#### NATIONAL DAM INSPECTION PROGRAM PHASE I INSPECTION REPORT

Identification No.: VT00012 Name of Dam: Lake Sadawga Dam Town: Whitingham County and State: Windham, Vermont Stream: Tributary to Lake Whitingham Date of Inspection: June 16, 1978

#### BRIEF ASSESSMENT

#### GENERAL

1

<u>\_\_\_\_</u>

÷.

Lake Sadawga Dam is an earthfill dam about 10 feet high, 400 feet long, a crest width of about 10 feet, and side slopes of 2 to 2.5H:1V. It contains a 60-foot-long masonry, control section with a height of 13.5 feet. There is one earthfill saddle dike, referred to as the West Dike, which is about 10 feet high, 265 feet long, has a crest width of 4 feet, and side slopes of about 1.5H:1V. The impounded water is used for recreation and to feed a sprinkler system in a factory downstream.

The dam is classed as "intermediate" in size, based on storage, and its hazard classification is "significant".

The drainage area is about 2800 acres and the reservoir surface area is 202 acres. The length of the reservoir is about 5700 feet and it contains 808 acre feet of water in the normal recreation pool. The water may be drained from the reservoir through a 24 foot diameter pipe by removing stoplogs. The upstream invert of the stoplog structure is about 16.2 feet below the top of the dam.

A flood equal to 50% of the PMF will overtop the main embankment by about 1.5 feet and the West Dike by about 0.5 feet.

The main embankment is in good condition. Regular maintenance is required in the form of control of vegetation, repair of riprap, and root removal.

The West Dike has steep side slopes and a narrow crest. If the water rises to within two feet from the top of this dike, which occurs in a flood about 15% of the PMF, it may become unstable. Hence its stability should be checked and the dike should be redesigned so that it will be equivalent to the main embankment.

A portion of the concrete cap on the spillway section is severely cracked and is in only fair condition. A monitoring system should be established to determine whether this portion is settling and an engineer should be retained to make necessary recommendations for repair of this control section.

Annual maintenance inspections and bi-annual technical inspections should be instituted. In addition, a flood warning system for downstream residents should be developed and implemented.

#### STATEMENT OF SIGNIFICANT FINDINGS

The following significant conditions were observed:

- 1. A large section of the original spillway shows cracking which may indicate settlement of this section of spillway.
- Large trees are growing on the right end of the embankment, and vegetation is growing profusely on the upstream slope, on the left embankment and on the West Dike.
- 3. The West Dike has a very narrow crest width together with steep side slopes.
- 4. The spillway capacity is inadequate to pass the design flood of 3800 cfs.
- 5. The embankment is wave cut at lake level due to erosion of fines from the embankment.

## STATEMENT OF RECOMMENDED ACTION

An engineer qualified in dam design should be engaged to redesign the West Dike to be safe when the maximum flood occurs, and to analyze alternatives and recommend a method for increasing the spillway capacity. In addition the cracking on the old spillway should be monitored to see if an ongoing settlement condition exists.

The large trees and roots on the right embankment should be removed and the holes repaired properly. The riprap on the upstream face of the embankment should be repaired. A maintenance program should be developed to insure that brush is removed annually from all parts of the dam and dike. Refer to Section 7 for detailed findings and recommendations.

John K. Juci

This Phase I Inspection Report on Lake Sadawga Dam has been reviewed by the undersigned Review Board members. In our opinion, the reported findings, conclusions, and recommendations are consistent with the <u>Recommended Guidelines for Safety Inspection</u> of Dams, and with good engineering judgment and practice, and is hereby submitted for approval.

Charles S. Tierco

Chief, Engineering Division

## PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through continued care and inspection can there be any chance that unsafe conditions be detected.

Phase I Inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test Flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

vit

#### SECTION 4: OPERATIONAL PROCEDURES

4.1 Procedures

None

4.2 Maintenance of Dam

The Vermont Department of Fish and Game maintain the dam by cutting brush and mowing both the dam, and the West Dike.

