19 ABSTRACT (Continue on reverse if necessary and identify by block number)

An integrated system combining both hardware and software has been developed to aid in the control and data acquisition of current experiments. The software is written in such a way as to be generally usable in a wide variety of experiments with little or no modification. The system is based on an IBM PC-XT and a CAMAC crate that can be filled with differing modules dependent upon experimental need.

A SYSTEM FOR INTERACTIVE COMPUTER CONTROL OF EXPERIMENTS

Introduction

An integrated system allowing computer control and data acquisition has been developed for the NRL quasi-optical gyrotron experiment. The motivation for this system is manyfold. First, it is necessary to simultaneously monitor several parameters; a difficult task using only oscilloscopes but simple for a computer. Secondly, a computerized system is potentially much more accurate than an experimenter reading numbers off of an oscilloscope and recording them in a notebook. The use of the computer allows the experimenter to visually monitor only the parameters of immediate interest while the computer quietly records all of the necessary data for future analysis. Additionally, since the data is already in the computer, data analysis and plotting is transformed into a process that takes a few minutes instead of large fractions of hours. Because much of this analysis can be done while the experiment is running, the taking of useless data can be held to a minimum. These facts all result in the ability to take much more complete and accurate data in a shorter time period than otherwise would be possible.

The quasi-optical gyrotron experiment for which this system was developed is a pulsed, repeatable experiment. Thus provision has been made to average the data over a number of different shots. Data to be taken falls into two broad categories. First is the data for which the entire wave form is desired, requiring a transient digitizer for each channel. Pulse lengths vary between 1 and 30 microseconds, so the software was written to digitize only the necessary time interval in order to avoid recording useless data during the shorter pulses. An example of this type of data is the output microwave pulse shape of the experiment. The second type of data to be taken requires only a single data point to be recorded each pulse. This is appropriate for parameters that do not change during the pulse such as the cavity magnetic field. Since this type of data requires very little storage space, virtually every experimental parameter can be measured and stored each pulse.

The software portion of this system was adapted from the PICAX program written by Robert Walraven. This provided the basic structure of the program, and only needed to be converted into a program capable of running on the IBM PC-XT. In addition, all of the experiment specific software such as the data taking, plotting, analysis, storage and experimental parameter control had to be developed. The users manual for the original PICAX, version

Manuscript approved December 16, 1985.

1, is attached, as is the manual and source listing for the current implementation, version 2. A short example of the program's usage is also attached.

Figure 1 shows a schematic of the hardware that is interfaced with the software. The IBM PC-XT™ is clearly the brains of the system, and communicates with the CAMAC crate through the crate controller. A wide variety of plug-ins is available for the crate, all of which can be controlled through the controller. The transient digitizers record the waveform data from the experiment while the digital to analog converter is used to control different pieces of the experimental apparatus. Additional capability is provided by the Data Translation DT2801 card which is used for its digital input and output as well as for recording the single point data from the experiment. To ensure that the data recorded all corresponds to the same point in time, each piece of single point data is held in a fast sample and hold circuit, and these are simultaneously triggered by a single trigger pulse. For accurate triggering and repetition rates an external pulse generator is used to trigger both the experiment and the diagnostics.

PICAX

A Program for Interactive Control and Acquisition for eXperiments

USERS MANUAL

Robert Walraven
Department of Applied Science
University of California, Davis
3 December 1981
Program version 1.0

PREFACE

The PICAX program was born in the laboratory. An embryonic version, written in 1978, was used for control and data acquisition for an experiment in plasma physics. Soon this early version was modified to be used with other unrelated experiments; it satisfied many needs that seem to be universally desirable in any program for control and data acquisition, namely,

* Interactive control
* User-controllable data acquisition
* Storage and retrieval of data on mass storage
* On-line analysis of data
* Plotting of data and analyzed results

PICAX, the current version of that early program, is the result of three years of experience with the needs of both casual and advanced users.

