REPLY TO ATTENTION OF NEDED

MAR 2 1 1980

Honorable Ella T. Grasso Governor of the State of Connecticut State Capitol Hartford, Connecticut 06115

Dear Governor Grasso:

Inclosed is a copy of the American Can Company Dam Phase I Inspection Report, which was prepared under the National Program for Inspection of Non-Federal Dams. This report is presented for your use and is based upon a visual inspection, a review of the past performance and a brief hydrological study of the dam. A brief assessment is included at the beginning of the report. I have approved the report and support the findings and recommendations described in Section 7 and ask that you keep me informed of the actions taken to implement them. This follow-up action is a vitally important part of this program.

A copy of this report has been forwarded to the Department of Environmental Protection, the cooperating agency for the State of Connecticut. In addition, a copy of the report has also been furnished the owner, American Can Company, Greenwich, Connecticut.

Copies of this report will be made available to the public, upon request, by this office under the Freedom of Information Act. In the case of this report the release date will be thirty days from the date of this letter.

I wish to take this opportunity to thank you and the Department of Environmental Protection for your cooperation in carrying out this program.

Sincerely,

MÁX B. SCHEIDER Colonel, Corps of Engineers Division Engineer

PHASE I INSPECTION REPORT

NATIONAL DAM INSPECTION PROGRAM

NATIONAL DAM INSPECTION PROGRAM

PHASE I INSPECTION REPORT

Inspection No.:	CT 00047
Name of Dam:	American Can Company Dam
Town:	Greenwich
County and State:	Fairfield, Connecticut
Stream:	Tributary to Louden Cove
Date of Inspection:	November 13, 1979

BRIEF ASSESSMENT

The dam at the American Can Company building in Greenwich, Connecticut, consists of the north wall of a parking garage which retains earth and the adjacent created pond (North Lake) to a depth of five levels below grade. The height of this wall is 53 feet.

There are no visible signs of physical distress and for reasons of fire protection, the water level is monitored very closely. Based on the visual inspection and a review of the technical data available, this dam is judged to be in GOOD condition.

This dam is classified as INTERMEDIATE in size and a HIGH hazard structure in accordance with the recommended guidelines established by the Corps of Engineers. The test flood for this dam is equal to the Probable Maximum Flood (PMF) and has an outflow discharge equal to 83 cfs. The maximum outflow capacity of the overflow weir under a stillwater condition at the top of the weir opening is equal to 500 cfs, which represents more than 100 percent of the test flood.

Rebuilding the headwall at the 48 inch outfall pipe is recommended within a 2 year period so that sedimentation buildup at this location can be monitored and clogging prevented. **Recommendations and remedial measures that should be implemented by the Owner within a two year** period after receipt of this Phase I Inspection Report are further described in Section 7.

JAMES P. PURCELL ASSOCIATES, INC.

Sudhir A. Shah, P.E. Vice-President Connecticut P.E. No. 8012

This Phase I Inspection Report on American Can Company Dam has been reviewed by the undersigned Review Board members. In our opinion, the reported findings, conclusions, and recommendations are consistent with the <u>Recommended Guidelines for Safety Inspection of</u> <u>Dans</u>, and with good engineering judgment and practice, and is hereby submitted for approval.

Chief, Engineering Division

PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I Investigation. However, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through continued care and inspection can there by any chance that unsafe conditions be detected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the spillway test flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and downstream damage potential.

The Phase I Investigation does not include an assessment of the need for fences, gates, no-trespassing signs, repairs to existing fences and railings and other items which may be needed to minimize trespass and provide greater security for the facility and safety to the public. An evaluation of the project for compliance with OSHA rules and regulations is also excluded.

