REPLY TO ATTENTION OF: NEDED

JUN 21 1979

Honorable Ella T. Grasso Governor of the State of Connecticut State Capitol Hartford, Connecticut 06115

Dear Governor Grasso:

I am forwarding to you a copy of the North Stamford Reservoir Dam Phase I Inspection Report, which was prepared under the National Program for Inspection of Non-Federal Dams. This report is presented for your use and is based upon a visual inspection, a review of the past performance and a brief hydrological study of the dam. A brief assessment is included at the beginning of the report. I have approved the report and support the findings and recommendations described in Section 7 and ask that you keep me informed of the actions taken to implement them. This follow-up action is a vitally important part of this program.

A copy of this report has been forwarded to the Department of Environmental Protection, the cooperating agency for the State of Connecticut. In addition, a copy of the report has also been furnished the owner, Stamford Water Company, 103 Summer Street, Stamford, Connecticut 06901.

Copies of this report will be made available to the public, upon request, by this office under the Freedom of Information Act. In the case of this report the release date will be thirty days from the date of this letter.

I wish to take this opportunity to thank you and the Department of Environmental Protection for your cooperation in carrying out this program.

Sincerely yours,

JOHN P. CHANDLER Colonel, Corps of Engineers Division Engineer

NATIONAL DAM INSPECTION PROGRAM PHASE I INSPECTION REPORT

Identification No.CT 00048Name of Dam:North Stamford Reservoir DamTown:StamfordCounty and State:Fairfield County, ConnecticutStream:Rippowam RiverDate of Inspection:25 October 1978

BRIEF ASSESSMENT

North Stamford Reservoir Dam is a concrete masonry gravity dam 350 ft. long, with a maximum height of 40 ft. An earth fill covers the downstream slope of the dam. To the right of the concrete dam there is an earth dike embankment 437 ft. long with a maximum height of 24 ft. The spillway at the right abutment has an ungated ogee crest 280 ft. long with provision for flashboards. The dam is operated as a water supply facility for the City of Stamford.

Maximum storage capacity of the reservoir to top of dike is about 2,330 acre-feet and the drainage area is 23.2 square miles. The reservoir is about 6,500 ft. long with a surface of 111 acres at spillway crest elevation. Based on both height and capacity criteria, the dam is classified as intermediate in size. Because of the threat to life and property which would result from the dam being breached, there being many homes, commercial establishments and the Merritt Parkway down-

stream, it has been classified as having a high hazard potential. Based on intermediate size and high hazard, the test flood is the full PMF.

a la We su

There is some seepage through the rock in the spillway outlet channel. Brush and several trees are growing on the earth dike. The concrete on the spillway abutment and center walls is spalling, and there are minor seeps at construction joints in the spillway overflow weir. The concrete dam, earth dike and spillway are all judged to be in generally good condition. The test flood inflow is 23,700 cfs. Of the test flood outflow of 23,800 cfs, 17,900 cfs would be discharged by the spillway, providing that the flashboards were not installed; 4,800 cfs would flow over the gravity dam and 1,000 cfs would flow over the dike. The gravity dam would be overtopped by 2.8 ft. and the dike by 0.8 ft. The facility could handle 38 percent of the test flood without any overtopping, with a 6,900 cfs. spillway discharge.

Within two years after receipt of this Phase I Inspection Report, the owner, the Stamford Water Company, should retain the services of a registered professional engineer to make further investigations, and should implement the results. These investigations should cover the potential overtopping of the dam and dike, and the present utilization of flashboards on the spillway crest, and the stability of the gravity dam.

The owner should also implement the following measures: (1) control growth on the earth dike and in the spillway discharge channel; (2) monitor seepage in the spillway outlet channel; (3) repair spalled concrete on the spillway abutment and center dividing walls; (4) institute procedures for a biennial periodic technical inspection; and (5) develop a formal surveillance and warning plan.

Frederick Esper

Vice President

This Phase I Inspection Report on North Stamford Reservoir Dam has been reviewed by the undersigned Review Board members. In our opinion, the reported findings, conclusions, and recommendations are consistent with the <u>Recommended Guidelines for Safety Inspection of</u> <u>Dams</u>, and with good engineering judgment and practice, and is hereby submitted for approval.

A CONSTR

PREFACE

This report is prepared under guidance contained in the <u>Recommended</u> <u>Guidelines for Safety Inspection of Dams</u>, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through continued care and inspection can there be any chance that unsafe conditions be detected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test Flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

PHASE I INSPECTION REPORT NORTH STAMFORD RESERVOIR DAM CT 00048

SECTION 1 - PROJECT INFORMATION

1.1 General

a. Authority

Public Law 92-367, August 8, 1972, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a national program of dam inspection throughout the United States. The New England Division of the Corps of Engineers has been assigned the responsibility of supervising the inspection of dams within the New England Region. Louis Berger & Associates, Inc. has been retained by the New England Division to inspect and report on selected dams in the State of Connecticut. Authorization and notice to proceed was issued to Louis Berger & Associates, Inc. under a letter of 24 August 1978 from Ralph T. Garver, Colonel, Corps of Engineers. Contract No. DACW33-78-C-0371 has been assigned by the Corps of Engineers for this work.

- b. Purpose
 - Perform technical inspection and evaluation of non-Federal dams to identify conditions which threaten the public safety and thus permit correction in a timely manner by non-Federal interests.
 - 2. Encourage and assist the States to initiate quickly effective dam safety programs for non-Federal dams.
 - 3. Update, verify and complete the National Inventory of Dams.

1.2 Description of Project

a. Location

North Stamford Dam and Reservoir are located on the Rippowam River in the City of Stamford, Fairfield County, in southwestern Connecticut. The dam site is situated about $\frac{1}{2}$ mile north of the Merritt Farkway Toll Road (Route 15) and just to the east of Route 137.

b. Description of Dam and Appurtenances

1. Dam and Dike

North Stamford Dam was originally constructed in 1908 as a straight concrete masonry gravity dam, spanning the main valley of the Rippowam River, with a length of about 350 ft. The top of the gravity dam is at elevation 200.* The dam has a top width of 9 ft., an upstream batter of $\frac{1}{2}$ in. per ft., and a downstream batter of 0.6 to 1. A 3 ft. deep by 5 ft. wide cutoff under the dam is indicated on the original drawings at about mid-point of the base width (Appendix B). No grouting, drainage or other foundation treatment is indicated. The height of the dam above river level is about 40 ft.