# 4.3 Maintenance of Operating Facilities

There is no routine maintenance of the operating facilities.

4.4 Description of Warning System in Effect

None for this dam.

4.5 Evaluation

The mowing program is effective in keeping brush from growing on the dam. The section of the dam west of the spillway structure has not been mowed for several years, and should be included in order for the maintenance program to be complete.

## d. Reservoir Area

Lake Sadawga has a large "floating island" which consists of bog vegetation that floats in the central part of the lake. The lake level on June 16, 1978 was at the crest of the service weir, elevation 96.2, as is required by the rules and regulations for the surface level of Sadawga Pond as amended 18 September 1964.

#### e. Downstream Channel

The channel rapidly falls away from the Route 100 bridge at a 3.6 per cent slope. The channel averages 20 feet in width and water, flowing out of bank, can rise to stages of about 10 feet without flooding homes. The channel is composed of ledge outcrops and has been riprapped on the downstream side of the bridge. Water will probably overtop the bridge for the Spillway Design Flood but not at elevations which will significantly impede the flow out of Lake Sadawga. The bridge has a hydraulic opening of about 180 square feet and the top of road is at about elevation 95.4.

#### 3.2 Evaluation

Based on visual examination, the embankments of the main dam are in good condition. The riprap needs repair, trees and shrubs must be cut, and the roots must be eliminated as a possible path of seepage.

Due to its steep side slopes and narrow crest width the West Dike appears to be only marginally adequate if the lake rises to within two feet below the top, as has been anticipated in the records available.

A portion of the concrete cap is in fair condition, since it is severely cracked and shows signs of settlement. It should be monitored to determine whether settlement is occurring. It is also recommended that the condition of the penstock where it penetrates the wall be determined. The concrete cap shows evidence of deterioration in the form of light scaling and medium surface cracks. A portion of the cap just to the right of the control section (see Photo 8 in Appendix C) approximately 4 feet x 8 feet in plan appears to have settled and cracked. This portion of the cap is located directly over the old 3.9-foot diameter penstock where it penetrates the masonry wall.

The control section in the spillway is approximately 9 feet long. It appears to be constructed in accordance with the plans entitled "Proposed Spillway, Sadawga Pond, Whitingham, Vermont" by Howard M. Turner, Consulting Engineer, 1957.

There is provision in the control section for stop planks, which if installed, would raise the lake level to the height of the original spillway.

The concrete in the control section, including the training walls appears relatively new and is in good condition.

The regulating outlet consists of a 6.3 feet by 8.4 feet drop inlet. The upstream face of the inlet is formed by two rows of stop planks which fit into steel channel sections imbedded in concrete. The drop inlet, flows into the remains of a 3.9 foot penstock which penetrates the masonry wall. This structure is in generally good condition. The condition of the old penstock, within the masonry wall is unknown.

On the left side of the control section is a control gate for an 8-inch penstock which is used by a small wood product factory. The gate is operated by a handwheel which is in a gate house on top of the spillway. The actual penetration of the masonry wall is accomplished by a 30-inch boiler section, which is filled with concrete on the downstream side of the wall in order to accomplish the transition to 8-inch cast-iron pipe. Just to the right of the right spillway training wall a path has been formed by pedestrians who climb to the top of the spillway structure.

Left Embankment - The embankment to the left of the spillway section is entirely overgrown with low trees to 15 feet high and with wild roses, on both upstream and downstream sides and on the crest.

No erosion was noted, except that a wave cut zone exists at lake level. The riprap appears in good condition. No filter material was evident beneath the riprap.

There was no seepage observed downstream of this embankment, which is arched downstream, in plain view, as it turns to meet the left abutment.

<u>Spillway Structure Foundation</u> - The spillway structure is founded on bedrock which is relatively flat-lying. One measurement showed a strike of N75E with a dip of 14° N. It appears that bedrock is shallow in the vicinity and that the embankment may be founded thereon.

