The Coordinating Research Council, Inc. (CRC) is a non-profit corporation supported by the petroleum and automotive equipment industries. CRC operates through committees made up of technical experts from industry and government who voluntarily participate. The four main areas of research within CRC are: air pollution (atmospheric and engineering studies); aviation fuels, lubricants, and equipment performance; heavy-duty vehicle fuels, lubricants, and equipment performance (e.g., diesel trucks); and light-duty vehicle fuels, lubricants, and equipment performance (e.g., passenger cars). CRC's function is to provide the mechanism for joint research conducted by the two industries that will help in determining the optimum combinations of petroleum products and automotive equipment. CRC's work is limited to research that is mutually beneficial to the two industries involved, and all information is available to the public.

ABSTRACT

AZ

The 1982 CRC High-Temperature Driveability Program was conducted at the US Army Proving Grounds near Yuma, Arizona, from September 20 through October 19, 1982, at nominal ambient temperatures of 70°F (21.1°C) and 95°F (35°C). CRC has conducted previous programs for the evaluation of vapor lock and hot start and driveability of 1971 and 1975 model passenger cars. Since 1975, vehicle designs have changed rapidly to meet more stringent exhaust emissions and fuel economy standards. These changes may affect vehicle high-temperature performance. The 1982 CRC High-Temperature Driveability Program investigated the effect of such changes on vapor lock performance of nineteen 1982 passenger vehicles at nominal temperatures of 70°F (21°C) and 95°F (35°C). The two-temperature vapor lock evaluation was used in updating ambient temperature corrections of volatility over a range of temperature from 70°F (21°C) to 95°F (35°C). Hot-start and driveability performance was evaluated at a nominal 95°F (35°C) temperature by two test procedures. A new city driveability procedure emphasized conditions that could cause performance problems encountered in heavy stop-and-go traffic after a period of temperature stabilization. Selected vehicles were also evaluated using the CRC Hot-Start and Driveability Procedure.

I. INTRODUCTION

The 1982 CRC High-Temperature Driveability Program was conducted at the US Army Proving Grounds near Yuma, Arizona, from September 20 through October 19, 1982. The series of road tests comprising the program were conducted at nominal ambient temperatures of 70°F (21°C) and 95°F (35°C).

CRC has conducted previous programs for the evaluation of vapor lock and hot start and driveaway of 1971 and 1975 model passenger cars. Since 1975, vehicle designs have changed rapidly to meet more stringent exhaust emissions and fuel economy standards. These changes may affect vehicle high-temperature performance. The 1982 CRC High-Temperature Driveability Program investigated the effect of such changes on vapor lock performance of nineteen 1982 passenger vehicles at nominal temperatures of 70°F (21°C) and 95°F (35°C). The vapor lock tolerance of each vehicle was determined for each temperature by evaluating incremental blends from a fuel series ranging in volatility from approximately 7.0 to 17.0 psi Reid vapor pressure. Various blends were tested to determine the fuel which would give a 25 percent increase in acceleration time relative to a base acceleration. This fuel in terms of $T_{V/L}=20$ defined the vapor lock tolerance of the vehicle. The two-temperature vapor lock evaluation was used in updating ambient temperature corrections of volatility over a range of temperature from 70°F (21°C) to 95°F (35°C). In addition, an alternate vapor lock procedure was run in two vehicles.

Hot-start and driveaway performance was evaluated at a nominal 95°F (35°C) temperature by two test procedures. A new test procedure that emphasized low speed, mild acceleration, and frequent idle periods was evaluated in this program. This City Driveability Procedure emphasized conditions that could cause performance problems encountered in heavy stop-and-go traffic after a period of temperature stabilization. A special pentane-rich fuel and one or more vapor lock fuels were tested in all vehicles using the City Driveability Procedure. Eleven of the vehicles were also evaluated using the CRC Hot-Start and Driveaway Procedure. Performance was expressed for both procedures in terms of CRC demerits, with poorer performance resulting in higher demerit levels.

Appendix A lists participants in the test program, members of the Program Panel, and members of the Data Analysis and Report-Writing Panel. The program proposal approved by the CRC Volatility Group is shown in Appendix B.

II. SUMMARY

- Vapor lock severity increased in most cases as fuel volatility and ambient temperature increased.
- The 1982 model cars tested had fewer vapor lock problems than 1975 and 1971 model cars tested in previous CRC programs. A fuel with $T_{V/L}=20$ of 124°F (ASTM Class C) satisfied 75 percent of 1982 model cars, 45 percent of 1975 model cars, and 20 percent of 1971 model cars at 95°F.
- For vapor lock tests, the ambient temperature correction factor for adjusting $T_{V/L}=20$ data was established to be 0.7°F $T_{V/L}=20$ per degree ambient temperature.
- There appeared to be no appreciable difference in vapor lock performance for cars with and without fuel return lines.
- The limiting vapor lock requirements were outside the range of test fuels for five of nineteen cars at a nominal 95°F (35°C) test temperature, and for seven of nineteen cars at a nominal 70°F (21°C) test temperature.
- Ten of twelve cars at their critical soak condition had more severe vapor lock requirements at 95°F (35°C) than at 70°F (21°C).
- Twelve of fourteen cars were idle soak limited at 95°F (35°C). At 70°F (21°C), six of twelve cars were idle soak limited, and six were key-off soak limited.
- Data did not establish a definitive relationship between a vehicle's vapor lock tolerance and its hot-start and driveaway performance.
- For the City Driveability Procedure, seven vehicles showed large changes in demerit levels with changes in fuel volatility.
- Both the City Driveability Procedure and the CRC Hot-Start and Driveaway Procedure showed volatility and vehicle effects.
- From these data, there is no clear advantage to recommend either the City Driveability Procedure or the CRC Hot-Start and Driveaway Procedure for driveability evaluations.

III. TEST VEHICLES

Eighteen passenger cars and one passenger van were tested in this program. Selection was based upon a list of twenty primary and five secondary vehicles listed in the test plan, contingent upon availability from rental agencies. In the selection of test cars, consideration was given to sales volume and vehicles of special interest. All vehicles were equipped with automatic transmissions, air conditioning, and Federal exhaust emission control devices. Vehicles are described in detail in Table I.

Prior to the start of the test program, the vehicles were delivered to a contractor for test preparation. Car preparation included installation of fuel tank drains, installation of a vacuum tee, checking and adjusting timing and idle speed, and checking integrity of emission control equipment. Thermocouples were installed on test vehicles by test participants at the start of the test program. One thermocouple was taped to the exterior of the fuel line as close to the carburetor or fuel injector as possible. For General Motors vehicles, a second thermocouple was installed in the fuel tank through the drain line. For all other vehicles, a second thermocouple was taped to the exterior of the fuel line as close to the fuel pump inlet as possible. At the conclusion of the test, the vehicles were returned to the contractor for removal of the tank drains. A flat 3/32-inch brass plate was soldered over the tank drain hole.

IV. TEST FUELS

Vapor lock test fuels consisted of three base fuels of 7.1, 11.8, and 16.3 psi Reid vapor pressure (RVP) identified as RMFV 90-82, 91-82, and 92-82, respectively. The fuel series design accommodated a 10.5 psi RVP fuel as representative of a typical summer fuel, and a 13.5 psi RVP fuel as representative of a typical winter fuel. Increased volatility was accomplished primarily by the addition of butane. Intermediate test fuels were blended on-site using two blending pumps. One blending pump dispensed the low and intermediate volatility fuels and blends of the low and intermediate fuels. The other pump dispensed the intermediate and high volatility fuels and blends of the intermediate and high fuels. Table II presents the average fuel inspection data for the odd number fuels available from the blend pumps. The blends were prepared by one laboratory and were shipped to participating laboratories for analysis. Individual inspection data by participating laboratories are presented in Appendix C.

