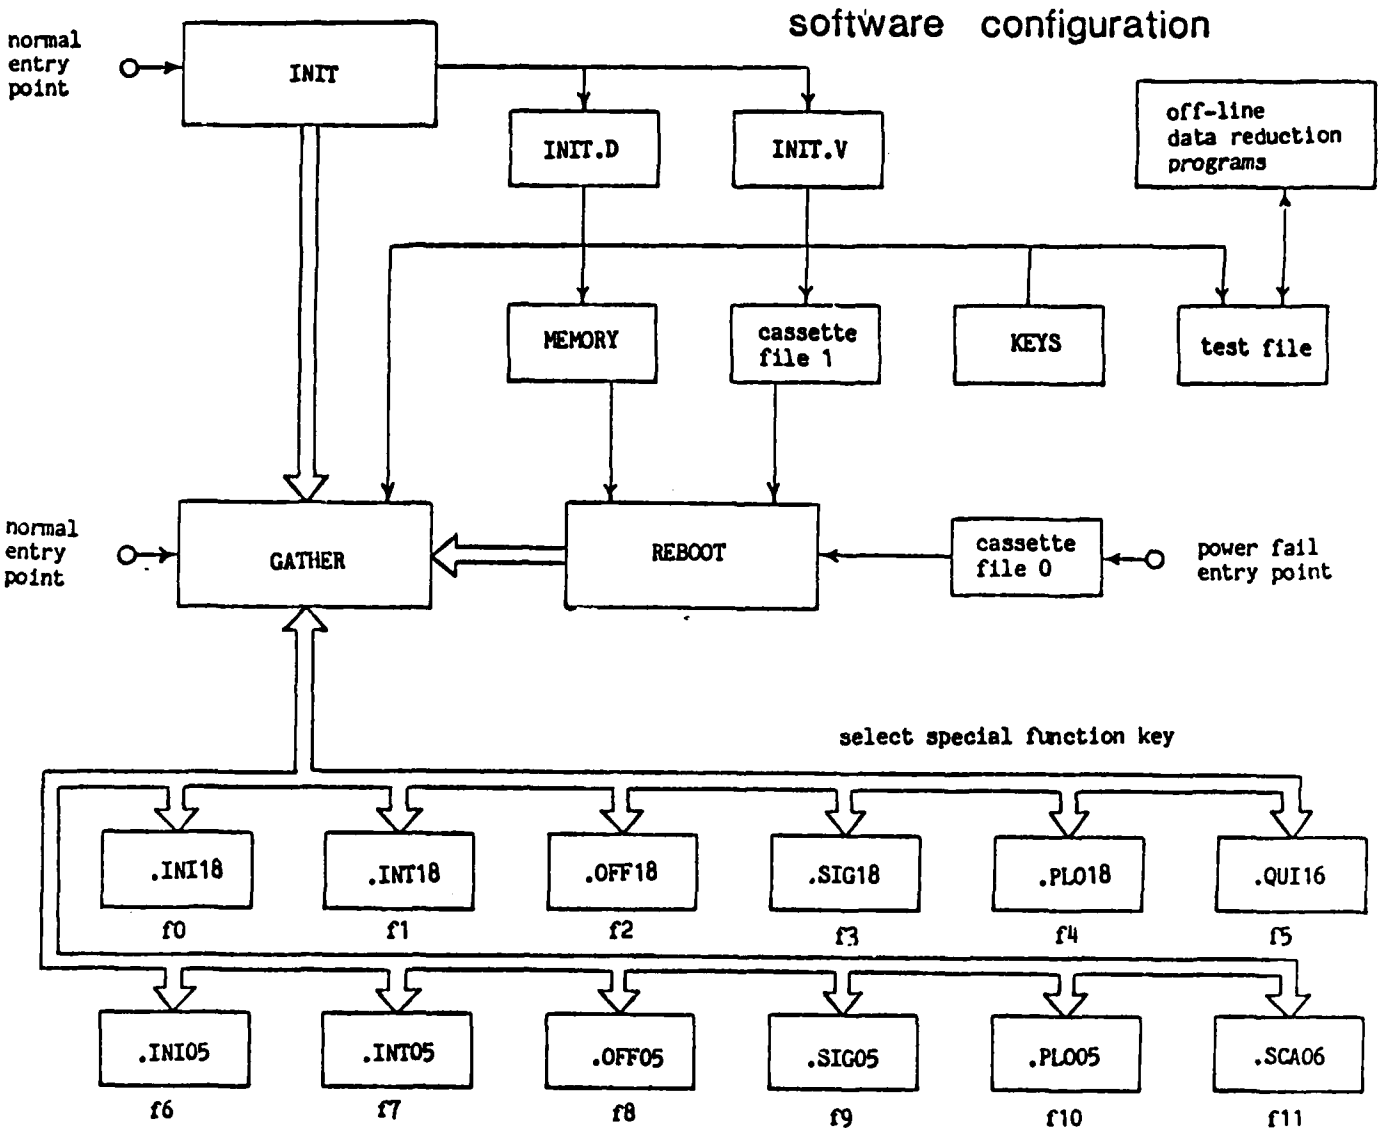
Figure 5.4 shows how the system programs interact. The small boxes denote data files and subroutines. Information flow is indicated by the arrows. An arrow to a file, such as INIT.V, indicates that a program writes to that file. An arrow away from a file, such as KEYS, indicates that the file is read from. There are three ways of entering the system: 1) through INIT, 2) through GATHER, and 3) through a power fail.