On the right abutment to the right of the main gravity section, the dam is continued as an earth dike embankment with a central concrete core wall. The dike at its junction with the gravity dam is about 14 ft. high, reducing to about a 9 ft. height some 150 ft. to the right, and then increasing to about a 24 ft. height at its extreme right, where it adjoins the spillway. The dike is curved in plan, its total length measuring about 437 ft. The dike embankment has its crest at elevation 202, 2 ft. above the top of the gravity dam. The dike embankment has a 12 ft. top width and 2 to 1 upstream and downstream slopes. The upstream slope is paved with 12 in. riprap; the downstream slope is sodded. The core wall extends from 2 ft. below the top of the dike (top of core wall El. 200) to depths of up to 26 ft., presumably to the level of firm bedrock. The concrete core wall has a 4 ft. top width, a $\frac{t_2}{2}$ in. per ft. upstream batter and a 0.4 to 1 downstream batter. The embankment upstream from the core wall is indicated to be selected rolled embankment. That downstream from the core wall was not compacted by roller.

Along the full face of the concrete gravity section, an earth fill now covers all but about the top 10 ft. of the downstream slope of the dam. This fill extends outwards from the concrete dam as a berm about 10 ft. wide, and then on a downward slope estimated at about 2 to 1. Since this fill is not shown on the original drawings, the construction

*Project datum is about 5 ft. below MSL

was probably done at a later date, presumably because of questionable stability of the original gravity dam and as a means of increasing the sliding and overturning safety factors of the structure.

2. Spillway

The spillway, as originally constructed in 1908, is located at a saddle about 650 ft. to the right of the main river channel and immediately beyond the right end of the dike section. The 150 ft. long spillway crest is an ogee-shaped concrete gravity overflow section about 23 ft. high, with a curved downstream apron shaped to discharge releases horizontally into an unlined converging channel. The spillway channel is excavated for the most part in bedrock, and the ogee overflow is founded on bedrock. Cutoff walls 3 ft. deep were excavated in bedrock at both the upstream and downstream toes of the overflow section. The crest of the spillway ogee dam is at elevation 196.0.

As originally constructed, a dike section with core wall, similar to that for the main dike, extended from the right end of the 150 ft. long spillway to contact the elevation 202 contour about 140 ft. to the right. In 1960, in order to provide additional spillway capacity, this right closure dike was modified and converted to an ogee overflow, adding about 130 ft. of spillway length. The dike fill was removed and the concrete core wall was cut down and capped with an ogee-shaped overflow section, with its crest at elevation 196.0. At the time of this modification, pipe inserts were installed into the crests of both the old and new spillways, for the purpose of anchoring 12 in. high flashboards on top of the crest. A side channel outlet was excavated to bedrock downstream from the new ogee overflow, to direct outflows into the downstream channel of the original spillway.

3. Outlets

Outlet pipes are carried through the concrete gravity dam as supply lines to the pumping station and for releases from the reservoir. Controls for these pipes are located in an outlet gate house at the upstream face of the dam, positioned about

60 ft. left of the right end of the dam. Two 30 in. pipes are carried to the pumping plant downstream from the dam, regulated by 30 in. día. gate valves near the bottom of the gate house well. A 36 in. dia. outlet bypass pipe leads from the reservoir to an outlet channel downstream from the dam. This is a low level reservoir outlet, with invert at about elevation 160, controlled by a 30 in. dia. gate valve in the bottom of the gate house well.

A high level intake was later added to the facility, which draws water from near the top of the reservoir through a long flume hung from the upstream face of the gravity dam. The flume leads to a 36 in. dia. intake pipe through the left abutment. This pipe feeds a micro-filter installed in a filter house high on the left abutment. A blowoff valve from the 36 in. dia. pipe leads to the small outlet canal below the dam.

c. Size Classification

North Stamford Dam is about 40 ft. high above downstream river level, impounding a storage of 1,570 acre-ft. to spillway crest level and a maximum of about 2,330 acre-ft. to the top of the earth dike. In accordance with both the height and capacity criteria given in <u>Recommended Guidelines</u> for Safety Inspection of Dams, the project falls into the <u>intermediate</u> category and therefore is classified accordingly.

d. Hazard Criteria

A breach failure of North Stamford Dam would release water down the Rippowam River, which traverses through major populated areas of Stamford. There are as many as 20 homes near river level along the river about $\frac{1}{2}$ mile below the dam, a major interchange of the Merritt Parkway is located about 1 mile downstream, and there are many homes and commercial establishments along the river reach south of the Parkway. The North Stamford Reservoir Dam has therefore been classified as having a <u>high</u> hazard potential in accordance with the <u>Recommended Guidelines for</u> the Safety Inspection of Dams.

e. Ownership

North Stamford Reservoir Dam is owned by Stamford Water Company.

f. Operator

Mr. Glenn Thornhill Chief Engineer Stamford Water Company 103 Summer Street Stamford, CT 06901

Telephone: (203) 324-3163

g. Purpose of Dam

The dam impounds a reservoir used as a source of municipal water supply for the City of Stamford.

h. Design and Construction History

Information obtained from the files of the State Department of Environmental Protection, Water Resources Division, and from Stamford Water Company, indicates that the dam, then known as Mill River Reservoir Dam, was built about 1908. The design by Albert E. Hill, Consulting Engineer, of New Haven, CT, included a concrete gravity dam 350 ft. long at the left abutment, an earth embankment with concrete core wall 437 ft. long, a concrete gravity ogee spillway 150 ft. long, and an earth embankment section with concrete core wall 140 ft. long at the right abutment. The top of the concrete dam was 4 ft. above the spillway crest and the top of the embankment sections were 6 ft. above it.

During the storm of October 15-17, 1955, the outflow exceeded the spillway capacity and the concrete dam was overtopped by $2\frac{1}{2}$ in. Subsequent studies by Clarence Blair Associates, Inc., Civil Engineers, of New Haven, CT, resulted in a recommendation to extend the spillway an additional 126 ft. towards the right abutment. Construction was carried out in 1961; the State's Certificate of Approval dated October 2, 1961, notes that, due to the omission of two 2 ft. piers, the effective length of the spillway addition is 130 ft., giving a total spillway crest length of 280 ft. 12 in. high flashboards were also installed on the crest of the spillway at that time.

i. Normal Operational Procedure

There are no formal operational procedures. According to the Chief Engineer, the reservoir is normally kept as full as possible. The 12 in. high flashboards are installed in May and removed in October each year. If a storm is anticipated, the reservoir is drawn down as much as 4 ft. below normal (to elevation 192). The 30 in. dia. blowoff gate is used for this evacuation.