NATIONAL DAM INSPECTION PROGRAM

PHASE I - INSPECTION REPORT

NAME OF DAM: AMERICAN CAN COMPANY DAM

SECTION 1

PROJECT INFORMATION

1.1 General

a. Authority: Public Law 92-367, August 8, 1972, authorized the Secretary of the Army through the Corps of Engineers to initiate a national program of dam inspection throughout the United States. The New England Division of the Corps of Engineers has been assigned the responsibility of supervising the inspection of dams within the New England Region. James P. Purcell Associates, Inc. has been retained by the New England Division to inspect and report on selected dams in the State of Connecticut. Authorization and notice to proceed was issued to James P. Purcell Associates, Inc., under a letter from William E. Hodgson, Jr., Colonel, Corps of Engineers. Contract No. DACW33-80-C-0002 has been assigned by the Corps of Engineers for this work.

b. Purpose of Inspection

- 1. Perform technical inspection and evaluation of non-Federal dams to identify conditions which threaten the public safety and thus permit correction in a timely manner by non-Federal interests.
- 2. Encourage and prepare the States to initiate quickly effective dam safety programs for non-Federal dams.
- 3. To update, verify and complete the National Inventory of Dams.

1.2 Description of Project

a. Location: The dam at the American Can Company Executive Office Building is located in the Town of Greenwich near the New York - Connecticut State Line (See Plate No. 1). The impoundment is in the watershed of an unnamed tributary to Rye Lake entering at Louden Cove. The dam is 3000 feet upstream of Louden Cove. The latitude is 41° -06'-00" and the longitude is 73° -43'-18". b. **Description of Dam and Appurtenances:** The extent of this dam can best be described as the concrete structural wall on the north side of the underground parking garage for the employees of the American Can Company.

The pond (North Lake) is created by the north wall of the building and extends up a small natural valley. There are no streams entering the pond, which is fed by stormwater runoff and groundwater.

A 15 foot wide overflow weir in an opening in the north wall maintains a constant water elevation in the pond. A 12 inch drain extends from the bottom of the pond through the building wall. A 3 foot by 8 foot vertical chase carries water from the weir and building to an outfall below the south side of the building and a small natural channel. Other pipes for the fire protection system extend from the pond to the building.

- c. Size Classification: The size classification of this dam is INTERMEDIATE as per the criteria set forth in the Recommended Guidelines for Safety Inspection of Dams by the Corps of Engineers. The impoundment storage at the top of the dam (top of the weir opening) is 26 ac.-ft. (the "small" category range is 50 to 1000 ac.-ft.) and the maximum height of the dam is 53 feet (within the "intermediate" category range of 40 to 100 feet). The size classification is based on the height criteria.
- d. Hazard Classification: The hazard classification of this dam is HIGH as per the criteria set forth in the Recommended Guidelines for Safety Inspection of Dams by the Corps of Engineers. The failure of the dam (building wall) would result in extensive damage to the lower levels of the American Company building, the loss of the fire protection water supply, and the possibility of the loss of more than a few lives should failure occur during commuting hours when the garage is full of people.
- e. **Ownership:** The dam is the wall of the building, which is owned and maintained by the American Can Company of Greenwich, Connecticut.
- f. Operator: The person in charge of the day-to-day operation of this dam is:

Mr. Vincent Lex, Jr. American Can Company American Lane Greenwich, CT 06830 Tel. (203) 522-2089

- g. **Purpose of Dam:** The purpose of this dam is to retain the earth and water on the north side of the garage for the office building. The water impounded by this dam is used primarily for fire protection and it also has an aesthetic function.
- h. Design and Construction History: North Lake and the dam was constructed in 1968 by the Turner Construction Company of New York as part of the garage for the office building of the American Can Company. The bottom of this pond, originally covered with bentonite, was recovered with a plastic liner in 1972 to prevent the loss of water and embankment material through the foundation drain (located along the building wall two feet below the fifth garage level). A piezometer, connected to the foundation drain, is located in the building. This pond has leaked once since the 1972 repairs, at which time the plastic liner was patched.

The original structural design for this building was done by Paul Weidlinger of New York and the design of the plastic liner repair was engineered by Mueser, Rutledge, Wentworth and Johnston of New York.

i. Normal Operational Procedure: North Lake has a very small drainage area and as a result, the water level fluctuates very little during a heavy storm. This facility requires no operation; however, the spillway and the piezometer at the lowest level of the north wall are checked during each shift (3 times each day).