If you are a PICAX user, send me your name and address so that I can send you information about problems and improvements. Also, if you have any suggestions about how PICAX could be improved, please let me know.

Robert Walraven

TABLE OF CONTENTS

INTRODUCTION

PICAX is a FORTRAN program written for the PDP-11 computer family and the RT-11 operating system. It is specifically designed to minimize the user's effort in programming for applications in which the computer is used for laboratory control and data acquisition by providing the following features:

* Standard commands that call user-written subroutines to control experiments, analyze and plot data, and read and write disk files.

* Standard, simple, relatively crashproof commands to OPEN, FIND, and CLOSE disk data files.

* DIR command to produce directory listings on the console or line printer.

* Commands that may be executed individually as they are typed or as a program of several commands (with simple looping capabilities).

* User-callable analysis subroutines for linear and non-linear fitting, digital filtering, Fast Fourier Transforms, correlation, etc., available in PICLIB library.

* Segmented structure suitable for efficient overlaid programming.

* Query feature for detailed descriptions of system and user commands.

SYSTEM COMMANDS

To use PICAX, you must first write FORTRAN-callable subroutines to perform at least some of the following operations:

* Initialize data and experiment
* Define user variables
* Take data
* Analyze data
* Plot data and results
* Write data to disk
* Read data from disk
* Describe user commands

The user-written subroutines must have specific standard names, and must be put in object modules with specific names so that the linker can place them properly in the overlay program it creates. Details on writing the user subroutines are given later.

Each command may be followed by up to four floating point numbers in free field format separated by commas. These numbers are called COMMAND VARIABLES, and are passed to the user-written subroutines through labeled COMMON.

Commands are executed in the immediate mode simply by typing the command code followed by a list of optional parameter values. For example, typing

```
PLOT -1,1.235,1E5
```

will cause a user-written plot subroutine to be called with the four command variables set to -1., 1.235, 1E5, and 0.0.

User variables are provided to define parameters for the user subroutines that you don't want to specify every time a command is typed. For example, you may wish to have user variables to describe the extent of the x-axis displayed in a plot, or the value to output to a D/A converter at the start of a run.

PICAX recognizes commands by looking for a one or two letter code. For example, any of the commands

```
DI6
DIR 6
DIRECTORY 6
DIXIECUP 6
```

will produce a directory listing on the line printer.

BRIEF LIST OF COMMANDS

The standard commands supported by PICAX are

A	Add to a user variable
AN	Analyze data
CL	Close the disk output file
DI	Directory listing
DO	Do loop
E	Erase screen
EX	Exit program
FI	Find an old disk file for output
GO	Go to program line
HE	Help the user out
HC	Make hardcopy of screen
K	Kill program
LC	List commands
LP	List program
LV	List user variables
O	Open a new disk file for output
PA	Pause
PL	Plot data
PR	Proceed with experiment
R	Read a record from disk
S	Start experiment
T	Enter title
V	Set a user variable
W	Write a record to disk
WA	Wait in units of 10 ms.
Z	Zero or init data

If you type a command and PICAX cannot find a match with one of the above commands, it will call the user-written routine UMATCH to see if the user has defined any additional commands.

DESCRIPTION OF COMMANDS

Note: Square brackets [] are used to indicate optional parameters for a command. The brackets should not be included when the command is actually typed.

A N,R — Adds the value R to user variable number N. For example,
```
A 5,-12.1
```
will add -12.1 to user variable 5.

AN — Calls a user written routine named UANLYZ to analyze data. Up to four command variables may be specified.

CL [LU] — Closes a disk file on logical unit LU if one is open for output. If LU is not specified, logical unit 2 is assumed.

DI [LU] — Produces a directory listing of DK:. The listing is normally output to the console, but
```
DI 6
```
will produce a listing on the line printer.

DO N,M — Do loop command for program mode. N specifies the line that ends the loop, and M specifies how many times to execute the loop. For example,
```
DO 30,5
```
means DO to line 30 five times.

