# **AEROSOL MEASUREMENTS AT AN OPTICAL PROPAGATION SITE ON THE OUTER HEBRIDES**

## **INTRODUCTION**

The United States, Great Britain, Canada, and Australia are each involved in research on optical propagation over water. Through Action Group 9, Subgroup J, of the Technical Cooperation Program (JAG-9 of TTCP) these countries exchange technology and data relative to overwater propagation.

Site choice and characterization have been important issues in the discussions of JAG-9. The first addresses the question, "How well does the site represent the open sea?" The second involves making measurements of certain parameters at the sites to determine the conditions there that would affect optical propagation.

Logistically, optical propagation sites for overwater-condition measurements are most desirable if the end points of the path are on land. Several sites exist that are used or have been used in the last 5 years. Cape Canaveral was a 5-km overwater path for NRL in 1974, 1975, and 1977. The participants of the U.S. Navy EOMET program chose San Nicolas Island, California, for their overwater path. Great Britain has an overwater path on South Uist, one of the Outer Hebrides Islands of Scotland. Canada has done extensive research and has selected a site at the southeast edge of Newfoundland, near Trepassey. Australia has the only tropical site, which is located in northern Queensland near Innisfael.

As part of the characterization if results at various sites are to be compared, some agreement must be reached as to what constitutes that characterization, since various experimenters with different instruments would certainly be involved. A result of discussions of this issue at the JAG-9 meetings was a recommendation that some intercomparison work be done so that not only equipment but procedures could be compared between member organizations. This would provide a technology exchange as well.

The authors had measured typical site-characterization parameters at several land-based sites in the United States [1-3] as well as on the open sea [4,5]. Our equipment is readily portable, and an onboard computer makes rapid, on-site comparisons possible.

Thus, as part of that intercomparison study we took our Aerosol Mobile Laboratory to the British overwater site near Benbecula on South Uist, one of the Outer Hebrides off the northwest coast of Scotland.

This report describes the South Uist site for technical and logistical aspects. Particular attention is paid to the particle size distributions we obtained at the land-based ends of the path. These aerosols are compared with results from Cape Canaveral, San Nicolas Island, and an open-sea site in the North Atlantic. The same instruments were used at all locations.

## **OPEN SEA VS COASTAL SITES**

Technical items to consider when looking at a proposed marine propagation site include all those aspects which answer the question, "Is it representative of the open sea?" For example, is there air

mass contamination from nearby major land masses? Are the weather patterns at least partially like those at sea? Do local disturbances, such as surf action, add unwanted components to the atmosphere? Do high local escarpments confuse the vertical lapse rate issues?

One consideration for the open-water simulation is an unencumbered fetch to the open sea. At the British site, although cyclonic air masses can bring air in from Europe, offshore winds can bring air from thousands of miles of open sea. Radon counts could possibly identify the best times for uncontaminated marine air. The map in Fig. 1 shows the location of the site.

Fig. 1 — Location of South Uist site

Concerning aerosols, a consideration of great importance is the existence of sea-spray particles produced not in open water but at the surfline. These particles can dominate the aerosol-particle size distribution. During our 2-week stay we had a variety of wind conditions, both in direction and intensity (Figs. 2 and 3). However, the surf was not strong, and the large-particle count was not high compared with other beach sites. The sea bed structure near the site appeared to minimize the breaking of the waves for the conditions we encountered. (Note that surf strength is not necessarily dependent on the local wind. Swells from storms at sea can cause strong surf, even under low-speed local wind.)

The volume density of particles is a good indication of large-particle dominance. Figures 4 and 5 show, for example, frequency of occurrence plots for the volume density at the South Uist site compared with volume densities from sites on beaches in Florida [1] and on San Nicolas Island [2]. A more important comparison in Fig. 6 shows the volume density at the South Uist site compared with that found in the open sea [5]. We note that volume-density comparisons are meaningful only if the particle counters cover the same size range of particles. For the above comparisons, we used the same instruments in each case.

We do not imply that there is no surf action to modify the aerosol at the site. Surf action was, however, less at our location than at other locations during this measurement period. On the negative side, about 200 m offshore there are exposed rocks which add to the spray. There are also a few further out. The site is not, fortunately, always downwind of the rocks. The tide too presents a variety of surf conditions because it moves in and out several hundred meters. This tidal characteristic might

even be advantageous—allowing a study of the variation. The total vertical tide excursion was about 5 m maximum during our stay. A final positive aspect for the site is that the escarpment is quite low. At high tide it is less than 4 m.