1.3 Pertinent Data

a. Drainage Area: The American Can Company Dam is located in Fairfield County, Connecticut. The drainage basin lies approximately 2 miles west of North Greenwich, Connecticut. The basin is oval in shape with a length of 0.11 miles and an average width of 0.2 miles, resulting in a total drainage area of 0.02 square miles. (See drainage basin map in Appendix D). The topography is a generally rolling to steep terrain, with elevations ranging from a high of 440 feet to a low of 361 feet at the overflow weir crest. The basin slope is steep having average grades of 18 percent. The normal surface area of the pond is 2.0 acres, which is 16 percent of the watershed.

All elevations used in this report are based on an assumed datum (ACCD) established for the construction of the American Can Company Building. No relation to the National Geodetic Vertical Datum (NGVD) has been established.

- b. Discharge at Dam Site: There are no specific discharge records available for this dam. Listed below are calculated discharge values for the overflow weir and outlet works.
 - 1. Outlet Works: A 12 inch drain pipe with an intake elevation of 343.0 feet, and a discharge capacity of 16 cfs at a pond elevation of 361.0.

- 2. Maximum Known Flood at Dam Site: Calculated to be 6 cfs based on a reported maximum depth of flow over the weir of 3 inches.
- 3. Overflow Weir Capacity at the Top of the Weir Opening: 500 cfs at elevation 365.6.
- 4. Overflow Weir Capacity at Test Flood Elevation: 83 cfs at elevation 362.4.
- 5. Gated Outlet Capacity at Normal Pool Elevation: 16 cfs at elevation 361.0.

1

- 6. Gated Outlet Capacity at Test Flood Elevation: 16.5 cfs at elevation 362.4.
- 7. Gated Outlet Capacity at the Top of the Weir Opening: 18 cfs at elevation 365.6.
- 8. Total Project Discharge at Top of the Weir Opening: 518 cfs at elevation 365.6.
- 9. Total Project Discharge at Test Flood Elevation: 99.5 cfs at elevation 362.4.
- c. Elevation (Ft. above American Can Company Datum ACCD):

SECTION 2

ENGINEERING DATA

2.1 Design

The design information available consists of the following:

- a. Structural computations done by Paul Weidlinger of New York.
- b. Several contract drawings from the original plans.
- c. A report by Mueser, Rutledge, Wentworth and Johnston, which outlines several suggested schemes for repair of the leakage problems experienced in 1972.

Refer to Appendix B-1 for the location of this information.

2.2 Construction

The construction of the dam (building) was started in 1968 by the Turner Construction Company. Since the newly created North Lake would not stay full and studies showed that the water was leaking out through the underdrain system, a plastic liner was installed on the lake bottom in 1972. This solution appears to have solved the problem as only one leak has been observed since. The lake was drained and a cavity was found where the liner had burst. The cavity was filled with sand and the iner was repaired.

2.3 Operation

No operation is required at this dam. However, for purposes of fire protection, there are two separate lines which feed different areas of the building as well as a sprinkler system which goes throughout the facility. The engineer in charge of maintenance, Mr. Lex, stated that the entire pond could be drained in less than 8 hours, if required, during an emergency.

2.4 Evaluation

Since there were no apparent visual signs of distress, there was no need for further review of the design data. The hydraulic capacity of the overflow weir and outlet works are discussed fully in Section 5.

SECTION 3

VISUAL INSPECTION

3.1 Findings

a. General: The visual inspection was conducted on the morning of November 13, 1979 and a copy of the visual inspection check list is contained in Appendix C of this report.

The following procedure was used.

- 1. Inspection of the lake area around the north side of the building.
- 2. Visual survey of the outside portion of the north wall above the waterline.
- 3. Survey of structural wall condition at 1st, 3rd, and 5th floor levels of garage.
- 4. Check of drainage outlet at the south side of the building.
- 5. Photographs were taken of the general view of the building as well as other items given attention during the inspections, and are included in Appendix C of this report.