E — Erase screen (if console is a Tektronix terminal).

EX — Exit the program (return to RT-11). PICAX disables control-C exiting so that the program is forced to perform any final housekeeping before stopping. Typing this command is the only way to get out of PICAX.

FI [LU] — Find an old disk file for input on logical unit LU. PICAX prompts the user for a file name, finds the file, reads the first record, and rewinds the file. If LU is not specified, 3 is assumed. Up to 6 logical units may be open for input at one time.

GO [N] — Begin the current program. If N is specified, the program is started at line N.

HE — Help the user out by typing some useful information.

HC — Make a hard copy of the screen.

K — Kill the current program. Deletes all lines of the program.

LC — List the valid defined commands, and give a brief description of each.

LP — List the current program.

LV — List the current values of the user variables and give a brief description of each variable.

O [LU][,N] — Open a new disk file for output on logical unit LU. If LU is not specified, 2 is assumed. PICAX prompts the user for a file name, closes any open files on the specified logical unit, and opens the new file. N is an optional file size. If N>0, a file is opened N blocks long. If N=0, a file is opened that is equal in length to half of the largest free space on the specified device. If N=-1, a file is opened that is equal in length to the largest free space on the specified device. Up to 6 logical units may be open for output at one time.

PA — Waits until a return is typed.

PL — Calls a user-written routine named UPLOT to plot data. Up to four command variables may be specified.

PR — Proceed with the experimental data acquisition after it has been interrupted by the user typing something. Up to four command variables may be specified.

R [LU] — Read a record from logical unit LU by calling the user-written subroutine UREAD. If LU is not specified, 3 is assumed. If no file is open for input on the specified logical unit, an error occurs. Up to four command variables may be specified, but the first must be the LU.

S — Start the experimental data acquisition by calling the user-written subroutine USTART. Up to four command variables may be specified.

T — Enter title. PICAX will prompt the user for a line of text to be used as a title.

V N,R — Set user variable number N equal to R. For example,

```
V3  12.1
```

sets user variable 3 to 12.1.

W [LU] — Write a record to logical unit LU by calling the user-written subroutine UWRITE. If LU is not specified, 2 is assumed. If no file is open for output, an error occurs. Up to four command variables may

be specified, but the first must be the LU.

WA N — Wait for N times 10 milliseconds before proceeding to the next command

Z — Zero data by calling the user-written subroutine UZERO. Up to four command variables may be specified.

The user may add additional commands to this list by specifying them in the user-written routine UMATCH.

If you do not remember what a particular command does, type the command followed by a question mark. PICAX will respond by giving you information about the command.

PROGRAM MODE

Commands may be executed as they are typed or in a group as a program. If a line number is typed before the command, the command is not executed immediately, but is entered into a program buffer. The following rules apply to programs:

1. A program may be up to 50 lines in length.
2. Line numbers may be any number in the range 1 to 999
3. Line numbers do not have to be in consecutive order.
4. Lines do not have to be typed in order; PICAX will automatically order the lines numerically.
5. To change a line, simply retype the new line with the same line number.
6. To delete a line, type the line number only.
7. To delete the entire program, type the command K.
8. To list a program, type the command LP.
9. To run a program, type the command GO. To start a program at a particular line number that is not the first line number, type the command GO followed by the line number.

The two commands DO and GO allow simple looping possibilities. A typical program with looping might look like this:

```
10 O 7
20 V5 = 10
30 DO 60,5
40 S 5,7
50 W 7,10.1
60 A 5,1
70 CL 7
80 GO 10
```

Line number 10 opens a file on logical unit 7. Line 20 sets user variable 5 to 10. Line 30 causes lines 40 through 60 to be executed in a loop 5 times. Line 40 causes the user-written subroutine USTART to be called with the command variables set to 5.,7.,0.,0. Line 50 causes the user-written subroutine UWRITE to be called for logical unit 7 with the command variables set to 7.,10.1,0.,0. Line 60 adds 1. to user variable 5. Line 70 closes unit 7. Line 80 loops back to the beginning.