GATHER controls twelve subroutines. Subroutines are swapped in and out of calculator memory at user request. The subroutines perform data handling routines while data is still being collected.



GATHER flow diagram

Figure 5.3



Thermal Vacuum Test Facility

Figure 5.4

By convention, the names of the subroutines on the disk all begin with a decimal point. They do not run in stand-alone mode because they lack variable and device declaration statements. They operate only when GATHER is running. To execute a subroutine during a test, press the special function key associated with that function. Some subroutines require additional user information. This is also entered by pressing special function keys. See the section on "Obtaining data during a test" for more information regarding subroutines.

GATHER operates two programmed interrupts. The 1st is a variable duration interrupt which controls the interval between measurement cycles. The 2nd interrupt is fixed at 5 seconds, and controls the TED. It has a lower priority than the 1st. It is possible to observe the effect of the interrupts by observing the digital voltmeter display.

All the remaining programs in the system operate independently of GATHER. They may be loaded into the calculator when a test is through. Section 9 contains program descriptions and sample outputs.

All programs that output data to the plotter/printer or graphics display terminal have names that are formatted in the following manner: .NNNDD, where the decimal point is present only if the file is a subroutine, NNN is is a 3-character mneumonic, and DD is the device address of the output terminal.

6.0 Running a Test

To run a clock test, follow the sequence of steps listed below:

1) Verify that all the appropriate devices are in the system, powered on, and working correctly (refer to sections 1 and 3).
2) Verify that the proper device addresses and select codes have been set (section 1).
3) Verify that the devices are properly interconnected (section 2).
4) Vent the vacuum chamber and open the front door.
5) Bolt the clock to the TED.
6) Bolt the TED to the chamber base plate.
7) Connect the power, analog monitor, and RF leads to the clock.
8) Connect power lines to the TED.
9) Connect the cable to the thermistor probe receptacle box.
10) Plug a thermistor into jack 0 and mount it to the TED. This thermistor MUST be in place.
11) Plug a thermistor into jack 1 and mount it to the chamber base plate. This thermistor MUST be in place as well.
12) Plug additional thermistors into the remaining jacks as necessary, being sure to record where they are placed so that the INIT file can be edited properly.
13) Close the chamber door and start the vacuum system.
14) When the pressure is below 100 millitorr, turn duplex power on.
15) Start the clock and verify that it is working. Check the counter frequency reading and the analog monitors (section 3).
16) Check the reference signal coming in from room 204.
17) Place a system disk in drive 0.
18) Place a data storage disk in drive 1.
19) Locate a Softcopy Graphics Tape and POWER FAIL TAPE.
20) Setup the initialization file by running INIT (section 5).
21) Run GATHER.

7.0 Obtaining Data During a Test

Before producing lists or plots on the plotter/printer, see if the print head is at the top of the page, and check the page boundaries. Replace the paper if the margin is colored red. Check the calculator printer from time to time, and replace the paper if it is low. A calculator printer error (eg, printer out of paper) will halt program execution.

Table II shows the subroutines called in when the twelve special function keys are pressed. Additional subroutines can be requested before the last one has finished running. Three subroutines require user input: .PL005, .PL013, and .SCA06. Instructions for these are printed on the calculator printer during execution. They require the selection of additional special function keys.