1.3 Pertinent Data

a. Drainage Area

The drainage area above the North Stamford Reservoir is about 23.2 square miles, being about 11 miles long and an average of about 2 miles wide. The area has a maximum width of about 4 miles at its mid-length. Above North Stamford Reservoir Dam and below Laurel Reservoir Dam, located about 2.8 miles upstream, the sub-drainage area on the Rippowam River is about 9 square miles; above Laurel Dam and below Mill River and Trinity Dams, which are about 3.6 miles farther upstream, the sub-drainage area on the Mill River is about 9.5 square miles; above Trinity Dam, the subdrainage area is 0.62 square miles; above Mill River Dam on the Mill River the sub-drainage area is 4.07 square miles. A sketch of the area showing the location of reservoirs and streams is illustrated on Sheet D-1. Appendix D.

The topography of the drainage areas are generally wooded, rolling terrain with occasional small pondages and swampy areas along the stream courses. The rim of the basin rises from between 150 to 200 ft. above the stream valley. The longest water course upstream from North Stamford Dam measures about 13.3 miles, with an average slope of about 40 ft. per mile.

No major developments are contained within the drainage area, but the terrain is moderately dotted with homes and small communities.

b. Discharge at Damsite

1. Outlet Works Conduit

The 36 in. dia. low-level outlet pipe has its invert at about elevation 160, providing a head of about 36 ft. with reservoir at spillway crest level. The discharge at this head is estimated to be about 195 cfs. At this discharge, reservoir evacuation would be at the rate of about 16 acre-ft. per hour. At spillway crest level, it would require about 6.5 hours to lower the level of the reservoir 1 ft., not considering inflow in the interim. As indicated on Sheet D-2, to evacuate the reservoir to Elevation 165, considering no inflow in the interim, would entail a period of about 4.9 days. With an average inflow of about 10 cfs. into the reservoir during the interim, a period of about 5.2 days would be needed for this evacuation. Evacuation of the reservoir in case of a flood would therefore be practically impossible.

An outlet discharge curve is shown on Sheet D-2, Appendix D.

2. Maximum Known Flood at Damsite

During the storm of October 15-17, 1955, the runoff exceeded the spillway capacity, and water $2\frac{1}{2}$ in. deep flowed over the top of the main dam. The flashboards were not installed on the spillway. The estimated discharge over the dam and spillway was 4,400 cfs. Neither the inflow into North Stamford Reservoir nor the state of outflows at the upstream reservoirs were determined.

3. Spillway Capacities

A spillway discharge curve has been prepared for the spillways as they presently exist. A discharge curve for outflows through the spillways and over the dam and dike are shown on Figure 1, Sheet D-3, Appendix D. Computations are shown on Sheet D-4. Pertinent discharges are as follows:

a.	Spillway capacity at top of concrete	
	dam E1. 200 -	7,350 cfs
Ъ.	Spillway capacity at top of earth	
	dike El. 202 -	14,600 cfs
c.	Spillway capacity at test flood	
	surcharge El. 202.7 -	17,500 cfs
d.	Total Project Discharge at Test	
	Flood Surcharge El. 202.7 -	23,000 cfs

4. Flashboarded Spillway Capacity

With the intent of increasing the reservoir yield by capturing and storing runoffs above spillway crest level, 12 in. high flashboards are installed on the spillway crest each spring and removed in the fall. The flashboards are held in place by pipe standards inserted in holes in the crest.

With the flashboards in place, the capacity of the spillway is accordingly reduced. A discharge curve for the spillway with 12 in. flashboards installed is shown on Figure 1, Sheet D-3. It will be noted that, with the reservoir level at the top of the gravity dam, elevation 200, the spillway discharge will be about 4,800 cfs, or 65 percent of that for the unobstructed crest. With the reservoir at the top of the earth dike, elevation 202, the spillway discharge will be about 10,400 cfs. or 70 percent of that of an unobstructed crest.

c. Elevations (Ft. above project datum, which is 3.84 ft. above MSL datum)

1. Streambed at centerline of dam - 160 2. Maximum tailwater - Not computed 3. Upstream invert of low-level outlet pipe - 160 4. Recreation pool - Not applicable 5. SECTION 2 - ENGINEERING DATA

2.1 Design

The dam was designed by Albert E. Hill, Consulting Engineer, New Haven, CT, in 1908. It was then known as Mill River Reservoir. Copies of the General Plan, Sections and Gatehouse drawings are included in Appendix B.

The fill at the downstream face of the gravity dam is not shown on the original drawings. It was presumably added later, on the basis that the structural stability of the dam was in question, and for the purpose of adding a safety factor against sliding and overturning. No documentation of design considerations toward this end have been retrieved.

The spillway proved inadequate to pass the outflow from the October 15-17, 1955, storm and the dam was overtopped by $2\frac{1}{2}$ in. A 130 ft. long spillway extension was designed by Clarence Blair Associates, Inc., Civil Engineers, New Haven, CT, in 1960. This firm also designed the 12 in. high flashboard installation at that time. Copies of the General Plan, Details, "As Built" and Flashboards drawings are included in Appendix B.

2.2 Construction

North Stamford Reservoir Dam is said to have been constructed in 1908-09, but it is not known by whom. No records have been found showing when the fill modification was added to the downstream face of the gravity dam. The 130 ft. extension of the spillway to the west of the original 150 ft. spillway was constructed in 1960-61.

2.3 Operation

The facility is operated as a water storage and supply reservoir by Stamford Water Company. There are no formal operating procedures.

2.4 Evaluation

a. Availability

The lack of in-depth engineering data did not allow for a definitive review. Therefore, the adequacy of this dam could not be assessed from the standpoint of reviewing design and construction data, but is based primarily on visual inspection, past performance history and sound engineering judgment.

b. Adequacy

The lack of in-depth data, such as engineering properties of the foundation and embankment materials, precludes any definitive review and assessment of the adequacy of this dam.

c. Validity

The validity of the engineering data acquired covering the dam and spillway structures is considered acceptable and is not challenged.

SECTION 3 - VISUAL INSPECTION

3.1 Findings

a. General

The visual inspection of North Stamford Reservoir Dam took place on 25 October 1978. At that time, the reservoir was about 1 ft. below spillway crest level.

The drawings show that the gravity dam, dike core wall and spillway crest are all carried down to bedrock foundation. This bedrock is not in evidence except at the spillway channel where it is well exposed on the right abutment. It is a granitoid gneiss, essentially massive and unweathered. There is a well developed high angle joint system in the rock at the spillway, striking more or less perpendicular to the spillway centerline. Minor seeps were noted from some of the vertical joints near the spillway crest.

b. Concrete Gravity Dam

The main concrete gravity dam has a 30 ft. high fill against its downstream face and only about 10 ft. of the dam was visible. The original concrete masonry facing and the downstream coping at the top of the dam have been resurfaced with gunite, and the original condition of the concrete before resurfacing could not be determined. From all appearances, that portion of the dam which was visible is in satisfactory condition.