PICAX PROGRAM FLOW

The following steps describe the program flow through PICAX as it is running:

1. Initialize PICAX. Call UINIT.
2. Write a '*' to prompt user.
3. If a return (after a line of input) or a control-C was typed, go to 8.
4. If the experiment is on (EXPT ON = .TRUE.), call UPDATE.
5. If a program is not running, go to 3.
6. Execute the next line of the program.
7. If the program is still running, go to 3. Otherwise, go to 2.
8. Turn experiment off (EXPT ON = .FALSE.). Turn program off.
9. If no characters were typed, go to 2.
10. If a control-C was typed, write an acknowledgement and go to 2.
11. If the typed input was not intelligible, write an error message, and go to 2.
12. If only a line number was typed, delete that line from the program and go to 2.
13. If a recognizable command was not found, write an error message and go to 2.
14. If there was a line number, insert the line into the program and go to 2. Otherwise, execute the command immediately and go to 2.

The logical variable EXPT ON determines whether an experiment is running or not. The logical variable PROG ON determines whether a program is running. These two variables may be accessed through the following COMMON block:

```
COMMON /P FLAGS/ PROG ON, EXPT ON, QUERY
LOGICAL PROG ON, EXPT ON, QUERY
```

The commands PR and S set EXPT ON to true before jumping to their respective user-written subroutines UPROCD and USTART. The command GO sets PROG ON to true.

UPDATE

Once the experiment is turned on (EXPT ON = .TRUE.), it will stay on either until the user types a return or control-C, or until the user-written subroutine UPDATE turns the experiment off. The commands PR and S should only be used to get the experiment going. If the experiment does need servicing, UPDATE should do whatever is required, and if the experiment is over, EXPT ON should then be set to false. In any case, UPDATE should return so that PICAX can check for input. If there is no input, UPDATE will be called again immediately. If there is input, however, EXPT ON will be set false and the input will be processed by PICAX. The experiment can be continued by typing PR or restarted by typing S.

Some experiments must be serviced rapidly, so the user may not wish to return to PICAX until the experiment is done. In this case the experiment cannot be interrupted by keyboard input.

OVERLAY STRUCTURE

PICAX is too large to fit in memory without using an overlay structure; this is primarily due to the inclusion of the AG-II graphics package. The overlay structure has been carefully designed to optimize the interactive response on a floppy-disk system. The overlay structure of PICAX consists of a root module and four overlay regions. The file PICAX.COM is a command file that performs the overlay linkage. All modules beginning with "PICAX" contain PICAX subroutines. All modules beginning with "AG2" are part of the AG-II graphics system. The user-written routines should be placed in the modules USERR, USER1, USER2, and USER3 as follows:

```
USERR:  UPDATE, UPLOT
USER1:  UANLYZ,UINIT,UPROCD,UREAD,
        USTART,UVLIST,UWRITE,UZERO
USER2:  UMATCH, UCMNDS,UINFO
USER3:  QUANAL,QUPLOT,QUPROC,QUREAD,
        QUSTRT,QUWRIT,QUZERO
```

USERR is a root module, and should contain any routines associated with fast data taking. That is why UPDATE is put there. The subroutine UPLOT is also placed in the root segment because all AG-II graphics routines that it might call are in the overlay modules. The module USER1 contains user-written subroutines that respond to various commands. The module USER2 contains subroutines for defining any additional commands that the user wishes to supply. USER3 contains help information about the user-written commands.

Modules with the names USERR.SKL, USER1.SKL, USER2.SKL, and USER3.SKL contain skeleton versions of all the required user-written subroutines, so that you only have to write the subroutines that are required by your specific needs.