Figure 1 shows the relationship of $T_{V/L=20}$ and percent evaporated at 158°F to RVP for the series of vapor lock fuels. The curves in Figure 1 correspond to least-squares equations; the fuel series curves were used to derive the other volatility values from measured RVP's when processing data from the vapor lock and driveability tests:

$$T_{V/L=20} = 213.05 - 9.9293 \text{ (RVP)} + 0.19306 \text{ (RVP}^2\text{)}$$
$$\% @ 158^\circ\text{F} = 5.94 + 1.8945 \text{ (RVP)} - 0.0099081 \text{ (RVP}^2\text{)}$$

A special fuel blend (RMFV 93-82), shown in Table II as Fuel 20 and used in simulated low-speed city driving tests, was intended to emphasize problems in the hot-start and driveaway application. It was a pentane-rich high volatility fuel. In order to relate other properties to measured RVP's on tank samples subjected to weathering during the road tests, samples of this fuel were allowed to evaporate to varying degrees, then RVP and T versus V/L curves were determined on-site at Yuma on the fresh and weathered samples. Subsequently, a retain sample was also weathered in several stages, and RVP and ASTM D 86 distillations were determined on the fresh and weathered portions at one of the cooperating laboratories. Data points and least-square curves for $T_{V/L=20}$ and percent evaporated at 158°F versus RVP of weathered RMFV 93-82 fuel are shown in Figure 1, along with corresponding curves for the vapor lock fuels. Equations for the volatility relations of weathered Fuel 20 are:

$$T_{V/L=20} = 215.71 - 9.919 \text{ (RVP)} + 0.1758 \text{ (RVP}^2\text{)}$$
$$\% @ 158^\circ\text{F} = -10.524 + 3.9496 \text{ (RVP)}$$

(For percent evaporated at 158°F, the linear equation fit the data as well as a second-order equation and was, therefore, used. Since the data were obtained in only one cooperating laboratory, the constant term in the equation was adjusted to match the point for the all-laboratory average RVP and percent evaporated at 158°F.)

V. TEST FACILITIES

Facilities made available for the test work at the US Army Yuma Proving Ground included a five-mile test track, fuel storage, a soak shelter, a cold room for fuel dispensing, and a petroleum testing laboratory. A fork-lift truck, a refrigerated trailer, a temporary soak shelter to accommodate three vehicles, and a mobile office trailer were provided by CRC.

The test course, shown in Figure 2, consisted of the following:

- Yuma Proving Ground Dynamometer Course - level blacktop with two-mile straightaway and half-mile loops at each end
- Gravel roads, one to two miles long, running between the dynamometer course and Arizona Highway Route 95
- A 7.5-mile section of essentially level blacktop highway - Arizona Highway Route 95

Car warm-up was achieved by proceeding from the dynamometer course via a gravel road to the highway, driving fifteen miles on the highway, returning to the dynamometer course to complete one lap around the course (five miles), and then proceeding to the soak shelter. All vapor lock and hot-start and driveaway evaluations were conducted on the dynamometer course.

Three roofless soak shelters, twelve feet by twenty-four feet and constructed of plywood with plastic end curtains, were used primarily for vapor lock testing. A permanent twenty-foot by forty-foot roofless soak shelter with doors at both ends was used primarily for hot-start and driveaway tests.

Dry-bulb air temperature was recorded at the soak area of the dynamometer test track at fifteen-minute intervals while testing was in progress.

On-site fuel analyses were performed in the Yuma Proving Ground Petroleum Laboratory. Reid vapor pressure was determined using an automatic RVP instrument supplied by Southwest Research Institute.

A refrigerated trailer van was used for the bulk storage of all test fuels, except the low volatility vapor lock fuel, which was stored outdoors. Daily fuel supplies were stored in a large walk-in refrigerator, and were dispensed to the test cars through two blend pumps. Fuel 20 was distributed through a separate portable pump. Both the refrigerator and refrigerated trailer were maintained at approximately 40°F.

Duplicate samples were taken from the fuel tanks, through the drain line, in one-quart bottles using a Quick-Chill Sampling Apparatus. Samples were taken through the drain line to prevent significant loss of tank pressure during sampling. For all tests, samples were taken during the soak and idle periods.

VI. TEST TECHNIQUES

The 1982 CRC High-Temperature Driveability Program used four test techniques, two for vapor lock and two for hot start and driveaway:

- 1975 CRC Vapor Lock Technique
- An alternate vapor lock technique which alters the timing of the accelerations
- CRC Hot-Start and Driveaway Technique
- City Driveability Procedure

A. 1975 CRC Vapor Lock Technique

The primary vapor lock technique used in this program was the same as used in the 1975 CRC High-Temperature Driveability Program. Vapor lock was evaluated at both 70°F (21°C) and 95°F (35°C). This technique and the data rating system used are described in detail in Appendix D. In brief, the percent gain in acceleration time may be established on any one fuel by comparing a wide-open-throttle acceleration, following a prescribed idle or soak period, with the average for base accelerations obtained during the warm-up operation. The limiting volatility for a 25 percent increase in acceleration time may then be defined by bracketing with fuels which produced higher or lower acceleration times.

B. Alternate Vapor Lock Procedure

A few runs were made with an alternate vapor lock technique that altered the timing of the accelerations. The procedure used was the same as the 1975 CRC Vapor Lock Technique, with the exception that the timed acceleration was from 0 to 30, 50, and 60 mph, instead of from 15 to 50, 60, and 70 mph.

C. CRC Hot-Start and Driveaway Technique

The CRC Hot-Start and Driveaway Procedure is described in detail in Appendix D. Briefly, it consists of the following:

- a. A prescribed warm-up during which a base start and run time are obtained.

- b. A ten-minute idle, followed by a back-up and abrupt stop at prescribed acceleration and deceleration rates.
- c. A series of accelerations of prescribed duration and rates, followed by prescribed decelerations and short idle periods.
- d. A twenty-minute engine-off soak, followed by a hot start and run of sixty seconds before driveaway.
- e. A repeat of Item c.

D. City Driveability Procedure

The City Driveability Procedure is a new hot-start and driveaway technique designed to appraise low-speed driveability and hot-starting problems. This new procedure was the primary driveability procedure used in the 1982 CRC High-Temperature Driveability Program, and was compared with the CRC Hot-Start and Driveaway Procedure for selected cars. The Procedure is described in detail in Appendix D. Briefly, it consists of the following:

- a. A prescribed warm-up.
- b. Simulated low-speed city traffic for four miles.
- c. A ten-minute idle soak, followed by an acceleration.
- d. Simulated low-speed city traffic for four miles.
- e. A twenty-minute key-off soak, followed by a hot start, followed by an acceleration.

For both driveability procedures, hesitation, stumble, surge, backfire, and stalls are recorded during acceleration and deceleration. Idle quality and stalls are recorded during idle periods, and cranking start time and total start time are recorded after engine-off soak. In addition to the number of times a malfunction occurs, the quality of all malfunctions, except stalls and start time, are evaluated as trace, moderate, or heavy. Sample data sheets are presented in Appendix D.

VII. TEST DESIGN

Since evaluation of vapor lock tolerance of the vehicle was necessary prior to hot driveability evaluations, only vapor lock testing for 95°F (35°C) was conducted for the first two days of the program, using four test crews. On the third day, the test crews were reassigned into five test crews: three vapor lock crews and two hot driveability crews. It was necessary to extend the test program a few days longer than had been originally planned in order to obtain the desired number of hot driveability test evaluations. By the end of the program, 115 95°F (35°C) vapor lock tests, 94 70°F (21°C) vapor lock tests, 66 City Driveability Procedure tests, and 20 CRC Hot-Start and Driveaway tests had been conducted. It was discovered during the test program that the low to intermediate blending pump had malfunctioned on October 4-6, dispensing 100 percent intermediate fuel for all settings. Although tests conducted during this time resulted in valid data, the desired volatility effects were not obtained for some runs.