<u>West Dike</u> - The west dike has very steep slopes (about 1.4H:1V) and a 3 or 4-foot-wide crest. The lake level is about 3 feet higher than the downstream toe and the freeboard is about 7 feet, which means that the top of the dike is about one foot higher than the dam embankment.

This dike is overgrown with shrubs and small trees. The records indicate that about 20 years ago this growth had been cut back.

A swampy zone exists for a distance of at least 100 feet downstream in a rather flat saddle that is shown on the USGS topographic map. There was no seepage evident from the downstream toe of the dike.

#### c. Appurtenant Structures

The concrete and masonry spillway, with the drop inlet regulating outlet, and the gated 8-inch penstock constitute the appurtenant structures of this dam.

The original spillway section is approximately 46 feet long. This spillway section is capped with old concrete. There is steel bar and masonry block embedded in the concrete. The purpose of the steel and masonry is unknown.

q

#### SECTION 3: VISUAL INSPECTION

#### 3.1 Findings

#### a. General

The on-site inspection of Lake Sadawga Dam was performed on June 16, 1978. Weather conditions were ideal for the inspection; clear, temperatures in the 70s. Runoff in the streams was considered normal for that time of year. No emergency conditions were observed on the day of the inspection.

The condition of the embankment was found to be good, and the spillway concrete was found to be in fair condition. The West Dike has steep slopes.

#### b. Dam

Figure 1 shows an approximate cross section, which was taken at a location about 73 feet right of the right spillway training wall. The freeboard is nearly 6 feet and the lake is quite shallow at this location. There is a head of only 2.6 feet across the embankment. The head is several feet high growing from the riprap.

At the lake level this riprap is wave cut slightly. No filter material appears to be present under the riprap. At one location about 56 feet right of the right spillway training wall, a zone about 10 feet wide along the upstream lake shore is eroded partway up the slope. At this location the embankment is arched upstream. This zone of erosion is at the location of minimum radius of curvature in plan view of the embankment.

Seepage was observed emanating from the downstream toeline along nearly the entire 300 foot length. Specific seeps were not observed, but the entire zone was wet downstream and a small channel had been dug to carry the water to an outlet. The wet zone is shown in Photo No. 3 in Appendix C. The dark green grass grows in the wetter areas.

4.

<sup>1</sup>Results of Howard M. Turner Report dated June 20, 1957.

#### f. Operator

The dam is operated by the Vermont Department of Fish and Game, Contact:

Mr. Ray Harwood, Regional Supervisor Telephone: 802-773-2657

#### g. Purpose

Lake Sadawga Dam is presently maintained for recreational purposes. One 8-inch pipe feeds a sprinkler system for a building downstream.

The dam was originally constructed to impound and control water for hydropower purposes.

#### h. Design and Construction History

No information is available on the design or construction history of this dam.

#### i. Normal Operation Procedures

There are no normal operational procedures associated with this dam.

#### 1.3 Pertinent Data

L

**F**.

11

#### a. Drainage Area

The drainage area is 4.33 square miles of rolling hills surrounding Lake Sadawga, including the drainage area of Lake Clara. The drainage is from hills which rise 430 feet above normal pond level. They are predominantly covered with soils described as glacial till with a hardpan or bed rock commonly within three feet of the surface.

The watercourses into the pond vary in characteristic from a well-defined 1.9 square mile basin formed north of Route 100 and the town highway just south of Route 100 to several smaller tributaries flowing from the hills immediately surrounding Lake Sadawga. The northern watercourse has an average slope of 130 feet per mile and is about 2.3 miles long while the smaller tributaries are about 0.8 mile long with slopes of roughly 440 feet per mile.

#### b. Description of Dam and Appurtenances

Lake Sadawga Dam is an earth dam with a concrete and masonry spillway section.