Before the inspection, the design and construction documents and aerial photographs were studied and reviewed.

- b. Dam: The north wall of the parking garage retains the earth and lake for 5 levels below grade. There was no seepage observed at any place on the face of this wall. The general condition of this wall was very good. No evidence of any settlement or movement was observed (Photos C-I, C-2).
- c. Appurtenant Structures: The overflow weir for this pond drains into a 3' x 8' vertical chase, outletting to a 48 inch RCP, which goes under the building and drains into the swamp area on the south side of the building. The weir was in good condition and seemed to be functioning very well. The maximum depth of water on the weir that anyone could recall was approximately 3 inches (Photos C-3, C-4). A 12 inch drain, controlled by a valve in the building (Photo C-5) also extends from the pond to the chase.
- d. Reservoir Area: An inspection of the immediate area of the lake showed there was no evidence of any movement of the embankment area next to the north wall of the building. The upstream area is mowed and maintained very well.

e. Downstream Channel: The downstream channel consists of a 48 inch diameter blowoff pipe which carries the spillway flow into a swampy area at the south side of the building. The outlet is covered with field stone to prevent access. However, overflow from the pond appears to be flowing freely, although the pipe is approximately 1/3 full of sediment (Photo C-9, C-10).

3.2 Evaluation

In general, the visual inspection showed this dam to be in good condition. There were no signs of any distress to any part of the north wall of the building. There appeared to be a need for improvement of the headwall arrangement at the outfall, due to the blockage and sedimentation.

SECTION 4

OPERATIONAL AND MAINTENANCE PROCEDURES

4.1 Operational Procedures

- a. General: The responsibility of the operation and maintenace for this facility is with the Maintenance Department of the American Can Company. The overflow weir level can be controlled with an adjustable stainless steel weir plate on the south face of the wall. Since the drainage area is so small, the water level has a very narrow range. The real maintenance concern at this site is that the plastic liner does not develop another leak, such that the water which is a source of fire protection, could be lost.
- b. Warning System: The warning system is the piezometer, which is located on the fifth level of the garage. The piezometer is monitored three times per day so that any groundwater pressure buildup (water not freely drained by the foundation drain), which would indicate a leak in the liner, could be detected. No written or formal operating procedure has been established. Each watch of the maintenance crew has been instructed to notify the supervisor if the piezometer reading changes from "zero" (Photo C-6).

4.2 Maintenance Procedures

- a. General: The building was designed so that its maintenance would be minimal. The outfall of this dam is hardly ever checked and as a result, the area near the headwall is in almost its natural condition.
- b. Operating Facilities: The three outlets to this pond penetrate the north wall at the third level. Two of these outlets feed the fire protection system and the third outlet is used to drain the pond. Insurance requirements are such that the pumps are exercised regularly (Photos C-7, C-8).

4.3 Evaluation

From the aspect of safety, the operational and maintenance procedures for this dam seem adequate. Improvement of the headwall arrangement at the outfall would help the monitoring of siltation at this point.

SECTION 5

EVALUATION OF HYDRAULIC/HYDROLOGIC FEATURES

5.1 General

The American Can Company building, built across a small natural valley, creates a pond against the north side of the building. The basin slopes are steep, having average grades of 18 percent. The impoundment has a total storage capacity of 18 ac.-ft. at elevation 361.0, the overflow weir crest. Each foot of depth in the pond above the overflow weir crest can accommodate approximately 2 ac.-ft. The overflow weir is a rectangular opening in the building wall and is 15 feet in length and 4.63 feet in height.

