Honorable Ella T. Grasso
Governor of the State of Connecticut
State Capitol
Hartford, Connecticut 06115

Dear Governor Grasso:

Inclosed is a copy of the Hartford Reservoir No. 1 Dam Phase I Inspection Report, which was prepared under the National Program for Inspection of Non-Federal Dams. This report is presented for your use and is based upon a visual inspection, a review of the past performance and a brief hydrological study of the dam. A brief assessment is included at the beginning of the report. I have approved the report and support the findings and recommendations described in Section 7 and ask that you keep me informed of the actions taken to implement them. This follow-up action is a vitally important part of this program.

A copy of this report has been forwarded to the Department of Environmental Protection, the cooperating agency for the State of Connecticut. In addition, a copy of the report has also been furnished the owner, Metropolitan District, Hartford, Connecticut 06101.

Copies of this report will be made available to the public, upon request, by this office under the Freedom of Information Act. In the case of this report the release date will be thirty days from the date of this letter.

I wish to take this opportunity to thank you and the Department of Environmental Protection for your cooperation in carrying out this program.

Sincerely,

Incl
As stated

Max B. Scheider

NATIONAL DAM INSPECTION PROGRAM

PHASE I INSPECTION REPORT

Identification No.: CT00001
Name of Dam: Hartford Reservoir No. 1
Town: West Hartford
County and State: Hartford County, Connecticut
Stream: Spice Brook
Date of Inspection: November 13, 1979

BRIEF ASSESSMENT

Hartford Reservoir No. 1 Dam is a 113-year old earth embankment, approximately 500 feet long with a maximum height of 42 feet, which currently impounds water for use at a downstream power generation facility.

It is estimated that enough surplus water from the impoundment is available to operate the power facilities between 40 and 60 percent of the year. Power produced at the facility is used at a nearby water filtration plant.

From 1867 to 1922 the reservoir functioned as part of the Hartford water supply system. In case of emergency, the reservoir could still be used to supplement the water supply system.

The watershed area for Hartford Reservoir No. 1 Dam encompasses approximately 3.9 square miles of mostly forested, mountainous land. With the water level at the primary spillway crest, Reservoir No. 1 covers approximately 27 acres and provides a storage capacity of 284 acre-feet. The maximum storage capacity of the reservoir is 619 acre-feet. Hartford Reservoirs 2, 3 and 5 are also located within the watershed and, in conjunction with Reservoir No. 1, account for 6 percent of the surface area.

Due to the 42-foot height of the dam, Hartford Reservoir No. 1 is classified in the "Intermediate" size category. The initial potential damage area in the event of a dam breach is the power generation facility located 100 feet downstream of the dam. The first residential hazard area is located about 2,000 feet downstream of the dam. A failure of the dam would result in excessive property damage at both of these locations and the possible loss of more than a few lives in the residential hazard area. Therefore, the dam is classified in the "High" hazard potential category. The recommended test flood for an "Intermediate" size, "High" hazard dam is the full Probable Maximum Flood (PMF).

The test flood peak inflow to Hartford Reservoir No. 1 was computed to be 5,590 cfs. The routed test flood outflow of 5,440 cfs would be contained below the top of the dam by 0.5 feet. The spillway system is capable of discharging 100 percent of the routed test flood outflow.

On the date of the inspection, Hartford Reservoir No. 1 Dam appeared to be in fair condition. However, several deficiencies were observed during the inspection. A permanently saturated condition exists at the downstream toe which has been partially corrected with the installation of a portion of the toe drain system. A depression of the downstream face of the embankment extends from the crest to the toe of the dam in the vicinity of the outlet works. An undulated area at the downstream toe of the slope was also observed. Animal burrow holes were observed in the downstream face, and trees are growing in the vicinity of the downstream toe and in the abutment regions. Some riprap has been displaced from the upstream face of the dam.

Within one year after receipt of this Phase I Inspection Report, the Owner should retain the services of a qualified registered professional Engineer to direct the removal of the trees in the vicinity of the abutments and at the toe of the downstream face of the dam. Voids left in the embankment by the removal of the trees should be filled with suitable, thoroughly compacted material.

The Owner should implement the following operation and maintenance measures: (1) Complete all work on the toe drain system; (2) the disturbed area at the downstream toe of the dam and the depression in the downstream face should be regraded and reseeded and monitored for future movement; (3) The stone riprap on the upstream face of the dam should be replaced where necessary; (4) Animal burrows on the downstream face of the dam should be backfilled; (5) A formal flood warning plan should be developed; and (6) a program of annual periodic technical inspection should be instituted.

O'BRIEN & GERE ENGINEERS, INC.

Date: *28 APRIL 1980*

This Phase I Inspection Report on Hartford Reservoir No. 1 Dam has been reviewed by the undersigned Review Board members. In our opinion, the reported findings, conclusions, and recommendations are consistent with the Recommended Guidelines for Safety Inspection of Dams, and with good engineering judgment and practice, and is hereby submitted for approval.

PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation: however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam *will continue* to represent the condition of the dam at some point in the future. Only through continued care and inspection can there be any chance that unsafe conditions be detected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

The Phase I Investigation does not include an assessment of the need for fences, gates, no-trespassing signs, repairs to existing fences and railings and other items which may be needed to minimize trespass and provide greater security for the facility and safety to the public. An evaluation of the project for compliance with OSHA rules and regulations is also excluded.

NATIONAL DAM INSPECTION PROGRAM
PHASE I INSPECTION REPORT
HARTFORD RESERVOIR NO. 1 DAM

SECTION 1

PROJECT INFORMATION

1.1 General

a. Authority. The National Dam Inspection Act (Public Law 92-367) was passed by Congress on August 8, 1972. Under this Act, the Secretary of the Army was authorized to initiate, through the Corps of Engineers, the National Program for Inspection of Dams throughout the United States. Responsibility for supervising inspection of dams in the New England Region has been assigned to the New England Division of the Corps of Engineers.

O'Brien & Gere Engineers, Inc. has been retained by the New England Division to inspect and report on selected non-federal dams in the State of Connecticut. Authorization and Notice to Proceed were issued to O'Brien & Gere by a letter dated November 6, 1979 and signed by Col. William E. Hodgson, Jr. Contract No. DACW 33-80-C-0014 has been assigned by the Corps of Engineers for this work.

b. Purpose. The purpose of inspecting and evaluating non-federal dams is to:

1. Identify conditions which threaten public safety and make the Owner aware of any deficiencies so that he may correct them in a timely manner.

2. Encourage and prepare the State to initiate an effective dam safety program for non-federal dams as soon as possible.

3. Update, verify and complete the National Inventory of Dams.

1.2 Description of Project (Information with regard to this dam was obtained from the Hartford, Connecticut, Metropolitan District).

a. Location. Hartford Reservoir No. 1 Dam is located on Spice Brook in the Town of West Hartford, Connecticut. Spice Brook flows into Trout Brook an estimated 4,000 feet downstream of the dam. Trout Brook discharges into the South Branch of Park River about 8 miles downstream of the dam. To illustrate the location of the structure, portions of the USGS quadrangle maps entitled "Avon, Conn." and "New Britain, Conn." have been incorporated and included as Figure 1 on page vi of this report, USGS reference coordinates for this dam are N41°45.1' and W72°46.5'.

The initial damage center is the Metropolitan District power generating facilities 100 feet downstream from the dam. The initial residential flood impact area is an estimated 2,000 feet downstream from the dam. Many residential flood impact areas are located in the ensuing miles along Trout Brook.

b. Description of Dam and Appurtenances. The dam is located on the north-eastern side of Hartford Reservoir No. 1. It is an earth embankment approximately 500 feet long with a maximum height of 42 feet. The dam has the following major features:

1. The upstream grass-covered face of the dam is on a slope of approximately 3H:1V. The lower portion of the upstream face of the dam, extending from an elevation of about 3 feet above pool elevation to an undetermined depth beneath the water surface, is protected with small riprap stones.

2. The dam crest is approximately 25 feet wide. A 14-foot wide paved road is located along the crest of the dam with a row of shrubbery on each side of the roadway.

3. The downstream face of the dam is on a slope of approximately 2H:1V and is grass-covered.

A section drawing and several photos of the features described above have been included in Appendix B and Appendix C, respectively.

The primary spillway is located at the northwestern end of the reservoir. The inlet consists of a 45-foot wide concrete weir and the outlet consists of a stone-lined channel about 20 feet wide and 1,700 feet long which outlets into Spice Brook an estimated 800 feet downstream of the dam.

A 108-foot wide auxiliary (emergency) spillway is located just to the left of the left abutment of the dam. This spillway is grass-covered and partially formed by a gabion wall along its right side. The elevation of the auxiliary spillway is an estimated 5.4 feet above the primary spillway elevation. Further information relative to the spillways is given in Appendices B, C and D.

The outlet works provide a means of conveying water to the downstream power generation facilities in addition to providing a means of draining the reservoir. The inlet facilities for the outlet works are located in the intake structure near the right abutment of the dam (constructed in 1978) and in the intake tower in the impoundment near the center of the dam. The outlet facilities are located in a gatehouse immediately downstream. Further downstream, a gate chamber houses valves which direct the flow towards the power generating facilities or towards Spice Brook.

c. Size Classification. Hartford Reservoir No. 1 Dam has a maximum height of 42 feet which places it in the "Intermediate" size category for height because it is greater than 40 feet but not greater than 100 feet high. It falls into the "Small" size category for storage because its maximum storage capacity of 619 acre-feet is less than the 1,000 acre-foot upper limit for "Small" size structures. Since the dam is considered "Intermediate" in size for height, it must be classified in the "Intermediate" size category for this report.