PICLIB

The module PICLIB.FOR contains a number of subroutines that are of interest in a data acquisition and analysis environment, and that may be called by the required user subroutines. The subroutines in PICLIB.FOR are

FILTER - A general non-recursive filter that may be used to perform lowpass, bandpass, highpass, and bandstop filtering of data.

KAISER - A subroutine required by FILTER.

BESIO - A subroutine required by FILTER that computes the zero-th order modified bessel function I(x).

H OF Z NR - Computes the transfer function of a non-recursive filter.

CURFIT - Performs a least-squares fit to a user-specified non-linear function.

FCHISQ - A subroutine required by CURFIT.

MATINV - A subroutine required by CURFIT that computes the inverse of a symmetric matrix.

FAST - Performs a fast fourier transform of data.

The documentation for these subroutines is provided in the source listings.

AG-II

The advanced graphics package (AG-II) is functionally equivalent to the Tektronix Plot 10 advanced graphics package. However, it has been written to run faster and to fit on an LSI-11 by making use of the RT-11 overlay structure. Sources and command files for preparing the AG-II overlay modules are available from Tektronix Plot-10 Software Marketing: contact Will Gallant at (503) 682-3411, ext. 3785. You may obtain a manual for the package from your local Tektronix office (Manual part no. 070-2244-00).

EXAMPLE USER SUBROUTINES

Let's look at how PICAX could be used in a typical laboratory situation. Suppose you want to write a program to control an experiment that is interfaced to a DRV11 16-bit digital input/output card at address 167770. Further, suppose you would like the program to do the following:

1. At the start of the experiment, load the output register with 0.

2. Turn on bit 15 of the output register. Suppose a positive transition of this bit is used to enable the external experiment.

3. Wait until the DRV11 status register (bit 7) goes high, indicating that data is ready. Then read the data.

4. Turn off bit 15 of the output register.

5. If 128 data points have been collected, stop the experiment. Otherwise increment the output register and go to step 2.

6. After data taking is over, allow the user to filter the data, plot it, and write raw data to disk.

7. Let the program read data from disk, so that the data can be analyzed at some later time.

We will define a labeled common to pass variables among the user subroutines:

```
COMMON /DEMO/ NDATA, DATA(128), NRUNS
```

where NDATA is the number of the next data point to be obtained from the experiment, DATA is an array to store the accumulated data, and NRUNS is the number of accumulated runs if new data is added to the data already in the array DATA.

The required user subroutines for this task are shown below. These subroutines interact with PICAX through labeled commons:

1. The command variables that follow a command may be picked up with

   ```
   COMMON /P C VAR/ N C VAR, CVAR(1)
   ```

   where CVAR(1) through CVAR(4) are up to four command variables that follow the command.

2. The PICAX logical variable EXPT ON must be set false in the user subroutine UPDATE when data taking is over. EXPT ON is referenced through

```
COMMON /P FLAGS/ PROG ON, EXPT ON, QUERY
LOGICAL          PROG ON, EXPT ON, QUERY
```

3. The title, if any, defined by the T command may be obtained from

```
COMMON /P TITLE/ LTITLE(36)
```

4. The user variables may be obtained from

```
COMMON /U VAR  / N U VAR, U VAR(1)
```

where N U VAR is the total number of user variables. The user variables should be set to their initial values in user subroutine UINIT. For convenience, the correct dimension for UVAR need only appear in UINIT, since the linker will set the length of the labeled common UVAR equal to its longest occurance. Everywhere else UVAR may be dimensioned 1.

The example user subroutines contain extensive documentation that is applicable to their use in PICAX, so it is recommended that the user read through these subroutine listings carefully.

Building a PICAX Program

To create a PICAX program, follow these steps:

1. The objects for the overlay version of the Advanced Graphics Package should be on SY:. If they are not, create them and put them there. (See the Advanced Graphics Package README file.) If there is not sufficient room on SY:, and they must be located elsewhere, then modify the command file PICAXL.COM appropriately.