5.2 Design Data

- a. No specific hydraulic or hydrologic design data is available for this watershed or the drainage structures of the American Can Company Dam. In lieu of existing design information, U.S.G.S. Topographic Maps (Scale 1" - 2000') were utilized to develop hydrologic parameters such as drainage area, basin length, time of concentration and other runoff characteristics. Elevation - storage relationships for the reservoir were approximated. Reservoir surface area and surcharge storage was computed using a lake plan prepared by the American Can Company (see Appendix B). Some of the pertinent hydraulic design data was obtained and/or confirmed by actual field measurements at the time of the visual field inspection.
- b. Outflow values (routing procedures) and dam overtopping analyses were computed in accordance with the guidelines developed by the Corps of Engineers. Judgment was used in calculating final values outlined in this report, which are quite approximate and should not be considered a substitute for actual detailed analysis.

5.3 Experience Data

Historical data for recorded discharges is not available for this dam. The maximum discharge to date was calculated to be approximately 6 cfs corresponding to a reported depth of flow over the overflow weir of approximately 3 inches.

5.4 Test Flood Analysis

Recommended Guidelines for the Safety Inspection of Dams by the Corps of Engineers were used for the selection of the "Test Flood". This dam is classified as

a HIGH hazard and INTERMEDIATE size structure. Guidelines indicate that the Probable Maximum Flood (PMF) be used as the test flood for these classifications. The watershed has a total area of 0.02 square miles. Snyder's lag was calculated to be 0.48 hours and a Snyder peaking coefficient of 0.625 was used. The 200 square mile, 24 hour Probable Maximum Precipition (PMF) is 22 inches. The Flood Hydrograph Package, HEC-1 computer program, developed by the Corps of Engineers was utilized to develop the inflow hydrograph, route the flood through the reservoir, and for the dam overtopping analysis. A test flood inflow was calculated to be 98 cfs. The inflow from 1/2 the PMF is 49 cfs. The 12 inch drain was assumed to be closed for this analysis.

The overflow weir capacity is hydraulically adequate to pass the test flood (PMF) and submergence of the overflow weir opening will not occur. The maximum outflow capacity of the overflow weir without submergence is 500 cfs. This corresponds to in excess of 100 percent of the test flood and a storage above the spillway level of approximately 6 ac.-ft. The maximum outflow discharge value for the test flood is 83 cfs corresponding to a depth of flow over the overflow weir of 1.41 feet and a storage above the spillway level of 3 ac.-ft. The outflow from 1/2 the PMF is 40 cfs. A spillway rating curve, outlet works rating curve, and a reservoir surface area-capacity curve are included in Appendix D of this report.

At the overflow weir crest elevation of 361.0, the capacity of the 12 inch drain outlet structure is 16 cfs. It will require approximately 1.5 hours to lower the water level the first foot assuming a water surface area of 2.0 acres and use of the outlet works to regulate the water level for expected inflows. Storage for impending flood conditions can be provided guickly by use of the outlet works if the pool level is high.

5.5 Dam Failure Analysis

This dam is classified as a high hazard structure. Failure discharge will cause damage to the American Can Company building. Loss of personal property is also possible because of the nature of the structure, as it is the north wall of the building. The loss of life is a possibility depending on the occupancy of the garage at the time of failure.

The calculated dam failure discharge is 9430 cfs at a pool level equal to the overflow weir crest. This level was chosen rather than the test flood level as having the greater hazard potential because a prefailure flow of the test flood would cause evacuation and/or a warning of flood conditions. Failure of the dam at normal pool level would catch the building occupants off guard and probably result in greater losses. Failure will produce a water surface level of approximately 3.5 feet deep at the 5th level parking area within the building.

Water surface elevations due to failure of the dam are listed in Appendix D. Probable consequences of a dam failure are limited to American Can Company building.

SECTION 6

EVALUATION OF STRUCTURAL STABILITY

6.1 1 Visual Observations

The maintenance staff routinely checks the equipment which could be used to drain the pond. No signs of physical distress in the north wall of this building is visible.

6.2 Design and Construction Data

The design and construction data available were construction drawings of the entire building, a study of the North Lake repair done in 1972, and structural computations for the north wall. The structural analysis done by Paul Weidlinger is contained in Appendix B of this report. No records or recollections of the construction for this building were readily available.