The level in the lake is maintained by a control section in the spillway. There is also a drop inlet, in which the invert elevation may be varied by use of stop planks. The drop inlet is connected to an abandoned 3.9' penstock which penetrates the masonry wall of the spillway on the east side. There is an 8-inch penstock on the west side which is still in service. Water in this penstock is maintained by a gate constructed in the concrete and masonry portion of the dam.

At the far west end of the lake is a dike, apparently constructed of earth and rock, which prevents water from outletting at that spot.

#### c. <u>Size Classification</u>

Lake Sadawga is a 202-acre impoundment. The dam is between 9 and 17 feet in height. The maximum storage potential of the lake is estimated at 1939 acre-feet. The Corps of Engineers recommends that dams which have a height greater than 40 feet but less than 100 feet, or have a storage volume greater than 1000 acre-feet but less than 50,000 acre-feet be classified as intermediate in size. The storage volume therefore governs, and results in a size classification of intermediate for this dam.

## d. Hazard Classification

A failure of Lake Sadawga Dam would route the resulting flood through Whitingham Village to Lake Whitingham, (see map in Appendix B). It is estimated that three or four lives might be endangered in the event of a dam failure, and that one building, State Route 100 and several town roads would suffer serious damage. The hazard category of Lake Sadawga Dam is therefore significant.

#### e. Ownership

The present owner of Lake Sadawga Dam is:

The Vermont Dept. of Fish and Game Montpelier, Vermont 05602 Commissioner, Edward Kehoe

Reportedly the previous owner of the dam was Mr. Houghton Sawyer of Whitingham.

NATIONAL DAM INSPECTION PROGRAM PHASE I INSPECTION REPORT NAME OF DAM: LAKE SADAWGA

SECTION I: PROJECT INFORMATION

#### 1.1 General

#### a. Authority

Public Law 92-367, August 8, 1972, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a National Program of Dam Inspection throughout the United States. The New England Division of the Corps of Engineers has been assigned the responsibility of supervising the inspection of dams within the New England Region. Dufresne-Henry Engineering Corporation has been retained by the New England Division to inspect and report on selected dams in the State of Vermont. Authorization and notice to proceed were issued to Dufresne-Henry Engineering Corporation under a letter of May 26, 1978 from Ralph T. Garver, Colonel, Corps of Engineers. Contract No. DACW33-78-C-0341 has been assigned by the Corps of Engineers for this work.