As opposed to the other sites, the optical path being used on South Uist while we were there was not overwater. The northern end of the path sat within 20 m of the high water mark; the southern end was over 100 m from the beach. A slightly inland site such as this might be better than one on the beach because for sea breezes the larger, surf-generated particles may drop out before reaching the site. We took data at each end, but the quantity of the data is probably not large enough to make such a determination with much statistical relevance.

## LOGISTICS

Logistical considerations are often as important as technical ones. Are land-based sites available with easy access? Is sufficient power available at a reasonable cost? Is local support available and responsive? Are local residents likely to interfere? For example, is the site secure from vandalism or from cows scratching their backs on guy wires for critically aligned equipment? Are personnel quarters available and reasonable in cost, accessibility, and acceptability? Are quarters and food a problem for off-hours operations?

The access to the site from our U.S. home base proved to be surprisingly straightforward, in part due to our relationship to the U.S. Navy. A U.S. Navy supply ship took our mobile aerosol laboratory from Charleston, South Carolina, to Holy Lock, Scotland. From there, we drove it directly to the site via a commercial ferry from Oban on the mainland of Scotland to Lock Boisdale on South Uist. The trip was simplified because the vehicle is self-powered, but local hauling firms could handle trailer transportation.

Because of our 60 Hz, 110 volt requirement, we took our own generator. Thus we only required fuel. Most modern electronic equipment will handle, at least with the assistance of a transformer, the European 50 Hz, 220 V lines. Our floppy discs were an exception, however, and required power supply modification.

For accommodations we made arrangements with the Officer's Mess of the Royal Artillery (RA), Benbecula, who operate the range where the site is located. This was possible because there were only 3 of us and because it was during the range downtime. They are not prepared to handle more than their own full crew when the range is in operation. This would have required that accommodations be found at one of the three small hotels on South Uist. The two largest of these are 40 to 60 minutes from the site and are fully booked with tourists during some seasons. In summary, very careful planning is required for accommodations.

Although the RA is responsible for the site in general, it is not a secure location, i.e., access by local residents is not restricted. Also, the immediate area is farmland, and cattle did graze about the equipment positions. But other than a cow blocking a transmissometer beam occasionally, we experienced no difficulty.

This section may not seem appropriate for a scientific report, but we think that for field work the issues discussed here often cause the greatest difficulties. Thus we include them to aid those who may follow.

## MEASUREMENTS

The equipment in this experiment has been described elsewhere [3-5] in detail so we will present only a brief version here.

## TRUSTY AND COSDEN

For meteorological measurements, we use an EG&G Model 110 to obtain air temperature and dewpoint and a Young prop vane for windspeed and direction. For aerosol measurements, we use Particle Measuring Systems (PMS) equipment. For small particles, the Active Scattering Aerosol Spectrometer Probe (ASASP) measures particles with radii from 0.14 to 0.75  $\mu\text{m}$ . For particles with radii between 0.75 and 15  $\mu\text{m}$ , we use the High Volume version of the Classical Scattering Aerosol Spectrometer Probe (CSASP). All data are initially processed by the PMS Data Acquisition System (DAS) and stored each second on computer compatible magnetic tape. This includes the analog meteorological data using the A/D convertors built into the DAS.

Simultaneous with writing on the mag tape, all data are also sent to a digital input in a PDP 11/34 computer. Both real-time and postprocessing capabilities give great flexibility to satisfy the individual field test requirements.

The results presented here are all from the postprocessing software, i.e., data reduced by operation on the original 1-s resolution PMS tape. The first step creates a standard format file [6] with operator-chosen averaging times. For this experiment, we chose 10 min.

Since a prime interest here is optical propagation, we do a Mie scattering calculation on each average aerosol particle size distribution for several wavelengths. We calculate total aerosol extinction using a modified Dave calculation. (It is modified in the sense that our Fortran package does not support double precision complex arithmetic, so we created a version with only real arithmetic.) Since the particle sizes in our distributions are all at the fixed bin centers, we do not do a Mie calculation each time. We do, however, for speed create a file that has the extinction efficiencies for each wavelength and each particle size. This makes the calculations very fast.

Appendix A shows the 10-min averages of the four meteorological parameters; the water/vapor pressure (calculated from the dew point); the number density, cross-sectional area density and volume density (calculated from the particle size distributions); and the calculated extinction due to aerosols for 4 wavelengths.

For completeness, we include in Appendix B all the 10-min-average aerosol size distributions obtained on this field trip. Note that we only include the first seven channels from the ASASP. We do this because of the double-valued sensitivity function that gives a machine-generated bump in the last eight channel positions. Our approach is to fit a curve through that area before doing the extinction calculation.