d. Hazard Classification. Several areas downstream of the dam could be identified as potential flood impact zones. The initial damage center is the Metropolitan District power generating facilities 100 feet downstream of the dam. These facilities would probably be destroyed by floodwaters resulting from a dam failure. The first residential area is located approximately 2,000 feet downstream of the dam near the point where Spice Brook flows under Old Mill Lane. The sill elevation of the lowest houses at this location was estimated to be 2 feet above the channel banks of the stream. The failure analysis indicated that a breach of Hartford Reservoir No. 1 Dam with the reservoir surface at the test flood elevation (0.5 feet below the top of the dam) would result in a flow depth of 5.7 feet above the channel banks, or 3.7 feet above the sill elevation of the lowest houses, at this initial residential damage area. A flood of this magnitude would cause excessive property damage and possible loss of life in this location. The failure analysis also indicated that a breach of the dam with the reservoir surface at the spillway crest would result in a flow depth of 2.8 feet above the low sill elevation, which would also cause excessive property damage and the possible loss of more than a few lives. Several other residential areas are located further downstream and could also be subjected to damage. The depth of flow immediately prior to failure was computed to be 1.7 feet above the low sill elevation with the reservoir at the top of the dam and estimated at 3.5 feet below the low sill elevation with the reservoir surface at the spillway crest. Therefore, a significant increase in hazard to loss of life downstream would result from a failure of the dam. Due to the conditions described above, Hartford Reservoir No. 1 is classified in the "High" hazard category.

e. Ownership. The dam is owned by the Metropolitan District, 555 Main Street, Hartford, Connecticut, 06101; Telephone: 203-278-7850.

f. Operator. Mr. Richard Allen, Purification Engineer for the Hartford Metropolitan District, is responsible for operation of the West Hartford reservoir system. His address is Metropolitan District, 555 Main Street, P.O. Box 800, Hartford, Connecticut, 06101; Telephone: 203-278-7850, ext. 332.

g. Purpose of Dam. The dam was originally constructed for Hartford water supply purposes. Since 1922, however, water from Reservoir No. 1 Dam has been primarily used to drive turbines for the production of hydroelectric power. In case of emergency, the reservoir could be used to supplement the water supply reservoirs.

h. Design and Construction History. The dam was originally constructed between 1864 and 1867 and was subsequently rebuilt in 1868. Modifications to the project, since that time, include the power generating facilities including the 30-inch diameter transfer pipe which was constructed in 1922, the raising of the primary spillway crest one foot and the construction of the auxiliary spillway in 1967 and the partial installation of the toe drain system and the reconstruction of the intake structure on the 30-inch transfer pipe which carries water to the power generation facilities, in 1978 and 1979. According to Mr. Allen, details of the original design and construction are not available.

i. Normal Operating Procedures. According to Mr. Allen, discharge from Reservoir No. 1 is normally directed to the power generation facility located about 100 feet downstream of the dam. Depending upon precipitation, flows for this purpose are generally available for 40 to 60 percent of the year. The primary spillway, whose crest was 1.5 feet above the reservoir surface at the time of inspection, is used only when all available upstream storage has been exhausted.

In anticipation of excessive runoff, personnel from the Metropolitan District will open valves on the low level discharge pipes to help lower the reservoir surface. However, Mr. Allen feels that such operations do not accomplish a great deal other than to exercise the valves.

1.3 Pertinent Data

a. Drainage Area. The area draining to Hartford Reservoir No. 1 encompasses 3.9 square miles of primarily forested, mountainous land. Included in this area are Hartford Reservoir Nos. 1, 2, 3 and 5 which account for about 6 percent of the drainage area. Elevations range from 800 along the Talcott Mountain Range to 256.5 at the normal reservoir surface of Hartford Reservoir No. 1.

b. Discharge at Damsite.

1. Outlet Works. Water may be drawn from the reservoir at two locations. One outlet is a set of two 24-inch diameter gate controlled pipes which originate in the intake tower and convey water to the gate house. Valves in the gate house may be opened to allow for the discharge to continue via twin 20-inch diameter pipes to a gate chamber located next to the power generation building. In the gate chamber discharge can be turned off, directed to the power generation facility, or diverted to Spice Brook. The estimated discharge capacity of the twin outlet pipes with the reservoir surface at the top of the dam is 190 cfs.

The second outlet consists of a 30-inch diameter cast iron pipe which extends from a new intake structure located at the right abutment of the dam to the gate chamber located next to the power generation building. The estimated discharge capacity of this pipe with the reservoir surface at the top of the dam is 100 cfs.

2. Maximum Known Flood. The flood of record at Hartford, Connecticut occurred over a three-day period in August, 1955 when the primary spillway was overtopped by 3 feet. Since that time the spillway crest has been raised one foot.

3. Ungated Spillway Capacity at Top of Dam. The ungated spillway capacity at the top of dam Elevation 265.3, is 6,130 cfs.

4. Ungated Spillway Capacity at Test Flood Elevation. At test flood Elevation 264.8, the ungated spillway capacity is 5,440 cfs.