The earth fill on the downstream face of the dam appeared in excellent condition, with no evidence of slope movement, boils, drainage or seepage (Appendix C, Photo Nos. 1 & 2). As noted in Section 1.2b, it is speculated that this fill was added to shore up the dam against sliding and overturning forces. Although the surface of the fill is sodded and appears quite stable, it is not believed that it would remain stable in the event of an overtopping of the dam, and that it would be easily eroded and washed away by any appreciable volume of overtopping flow. Information was not available whether damage was sustained to this fill during the 1955 flood, when the dam was overtopped by 2^{1}_{2} in.

The intake flume, which leads to the high level outlet pipe to the microfilter house on the left abutment, is hung along the upstream face of the concrete dam by steel straps connected to the crest of the dam.

c. Dike Section

The earth dike on the right abutment appears to be in good condition. The upstream slope is covered with rock riprap generally not exceeding 12 in. in size. The riprap slope appears stable and in good condition. Several trees are growing on the upstream slope, two of which are about 12 in. in diameter (Appendix C, Photo Nos. 3 & 4). A light brush growth covers the downstream slope and grass is well established on both the crest and downstream slope. The downstream slope appears stable and shows no evidence of seepage or boils. Since this dike is at a higher level on the abutment than the main river channel to the left and the spillway channel to the right, it would not be expected that seeps would exit along its toe.

d. Spillways

The concrete in the ogee overflow sections of the spillway is in generally fair to good condition, with some cracking and spalling evident in the old spillway section and with small seeps and efflorescence issuing from some of the joints (Appendix C, Photo Nos. 5, 6, 7 & 8). Spalling has occurred at the top and along the base of the guide wall which was the original right training wall of the old spillway (Appendix C, Photo No. 8). Some minor seepage was noted below the concrete ogee of the new spillway section, emanating from the nearly vertical joints in the bedrock. Some slight seepage appeared below the old ogee section (Appendix C, Photo No. 9). The collective seepage was in evidence at the lower end of the spillway outlet channel near the bridge about 200 ft. downstream, and was estimated to be between 40 and 60 gpm.

The outlet channel downstream from the spillway is either excavated or scoured to exposed bedrock (Appendix C, Photo Nos. 11 & 12). The side channel below the new spillway crest is excavated to bedrock and low concrete walls protect the slope on the lower side where top of bedrock was at a low level. The bridge downstream from the spillway outlet channel has about a 40 ft. wide by 14 ft. high arched waterway and may form a constriction at lower flows and be overtopped for higher flows, to produce some backwater effect; however, it does not appear that such backwater would affect flow over the spillway crest, even for a major flood event.

Although no flashboards were on the spillway crest at the time of the inspection, insert holes were visible along the crest, spaced at about 6 ft. centers. A cable was strung across the crest between walls, presumably as a safety precaution for workers when the flashboards are installed or removed. No operating bridge deck spans the spillway crest, and there is no means of access to the boards except along the crest. It is not known whether the flashboards can be removed when water is against or overtopping them. It is believed that, in the event the boards are being overtopped, there would be no practical means of effecting their removal until the reservoir receded below spillway crest level.

The use of flashboards on the spillway crest will considerably reduce the ability of the project to handle larger magnitude floods, as is noted in Section 1.3b. Once installed, it does not appear that they could be quickly removed in anticipation of a severe storm. Sudden removal while the reservoir level was near their top could result in a larger flood wave downstream than would be the case for gradually increasing spills over the ungated crest.

e. Reservoir Area

, 15. 30a - 20a - 10a - 10a

The shoreline upstream from the dam appears to be stable on both left and right abutments. The shoreline along the left reservoir bank for a distance of approximately 500 ft. has hand-placed stone protection. The right shoreline appears to be quite stable with good tree growth and no evidence of slides or movements.

No homes are built close to shoreline at this reservoir and there are no constraints on reservoir rise within the surcharge storage space. Lakeside Drive traverses along the left side of the lower portion and crosses over at about mid-length of the reservoir. The reservoir waterway under this crossing was not examined to determine whether it would constrict flow through the pond at high inflows. It is not known whether this roadway crossing would be inundated by high reservoir levels.

f. Downstream Channel

The waterway under the bridge 200 ft. downstream from the spillway has an opening of about 400 sq. ft., with its bottom at about elevation 165 to 170. Approximate computations show that spillway discharges in excess of about 7,500 cfs will be constricted and the bridge will be overtopped. It is not expected that backwater because of the constriction will be of such height as to drown out the spillway crest.

If the bridge is overtopped, several adjacent homes will be threatened. About ¹: mile downstream there is a housing development of up to 20 homes which appear to be within the flood plain for high outflows from the reservoir. The Merritt Parkway and a major interchange are close to river level about 1 mile below the dam. The Rippowam River crosses under the Merritt Parkway and traverses through the City of Stamford downstream.

The river from the dam to the vicinity of the Merritt Parkway is confined and little valley storage will be available at river stages up to a 15 ft. depth. The river valley beyond the highway opens up somewhat, but valley storage does not appear to be large. It is believed that a flood wave owing to a major breach at North Stamford Dam would persist, with but little diminishing discharge, until tidewater level is reached.

3.2 Evaluation

The visual inspection of the dam and its appurtenant structures revealed sufficient information to permit an assessment to be made of those features affecting the safety and stability of the structure. The North Stamford Reservoir Dam and appurtenant works are judged to be in good condition.

SECTION 4 - OPERATIONAL PROCEDURES

4.1 Procedures

The North Stamford Reservoir Dam is operated by personnel of the Stamford Water Company, who are stationed at the filter plant immediately below the dam. Reservoir operation entails mainly the release of stored water from the reservoir as water supply needs warrant. 12 in. high flashboards are fixed to the spillway in May and removed in October each year. The reservoir is normally maintained as full as possible, but is said to be drawn down as much as 4 ft. below normal storage level in anticipation of a storm, by using the 30 in. dia. blowoff gate. No documented operating procedures have been prepared.

4.2 Maintenance of Dam

Periodic maintenance of both the concrete structures and the embankment section of the dam is carried out by the Water Company. No documented maintenance instructions have been prepared.

4.3 Maintenance of Operating Facilities

All gate values are said to be serviceable and inspected regularly. No specific maintenance program is in effect.

4.4 Warning System

No warning system is in effect at this dam.

4.5 Evaluation

The North Stamford Reservoir Dam has simple operating devices and therefore requires no detailed operating procedures. It is recommended, however, that these procedures should be formalized and put into writing. Maintenance involves periodic growth removal from the dam, repair of damaged concrete structures, and surveillance regarding seeps, slope damage, animal burrows, etc. A formal warning and emergency evacuation system should be developed.