To allow readers to use these data for their own calculations, Appendix C gives the bin edge locations for the two aerosol spectrometer probes.

## RESULTS AND DISCUSSION

To determine if a site is truly sea-like would require a long term characterization which could be compared with a long term open sea characterization. The longest open sea measurement [5] is only a month long. The measurement at South Uist lasted only two weeks. The best that can be done is to show the results and compare similarities. We started the process in the Open Sea vs Coastal Site section by comparing the volume density of particles at various sites. There we saw higher volume densities at the beach sites. Modelers, however, are more likely to have only air temperature, relative humidity, and wind velocity data.

In the open sea and on San Nicholas Island, the variation of air temperature and relative humidity was small. Figures 7 and 8 compare the frequency-of-occurrence of these two parameters at the three locations. All three sites are obviously cold and wet for the measurement periods.

NRL REPORT 8800

TRUSTY AND COSDEN

Fig. 8 — Relative humidity frequency-of-occurrence. (a) South Uist, (b) Open sea (57°N 20°W), and (c) San Nicolas Island.

In the open sea, wind direction effectively plays no role in the determination of aerosol size distribution. So Fig. 2 stands alone for the South Uist measurement. On the other hand, wind direction is very important for beach sites because it determines the aerosol source. Since the beach has a north-south direction, Fig. 2 shows that most of the time the wind was from the sea.

Windspeed is an important factor for aerosol generation at both open sea and beach sites. We compare the frequency-of-occurrence plots for that parameter in Fig. 9. For marine modeling work, we might want to include in the South Uist distribution only those data that are associated with winds from the open sea. Of course, there would still be the surf spray component to contend with. There is a limitation on the high windspeed end for the open sea results. The equipment became subject to inundation for those conditions, so we ceased measurements when they occurred. On South Uist, only rain caused us to shut down.

Since optical propagation is the driving force behind these measurements, a direct comparison of calculated aerosol extinction is in order. Figures 10, 11, and 12 do this for wavelengths of 0.55, 3.8, and 10.6  $\mu\text{m}$ . The better transmittance for longer wavelength on the open sea relates to the fewer large particles found there.

Of course, aerosols are not the only factors that contribute to extinction in the infrared. There is water vapor absorption as well. How that affects the distribution of the total extinction is shown in Figs. 13 and 14. Using a curve fit response for the  $P_2(8)$  line of the DF Laser, we have calculated the molecular absorption for all the dewpoint measurements. Since the conditions were quite wet most of the time, this gave very little variation in the results, as Fig. 13 shows. Each individual molecular absorption result was added to each aerosol extinction to produce the distribution of the total, Fig. 14. There is only a slight shift in the peak of the distribution compared with Fig. 11a, but it becomes sharper. It does point out that generally the aerosols contribute slightly more to the extinction than the water vapor for that wavelength. Reference 5 presents the same plots for both 3.5 and 10.6  $\mu\text{m}$  for the similar at-sea conditions. There, as would be the case here as well, at 10.6  $\mu\text{m}$  the water vapor is the dominant absorber.

It is possible to divide the data from the open sea and from South Uist into sections that have similar windspeeds and relative humidities so aerosol size distributions could be compared. Those simple comparisons, however, would not take into account the time factor involved with the aerosol generation. We think that a larger data set would be necessary to draw proper conclusions. We have, in Figs. 15(a) through 15(i), presented an aerosol size distribution for each day of the South Uist measurement period. The distributions are quite similar to those found at-sea except for a slight increase in the large particle count.

In conclusion, we find the South Uist site to be as close to an open sea site as any we have encountered. The aerosol particle size distributions are more like those in the open North Atlantic than the ones we obtained at Cape Canaveral, San Nicolas Island, and elsewhere. Weather patterns at South Uist are also similar to those in the North Atlantic. If extended data sets show that certain wind directions produce open-sea-like distributions, it would appear to be technically ideal. The logistical problems may place some limitations on operations there, but with proper planning they can be dealt with. This site can provide valuable optical propagation data that are representative of open sea conditions.

## ACKNOWLEDGMENTS

The authors thank those who made this experiment not only possible but pleasant. From RAE Farnborough, Russell Allan was instrumental in arranging the the experiment initially, and Paul Ash-down was with us daily to see that our technical needs were met while we were on South Uist. At the RA Officer's Mess, everyone was helpful and pleasant and our stay was very comfortable. This allowed us to devote our energies to the experiment.