5. Gated Spillway Capacity at Normal Pool Elevation. Not Applicable.

6. Gated Spillway Capacity at Test Flood Elevation. Not Applicable.
7. Total Spillway Capacity at Test Flood Elevation. See 4 above.
8. Total Project Discharge at Top of Dam. The total project discharge at top of dam Elevation 265.3, including the outlet works, is 6,320 cfs.
9. Total Project Discharge at Test Flood Elevation. The total project discharge at test flood Elevation 264.8, including outlet works, is 5,630 cfs.

| Invert Elevation | 250 + |
| Size | 30-inch diameter |
| Description | Cast Iron Pipe |
| Control Mechanism | Gate Valve in the gate chamber |

SECTION 2

ENGINEERING DATA

2.1 Design

According to Mr. Peter Revill, Chief Design Engineer for the Hartford Metropolitan District, none of the original design information with respect to the construction of Hartford Reservoir No. 1 dam (from 1864 to 1867) is available. Design information, for the primary and auxiliary spillway modifications made in 1967 and the water intake and toe drain system improvements of 1978 and 1979, is available from the Hartford Metropolitan District. Several of the available drawings have been reproduced and included in Appendix B.

2.2 Construction

Construction information exists for the primary and auxiliary spillway modifications made in 1967, the water intake improvements made in 1978 and the toe drain system which is still not completely installed in the downstream portion of the dam.

2.3 Operation

Normal operation of the dam consists of opening and closing valves in the downstream gate chamber, depending upon the availability of surplus water. If water is available, the appropriate valves are opened to direct the flow to the power generation facilities. If water is not available the valves are closed. In the event high inflow to the reservoir is anticipated valves are opened to permit discharge into Spice Brook to help lower the pool level.

2.4 Evaluation

a. Availability. Several drawings of Hartford Reservoir No. 1 Dam and related appurtenances and records of piezometer readings of groundwater levels from July, 1977 to December, 1977 are available from the Hartford Metropolitan District. Many of the drawings and related data have been included, at least in part, in Appendix B.

b. Adequacy. Sufficient information has been obtained during the field investigation, from the available drawings and data, and through subsequent telephone conversations with Metropolitan District personnel, to conduct a Phase I dam evaluation.

c. Validity. Other than the 2.1-foot elevation difference between Hartford Metropolitan District datum and NGVD, it appears that the information obtained from the Metropolitan District is valid.

SECTION 3
VISUAL INSPECTION

3.1 Findings

a. General. Hartford Reservoir No. 1 Dam was inspected on November 13, 1979. At the time of inspection, the reservoir level was approximately 1.5 feet below the crest of the primary spillway. Underwater areas were not inspected.

A checklist of observations and comments made during the field inspection is included as Appendix A of this report.

b. Dam. The dam, which appears to be in fair condition, is approximately 500 feet long with a maximum height of 42 feet. The following features were noted during the field inspection:

1. The upstream face of the embankment is grass-covered with some riprap protection on the lower portion of the slope. The riprap extends from an elevation approximately 3 feet above the observed pool level to an undetermined depth below the water surface. Several small bushes were observed growing along the top edge of the riprap portion of the slope. Some riprap stone is missing on the upstream face of the dam.

2. The crest of the dam is approximately 25 feet wide and, at the time of the inspection, was 10.3 feet above the reservoir surface. A 14-foot wide paved access road along the crest of the dam appears to be in good condition. Rows of shrubbery line each side of the roadway.

3. The downstream face of the embankment is grass-covered; however, the following deficiencies were noted during the inspection: a) A permanently saturated condition at the downstream toe; b) Several evergreen trees were observed in the vicinity of the abutments and at the toe of the slope in the vicinity of the gate house; c) Animal burrows were observed in the downstream embankment face; d) An undulated area at the downstream toe of the slope near the gate house was observed. It could not be determined if the irregularities at the downstream toe of the slope were caused by embankment movement or the recent installation of a toe drain system; and e) a depression in the downstream slope, which extends from the crest of the dam to the toe and parallels the alignment of the outlet pipes through the embankment, was observed.

Several photos of the dam have been included in Appendix C.

c. Appurtenant Structures. The primary and auxiliary spillways appeared to be in good condition on the date of the inspection. The intake tower, the access bridge, the intake structure and the downstream gate house appear to be well maintained and in good condition. Some minor spalling was noted on the gate house near the water surface. The gate valves inside these structures were not inspected; however, Metropolitan District personnel said they are operable. The gate chamber and the gate valves at the downstream power house also appeared to be in good condition at the time of inspection. Drawings and photos of the primary and auxiliary spillways, the intake tower, the downstream gate house, the intake structure, the gate chamber and the power generation building are included in Appendix B and Appendix C, respectively.

d. Reservoir Area. The terrain along the perimeter of the pond is well vegetated and appears to be stable and free of erosion. The slope of the terrain around the pond varies from 2 percent to 25 percent.

e. Downstream Channel. Water discharging from the power generation building or through the low level outlet enters Spice Brook. The Brook flows through a well defined natural stream channel which is relatively clear of major obstructions. Spice Brook discharges into Trout Brook an estimated 4,000 feet downstream from the dam.

3.2 Evaluation. The deficiencies noted during inspection of the dam were the permanently saturated condition at the downstream toe (apparently due to seepage through the embankment) which has been partially corrected with the installation of a portion of the toe drain system, the disturbed area at the toe of the downstream face of the dam and the depression in the downstream face of the dam. The disturbance at the toe was most likely created during installation of the toe drains in 1978 and should be renovated as recommended in Section 7. The depression is probably the result of improper compaction around the outlet pipes.