Table II: Subroutines

special function key	subroutine name	output device	description
f0	.INI18	718	Lists the contents of the INIT file on the display terminal.
f1	.INT18	718	Plots time interval average measurements as a function of time on the display terminal.
f2	.OFF18	718	Plots fractional frequency offset as a function of time on the display terminal.
f3	.SIG18	718	Plots Allan Variance as a function of averaging time on the display terminal. The values of the plotted points are printed on the calculator printer.
f4	.PLO18	718	Plots scanner channel data as a function of time on the display terminal. This subroutine requires selection of a channel number. A channel number and name are displayed on the calculator. Special function key f0 increments the count, f1 decrements the count, and f2 plots the displayed channel.
f5	.CUI16	16	Produces a calculator printer listing of key status variables.
f6	.INI05	705	Lists the contents of the INIT file on the plotter/printer.
f7	.INT05	705	Plots time interval average measurements as a function of time on the plotter/printer.
f8	.OFF05	705	Plots fractional frequency offset as a function of time on the plotter/printer.
f9	.SIG05	705	Plots Allan Variance as a function of averaging time on the plotter/printer. The values of the plotted points are printed on the calculator printer.
f10	.PLO05	705	Plots scanner channel data as a function of time on the plotter/printer. This subroutine requires selection of a channel number. A channel number and name are displayed on the calculator. Special function key f0 increments the count, f1 decrements the count, and f2 plots the displayed channel.
f11	.SCA06	706	Produces a plotter/printer listing of data collected through the scanner. This subroutine requires an additional entry. Press special function key f0 to list all the data, and f1 to list data collected since midnight.

If the calculator error halts for any reason while a subroutine is executing, turn the calculator off and back on, or enter:

ldp <execute>

This will load in the REBOOT program, and program execution will pick up where it left off.

If an error halts the program, and the program is simply restarted in the wait loop, the interrupts will no longer be functional and GATHER will not collect data.

8.0 Obtaining Data Once a Test is Through

This section describes the various forms of hard copy that can be obtained using system programs. Each block contains the program file name, the required inputs, a description of the program, and the name of the display terminal version, if one exists.

program: INIT
input: default or variable file, list, printer

07-29-83	Gen Purpose Plot	User Entry	5	N.A.	N.A.	Kevin M. Miller

9.0 Program Library

Figure 9.1 shows a catalog listing of the programs on the system disk. The file name is followed by a character which indicates the file type. P = program, D = data, M = memory, and K = keys. The next three columns contain data which indicate the number of records, the beginning track number, and the beginning record number.

Figure 9.1

Beginning on the next page is a short description of the files not documented elsewhere in this paper. Following that is a line printer listing of each of the programs contained on the disk.

File Descriptions

MAGPRG - is a program that copies programs onto magnetic tape. The program requires an Ideas 4600 series tape controller on bus 7 set to device address 16. The tapes produced are PIP-readable ANSI standard format. The program loads files in at line 100 to prevent skewing of the margins, so the blank lines on the program listing are necessary. To remove the line numbers in an editor, delete the first three columns.

KEYS - is a key file that contains *sfg statements. This file is called by GATHER to enable the keyboard execution of subroutines. The asterix on a special function command is the same as <execute>.

MAGDAT - is a program that copies test file data onto magnetic tape. The program requires an Ideas 4600 series tape controller on bus 7 set to device address 16. The tapes produced are PIP-readable ANSI standard format.

SCREEN - is a keys file that loads special function keys for listing programs and catalogs on the display screen. The Softcopy graphics Library binary program must also be loaded. The keys have the following functions:

f0 sets the program line counter to 0
f1 displays the next 35 lines of program
f2 clears the screen
f3 displays a catalog of drive 0
f4 displays a catalog of drive 1

PATCH - takes files that have been prematurely closed because of an interrupted test, and patches them up so they can be read by data handling routines. This is a program worth knowing about.

The pages that follow contain a line printer listing of each of the system programs.

10.0 Operating the Vacuum Chamber

Follow the steps below to evacuate the chamber manually:

1) press the POWER ON button
2) if the alarm goes off, press ALARM RESET
3) set the operation mode to MANUAL
4) close all valves
5) start the ROUGH and BACKER pumps
6) check the chamber doors for obvious leaks
7) open the ROUGH and FORELINE valves
8) when foreline pressure drops below 100 millitorr, turn the DIFFUSION PUMP on
9) set the red trip-point needle on the foreline pressure gauge to 100 millitorr
10) turn duplex power on
11) when chamber pressure drops below 50 millitorr, close the ROUGH valve
12) open the HIGH VAC valve
13) pressure should drop on the chamber pressure gauge
14) when it is no longer readable, turn the IONIZATION GAUGE on
15) turn the filament on whenever a pressure reading is desired, but do leave it on long as the filament has a short half life
16) set the THERMOCOUPLE select switch to the chamber base plate
17) turn THERMAL CONTROL on to control temperature inside the chamber

To turn the vacuum chamber off:

1) turn the IONIZATION GAUGE off
2) turn THERMAL CONTROL off
3) wait 1 minute for compressor fan to cut off if refrigeration was on
4) close all valves
5) turn the DIFFUSION PUMP off
6) if the chamber temperature is above 0 degrees C, the VENT VALVE can be opened
7) press the POWER OFF button

END