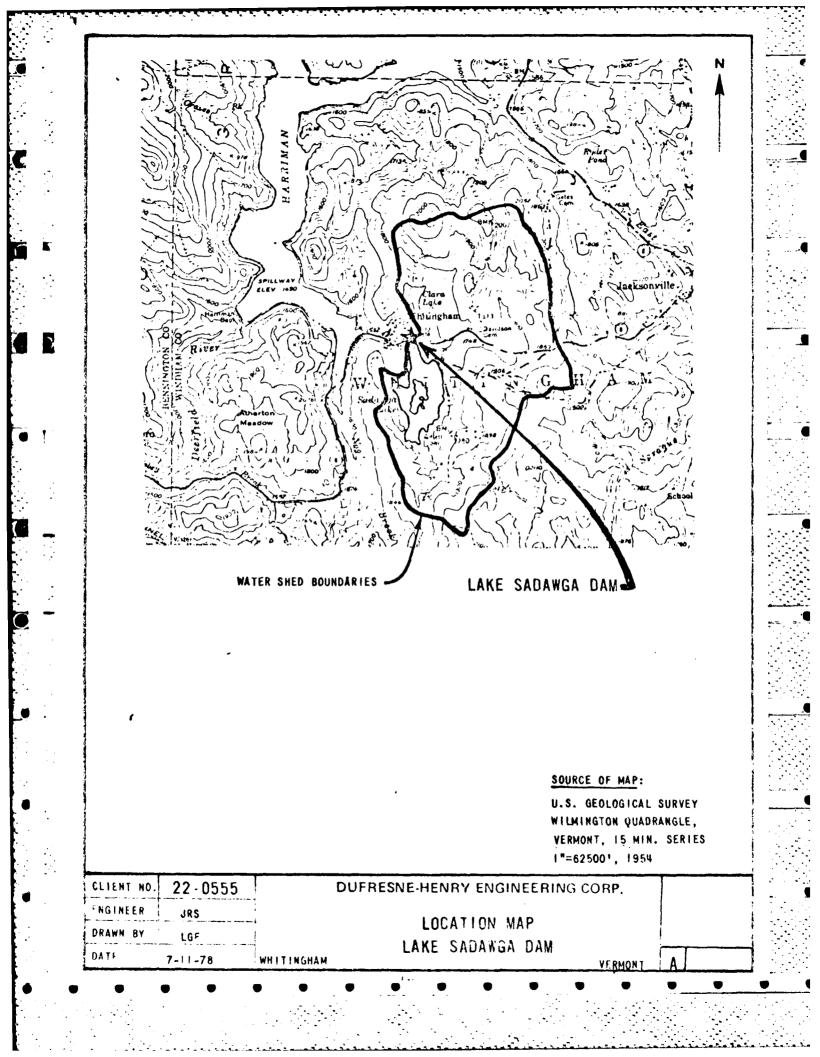

## b. Purpose

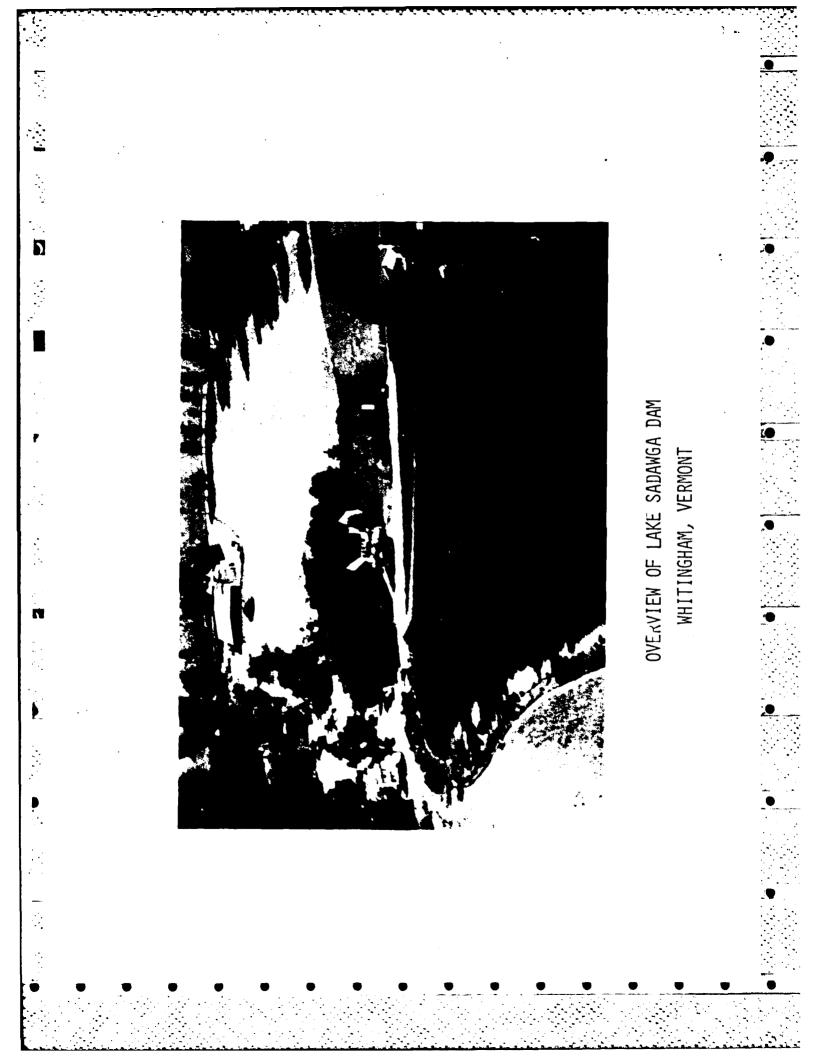

- Perform technical inspection and evaluation of non-Federal dams to identify conditions which threaten the public safety and thus permit correction in a timely manner by non-Federal interests.
- 2. Encourage and prepare the states to initiate quickly effective dam safety programs for non-Federal dams.
- 3. To update, verify and complete the National Inventory of Dams.