Other observed deficiencies include evergreen trees growing in the vicinity of the abutments on the downstream face of the dam and in the vicinity of the downstream toe of the dam. Some riprap stone is missing on the upstream face of the dam and brush was observed growing from between riprap stones. Animal burrows were noted in the downstream embankment face. These conditions should also be improved as recommended in Section 7.

SECTION 4

OPERATION AND MAINTENANCE PROCEDURES

4.1 Operational Procedures

a. General. According to Mr. Allen, the primary function of Hartford Reservoir No. 1 is to impound water for the power generation facilities located about 100 feet downstream of the dam. Normal operation consists of discharging water through the power generation building when surplus water is available. Generally, water is available for power generation between 40 and 60 percent of the year.

Three sets of gates control low level discharges from the reservoir. An intake tower is located in the reservoir near the center of the dam. The operator may control the pool level from this structure by operating the appropriate sluice gates. However, the valves on the low level discharge pipes in the downstream gatehouse must also be opened for discharge to occur. Still further downstream, valves may be operated at a gate chamber to direct the flow either to the power generation facilities or to Spice Brook. The gates in the intake tower are normally closed so that the pipes through the embankment are not under pressure.

b. Description of Any Warning System in Effect. Currently, there is no formal warning system in effect. According to the Owner's representative, Mr. Peter Revill, the Labor Foreman will monitor reservoir levels during periods of unusually heavy runoff and/or rainfall.

4.2 Maintenance Procedures

a. General. The Metropolitan District employs a maintenance crew, headed by Mr. Rudy Wegscherder, who operates and maintains the West Hartford reservoir system. Maintenance of the dams and grounds is performed on a routine basis.

In 1972, the Metropolitan District installed three piezometers at the toe of the downstream slope to monitor groundwater levels. The owner had become aware that the downstream toe was constantly saturated and the piezometers were installed to assess the need for a toe drain. Records of groundwater levels were kept from July, 1977 to December, 1977 and are available from the Metropolitan District. Based upon an analysis of the data collected during this 6-month period, it was decided that a toe drain could alleviate the seepage problem. A toe drain was designed and, at the time of the inspection, approximately half of the proposed system had been installed.

b. Operating Facilities. According to the Owner's representative, valves and sluice gates controlling discharge from Reservoir No. 1 are kept in good operating condition and are serviced as required.

4.3 Evaluation

The current operation and maintenance program appears to be good with the following exceptions:

1. Growth of large trees on the dam, or any other type of vegetation with an extensive root system, should not be permitted. In addition, any growth which prohibits good visibility of the slope should be removed from the dam.
2. Animal burrow holes, observed on the downstream face of the dam, should be properly backfilled.
3. All surfaces of the dam should be kept in good condition. In particular, the rough area at the toe of the downstream slope should be re-graded and seeded.

SECTION 5

EVALUATION OF HYDRAULIC/HYDROLOGIC FEATURES

5.1 General

The drainage area for Hartford Reservoir No. 1 Dam encompasses 3.9 square miles which are mostly forested. The local drainage area (excluding the area drained by the other Hartford Reservoirs) is approximately 2.2 square miles. However, South Flood Control Dam drains 1.3 square miles of this local drainage area, limiting the direct runoff area for Hartford Reservoir No. 1 to 0.9 square miles. Hydraulic information for South Flood Control Dam is included in Appendix D. The normal water surface area of Hartford Reservoirs 1, 2, 3 and 5 accounts for an estimated 6 percent of the total drainage area.

The portion of the watershed draining to Reservoirs 2, 3, and 5 is undeveloped and almost entirely forested. The only development within the entire drainage basin is located 0.5 to 1.0 miles to the southwest of Reservoir No. 1 in an area called Oakland Gardens.

The topography is predominantly mountainous, ranging in elevation from 800 along the Talcott Mountain range to 256.5 at the normal reservoir surface of Hartford Reservoir No. 1.

5.2 Design Data

According to the Owner's representative, hydraulic and hydrologic data used for the original design of the Hartford Reservoir No. 1 Dam, is not available. The design of the auxiliary spillway, built in 1967, was based upon the peak runoff anticipated during a 34-hour, 18.25-inch rainfall.

5.3 Experience Data

The flood of record in Hartford occurred in August, 1955, as a result of rain which fell over a three day period during Hurricane Diane.

The maximum water surface observed at Reservoir No. 1 was approximately three feet above the primary spillway crest. Since that time the primary spillway crest has been raised one foot.

5.4 Test Flood Analysis

The recommended test flood for an "Intermediate" size, "High" hazard dam is the full Probable Maximum Flood (PMF).

Hydraulic and hydrologic calculations were performed with the assistance of the HEC-1-DB computer program. The flood hydrographs were constructed from Snyder unit hydrographs using average coefficients, an initial infiltration of zero and a constant loss rate of 0.05 inches per hour. The Hop Brook Adjustment Factor was used to reduce the Probable Maximum Precipitation based upon the size of the drainage area.

Stage-discharge and stage-storage relationships were developed for each of the upstream reservoirs and input into the computer for the purpose of routing the test flood to Hartford Reservoir No. 1 Dam. Water surface elevations at all upstream reservoirs were assumed to be at their respective spillway crests at the beginning of the hypothetical storm event.