SECTION 5 - HYDRAULIC/HYDROLOGIC

5.1 Evaluation of Features

a. General

The drainage area above North Stamford Reservoir is about 23.2 square miles. As noted in Section 1.3a, the Mill River tributary of the Rippowam River upstream from North Stamford Reservoir has several major dams and reservoir storages along its course, which will considerably affect the runoff characteristics of the basin. It was decided that the configurations, slopes and runoff influences are sufficiently different for the various sub-areas of the tributaries above North Stamford and Laurel Reservoir to warrant a more detailed hydrologic analysis on the basis of each impoundment and associated sub-basin area.

The general topographic characteristic of the basin is best described as rolling terrain, for which the March 1978 Preliminary Guidance Report from the NED gives a suggested CMS value for a 23 square mile drainage area of about 1,400 CSM. On this basis the inflow into North Stamford Reservoir would approximate 31,500 cfs. The more detailed analysis discussed below was undertaken to verify this approximation or to ascertain an inflow value based on the more specific basin criteria.

The project is basically a low surcharge storage - high spillage project. Part of the dam is a concrete gravity structure and part is an earth embankment with concrete core wall.

b. Design Data

No design data was recovered for this dam.

c. Experience Data

As noted in Section 1.3b, the estimated reservoir outflow through the spillway and over the concrete gravity dam during the October 1955 storm was estimated at 4.400 cfs. No estimate of the reservoir inflow was recorded.

d. Visual Observations

No evidences which would indicate possible high flows through the reservoir or in the downstream channel have been noted or recorded.

e. Test Flood Analysis

1. Drainage Areas

The 23.2 square mile basin drainage area above North Stamford Reservoir was divided into four sub-areas for the hydrologic and hydraulic analysis. A flood hydrograph was prepared for each sub-area and flood routings were conducted where flows passed through the reservoirs sited on the streams. These sub-areas, noting locations, drainage area size, water course length and river slope, and the sizes of the impoundments are delineated and tabulated on Sheet D-1 in Appendix D.

2. Reservoir Areas and Capacities

At normal storage level, North Stamford Reservoir impounds about 1,570 acre-ft. For determining reservoir surcharge capacity, planimetered areas were taken from contours delineated on the USGS 2,000 ft. per in. quadrangle sheets. Area capacity curves for North Stamford Reservoir are shown on Figure 2, Sheet D-5, Appendix D. Computations for area-capacities are shown on Sheet D-6.

For determining surcharge storages at the upstream reservoirs for use in flood routings, areas were similarly planimetered and storages computed. Laurel Reservoir areas and capacities are shown on Sheets D-6 and D-7; Trinity Reservoir and Mill River areas and capacities are shown on Sheets D-6 and D-8.

3. Outflow Discharge Capacities

For use in the flood routings of the inflows through the various impoundments, discharges were computed through the spillways and over the tops of the dams on the several reservoirs upstream. These are shown for Trinity Dam on Sheet D-4; and for Laurel and Mill River Dams on Sheet D-9. Spillway and dam overtopping capacities for North Stamford Dam are shown on Figure 1, Sheets D-3 and D-4.

4. Test Flood

North Stamford Reservoir Dam is about 40 ft. high and impounds about 2,300 acre-ft. to top of dam. As noted in Section 1.2c, it is therefore categorized in the intermediate classification. As noted in Section 1.2d, the hazard potential is classified as high. The <u>Recommended Guidelines for Safety Inspection</u> of <u>Dams</u> requires that for hydraulic evaluation the dam adequacy be tested for a full PMF.

5. Precipitation Data

Precipitation data was obtained from Hydrometeorological Report No. 33, which for the southwestern Connecticut area approximates 24.5 in. of 6 hour point rainfall over a 10 square mile area. This value was reduced by 9 percent to apply to a 23.2 square mile total area, and by an additional 19 percent to conform to the area fit reduction criteria. The 6 hour rainfall was distributed into $\frac{1}{2}$ hour incremental periods as suggested in COE Publication EC1110-2-1411. Infiltration losses of 1 in. during the first hour and 0.2 in. during each succeeding hour were assumed. The net rainfall excesses for developing the runoff hydrographs are shown on Sheet D-10, Appendix D.

6. Drainage Basin Criteria

In order to evaluate the sub-drainage basin characteristics for lag and transport times needed to develop the sub-basin hydrographs and upstream reservoir outflow patterns, a river profile of the streams and reservoirs was prepared from the USGS quadrangle sheets. This profile is shown on Fig. 3, Sheet D-11. The incremental stream lengths for each sub-drainage basin were evaluated for time of concentration, lag time, and resulting flow velocity. The resulting values are recorded on Sheet D-12, Appendix D. Time-of-concentration and lag times were selected so as to produce a weighted average equivalent flow velocity within the various sub-basin streams of about 0.75 ft. per second, and a reservoir outflow transport velocity between reservoirs of about 1.5 ft. per second.

7. Selected Unitgraph

The unitgraph used for developing the various sub-basin inflow hydrographs is the curvilinear adaptation of a triangular unitgraph, shaped as described in <u>Design of Small Dams</u>. These unitgraphs for the variously adopted time-to-peak values selected for the differing sub-basins are shown on sheets D-13 and D-14.

8. Runoff Hydrographs and Flood Routings

Runoff hydrographs were prepared for each of the sub-areas selected. After the appropriate routings through Trinity, Mill River and Laurel Reservoirs, the runoff hydrographs were combined to form the inflow hydrograph into North Stamford Reservoir. This inflow hydrograph was then routed through North Stamford Reservoir to ascertain reservoir outflows and surcharge storage encroachments.

Printout sheets of the HEC-1 computer solution for PMF, 0.5 PMF and 0.35 PMF flood events are included in Appendix D.

The results of these routings are summarized below:

Flood Magnitude		Maximum Outflow from Reservoir cfs	Maximum Spillway Outflow * cfs	Maximum Outflow over Gravity Dam ofs	Maximum Outflow over Dike cfs
Full PMF	202.80	23,800	17,900	4,800	1,000
0.5 PMF	200.85	. 11,000	10,200	800	5
0.35 PMF	199.80	. 6,900	6,900	0	n

For the full PMF, with a 2.8 ft. overtopping of the gravity dam (Elevation 200), approximately 2,500 acre-ft. of the runoff would spill over the gravity dam, during a 13-hour period. For the 0.5 PMF, the 0.85 ft. overtopping would discharge about 360 acre-ft. during a 5-hour period.

*Assuming flashboards not installed.

On Fig. 4, Sheet D-15, the relationship of total outflow discharge to the percentage of the PMF inflow is plotted. It is indicated that a 0.38 PMF event could be accommodated before the gravity dam would be overtopped.

In the event that the gravity dam and earth dike were raised to about elevation 204, all inflows for floods up to the PMF could be handled through the spillway, with no threat of damage to the facilities below the dam or to an overtopping of the dam or dike.