#### 1.2 Description of Project

a. Location

Lake Sadawga Dam is located in the Town of Whitingham, Windham County, Vermont. More specifically the dam is located approximately 0.25 miles southeast of Whitingham Village on Route 100.

#### SECTION 5: HYDRAULIC/HYDROLOGIC

## 5.1 Evaluation of Features

#### a. Design Data

The only data available is contained in the report by Howard M. Turner in 1957. In this report he was proposing modification to the spillway section to its present form. In his analysis he makes reference to a "rare flood" of 1680 cfs which is reduced by pond storage to an outflow of 540 cfs. This outflow would result in a stage of 99.4 in the pond based on his supporting computations.

One-half of the Probable Maximum Flood (1/2 PMF) has been selected as the Test Flood for this impoundment. This flood was computed using hydrograph methods via the Generalized Computer Program HEC-1. The results of the current hydrograph analysis show that the inflow would be on the order of 7500 cfs and the outflow would be about 3800 cfs. Consequently the previously existing data does not conform to the present design criteria.

#### b. Experience Data

There are no accounts of overtopping or significantly high water levels in Lake Sadawga.

#### c. Visual Observations

The impoundment is being operated in accordance with the rules and regulations for the surface level of Sadawga Pond as amended 18 September 1964. The stop log structure is in serviceable condition and could be used to draw the lake down in the event of an emergency.

#### d. Overtopping Potential

The Test Flood of 1/2 PMF will overtop the earth embankment near the spillway by about 1.5 feet and the West Dike by about 0.5 feet.

#### e. Results of Dam Failure

(1) <u>Main Dam</u>

A wave of water about 11 feet high would flow down the existing channel away from Lake Sadawga. This would <u>not</u> be high enough to cause serious damage as there is channel capacity to at least 10 feet above the stream bed.

## (2) West Dike

.

•

\_\_\_\_

6

5

.

A wave of water about 7 feet high would flow through the woods and swamp area to the west of Lake Sadawga. Its height would be somewhat diminished when it reached the Village area but still could sustain considerable damage to a church and possibly Route 100.

#### SECTION 6: STRUCTURAL STABILITY

#### 6.1 Evaluation of Structural Stability

#### a. Visual Observations

e.

J

1

Based on visual observations there appears to be little cause for concern currently about the stability of this dam. However, large trees are growing near the right abutment, which will lead eventually to rotting roots and possible paths for internal erosion. Similarly shrubs and low trees are being allowed to grow on the upstream side of the right embankment and over the entire left embankment and West Dike.

The riprap is wave cut, probably due to continual plucking of fines from the embankment through the voids between stones.

The West Dike has a crest width of only a few feet. In the records it appears that for a "rare storm" (1640 cfs inflow, 11% of PMF) the freeboard will drop to only 2 feet. Under these conditions the West Dike will be in substantial danger of eroding through due to only minor wave action, because the crest is narrow and the slopes are steep.

See Section 3.1.c. for comments on the cracking of the concrete cap of the spillway.

#### b. Design and Construction Data

There are no design or construction data available on which to base an analysis of the stability of this dam.

#### c. Operating Records

There are no operating records available that relate to the structural stability of this dam.

#### d. Post-Construction Changes

There are no data available concerning post-construction changes. From the appearance of the concrete, and the June 20, 1957 letter from Mr. Turner to Mr. Thieme, it would seem that changes have been made at the control section. In particular, a 9 foot section of the spillway was lowered 2.7 feet to prevent overtopping during a "rare" storm.