The peak inflow and outflow rates for the test flood at Hartford Reservoir No. 1 Dam were computed to be 5,590 cfs and 5,440 cfs, respectively. The peak outflow corresponds to a reservoir stage of 8.3 feet above the primary spillway crest (0.5 feet below the top of the dam). The spillway system is capable of discharging 100 percent of the routed test flood outflow.

5.5 Dam Failure Analysis

Failure of the dam at Hartford Reservoir No. 1 was simulated through the use of the HEC-1-DB computer program, assuming that a 300-foot wide and 35.3-foot deep breach with vertical side slopes would develop within 2 hours from the start of the failure. Failure was assumed to occur with the pool level at the test flood elevation in the first case and at the spillway crest for the second case. The resulting outflow for each case was routed to the first major residential damage center, located approximately 2,000 feet downstream of the dam at the point where Spice Brook flows under Old Mill Lane. The flow at the damage center immediately prior to failure of the embankment was computed by routing the test flood spillway discharge to the hazard center for the reservoir at test flood elevation case and was assumed to be equivalent to the flow observed during the visual inspection for the reservoir at spillway crest case. These flows were compared to the breach flows to assess the increase in hazard caused by a failure of the embankment. Refer to Appendix D for the assumed channel cross-section at this point.

The failure analysis indicated that a breaching of the dam with the reservoir surface at the top of the dam would result in a stream depth of 7.7 feet, or 5.7 feet above the channel banks, with a corresponding flow of 6,000 cfs at the damage area. The estimated sill elevation of the lowest houses in this area is 2 feet above the channel banks. Therefore, the breach flood would inundate the house with 3.7 feet of water causing excessive property damage and the possible loss of more than a few lives. With the reservoir surface at the spillway crest, a breach flood would result in a stream depth of 6.8 feet and a corresponding flow of 4,480 cfs. This flood would also cause excessive property damage and the possible loss of more than a few lives.

The stream depth and quantity of flow at the hazard center immediately prior to failure of the dam were computed to be 5.7 feet and 3,070 cfs, respectively, with the reservoir surface at the test flood elevation. A stream depth of 0.5 feet and flow of 35 cfs were estimated with the reservoir surface at the spillway crest. Therefore, a dam breach would result in a significant increase in hazard to loss of life downstream.

The initial damage center is the Metropolitan District power generating facilities 100 feet downstream of the dam. These facilities would probably be destroyed by floodwaters resulting from a dam failure.

SECTION 6

EVALUATION OF STRUCTURAL STABILITY

6.1 Visual Observations

A permanently saturated condition exists at the downstream toe which has been partially corrected with the installation of a portion of the toe drain system. An undulated area was observed at the downstream toe of the dam, near the location where toe drains were installed in 1978. It could not be determined if the area was undulated as a result of the toe drain installation or because of embankment displacement. A depression of the downstream face which follows the alignment of the outlet pipes and extends from the crest to the toe of the dam was also observed during the inspection. This depression appears to be a result of improper compaction around the outlet pipes. However, seepage could have been a contributing factor.

Several other deficiencies which were observed during the inspection, such as trees growing on the downstream face of the dam near the abutments and near the downstream toe, riprap displacement on the upstream face, and animal burrow holes on the downstream face, could lead to structural damage if they are not removed and/or repaired.

No other indications of structural deficiency were observed. Photos of the dam are included in Appendix C.

6.2 Design and Construction Data

According to the Owner's representative, no data with regard to the original design and construction of the dam at Hartford Reservoir No. 1 is available.

6.3 Post Construction Changes

Since the original construction of the dam between 1864 and 1867, there have been three major construction changes: 1) According to Metropolitan District records, the dam was rebuilt in 1868; 2) Power generation facilities (and presumably the 30-inch transfer pipe) were constructed in 1922; and 3) The auxiliary spillway was built and the primary spillway was raised one foot in 1967. In addition, recent modifications to the dam include the installation of a toe drain (construction not yet completed) and reconstruction of the intake structure on the 30-inch transfer pipe which carries water to the power generation facilities.

6.4 Seismic Stability

Hartford Reservoir No. 1 Dam is located in Seismic Zone 1 on the Seismic Zone Map of Contiguous States. A dam located in Seismic Zone 1 need not be evaluated for seismic stability, according to the Recommended Guidelines for Phase I Dam Inspections.

SECTION 7

ASSESSMENT, RECOMMENDATIONS & REMEDIAL MEASURES

7.1 Dam Assessment

a. Condition. The dam appears to be in fair condition. The Owner has been cognizant of a seepage problem at the site for at least 3 years because of the permanently saturated conditions observed at the toe of the dam. This condition was observed during the inspection of the site but, because of the installation of the drains in 1978, the situation has improved, but still exists. Additional drain installation work is planned. The undulated area at the downstream toe of the dam, where the toe drains were installed in 1978, could be the result of the toe drain installation or embankment displacement. The depression on the downstream face of the dam which follows the alignment of the outlet pipes and extends from the crest of the dam to the toe could be the result of improper compaction or seepage around the outlet pipes.