- f. Dam Failure Analysis
 - 1. Breach Failure of Gravity Dam

Since an overtopping of the gravity dam could wash away the fill at the toe of the dam, its resistance against sliding and overturning could be reduced and a failure of a portion of this dam could conceivably occur. With the water at the top of the dam, a breach outflow as suggested in the NED March 1978 Guidance Report, with an assumed failure width of about 100 ft. would produce a flood wave of about 42,500 cfs. (See computations on Sheet D-16). The spillway discharge of 6,900 cfs. added to the breach outflow would give a discharge downstream of about 49,400 cfs. The stage-discharge for the river reach immediately before the breach shows that a depth of less than 10 ft. would prevail down river above the Merritt Parkway crossing. After the breach, the stagedischarge for a flow of about 50,000 cfs. shows that this depth would increase to more than 25 ft. At this depth, the valley storage will capture about 1,000 acre-ft. of the outflow, somewhat diminishing the flood wave downstream. However, more than 20 homes and several commercial establishments are well within the flood plain for such a discharge. Delineated on Figure 4, Sheet D-17 (Quad sheet graphic), is the approximate area which could be flooded by a breach failure of the concrete dam.

SECTION 6 - STRUCTURAL STABILITY

6.1 Evaluation of Structural Stability

a. Visual Observations

The field investigations of the earth embankment revealed no significant displacements or distress which would warrant the preparation of slope stability computations based on assumed soil properties and engineering factors. Data on the engineering characteristics of the embankment material is lacking. Depth of cutoff wall is not known.

The placing of an earthfill at the toe of a concrete gravity dam is unusual. This points to the premise that, at some later time after the dam was constructed, the fill was added because of concern about stability of the dam. No engineering data has been recovered in this regard, however, and it is not known with certainty what prompted the addition.

The downstream fill reduces sliding and overturning forces on the concrete dam and ensures a higher factor of safety for the structure. A flow of any magnitude over the dam would in all probability wash out most of the earthfill at the toe, and thereby threaten the stability or bring about the failure of the structure.

Specific items noted during the investigation which should be corrected and/or continually observed are listed in Section 7.3.

b. Design and Construction Data

No plans or calculations of value to a stability assessment are available for this dam.

c. Operating Records

There are no formal operating records for this dam.

d. Post Construction Changes

The results of the field inspection and a check of the available records produced no evidence of changes which might adversely influence stability of the embankment. Lengthening of the spillway in 1961 increased the hydraulic capacity.

e. Seismic Stabilíty

F.

The dam is located in Seismic Zone No. 1 and, in accordance with recommended Phase I guidelines, does not warrant seismic analyses.

Ē,

SECTION 7 - ASSESSMENT, RECOMMENDATIONS & REMEDIAL MEASURES

7.1 Dam Assessment

a. Condition

On the basis of the Phase I visual examination, the North Stamford Reservoir Dam appears to be in good condition and functioning adequately. The deficiencies indicate that some additional routine maintenance is desirable.

b. Adequacy of Information

The lack of in-depth engineering data did not allow for a definitive review. Therefore, the adequacy of this dam could not be assessed from the standpoint of reviewing design and construction data, but is based primarily on visual inspection, past performance history and sound engineering judgment.

c. Urgency

The recommendations enumerated below should be implemented by the owner within two years after receipt of the Phase I Inspection Report. The remedial measures should be implemented within one year.

d. Need for Additional Investigation

The visual inspection identified a number of potential problems. Additional investigations are required as recommended in Para. 7.2.

7.2 Recommendations

It is recommended that the owner should retain the services of a competent registered professional engineer to make investigations and studies of the following items, and, if proved necessary, design appropriate remedial works:

- 1. Determine whether the dam and dike should be raised to prevent overtopping during severe floods.
- 2. Review the use of flashboards on the spillway crest and determine the feasibility of either abandoning their use altogether, or of substituting gates which could be operated in anticipation of, or for management of, flood inflows.
- 3. Investigate the stability of the gravity dam.

7.3 Remedial Measures

- a. Operation and Maintenance Procedures
 - 1. Brush growth on the earth dike should be removed and controlled on a regular basis.
 - 2. A program for gradual removal of trees from the earth dike should be adopted.
 - 3. Brush growth in the riprapped slope in the right side of the spillway discharge channel should be cleaned out.
 - 4. Seepage quantity and clarity in the spillway outlet channel should be monitored periodically during periods of high reservoir level (but without any discharge over the spillways), and at least once a year. The downstream toe of the embankment should be checked for seepage biannually.
 - 5. Spalled concrete on the downstream spillway abutment and center dividing walls should be repaired to prevent further deterioration.
 - Procedures for a biennial periodic technical inspection of the dam, dike and appurtenant works should be instituted.
 - 7. A formal surveillance, flood warning and emergency evacuation plan should be developed.

7.4 Alternatives

The only practical alternative to those discussed in Para. 7.2 is to increase spillway capacity, either by lengthening the sill at the present elevation, or by providing movable gates.

VISUAL EXAMINATION OF	OBSERVATIONS AND REMARKS
Foundation	Apparently on bedrock. Foundation treatment unknown. Earth fill covers d/s face.
Surface cracks, concrete surfaces	Visible surfaces repaired with gunite in 1962 and 1977. Minor cracking evident, no seepage observed.
Structural cracking	Nothing of consequence evident.
Vertical and horizontal alignment	Good .
Monolith joints	No seepage evident.
Construction juints	No seepage evident.

February 28, 1961

Mr. Merwin E. Hupfer Senior Sanitary Engineer Mater Resources Commission State Office Building Hartford 15, Conn.

Re: North Stamford Dam =17 Stamford Water Co.

Dear Mr. Hupfer:

On Feb. 20, 1961, with Roger C. Brown, I inspected foundation and work to date on the spillway extension for the above captioned dam.

Ledge foundation is massive, renerally fine grained bluegray granite, with occasional pinkish pegamatite dikes a few inches thick. Joints, both horizontal and vertical, are thin, tight, and roughly at right angles. I noticed no wide fault clanes that might be water conveying.

Old concrete in core wall is of very good quality.

Enclosed are photographs for record purposes. One shows a man standing at a joint in the old core wall where there is a small leak. It is proposed to pressure grout this rock seam and joint in old concrete after base concrete has been poured.

The project is proceeding satisfactorily insofar as the Cormission is involved and foundation is approved for youring of concrete.

Yours very truly,

A-Care -J. W. Cone

JNC/dr Enc: 6 photos cc: Mr. Romer C. Brown

North Stamford Dam

The Certificate of Approval dated September 19, 1961 was supercedad by the attached Certificate dated October 2, 1961 in order to <u>remove</u> the incorrect 126' opillway length. The original plans showed a 160' spillway with 2 - 2 piers, giving an effective length of 126'. The piers were not constructed, giving an effective length of the entire 130'.