VIII. AMBIENT CONDITIONS

Ambient conditions were not altogether favorable during the test program. During the first week, attempts were made to evaluate vapor lock at 70°F (21°C), but ambient temperatures were such that the maximum temperature was exceeded before completion of a test. During the second test week, temperatures did not exceed 90°F (32°C); therefore, no hot driveability or 95°F (35°C) vapor lock tests were conducted. During the third test week, high winds and cool temperatures precluded extensive testing. Although more normal conditions prevailed during the fourth week, temperatures were somewhat cooler than desired. To facilitate obtaining additional test hours, it was decided during the fourth week to reduce the starting temperature for hot driveability tests to 85°F (29°C) from 90°F (32°C).

IX. ON-SITE DATA RECORDING AND PROCESSING

Preliminary data processing was conducted on-site with the aid of a microcomputer and printer. Data recorded by the test crews were transcribed from the original data sheets (sample in Appendix D) to computerized spread sheets with similar data arrangement.

For vapor lock tests, average RVP's for duplicate samples were entered on each spread sheet. The computer program automatically calculated percent increases in acceleration time and fuel $T_v/L=20$, both unadjusted and adjusted to 70°F or 95°F (21°C or 35°C). Correlation used on-site to estimate $T_v/L=20$ from RVP were based on the supplier's fuel data. When volatility data were subsequently obtained on the vapor lock fuels from cooperative laboratories, the spread sheets were recalculated with new constants from the final correlation formula. Final printouts from the vapor lock tests are shown in Appendix G.

For driveability tests, the computer program calculated driveability demerits. Results from each driveability test occupy one entire page; therefore, only summary results are included in Appendix F. A complete set of driveability printouts is available for inspection at the CRC offices.

X. DISCUSSION OF RESULTS

A. Vapor Lock

1. Limiting $T_v/L=20$

Vapor lock limiting $T_v/L=20$ is shown in Table III for each car corrected to ambient temperatures of 95°F (35°C) and 70°F (21°C). This is the $T_v/L=20$ for a 25 percent increase in acceleration time at the most critical soak and speed condition. At 95°F (35°C), six of the nineteen cars tested were not fully characterized as to limiting volatility with the fuel series. Cars 2, 3, 8, 13, and 18 did not encounter vapor lock on the most volatile fuel tested. Car 1 encountered vapor lock with the least volatile fuel tested. Of the cars characterized for critical soak condition at 95°F (35°C), twelve were idle soak-limited, and two were engine-off soak-limited.

At 70°F (21°C), seven of the nineteen cars tested did not encounter vapor lock on the most volatile fuel tested, and were not, therefore, fully characterized as to limiting volatility. Of the cars characterized for critical soak condition at 70°F (21°C), six were idle soak-limited, and six were engine-off soak-limited. Of the twelve cars characterized for critical soak conditions at both temperatures, five cars which were idle limited at 95°F (35°C) were engine-off limited at 70°F (21°C), one car which was engine-off limited at 95°F (35°C) was idle limited at 70°F (21°C), and six cars had the same limiting condition at both temperatures.

Of the twelve cars for which limiting $T_{V/L}=20$ was obtained at 70°F (21°C), ten had higher $T_{V/L}=20$ for limiting vapor lock at 95°F (35°C). Two cars, 9 and 11, had higher $T_{V/L}=20$ for limiting vapor lock at 70°F (21°C). For these two cars, no explanation of the reversal of expected results was obtained.

2. Ambient Temperature Vapor Lock Corrections

Vapor lock tests were conducted over a range of 87°F (30°C) to 111°F (44°C) for 95°F (35°C) vapor lock, and a range of 65°F (18°C) to 85°F (29°C) for 70°F (21°C) vapor lock. The $T_{V/L}=20$ test data were corrected from actual ambient test conditions to nominal 95°F (35°C) and 70°F (21°C) temperatures using a previously established CRC expression, where:

$$\text{Adjusted } T_{V/L}=20 = \text{Actual } T_{V/L}=20 + K \left(\frac{95}{70} - \text{Air Temperature} \right)$$

The K value used was K=1.

The 70°F (21°C) vapor lock tests were performed at both idle and engine-off soak conditions, so that comparable soak condition data would be available for both test temperatures. Comparable soak condition limiting $T_{V/L}=20$'s are shown in Table IV for the ten cars that were characterized at both test temperatures. The ten cars show an average limiting $T_{V/L}=20$ difference of 17.1 between the two test temperatures, giving a 0.68 $T_{V/L}=20$ correction for a one-degree change in ambient temperature. For convenience, the correction was rounded off to 0.7. The 0.7 factor is significantly different from the 1.0 previously used adjustment factor. It also shows a significant difference from a zero correction factor. With the exception of Table IV, all adjusted vapor lock data presented in this report use a K factor of 0.7 for ambient temperature correction.

3. Vapor Lock Distributions

Figure 3 shows distribution lines for limiting $T_{V/L}=20$ for 95°F (35°C) for 1971 and 1975⁽¹⁾ cars tested in previous CRC programs compared with 1982 cars tested in this program. These data show a trend of decreasing vapor lock severity with more recent model year cars. A fuel with a 124°F (51°C) $T_{V/L}=20$ would satisfy 20 percent of the 1971 cars tested, 45 percent of the 1975 cars tested, and 75 percent of the 1982 cars tested under the conditions of the CRC Vapor Lock Test at 95°F (35°C).

(1) Coordinating Research Council, Inc., "Driveability Performance of 1975 Passenger Cars at High Ambient Temperatures," CRC Report No. 490, November 1976.

The distribution of limiting $T_{V/L}=20$ values for the 1982 cars tested at 95°F (35°C) and 70°F (21°C) is shown in Figure 4 for their most severe soak and speed conditions. Six cars at 95°F (35°C) and seven cars at 70°F (21°C) had indeterminate values, because their requirements were outside the volatility range of the test fuels. The level of volatility distribution is different with the cars having a higher vapor lock severity at 95°F (35°C). The slopes of the distribution lines are different with a trend towards converging at the more severe vapor lock level.

The distribution of limiting $T_{V/L}=20$ values at 95°F (35°C) for 1982 cars with and without fuel return lines are shown in Figure 5. The slopes of the distribution lines are different, with the cars having fuel return lines showing a lower slope. There is no appreciable difference in vapor lock performance for cars with and without fuel return lines.

4. Alternate Vapor Lock Procedure

An alternate vapor lock procedure was run on two cars at 95°F (35°C). The alternate vapor lock procedure was the same as the CRC procedure, except accelerations were timed from 0 to 30, 50, and 60 mph. Limiting $T_{V/L}=20$'s for the alternate procedure and the CRC procedure are shown in Table V. Car 5 showed similar limiting $T_{V/L}=20$'s for both procedures. Car 14 was more severe on the CRC procedure. Based upon the limited data available, no conclusion can be reached as to the performance of this alternate procedure.

B. Comparison of City Driveability Procedure Versus CRC Hot-Start and Driveaway Procedure

In previous CRC tests, the CRC Hot-Start and Driveaway Procedure has shown it is capable of defining car performance in terms of fuel volatility. In this program, a limited number of tests were run using the CRC Hot-Start and Driveaway Procedure and a greater number were run using a new City Driveability Procedure. The purpose of these tests was to compare results of the two procedures and their ability to define car performance by segregating fuel effects. Detailed descriptions of both procedures are provided in Appendix D. The City Driveability Procedure includes thirty-four 0-20 mph accelerations, followed by idle periods and two 0-30 mph part-throttle accelerations. The CRC Hot-Start and Driveaway Procedure includes a back-up maneuver with moderate to severe braking, idle periods, and sixteen accelerations to different speeds at varied rates. Both procedures were completed by trained raters. Comparisons of trained rater results are provided in Appendix E.