Other deficiencies include trees growing on the downstream face of the dam, near the abutments and near the downstream toe, riprap displacement on the upstream face and animal burrows in the downstream face.

Recommendations and operation and maintenance measures which should be implemented are discussed in Sections 7.2 and 7.3.

b. Adequacy of Information. Sufficient information has been obtained through field observations, from data supplied by the Metropolitan District and through subsequent telephone conversations with Metropolitan District personnel to conduct a Phase I dam evaluation.

c. Urgency. The recommendations and remedial measures presented in this Section should be implemented within one year of receipt of this Phase I Inspection Report.

7.2 Recommendations

It is recommended that the Owner retain a qualified registered professional engineer, experienced in the design and construction of dams, to direct the removal of the trees in the vicinity of the abutments and at the toe of the downstream face of the dam. Voids left in the embankment by the removal of the trees should be filled with suitable, thoroughly compacted material.

7.3 Remedial Measures

a. Operation and Maintenance Procedures. The Owner should implement the following operation and maintenance measures:

1. The toe drain construction should be completed.

2. The area at the downstream toe of the dam, in the vicinity of the new toe drain installation, should be regraded, seeded and monitored for future movements.

3. The depression in the downstream face should also be regraded, reseeded, and monitored for future settlement.

4. Extraneous vegetation should be removed from the riprapped portion of the upstream face of the dam and riprap should be replaced where necessary.

5. Animal burrows, in the downstream face of the dam, should be backfilled to eliminate possible seepage paths.

6. A formal surveillance and flood warning plan should be developed.

7. A program of periodic annual technical inspection should be instituted.

7.4 Alternatives

No valid alternatives to the recommendations described above are considered feasible for this site.

APPENDIX A

INSPECTION CHECKLIST

VISUAL INSPECTION CHECK LIST
INSPECTION TEAM ORGANIZATION

Project: Hartford Reservoir No 1 Dam
National I.D. #: CT 00001
Location: Hartford, Connecticut
Type of Dam: Earth Embankment
Inspection Date(s): November 13, 1979
Weather: Overcast, Mid 50's
Pool Elevation: 256.5 ± MSL

Inspection Team

Notes: All elevations are referred to Met. Dist. Datum.
(SCS) Indicates Flood Detention Reservoirs
presently being built by the Soil Conservation Service.

* Reservoir No. 3 discharges include flows
over bituminous surfaced emergency spillway with
crest at El. 396.5.

ϕ Present discharge capability of Res. No. 1
is approximately 3,500 cfs over existing spillway
crest at El. 258.6. No revisions are proposed
at this time due to the need for additional field
information and engineering study (currently
in progress).

PROJECT STORM - The reservoir proposals
are based on passing this storm with
normal freeboard for wave and wind
action. The storm is basically a repeat
of the August 1955 storm, as it occurred
over Westfield, Mass., relocated to occur
over the West Hartford reservoirs.

EMERGENCY STORM - The reservoir proposals
are based on passing this storm with
nominal freeboard. The storm is arbitrary
and synthetic consisting of a 2-hour
rainfall total of 13.55" (2/3 of maximum
possible), preceded and followed by
light rainfall.

WEST HARTFORD RESERVOIR NO. 1

Statistics Pertinent to
PROPOSED EMERGENCY SPILLWAYWatershed Area -

| | | |
|------|---------|--|
| 1.30 | Sq. mi. | above South Flood Control Reservoir |
| 0.60 | " | " " Reservoir No. 3 |
| 1.50 | " | " " Reservoir No. 5 (including Reservoir No. 2 and 30% of Talcott Flood Control Reservoir) |
| 1.00 | " | " Independent |
| 4.40 | " | " TOTAL |

Capacity of Reservoir - 137 Million Gallons or 420 Acre-Feet

Dam - Earth fill type, completed in 1868, maximum height of about 43 feet, top width of about 25 feet, top at El. 267.4 Met. Dist. Datum, 8.8-foot freeboard on principal spillway.

Principal Spillway - Concrete weir, crest at El. 258.6, about 45 feet long. Discharge channel in earth cut, base width about 18 feet, dry rubble toe walls, average invert slope of about 0.01. Stone masonry arch bridge over spillway channel, 18-foot span and 12-foot height.

Proposed Emergency Spillway - Earth cut, 100-foot base width, invert crest at El. 264.0 with 0.01± slope.

Maximum Flood on Record (99-years of record) -

Occurred in August 1955 when the reservoir was empty and resulted in maximum water level at El. 261.6±, or 3.0 feet above crest of principal spillway and leaving 5.8 feet of freeboard. Principal spillway peaked at 600 to 700 cubic feet per second (cfs).

Repeat of Maximum Flood on Record -

If the August 1955 storm reoccurred with the reservoir full at the start of the storm and including the effects of upstream reservoirs and improvements built since 1955, the reservoir level would again crest at El. 261.6, or 3.0 feet above crest of principal spillway and leaving 5.8 feet of freeboard on the dam. This maximum water level would still be 2.4 feet below the crest of the emergency spillway.