6.3 Post-Construction Changes

The following changes to the American Can Company Dam facility have been noted since its construction in 1968.

- a. Leaking and soil loss through the underdrain system of the foundation drains.
- b. Repair of above item by the installation of a plastic liner over the bottom of the pond adjacent to the north wall, and one subsequent repair of the liner.

6.4 Seismic Stability

This dam is in Seismic Zone 1 and, hence, does not require evaluation for seismic stability according to the Corps of Engineers Recommended Guidelines.

SECTION 7

ASSESSMENT, RECOMMENDATIONS AND REMEDIAL MEASURES

7.1 Dam Assessment

- a. Condition: After study of the available documents, reports, structural analyses, and the results of this inspection, the conclusion is that the general condition of the dam at the American Can Company facility is GOOD. There is no cause to doubt the structural stability of the north wall based on visual observations.
- b. Adequacy of Information: The information that was available seemed adequate to make an assessment of the condition of this facility.
- c. **Urgency**: It is considered that the recommendations suggested below be implemented within 2 years.

7.2 Recommendations

It is recommended that the owner engage a qualified registered engineer to carry out the following actions:

- a. The headwall at the outfall of the 48 inch diameter drainline should be rebuilt so that the flow line of this pipe can be observed to monitor sediment buildup.
- b. The assumed datum used by the American Can Company should be related to the N.G.V.D.

7.3 Remedial Measures

- a. Operation and Maintenance Procedures
 - 1. Trees and brush on the downstream area around the outfall be removed to facilitate the visual observation of this outlet. This would preclude any problem of a possible plugged outlet during an emergency.
 - 2. Schedule a regular maintenance check of this area for monitoring of any blockages.
 - 3. Institute a program of biennial periodic technical inspection.
 - 4. Develop a formal flood warning and surveillance plan, including roundthe-clock monitoring during heavy precipitation.

7.4 Alternatives

None.

AMERICAN CAN COMPANY DAM

Dam Failure Analysis

1.	Failure discharge with pool at top of weir $(elev, 361.0) = 9430$	CFS
2.	Depth of water in reservoir at time of failure = 18.0	_ft.
3.	Maximum depth of flow downstream of dam = 3.5	_ft.
4.	Water surface elevation just downstream) of dam at time of failure) = 324.5	
	The failure discharge of 9430 CFS will enter The American	
Can	Company Building and be contained.	
	The failure discharge will be contained within the building	
res	ulting in 3.5 feet of water in its lowest parking level	

(5th level). The failure profile will have the following hydraulic

characteristics:

DISTANCE FROM THE DAM	WATER SURFACE ELEVATION	REMARUS
0	361.0	Upstream of dam
0	324.5 (within building)	Downstream of dam

"Rule of Thumb Guidance for Estimating Downstream Dam Failure Analysis"

DATA

Name of Dam American Can Company
Location South of Mount Pleasant, New York
Drainage Area 0.02 sq. mi., Top of Dam* 365.6
Spillway Type Overflow- sharpcrest, Crest of Spillway 361.0
Surface Area 3 Crest Elev. 2.3 Acres = 0.004 sq. mi.
Pool Bottom Near Dam = 343.0 Upstream, 300.9 Downstream
Assumed Side Slopes of Embankments = 2.5:1 upstream, vertical downstream
Depth of Pool at Dam (Yo) = 18 Feet
Mid-Height Elev. 352.0
Length of Dam at Crest = 330 Feet
Length of Dam at Mid-Height =294 Feet
25% of Dam Length at Mid-Height = $W_b = -73.5$ Feet
Step 1
Storage (S) at time of failure <u>18</u> Ac-FT (Equal to top of weir)
Step [*] 2
Peak Failure Discharge $Q_{p1} = 8/27 W_b \sqrt{g} Y_0 3/2$
= 1.68 W _b Yo ^{3/2} $= 9430$ cfs

Failure is assumed to coincide with pool elevation at top of weir.

* Top of overflow weir opening.