#### e. Seismic Stability

This dam is in Seismic Zone 2 and therefore need not be analyzed for seismic forces, according to the guidelines for Phase I inspection.

## SECTION 7: ASSESSMENT, RECOMMENDATIONS/ REMEDIAL MEASURES

## 7.1 Dam Assessment

#### a. Condition

Based on the records and visual observations, there are no significant concerns about the structural stability of this dam. The wave cut riprap and the large trees on the embankment could ultimately lead to difficulties if not repaired.

The West Dike has such a narrow crest and steep slopes that it would be subject to washout if the freeboard were ever reduced from its present value of 6 feet to only 2 feet, which would occur during a "rare" flood (equivalent to 11% of the PMF).

The concrete cap on a portion of the control section is in fair condition. It contains large cracks and may be settling.

#### **b.** Adequacy of Information

The assessment of the condition of the dam was based primarily on the visual inspection.

c. Urgency

..

. -

È

.

The recommendations given in Sections 7.2 and 7.3 should be carried out within 12 months in the control section and within two to four years for the balance of the work.

#### d. Necessity for Additional Information

Additional information needed to carry out the recommendations in Sections 7.2 and 7.3 should be obtained.

#### 7.2 Recommendations

An engineer qualified in the design of earth dams should be engaged to:

- 1. Redesign and rebuild the West Dike to make it equivalent to the dam.
- 2. Monitor settlement of the cracked portion of the control section and redesign this structure as necessary.

- 3. Investigate the condition of the penstock that penetrates the control section and make any necessary recommendations.
- 4. Develop a procedure for removing roots of large deciduous trees in the dam without endangering the dam.
- 7.3 Remedial Measures

•

.

5

1

a. Alternatives

Not applicable.

## b. Operating and Maintenance Procedures

- 1. Make an annual maintenance inspection of the dam.
- 2. Make a bi-annual technical inspection of the dam.
- 3. Repair the riprap that has been wave cut.
- 4. Repair eroded spots in embankment.
- 5. Cut all vegetation and maintain it cut, for both the main dam and the West Dike.
- 6. Repair spalled and cracked concrete.
- Develop and test regularly a flood warning system for the downstream residents.

#### MEMORANDUM

To: File

From: Donald H. Spies

Subject: Lake Sadawga Dam - Whitingham

On August 25, 1975, the writer made an inspection of the subject structure. The right embankment appears to be in good condition. Some water was noted along the toe, but it was not determined whether the water was from seepage or local drainage. It was also noted the upstream face is heavily overgrown with brush which should be brought under control.

The spillway section also seemed to be in good condition. Some small trees are growing on the downstream face and should be removed before the root systems damage the stone work. There is some leakage through the stones, but doesn't appear to be a problem at the present. This condition should be observed periodically to detect changes.

The left embankment is quite overgrown with brush which should be cut and removed.

The dike on the northwest bay seems to be stable. Some of the brush and trees are starting to grow and should be cut back. Water was noted at the toe but appears to be an accumulation from local drainage and not seepage.

DHS/vd1

Edward F. Kehoe, Commissioner, Fish & Game

Lake Sadawga Dams -Whitingham

Donald H. Spies

October 28, 1971

Main Dam

On October 4, 1971, the writer inspected the subject structure. The dam is essentially a concrete and masonry structure with an earth fill wing wall on each end. Overall, the dam was in fairly good shape. However, the masonry is leaking in quite a few places. The west wing wall is heavily overgrown with brush and small trees. There is some growth on the east embankment and a little in the masonry portion.