In both cycles, driveability problems are quantified by assigning them numerical values that increase as problem severity increases. These values are termed "demerits;" large total demerit values are indicative of poor driveability. Seventeen comparison tests were completed in which the cars were run through both procedures with the same fuel and driver. The demerit values obtained are shown in Table VI. Average demerits of the City Driveability Procedure were about twice the average of the CRC Hot-Start and Driveaway Technique. The total weighted demerit (TWD) values for comparable runs are plotted in Figure 6. The linear relationship between the two cycles was:

$$\text{TWD(CITY)} = 1.48 \text{ TWD(CRC)} + 92.6$$

$$R^2 = 0.23$$

Three cars were significantly more severe on the CRC procedure than the new procedure (cars 7, 9, and 14). Although no single driving problem caused the differences in demerits between the two procedures, demerits from driving stalls were about 34 to 51 percent higher for the CRC technique with the most volatile fuel. Correlation between the procedures was improved significantly when these cars were deleted from the model:

$$\text{TWD(CITY)} = 3.15 \text{ TWD(CRC)} - 98.9$$

$$R^2 = 0.69$$

To segregate fuel effects, regression models typically are developed which relate fuel volatility characteristics (i.e., $T_{V/L=20}$, RVP, %@158°F, or distillation temperatures) to car performance. Unfortunately, this fuel set was not designed to segregate volatility effects on driveability, nor were the tests performed in a balanced scheme which lends to proper model development. Consequently, models that identify the significant volatility parameter could not be developed for either test. Some regression work was completed with data from the City Driveability Procedure, but it is in a very general form (see Appendix F). Although the data indicate that both tests can separate fuels of different volatility, the ability of the new City Driveability Procedure versus the CRC Hot-Start and Driveaway Procedure to identify significant fuel parameters that affect car performance cannot be determined from this program. To evaluate the two test techniques, another program specifically designed to assess hot-weather driveability is required.

C. Comparison of Vapor Lock Versus City Driveability

To determine if there was a relationship between vapor lock performance and the City Driveability Procedure performance, a ranking was made of vapor lock and driveability performance. The ranking of the City Driveability Procedure performance was made with data obtained from the runs using the pentane-rich fuel (Fuel 20), since all nineteen cars were run on this fuel. The vehicles were ranked in order of decreasing vapor lock volatility tolerance and of increasing hot-start and driveaway total weighted demerits. These rankings are shown in Table VII and plotted in Figure 7. Those cars with undetermined limiting $T_{V/L}=20$ were ranked equally, and were not included in the data regression analysis. The regression line shown in Figure 7 has a positive slope of 0.34 and a coefficient of determination of 0.20. These data do not establish a strong relationship between a vehicle's vapor lock volatility tolerance and its city cycle hot-start and driveaway performance.

D. Fuel System Temperature Measurements

Fuel system temperatures were obtained on seventeen of the test vehicles for 95°F (35°C) vapor lock tests and for fourteen of the vehicles for 70°F (21°C) vapor lock tests. The following temperature measurements were obtained:

- o Surface temperature of the fuel line at the inlet to the carburetor or fuel injector for all vehicles.
- o Temperature of the fuel in the fuel tank for all General Motors vehicles.
- o Surface temperature of the fuel line at the inlet to the fuel pump for all non General Motors vehicles.

The average temperature of the fuel line at the inlet to the carburetor or fuel injector for all runs for each soak for each vehicle are listed in Tables VIII and IX for the 95°F (35°C) and 70°F (21°C) vapor lock tests, respectively. Tables X and XI show similar data for the fuel pump and fuel tank temperatures. Temperature data between idle and key-off soaks in some cases are not comparable. This is due to the nature of the vapor lock test, since after a few runs, idle or key-off is established as the limiting condition and further runs are not made on the non-limiting condition. In these cases, the number in parentheses is the average temperature for the runs in which both soak conditions were run.

There was no apparent correlation between vapor lock performance and fuel system temperatures. It would be expected that the critical soak condition that produced the highest carburetor and/or fuel pump temperature would be the most critical vapor lock condition. Table XII shows that for twelve cases, the most critical vapor lock soak condition also showed the highest carburetor and fuel pump temperatures. It also shows that for thirteen cases, the highest carburetor and/or fuel pump temperatures did not occur for the most critical vapor lock condition.

**PROGRAM: 1982 CRC HIGH-TEMPERATURE
DRIVEABILITY PROGRAM**

1982 CRC HIGH-TEMPERATURE DRIVEABILITY PROGRAM

CRC Project No. CM-118-82

Prepared by the
Program Panel
of the
CRC Light-Duty Volatility Group

February 1982

Revised: May 1982

1982 CRC HIGH-TEMPERATURE DRIVEABILITY PROGRAM

Objective

Determine vapor lock performance of a selected group of 1982 cars at nominal temperature of 70°F and 95°F. Determine hot start and driveaway performance of the same group of cars at a nominal temperature of 95°F.

Introduction

CRC has conducted high temperature programs for the evaluation of vapor lock and hot start and driveability on 1972 and 1975 model passenger cars. Since 1975, changes in vehicle design that may affect high temperature performance are exhaust emission systems, design for fuel economy, and introduction of new front wheel drive designs. This program will indicate the effect of such changes on vapor lock performance at a nominal temperature of 95°F. In addition, vapor lock will be evaluated at a nominal temperature of 70°F. The lower temperature vapor lock evaluation will be useful in updating ambient temperature corrections of volatility and in giving guidance for volatility specification for a range of temperatures from 70 to 95°F.

A new hot start and driveaway procedure will be investigated in this program. The new procedure emphasizes conditions that might cause performance problems encountered in heavy stop and go traffic after a period of temperature stabilization. Selected cars will compare performance results from the 1975 CRC hot start and driveaway procedure to the new procedure.

Test Fuels

Vapor lock test fuels consisting of three base fuels of 6.0, 12.0, and 17.0 RVP are identified as RMFV 90-82, 91-82, and 92-82, respectively. The fuel series is representative of a typical 10.5 lb. RVP summer fuel and a 13.5 lb. RVP winter fuel. Test fuel specifications are shown in Attachment A.

A special fuel blended to emphasize hot start and driveaway problems is also shown on the fuel specification sheet as RMFV 93-82. Use of this fuel is discussed in the test procedure section.

Test Cars

Twenty-one test vehicles are selected for the test program as follows for 1982:

| <u>Car No.</u> | <u>Make and Model</u> | <u>Engine Size, Liter/Type</u> |
|----------------|---|--------------------------------|
| 1 | GM T Body Chevrolet Chevette Pontiac T-1000 | 1.6/L-4 |
| 2 | GM J Body Chevrolet Cavalier Pontiac J-2000 Buick Skyhawk Oldsmobile Firenza Cadillac Cimmaron | 1.8/L-4 |
| 3 | GM A Body Chevrolet Celebrity Pontiac A-6000 Buick Century Oldsmobile Ciera | 2.5/L-4 |
| 4 | GM X Body Chevrolet Citation Pontiac Phoenix Buick Skylark Oldsmobile Omega | 2.8/V-6 |
| 5 | GM G Body Chevrolet Malibu Chevrolet Monte Carlo Pontiac Bonneville Pontiac Grand Prix Buick Regal Oldsmobile Cutlass | 2.8/V-6 |
| 6 | GM G Body Chevrolet Malibu Chevrolet Monte Carlo Pontiac Bonneville Pontiac Grand Prix Buick Regal Oldsmobile Cutlass | 3.0/V-6 |
| 7 | Buick Regal | 3.8/V-6 |
| 8 | Buick LeSabre | 4.1/V-6 |
| 9 | Ford Escort-Mercury Lynx | 1.6/L-4 |
| 10 | Ford Mustang-Mercury Capri | 2.3/L-4 |
| 11 | Ford Futura-Granada | 3.3/L-6 |

| <u>Car No.</u> | <u>Make and Model</u> | <u>Engine Size, Liter/Type</u> |
|----------------|------------------------------|--------------------------------|
| 12 | Ford Futura-Granada | 3.8/V-6 |
| 13 | Ford Futura-LTD-Thunderbird | 4.2/V-8 |
| 14 | Plymouth Reliant-Dodge Aries | 2.2/L-4 |
| 15 | Datsun 210 | 1.4 or 1.5/L-4 |
| 16 | Toyota Corolla | 1.8/L-4 |
| 17 | Volkswagen Rabbit | 1.6/L-4 |
| 18 | Honda Accord | 1.8/L-4 |
| 19 | Chevrolet Van | 5.0/V-8 |
| 20 | Ford Van | 4.9/V-8 |
| 21 | Dodge Van | 3.7/L-6 |