STATE OF CONNECTICUT WATER RESOURCES CONVISSION Room 317, State Office Deficient Hartford, Connecticut

CERTIFICATE OF APPROVAL

Date Oct. 2, 1961

e

To: Stamford Water Company

103 Summar Streat

Stamford, Connecticut

NAME OF STRUCTURE: North Stanford Dam

This is to certify that the following construction work:

Lengthening of spillway and installation of 12-inch collapsible

type flashboards at the subject dam in accordance with "as-built"

plans consisting of two sheets marked M-754 and M-688 respectively,

certified on September 14, 1961 to show the spillway and flashboards

substantially as constructed, and prepared by Clarence Blair Associates,

Inc., an approved set of which is enclosed,

on your property	on Rippowan River
in the Town (s) of _	Stanford
for which construction	on permit was issued December 7, 1960 , has been
completed to the sat:	isfaction of this Commission and that such structur
is approved as of dr	te of this Certificate.

WATER RESOURCES COMMISSION

BY: Millian S. Wise, Director

Enclosure: Plans

Note: The owner is required by law to record this Cartificate in the land records of the town or towns in which the dam, dike or similar structure is located.

June 21, 1972

Mr. Arthur Ball, President Stamford Water Company 103 Summer Street Stamford, Connecticut 06901

> Re: North Stamford Reservoir Laurel Reservoir Stamford

Dear Mr. Bell:

The undersigned inspected the subject dams on June 16, 1972.

I had the pleasure of meeting your engineer, Mr. Charles MoInerney, at the Morth Stamford Reservoir site. As mentioned to him, your company should be commanded for its maintenance program at these two sites. Both dams appeared to be in good condition with the exception of minor maintenance requirements.

Shall tree growth that has started on the dam at the North Stamford Reservoir should be removed. A program of woodchuck control must be subpled to prevent burrowing of holes into the embankments.

At Laurel Reservoir the woodchuck population is even greater. The bruch growth found on the dam is not objectionable from the stanopoint of the cafety, however its removal might discrutage woodchucks from the state. When thetericration of concrete in various areas on top of the dam are not of a sorious natures but from the standpoint of good maintenance and applearance should be repaired.

Hay we hear of your intentions in regard to there recters.

Very traly groups,

Victor F. Galguesti Supt. of Dim Malmienence

Re: Safety of Dams

Attention: Mr. William M. Conron, President

Gentlemen:

At your request we have made inspections of the dams impounding the storage reservoirs of your Company.

There are four of these dams, all on Mill or Rippowan River or some of its tributaries. The four dams will be discussed in the following order.

- 1. North Stamford
- 2. Laurel
- 3. Mead Pond
- 4. Trinity Lake

1. <u>North Stamford Dam</u> is the most southerly of the four dams and is located about 3,000 feet northerly of the Merritt Parkway. It was constructed in 1908-1909 and impounds North Stamford Reservoir, covering an area of 114 acres and having a total capacity of 512 million gallons. Spillway level of the dam is 196 feet above mean high water in Stamford Harbor.

The easterly portion of the dam, about 420 feet in length is \tilde{c} gravity section dam of concrete, founded on a ledge rock, with a maximum height of about 65 feet. The top of the dam is four feet above the spillway level. The downstream face of the gravity section is covered by earth embankment up to about 10 feet below the top of the dam. From the westerly end of the gravity section for about 410 feet westerly, the dam is of earth embankment with a heavy concrete corewall founded on ledge rock. The earth embankment has a slope of one vertical on two horizontal on both upstream and downstream sides, the upstream side being covered with a 12 inch layer of stone riprap.

Stamford Water Company

Westerly of the embankment and corewall section is the original spillway, 150 feet long, consisting of a gravity ogee section of concrete founded on ledge rock. Maximum height of the spillway section is about 27 feet.

Westerly of the original spillway, an additional spillway 190 feet in length was constructed in 1960 and 1961. This is a gravity overflow section of concrete placed on and over the original concrete corewall in this section. Overflow level is the same as on the original spillway. Total length of spillway is now 280 feet.

Certified "as built" plans of the original dam show that the design of the gravity sections included ample factors of safety. The corewall section used in the embankment is unusually heavy.

The spillway, as presently constructed, has an estimated discharge capacity of approximately 7900 cubic feet per second at full depth of 4 feet. The total drainage area tributary to this dam is 21.49 square miles, so the spillway has a discharge capacity of 368 cubic feet per second per square mile. The estimated peak discharge at this dam during the flood of 1955, the flood of record in this vicinity, was 200 cubic feet per second per square mile.

Based on inspection of the plans and of the structure itself, it is my opinion, that North Stamford Dam is conservatively designed and is entirely safe. Some surface disintegration and spalling off of sharp corners of the concrete is evident on the exposed surface of the gravity section of the dam. This surface deterioration is unsightly but in no way affects the safety of the structure.

2. Laurel Dam is north of North Stamford Reservoir and is about 6000 feet southerly of the New York State line. It was constructed in 1923-24 and impounds Laurel Reservoir, covering an area of 265 acres and having a total capacity of 2253 million gallons. Spillway level is 310 feet above mean high water in Stamford Harbor.

The dam is a gravity section concrete structure, founded on ledge rock, about 1680 feet in length with a maximum height of 63 feet. The downstream face of the dam is covered with embankment up to a level about 10 feet below the top of the dam. At the westerly end of the main dam, there is a concrete spillway section 100 feet long and 5 feet deep. Maximum height of the spillway section is about 15 feet. Westerly of the spillway section there is about 120 lineal feet more of gravity section dam with embankment. The spillway has an estimated "Ischarge capacity" of approximately 3700 cubic feet per second at full depth of 5 feet. The total dramage area tributary to Laurel Dam is 13,43 square miles. The spillway then has a discharge capacity of 275 cubic feet per second rul-

Attention: Mr. Victor F. Galgowski Superintendent of Dam Maintenance Water and Related Resources

Re: Latrei Roservois Dam

Dear Mr. Galgowski:

In accordance with your request, we have examined the subject dam in order to ascertain its structural soundness and stability. Prior to our visit to the site, we went to the Town Hall offices and attempted to obtain any structural drawings of the subject installation. We were advised that no plans were on file and that the Town officials had no knowledge whatsoever of the construction of the dam.

Upon visiting the site, we found the structure to be a combination concrete and earthen dam containing two major spillways. The overall length of the dam and spillways is approximately 875 feet. In addition, there are two valve houses in the vicinity of the concrete portion of the dam; one at the end, and the other approximately at the center. The concrete portion of the dam has an earthen face with approximately a one on one slope. Said slope is fully covered with vegetation.