Water Bureau's Project Storm -

This storm is a reconstruction of the August 1955 rainfall over a 20-square mile area in Westfield, Mass. transposed to our West Hartford Reservoirs. This storm totals 18.24 inches in 34 hours and is the design storm used for the Park River Flood Detention Reservoirs. The reservoir level would crest at El. 264.7, or 6.1 feet above crest of principal spillway and leaving 2.7 feet of freeboard. Principal spillway would peak at 1,650 cfs and the emergency spillway, with an 0.7-foot overflow head, would peak at 170 cfs with 0.4-foot flow depth and 4.0-foot per second (fps) velocities.

Maximum Spillway Capacities -

With the reservoir level a nominal 6" below the top of the dam, the principal spillway would discharge about 2,500 cfs and the emergency spillway would discharge about 1,500 cfs with about 2-foot flow depth and velocities of about 8 fps. This 4,000 cfs total discharge capacity is approximately two times the peak inflow rate from the project storm and three times the peak inflow rate from a repeat of the August 1955 storm.

WEST HARTFORD RESERVOIR NO. 1

Statement of Purpose for
PROPOSED EMERGENCY SPILLWAY

In the fall of 1964, the Water Bureau made certain revisions to its Reservoirs 2, 3, 5 and 6 in West Hartford and Bloomfield, to improve their hydrologic capacity and safety. Since major structural changes to a dam were required only on Reservoir 5, a formal construction permit was issued by your Commission for that project and the balance of the improvements were authorized without formal permits.

No improvements to Reservoir 1 were made at that time since the necessary field work and engineering studies were not complete. Unlike the other reservoirs, Reservoir 1 is not vital to the operations and safety of our Water Treatment Plant, so that the expense of any improvements must be justified only by the increased safety to property downstream thereof. To this end, we propose to construct an emergency spillway to augment the existing principal spillway. It would be constructed at such a level that the existing principal spillway would discharge twice its maximum flow on record before the emergency spillway would start to function. The emergency spillway would function to prevent overtopping of the dam proper for larger flows.

Attached is a locality plan, a plan of the proposed improvements, a tabulation of pertinent physical and hydrologic statistics, and a set of the proposed contract and construction drawings. This proposal was discussed in general in October 1965 with Mr. Curry and our engineering staff. The "gabions" are galvanized wire mesh baskets filled with quarry stone and would prevent flow and scour along the toe of the dam. The overflow velocities are within the design range of the Soil Conservation Service flood detention dams and the oiled gravel roads across the invert would minimize the chance of scour.

Funds are available in the 1967 Water Bureau budget for this work and it should be completed before the 1967 hurricane season if possible. To accomplish this, we must lower the 42-inch water main crossing the spillway area by April 1 so that early receipt of the permit is vital.

(2) SOIL MECHANICS & ENGINEERING PRACTICES, TERZAGHI & PECK.

ASSUMPTIONS: BASED ON SIEVE ANALYSIS CLASSIFICATION OF SOIL IN THE VICINITY
(THE DRAIN PROJECT) THE SOIL CHARACTERISTICS SHOULD CLOSELY
✓ APPROXIMATE THOSE CHARACTERISTICS WHICH ARE DISPLAYED BY
CATEGORY # 4 OF TABLE G.3 ON PAGE 28 OF TERZAGHI
AND PECK (por. 30%, $e = 0.43$, 116 lb/c.f. dry, 135 lb/c.f. sat.)
- Also 12% moist -

FROM LACK OF READILY AVAILABLE INFORMATION ASSUME THAT
THE ADJUNCTS OF THE MAIN EMBANKMENT HAVE A NEGLECTABLE
✓ EFFECT ON THE STRUCTURE. WHEN TAKEN INTO ACCOUNT THESE
ADJUNCTS WILL HAVE A POSITIVE INFLUENCE ON THE SAFETY OF
THE STRUCTURE.

✓ THE MAIN DIMENSIONS OF THE STRUCTURE ARE AS IN THE DIAGRAM
ABOVE. MOST OF THESE DIMENSIONS WERE TAKEN FROM THE
PRELIMINARY DRAIN PROJECT STUDIES.

Dam Inspection

Mr. Leneord Beck
O'Brien and Gere
1617 J. F. Kennedy Blvd.
Suite 1760
Philadelphia, PA 19103

Dear Len:

In reply to your request for data on the Talcott Reservoir, I have taken the following data from the construction drawings. (I assume you have our 1" = 200 ft. scale maps of the area for location purposes.)

South Dam: principal spillway is a 30" pipe through dam, emergency spillway is 40 ft. wide, crest at Elev. 452.5.

North Dam: principal spillway is a 30" pipe through the dam, emergency spillway is 90 ft., crest at Elev. 452.5.

Both emergency spillways are grassed earth with crests 30' long (i.e. parallel to flow) and approach and discharge slopes ranging from 2 to 7%. The design high water level is at Elev. 455.4.

As I recollect, the spillways are designed to drain their proportionate share of the watershed. Our records state that 0.5 sq. mile of Reservoir No. 2 watershed lies above the flood control dam. I hope this information is of help to you.

Sincerely,

Peter J. Revill
Peter J. Revill,
Chief Design Engineer