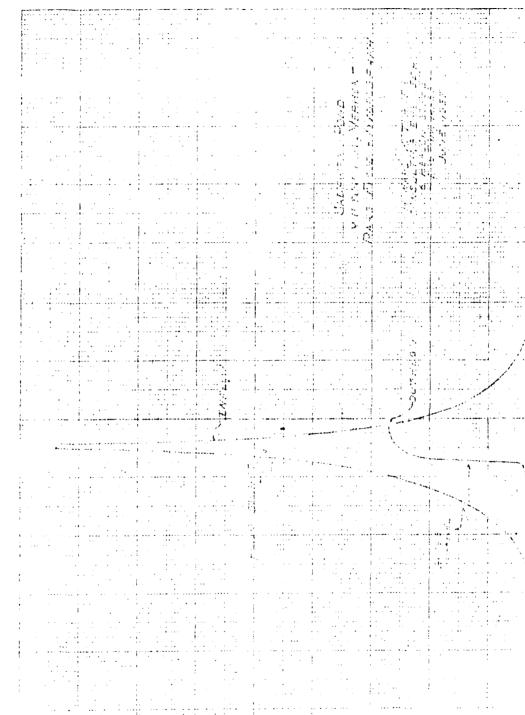

The door to the gatehouse has been removed and it was noted that there was no lock on the gate wheel. Also, the penstock leaks quite badly.

#### West Dam

The subject dam was inspected by the writer on October 4, 1971. It is an earth fill dam with no spillway. The purpose of this structure apparently is to prevent the lake waters from flowing out a low area. The width of the dam is quite narrow (about 3' at the top) and the slopes are quite steep (almost 1 on 1). However, the dam appears to be holding up quite well and there was no noticeable leakage. It was noted that the brush had been cut down some time ago, but it is starting to come back. Possibly, something could be sprayed on the brush to retard its growth.

 $\mathbf{h}$ 

with the level 1.2 ft. below the top of the abutments. This is too low for safety when wave action is considered, but the fact may be of interest.

I recommend the following:

(1) That the present 4 ft. pensiock opening below the dam be put in shape with an adequate flood gate at its entrance so that this can be used during times of high f bod to reduce the height of the water over the dam, and that the gate to the small pipe be put in sulfable operating condition.

(2) That the low spillway be reduced 2.3' in height with the remaining 1' of this wall shaped as shown.

Yours very truly,

Howard M. Turner

- HMT/sb

OWARDM. TURNER CONSULTING ENGINEER 6 BEACON STREET BOSTON 8, MASS.

K

T

June 20, 1957

Mr. Reinhold W. Thieme, Commissioner Water Conservation Board Montpelier, Vermont

Dear Sir:

Last December, I made a study of the flood conditions of Sadawga Pond. This was figured on a drainage area, taken from the maps then existing, of 5.2 sq. miles and a pond area of 179 acres. You have given me new figures on these, from maps as yet unpublished from the United States Geological Survey which show that the drainage area of Sadawga Pond including Lake Chara is 4.33 sq. miles and the area of the pond is 202 acres. This, of course, materially changes the basis of flood discharge. This report is written using these revised figures.

At the recent hearing, it was suggested that if the old spillway area 9' wide by 3.3' high be opened again, it would be safe for flood purposes. I have been through this and have estimated the "rare" flood with the revised drainage areas, to be 1680 c.f.s. (cubic feet per second).

I have found that sufficient flood capacity can be obtained with the gates and the spillway lowered 2.3 ft. The low wall 1' high across this 9' spillway should be shaped as shown to give a good discharge coefficient.

With this spillway, assuming that the pond is full to the new crest of the spillway when the flood starts and that the gates are opened when the water is cheat two foct over the spillway, the storage of the pond above the dam, 23, 200, 000 cu. ft., will reduce the flood to an outflow of 540 c.f.c. with the water level 3. 2' over the new low crest of the spillway and 0.5' over the long, main crest. This maximum water level will be two feet from the top of the abutment and embankment on both sides of the dam which is a satisfactory margin. I enclose a hydrograph of this flood slowing the outflow over the spillway.

It may be of interest to know that if for any reason, the gates fail to be opened, the spillway proposed will handle the flow of a rare flood