The earthen portion has a downstream slope of approximately one on three, and the back of the dam is earth with boulders and loose riprap at a slope of approximately one on two. The spillway sections are approximately 125 feet in length separated by reinforced concrete cheek walls. Atop each spillway there are timbers which can be used to adjust the level of the reservoir. The spillways are shaped generally in accordance with the typical section on the enclosed drawing. Said drawing indicates the approximate layout of the entire structure. State of Connecticut Page 2

In the earthen section there was no evidence of leaks, boils, or fissures: and, in general, the vegetation seems to be well maintained. Atop the concrete section of the dam in the vicinity between the gate houses, the top of the concrete is badly spalled in many areas and should be pointed up. The masonry spillways have several cracks which also should be cleaned out and pointed up. These things I would consider in normal maintenance and perhaps should be taken care of prior to the freezing weather this winter.

In general, it is our considered opinion that <u>Laurel Reservoir</u> Lam is in ... excellent condition and if maintained as stated above should serve the community for many years to come.

Should you have any questions regarding this report, feel free to contact me.

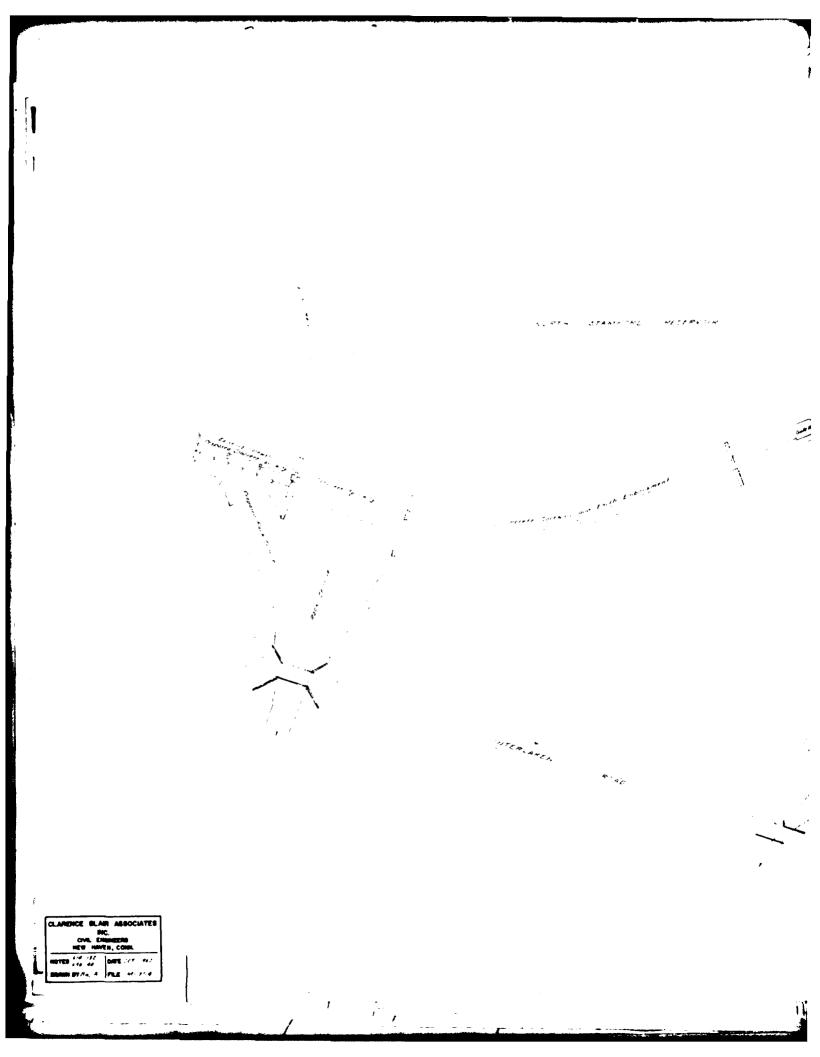

Respectfully submitted,

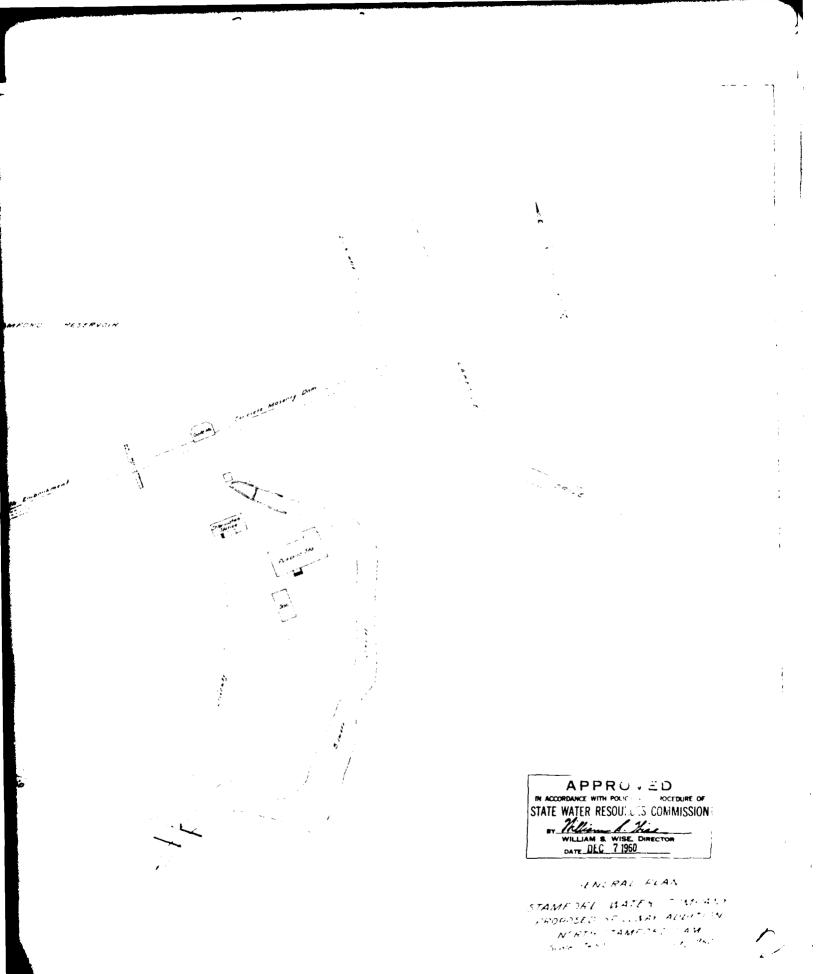

S. E. MINOR & CO., INC.