In some cases, several vehicles are listed, such as Chevrolet Celebrity, Pontiac A-6000, Oldsmobile Ciera, or Buick Century for a General Motors A-body car with a 2.5-liter engine. The actual car to be tested will be determined by a particular model of the choices listed being available from the rental agency. If one or more of the selected vehicles are not available, alternate selections are as follows:

1. Dodge Diplomat, or equivalent, with a 3.7-liter engine
2. Cadillac Deville with a 4.1-liter engine
3. Lincoln with a 5.0-liter engine
4. Chevrolet S-10 pickup truck
5. Ford Ranger pickup truck with a 2.3-liter engine

All vehicles are to be equipped with automatic transmission and air conditioning. Car preparation will include checking timing, idle speed, emission control system operation, installation of vacuum gauge lines, installation of temperature thermistors and installation of fuel tank drains.

Vapor Lock Test Procedure

The vapor lock test procedure will essentially be the same as used in the 1975 CRC program. A copy of this procedure is shown as Attachment B. Sections 12a, b, c, d, and e will change the speed for determining increases in acceleration times from 70 mph to 60 mph. Test temperatures will be 65 to 80°F for the lower temperature portion of the program and 90 to 105°F for the higher temperature portion. Data will be corrected to 70 and 95°F for the lower and higher temperatures of the program.

If time allows, selected cars will be evaluated by an alternate vapor lock procedure. Vapor lock evaluation will be made by timing accelerations from 0 to 30, 50, and 60 mph. All other aspects of the alternate procedure will be the same as the CRC procedure. Purpose is to compare the severity of timed accelerations from 0 to 30, 50, and 60 mph of the alternate procedure with timed accelerations of 15 to 50, 60, and 70 mph of the current CRC procedure.

Hot Start and Driveaway Test Procedure

The hot start and driveaway test procedure is designed to appraise low speed driveability and hot starting problems. The procedure is based on a similar procedure devised and conducted by Amoco Oil Company. The procedure consists of stabilization at 55 mph, simulated city traffic for 4 miles to maximize engine heating, a 10 minute idle soak, simulated city traffic for 3 miles, a 20 minute key-off soak, and simulated city traffic for 3 miles. Details of the procedure are included as Attachment C. Stabilization will be run on the highway and the simulated city course in a marked course on the Yuma Proving Grounds Dynamometer Track.

Each car will make the following runs:

- two fuels bracketing the critical vapor lock fuel (± 1 lb. RVP)
- duplicate tesets with Fuel RMFV 93-82
- the lowest volatility fuel (6 lb. RVP) only if problems occur with Fuel RMFV 93-82.

Fuel RMFV 93-82 is a high volatility, pentane-rich fuel that is designed to emphasize problems occurring in simulated low speed city driving. Fuel samples will be obtained at the end of each soak and inspected for RVP using an automatic RVP apparatus.

If time allows, up to five selected cars that had hot start and driveaway problems on the new procedure will also be run on the 1975 CRC Hot Start and Driveability Procedure. This will allow comparison of the severity of the two procedures. The 1975 CRC Hot Start and Driveability Procedure is included as Attachment D.

Temperature Measurements

Temperature measurements will be obtained at two locations on all vehicles. A common point of temperature measurement will be the surface temperature of the vehicles fuel line at a position of 6 to 12 inches from the carburetor. The second temperature point will be selected by the various car manufacturers or by panel members if a recommendation is not made by the manufacturers. Temperatures will be obtained during the first and last minute of all soak periods for vapor lock and hot start and driveaway tests.

Test Location and Schedule

Suitable temperatures and facilities are available at the Yuma Army Proving Grounds. Suggested timing is September 20, 1982 to October 15, 1982. Twenty-three test days are available. Two days are rescheduled for test site setup and driver practice. Temperature studies indicate a daily average of 2.2 hours of 70 to 80°F temperatures, and 5.1 hours of 90 to 100°F temperatures. Additional test time is probably available because of extending the test temperatures to 65 to 80°F and 90 to 105°F. With three-man test crews a full vapor lock test requires 55 minutes. After establishing the most severe soak, idle or key off, a vapor lock test requires 35 minutes. With the assumption that three vapor lock tests (one out of three to be a full vapor lock test) can be averaged for the 2.2 hours available at the lower temperatures and six at the higher temperatures, it will require 14 test days to complete the 65 to 80°F vapor lock tests and 7 days to complete the 90 to 105°F vapor lock tests. The hot start and driveaway tests will require 12 days to complete at 90 to 100°F. This leaves an allowance of 7 days at the lower temperature and 2 days at the higher temperature for adverse weather or alternate vapor lock procedure.

Manpower

Manpower requirements are based on a four-week test program, twenty-one test vehicles, and three test crews. Requirements are as follows:

- 3 Drivers-Raters
- 3 Observers
- 3 Preparers and Warmup
- 1 Data Analysis
- 1 Lab Operator
- 1 Track Boss
- 1 Track Assistant and Fuel Dispenser

ATTACHMENT BCRC VAPOR LOCK TEST PROCEDURE

1. Drain gasoline tank and refill with 8 gallons (6 gallons with tanks of 16-gallon capacity or less) of test fuel for the next test. Test fuel shall not be put in tanks more than 10 minutes before the start of the test. Take fill sample in duplicate if scheduled.
2. Drive 20 miles at 55 mph for vehicle warm-up, establishing base total start time after 15 miles of operation.
3. Obtain baseline acceleration time on the track following 15 miles of warm up by accelerating from a stop, at light throttle, to reach 10 mph within 5 seconds. Then accelerate at the desired throttle position (wide-open throttle) to 70 mph, timing by stopwatch from 15 mph to 50, 60, and 70 mph, as indicated by speedometer. Record acceleration times and note surging or abnormal vehicle performance. Complete one lap around the track at 55 mph and return to wind shelter.
4. Park car in soak shed for 15 minutes with engine off. Obtain soak fuel sample in duplicate.
5. At end of soak period, start car using vehicle manufacturer's recommended procedure. Record start time to nearest 0.1 second and number of stalls. Idle for 5 seconds in neutral after the original start and any restarts, and record any abnormality in the stability of idle performance. Accelerate from soak shed as described in Item 6.
6. Turn headlights on. Obtain wide-open throttle acceleration time by accelerating from the soak shed at part throttle to reach 80 mph in 5 seconds, and then accelerate at wide-open throttle to 80 mph, recording time from 15 mph to 50, 60, and 70 mph. Record acceleration time and abnormal vehicle performance. In this technique, a transient and/or abnormal change in acceleration rate is called surge. The intensity of surge may vary, as described below:

Satisfactory (S) - A rating indicating no malfunction. Some loss in acceleration may be measured, but no surging in the accepted understanding of the term may be recognized.

Trace (T) - A rating that is just discernible to a test driver; or might not be observed by the casual driver.

Moderate (M) - A rating that is judged to be probably noticeable to the average driver and definitely noticeable to the test driver. It is occasional in frequency and is associated with limited delays in acceleration rather than an actual decrease in speed.

Heavy (H) - A rating that is pronounced and judged to be obvious to any driver. It is persistent or constant in frequency and is associated with prolonged delays in acceleration or even actual decreases in speed level reached.

Lock (L) - That which completely stalls the engine over a stretch of at least 3/10 of a mile, or a period of time in excess of 20 seconds.

Turn headlights off at north turn.

7. Complete two laps around the track at 55 mph, to restabilize temperatures.
8. Idle for 10 minutes in neutral in the soak shed. Record number of stalls. Obtain "idle" fuel sample in duplicate.
9. At end of idle period, accelerate from soak shelter as described in Item 6.
10. Complete one lap around the track at 55 mph; return to fueling area.
11. Car volatility tolerances are to be defined only for the more critical condition (soak or idle); the remaining tests will be run as follows:
 - a. If the fuel selected for the previous test was either too volatile or too low in volatility to determine whether the idle or the soak acceleration was the more critical, the soak and idle procedure shall be repeated on a new test fuel.
 - b. If, during the preceding test, the soak acceleration is found to be appreciably more critical than the idle acceleration (>20% increase in acceleration time) with a fuel giving 25 to 75% loss in acceleration performance, the remaining tests will be run using only the soak procedure, otherwise the idle procedure will be used in all cases.
12. Continue testing with other fuels of different T-V/L levels to obtain curves of acceleration time from 15-50, 15-60, and 15-70 mph versus fuel volatility. To establish the vehicle limiting T-V/L data, a minimum of five fuels of each series will be tested at the desired limiting condition (soak or idle). Fuels will be selected with the following objectives:
 - a. A fuel with sufficient volatility to cause acceleration time to 70 mph to increase between 50 and 100%.
 - b. A fuel with sufficient volatility to cause acceleration time to 70 mph to increase between 25 and 50%.

- c. A fuel with sufficient volatility to cause acceleration time to 70 mph to increase between 10 and 25%.
- d. A fuel with sufficient volatility to result in less than a 10% increase in acceleration time, or if minimum acceleration time exceeds 10%, two fuels giving essentially equal performance and differing by at least 4°F in the temperature for 20:1 V/L ratio (0.5 to 1.0 lb RVP).
- e. A fuel estimated to give a 25% increase in acceleration time to 70 mph.

ATTACHMENT C

CITY DRIVEABILITY PROCEDURE
AND DRIVEABILITY RATINGS

1. Stabilize engine and fuel system temperatures by driving 15 miles at 55 mph.
2. Drive 4 miles in "city" traffic simulated as follows:
 - A. Within each mile stop 4 times for a 15 second idle, and at the end of each mile idle for 30 seconds to record driveability problems. All idle soaks should be about 0.2 miles apart.
 - B. Maximum car speed should be 20 mph.
 - C. Accelerate very gently following each idle by dropping the engine vacuum at the start of an acceleration by 5" Hg below its idle value and hold the throttle at this position until the car reaches 20 mph.

The purpose of this portion of the test is to maximize engine heating and underhood temperatures. During this portion of the test, the driver should rate the severity of subjective problems, such as hesitation, stumble, surge, idle roughness, and backfire; and count the number of stalls.

3. Idle for 10 minutes in the soak shelter with the transmission in neutral or "Park" for safety. Appraise idle quality, record stalls and restart times if stalling occurs. Obtain fuel samples for RVP inspection.
4. Leave the soak shelter and make a 0-30 mph part-throttle (3" Hg manifold vacuum) acceleration. Observe severity of any acceleration problems including hesitation, stumble, and surge.
5. Drive 3 miles in city traffic per Step 2 above.
6. Park in a soak shelter for 20 minutes with key off. Observe hot start stalls and measure restart time. Obtain fuel samples for RVP inspection.
7. Repeat Step 4 above.
8. Compile driveability demerits for the cycle using an appropriate rating scale, which weighs problems according to their relative severity.

ATTACHMENT DCRC HOT START AND DRIVEAWAY PROCEDURE

1. Drain fuel tank and fill with 8 gallons of test fuel.
2. Drive 20 miles at 55 mph for vehicle warm-up, establishing base total start time after running 15 miles of operation.
3. Pull into soak shed and idle in neutral for 10 minutes. Record idle speed and quality initially, after 5 minutes, and at the end of 10 minutes.
4. Back vehicle out of soak shed for approximately 30 feet and stop abruptly (10 ft./sec.²). Record idle quality during 10-second idle in drive. Also number of stalls, and restart time, if any.
5. Accelerate from 0 to 30 mph at 5 ft./sec.², stop abruptly (20 ft./sec.²). Evaluate and record hesitation, stumble, surge, and stall.
6. Idle in drive for 15 seconds, recording idle quality.
7. Accelerate at 5 ft./sec.² from 0-45 mph. Evaluate and record hesitation, stumble, surge, and stall.
8. Make four successive accelerations from 0-25 mph at 5 ft./sec.². Decelerate moderately, using brake, and idle for 15 seconds following each acceleration. Record hesitation, stumble, surge, stall, and idle speed and quality for each cycle of operation.
9. Immediately following final 15 second idle in Item 8, accelerate at 8" Hg. constant manifold vacuum from 0-55 mph. Record hesitation, stumble, surge, and stalls.
10. Complete 10 miles at 55 mph for temperature restabilization.
11. Pull into soak shed and idle in drive for one minute. Record idle speed and quality.
12. Turn off engine and soak for 20 minutes. Obtain duplicate fuel sample.
13. At the end of the soak period, with the transmission in park or neutral, set the throttle to manufacturer's recommendation. Engage the starter immediately after opening throttle. Do not pump the throttle before making the start. If the engine does not start after 15 seconds of cranking, depress throttle to floor board; crank an additional 15 seconds to check for overrich condition. If engine does not start, manipulate throttle as required to start engine. Record initial start time and detail any abnormal starting procedure.

14. When engine starts, allow it to accelerate to 1000 rpm before de-energizing start motor and releasing throttle to idle position. The engine must continue to run for one minute after the throttle is returned to idle to constitute a successful start and run test. If engine stalls, immediately repeat starting and idle procedure. If engine stalls 4 times in succession, increase idle speed as required to keep engine running. Evaluate and record idle quality and speed, number of stalls, and total starting time. Total starting time is the cumulative period of time the starter motor is engaged. The time interval that the engine is idling between stalls is not included in total starting time.
15. Repeat Items 4 through 9 and return to fueling area.

A P P E N D I X D

TEST PROCEDURES
AND
DATA RATING SYSTEMS

I. TEST PROCEDURES

A. CRC Vapor Lock Test Technique

1. Drain gasoline tank and refill with six gallons of test fuel for the next test. Test fuel shall not be put in tanks more than 10 minutes before the start of the test.
2. Drive 20 miles at 55 mph for vehicle warm-up, establishing base total start time after 15 miles of operation.
3. Obtain baseline acceleration time on the track following 15 miles of warm up by accelerating from a stop, at light throttle, to reach 10 mph within 5 seconds. Then accelerate at the desired throttle position (wide-open throttle) to 70 mph, timing by stopwatch from 15 mph to 50, 60, and 70 mph, as indicated by speedometer. Record acceleration times and note surging or abnormal vehicle performance. Complete one lap around the track at 55 mph and return to wind shelter.
4. Park car in soak shed for 15 minutes with engine off. Obtain soak fuel sample in duplicate.
5. At end of soak period, start car using vehicle manufacturer's recommended procedure. Record start time to nearest 0.1 second and number of stalls. Idle for 5 seconds in neutral after the original start and any restarts, and record any abnormality in the stability of idle performance. Accelerate from soak shed as described in Item 6.
6. Turn headlights on. Obtain wide-open throttle acceleration time by accelerating from the soak shed at part throttle to reach 10 mph in 5 seconds, and then accelerate at wide-open throttle to 70 mph, recording time from 15 mph to 50, 60, and 70 mph. Record acceleration time and abnormal vehicle performance. In this technique, a transient and/or abnormal change in acceleration rate is called surge. The intensity of surge may vary, as described below:

Satisfactory (S) - A rating indicating no malfunction. Some loss in acceleration may be measured, but no surging in the accepted understanding of the term may be recognized.

Trace (T) - A rating that is just discernible to a test driver, or might not be observed by the casual driver.

Moderate (M) - A rating that is judged to be probably noticeable to the average driver and definitely noticeable to the test driver. It is occasional in frequency and is associated with limited delays in acceleration rather than an actual decrease in speed.

Heavy (H) - A rating that is pronounced and judged to be obvious to any driver. It is persistent or constant in frequency and is associated with prolonged delays in acceleration or even actual decreases in speed level reached.

Lock (L) - That which completely stalls the engine over a stretch of at least 3/10 of a mile, or a period of time in excess of 20 seconds.

7. Complete two laps around the track at 60 mph, to restabilize temperatures.
8. Idle for 10 minutes in neutral in the soak shed. Record number of stalls. Obtain "idle" fuel sample in duplicate.
9. At end of idle period, accelerate from soak shelter as described in Item 6.
10. Complete one lap around the track at 60 mph, and return to fueling area.
11. Car volatility tolerances are to be defined only for the more critical condition (soak or idle); the remaining tests will be run as follows:
 - a. If the fuel selected for the previous test was either too volatile or too low in volatility to determine whether the idle or the soak acceleration was the more critical, the soak and idle procedure shall be repeated on a new test fuel.
 - b. If, during the preceding test, the soak acceleration is found to be appreciably more critical than the idle acceleration (>20% increase in acceleration time) with a fuel giving 25 to 75% loss in acceleration performance, the remaining tests will be run using only the soak procedures; otherwise the idle procedure will be used in all cases.
12. Continue testing with other fuels of different T-V/L levels to obtain curves of acceleration time from 15-50, 15-60, and 15-70 mph versus fuel volatility. To establish the vehicle limiting T-V/L data, a minimum of five fuels will be tested at the desired limiting condition (soak or idle). Fuels will be selected with the following objectives:
 - a. A fuel with sufficient volatility to cause acceleration time to 70 mph to increase between 50 and 100%.
 - b. A fuel with sufficient volatility to cause acceleration time to 70 mph to increase between 25 and 50%.

- c. A fuel with sufficient volatility to cause acceleration time to 70 mph to increase between 10 and 25%.
- d. A fuel with sufficient volatility to result in less than a 10% increase in acceleration time; or if minimum acceleration time exceeds 10%, two fuels giving essentially equal performance and differing by at least 4°F in the temperature for 20:1 V/L ratio (0.5 to 1.0 lb RVP).
- e. A fuel estimated to give a 25% increase in acceleration time to 70 mph.

B. CRC Hot Start and Driveaway Test Technique

1. Drain fuel tank and fill with six gallons of test fuel.
2. Drive 20 miles at 55 mph for vehicle warm-up, establishing base total start time after running 15 miles of operation.
3. Pull into soak shed and idle in neutral for 10 minutes. Record idle speed and quality initially, after 5 minutes, and at the end of 10 minutes.
4. Back vehicle out of soak shed for approximately 30 feet and stop abruptly (10 ft./sec.²). Record idle quality during 10-second idle in drive. Also record the number of stalls, and restart time, if any.
5. Accelerate from 0 to 30 mph at 5 ft./sec.², and stop abruptly (20 ft./sec.²). Evaluate and record hesitation, stumble, surge, and stall.
6. Idle in drive for 15 seconds, recording idle quality.
7. Accelerate at 5 ft./sec.² from 0-45 mph. Evaluate and record hesitation, stumble, surge, and stall.
8. Make four successive accelerations from 0-25 mph at 5 ft./sec.². Decelerate moderately, using brake, and idle for 15 seconds following each acceleration. Record hesitation, stumble, surge, stall, and idle speed and quality for each cycle of operation.
9. Immediately following the final 15-second idle in Item 8, accelerate at 8" Hg constant manifold vacuum from 0-55 mph. Record hesitation, stumble, surge, and stalls.
10. Complete 10 miles at 55 mph for temperature restabilization.
11. Pull into soak shed and idle in drive for one minute. Record idle speed and quality.

12. Turn off engine and soak for 20 minutes. Obtain duplicate fuel sample.
13. At the end of the soak period, with the transmission in park or neutral, set the throttle to manufacturer's recommendation. Engage the starter immediately after opening throttle. Do not pump the throttle before making the start. If the engine does not start after 15 seconds of cranking, depress throttle to floor board; crank an additional 15 seconds to check for overrich condition. If engine does not start, manipulate throttle as required to start engine. Record initial start time and detail any abnormal starting procedure.
14. When engine starts, allow it to accelerate to 1000 rpm before de-energizing start motor and releasing throttle to idle position. The engine must continue to run for one minute after the throttle is returned to idle to constitute a successful start and run test. If engine stalls, immediately repeat starting and idle procedure. If engine stalls four times in succession, increase idle speed as required to keep engine running. Evaluate and record idle quality and speed, number of stalls, and total starting time. Total starting time is the cumulative period of time the starter motor is engaged. The time interval that the engine is idling between stalls is not included in total starting time.
15. Repeat Items 4 through 9 and return to fueling area.

C. City Driveability Procedure

1. Stabilize engine and fuel system temperatures by driving 15 miles at 55 mph.
2. Drive 4 miles in "city" traffic, simulated as follows:
 - a. Within each mile, stop 4 times for a 15-second idle, and at the end of each mile, idle for 30 seconds to record driveability problems. All idle soaks should be about 0.2 miles apart.
 - b. Maximum car speed should be 20 mph.
 - c. Accelerate very gently following each idle by dropping the engine vacuum at the start of an acceleration by 5" Hg below its idle value and hold the throttle at this position until the car reaches 20 mph.

The purpose of this portion of the test is to maximize engine heating and underhood temperatures. During this portion of the test, the driver should rate the severity of subjective problems, such as hesitation, stumble, surge, idle roughness, and backfire; and count the number of stalls.

3. Idle for 10 minutes in the soak shelter with the transmission in neutral or "Park" for safety. Appraise idle quality, record stalls and restart times if stalling occurs. Obtain fuel samples for RVP inspection.
4. Leave the soak shelter and make a 0-30 mph part-throttle (3" Hg manifold vacuum) acceleration. Observe severity of any acceleration problems including hesitation, stumble, and surge.
5. Drive 3 miles in city traffic per Step 2 above.
6. Park in a soak shelter for 20 minutes with key off. Observe hot start stalls and measure restart time. Obtain fuel samples for RVP inspection.
7. Repeat Step 4 above.
8. Compile driveability demerits for the cycle using an appropriate rating scale which weights problems according to their relative severity.

II. DATA RATING SYSTEMS

A. Vapor Lock Rating System

Reid vapor pressures measured on samples from the car tank for each road test were converted to equivalent $T_{V/L}=20$ based on the correlation established in Section IV. These values were then adjusted for the difference between ambient air temperature at the time of testing and the reference temperature of 95°F or 70°F as follows:

$$\text{Adjusted } T_{V/L}=20 = \text{Actual } T_{VL=20} + K \left(\frac{95}{70} - \text{Air } T \right)$$

K = 0.7

Printouts of complete vapor lock data for each car are presented in Appendix G. Because surge was encountered in many of the base accelerations*, average base acceleration times were taken from those accelerations judged to best represent base-line performance.

* The frequency of surge in base accelerations in this program may be related to the slight delay at the end of the warm-up run needed to stop and allow the test crew to replace the warm-up driver.

Adjusted temperatures at V/L=20 were plotted against percent increase in car acceleration time at 15-50 mph, 15-60 mph, and 15-70 mph for all test sets. From these plots the most critical speed range and the limiting temperature at V/L=20 (hereafter described as $L_{T_{V/L=20}}$) were determined for 25% as in previous programs*.

B. Driveability Demerit Rating System

Starting Time - Time recorded in seconds (hot-start time is the sum of times for initial start and all re-starts).

Stalls at Idle - Number of occurrences during each maneuver or time period.

Stalls, Driving - Number of occurrences during each maneuver.

Idle Roughness)

Backfire) Severity of any occurrence rated as trace (T),
 Hesitation) - moderate (M), or heavy (H) during each
 Stumble) maneuver.
 Surge)

Weighted demerits are assigned to each malfunction as summarized below:

Weighted Demerits**

Starting time:

Seconds - 2.0
(but zero if negative)

Stalls at idle:

8

Stalls, driving:

32

| | T | M | H |
|----------------|---|----|----|
| Idle roughness | 1 | 2 | 4 |
| Backfire | 6 | 12 | 24 |
| Hesitation | 6 | 12 | 24 |
| Stumble | 6 | 12 | 24 |
| Surge | 4 | 8 | 16 |

The total weighted demerit (TWD) value for each run was computed by adding the weighted demerits for the several malfunctions in each maneuver or idling period, subject to the following constraints:

* For example, reference, "1966 CRC Vapor Lock Tests," CRC Report No. 420.

** "Evaluation of a High Temperature Driveability Test Procedure - 1971 Yuma Program," CRC Report No. 455.

1. Only one driving stall was counted per maneuver.
2. No more than three idling stalls were counted per idling interval.
3. No more than five idling stalls were counted for the whole hot-start and idle procedure (lines 14-18 of data sheet).
4. For each maneuver or idling interval, only the one malfunction giving the highest weighted demerits was counted. Thus, if heavy hesitation (24 weighted demerits) and a stall were recorded in the same maneuver, only 32 weighted demerits were counted towards the TWD.

RATER COMPARISONS

CITY DRIVEABILITY PROCEDURE

APPENDIX E

RATER COMPARISONS - CITY DRIVEABILITY PROCEDURE

Past programs have shown large differences can exist among raters when evaluating vehicle driveability. To evaluate rater differences, data on cars driven by the same rater on the same fuels provide the best measures of biases. Ratings were obtained by each rater on the same fuel (No. 20) for only two vehicles:

| Vehicle | Total Weighted Demerits | | | | St. Dev. | St. Dev. %* |
|---------|-------------------------|----------|----------|---------|----------|-------------|
| | Rater 04 | Rater 10 | Rater 17 | Average | | |
| 10 | 917 | 874,766 | 530 | 755.7 | 201.4 | 27 |
| 12 | 884 | 793,761 | 812 | 824.3 | 54.6 | 7 |

*Standard deviation as percent of the mean.

Because of the inconsistencies indicated above and the small amount of data, rater severity values could not be developed to correct the TWD values for each vehicle/fuel combination.

Repeatability can best be measured by comparison tests performed by individual raters on the same vehicle/fuel combinations. Repeat ratings were completed by Rater 04 with three vehicles and by Rater 10 with two vehicles:

| Rater | Car | Fuel | Run 1 | Run 2 | Average | St. Dev. | St. Dev., % |
|-------|-----|------|-------|-------|---------|-------------|-------------|
| 04 | 9 | 1 | 184 | 269 | 226.5 | 60.1 | 26.5 |
| | 14 | 1 | 112 | 48 | 80.0 | 45.3 | 56.6 |
| | 14 | 20 | 393 | 567 | 480.0 | 23.0 | 25.6 |
| | | | | | | Avg. = 36.2 | |
| 10 | 10 | 20 | 874 | 766 | 820.0 | 76.4 | 9.3 |
| | 12 | 20 | 793 | 761 | 777.0 | 22.6 | 2.9 |
| | | | | | | Avg. = 6.1 | |

Rater 04 may have had difficulty repeating ratings, or the particular cars Rater 04 ran for repeatability were not consistent in driveability. No repeatability data were available for Rater 17.

**EFFECTS OF FUEL VOLATILITY CHANGES
CITY DRIVEABILITY PROCEDURE**

APPENDIX F

EFFECTS OF FUEL VOLATILITY CHANGES - CITY DRIVEABILITY PROCEDURE

Total weighted demerit values obtained with the nineteen test fuels are shown in Table F-1 and illustrated in Figure F-1. As indicated, all vehicles were tested on at least two fuels, and every vehicle was tested on Fuel 20. As time permitted, vehicles with high demerit levels with Fuel 20 were tested using the vapor lock fuels. The test plan called for each car to run two vapor lock fuels bracketing the critical fuel. Because bracketing fuels varied for the different vehicles, an unbalanced data set was created, causing significant difficulty in model development.

Initially, to determine if changes in fuel volatility significantly affected TWD ratings, the data for vehicles tested on the extreme fuels were averaged and compared. In this data set, seven vehicles were tested on two fuels of widely different volatility (Vehicles 1, 4, 6, 9, 10, 12, and 14 on Fuels 1 and 20). Although these data are limited, the average TWD values follow the expected trend, increasing considerably as fuel volatility increases:

| <u>Fuel No.</u> | <u>Avg. TWD for Seven Vehicles</u> | <u>Inspections</u> | | |
|-----------------|------------------------------------|--------------------|-----------------|--------------|
| | | <u>RVP, psi</u> | <u>T V/L=20</u> | <u>% 158</u> |
| 1 | 219 | 7.1 | 152.5 | 19.2 |
| 20 | 552 | 13.4 | 107.2 | 42.4 |

The analysis was expanded to include data for all fuels and all vehicles, rater biases, car biases, and ambient temperature. Ambient temperature was found to be insignificant in the temperature range tested and was excluded from further model development. The expanded model, excluding ambient temperature, was:

$$\begin{aligned} \text{TWD} = & b_0 + b_1 C_1 + b_2 C_2 + \dots + b_{19} C_{19} + b_{20} R_{04} \\ & + b_{21} R_{10} + b_{22} R_{17} + b_{23} T V/L=20 \\ & + b_{24} \%158 + b_{25} RVP \end{aligned}$$

where:

C = dummy variable for Cars 1-19
R = dummy variable for Raters 04, 10, 17

The three fuel variables did not appear to be significant, indicating the combination of variables did not correlate with TWD. Rater coefficients were insignificant; therefore, the rater effect was eliminated from further model development. Correlation and regression coefficients are shown in Table F-II.

Fuel variables were next examined individually. The models used were developed using the common log of the TWD values. A constant of 10 was added to the TWD term to raise it above zero.

Models used for separately correlating RVP, %158, and $T_{V/L=20}$ were:

RVP:

$$\begin{aligned}\text{Log (TWD + 10)} &= b_1 C_1 + b_2 C_2 + \dots + b_{19} C_{19} \\ &\quad + b_{25} (\text{RVP} - 12.4)\end{aligned}$$

%158:

$$\begin{aligned}\text{Log (TWD + 10)} &= b_1 C_1 + b_2 C_2 + \dots + b_{19} C_{19} \\ &\quad + b_{24} (\%158 - 33.7)\end{aligned}$$

$T_{V/L=20}$:

$$\begin{aligned}\text{Log (TWD + 10)} &= b_1 C_1 + b_2 C_2 + \dots + b_{19} C_{19} \\ &\quad + b_{23} (T_{V/L=20} - 120.3)\end{aligned}$$

Results follow the expected trend -- TWD values increase as fuel volatility increases. All three fuel variables appear to be equally good predictors of hot-weather driveability and not just $T_{V/L=20}$, as for the 1975 CRC program. When using individual fuel variables, the model correlation coefficients improved. Correlation and regression coefficients are shown in Table F-II.