2. The objects for PICAX should be on DK:. If they are not, compile the source files and put the objects there. (PICAXR.FOR, PICAX1.FOR, PICAX2.FOR, PICAX3.FOR, DIREC.FOR, IOFILE.FOR)

3. Modify the skeleton user modules USERR.SKL, USER1.SKL, USER2.SKL, and USER3.SKL as needed for your application. Compile the resulting sources and put them on DK:.

4. Run the command file PICAXL.COM to link the program together. The resulting file is PICAX.SAV.

PICAX

A Program for Interactive Control and Acquisition for experiments

IBM PC-XT Version
Users Manual

Tom Hargreaves
JAYCOR
205 S. Whiting Street
Alexandria, VA 22304
September 10, 1985
Program Version 2.0

PREFACE TO VERSION 1.0

The PICAX program was born in the laboratory. An embryonic version, written in 1978, was used for control and data acquisition for an experiment in plasma physics. Soon this early version was modified to be used with other unrelated experiments; it satisfied many needs that seem to be universally desirable in any program for control and data acquisition, namely,

* Interactive control
* User-controllable data acquisition
* Storage and retrieval of data on mass storage
* On-line analysis of data
* Plotting of data and analyzed results

PICAX, the current version of that early program, is the result of three years of experience with the needs of both casual and advanced users.

If you are a PICAX user, send me your name and address so that I can send you information about problems and improvements. Also, if you have any suggestions about how PICAX could be improved, please let me know.

Robert Walraven

PREFACE TO VERSION 2.0

This version of the PICAX program has been modified from the original to run on the IBM PC-XT personal computer under the PC-DOS operating system. The user modules have also been writen for the NRL Quasi-optical Gyrotron Experiment, although they are sufficiently general that they should be of general use with little or no alteration. I would like to thank Robert Walraven for the free use of the original code, without which this would have been a much more time consuming project. He can be contacted at:

Dr. Robert Walraven
Department of Applied Science
University of California, Davis
Davis, California 95616

Tom Hargreaves

TABLE OF CONTENTS

INTRODUCTION

This version of PICAX is written in Microsoft FORTRAN for use on an IBM PC-XT using the PC-DOS operating system. Furthermore, the user subroutines have been written specifically for use on the NRL Quasi-optical Gyrotron experiment, however, the program should be useful in a wide variety of experiments with little or no modification. PICAX in its current state has the following features:

* Data acquisition.
* Data analysis.
* Data storage.
* Data plotting.
* On line help.
* No overlay structure.

The theory behind this implementation of PICAX is to measure all of the relevant experimental parameters simultaneously. Of course, care must be taken to ensure that the computer knows which channel of the data acquisition system corresponds to each parameter.

This manual is designed to be used in conjunction with the USERS MANUAL for PICAX version 1.0.

SYSTEM COMMANDS

The system commands are described in detail in the PICAX Users Manual for version 1.0. Here is a brief listing of the commands supported by PICAX:

A	Add to a user variable
AN	Analyze data
CL	Close the disk output file
*DI	Directory listing
DO	Do loop
E	Erase screen
EX	Exit program
FI	Find an old disk file for output
GO	Go to program line
HE	Help the user out
HC	Make hardcopy of screen
K	Kill program
LC	List commands
LP	List program
LV	List user variables
O	Open a new disk file for output
PA	Pause
PL	Plot data
PR	Proceed with experiment
R	Read a record from disk
S	Start experiment
T	Enter title
V	Set a user variable
W	Write a record to disk
WA	Wait in units of 10 ms.
Z	Zero or init data

* This command is not currently implemented in PICAX version 2.0.

Note that any command followed by a question mark and a return will cause the on line help package to print out detailed information covering the use of the command in question.

USER COMMANDS

There is currently only one user written command:

TR Trigger on/off

This command sets bit 0 of port 0 on the Data Translation card either high (5 volts) or low (0 volts) depending on the number that follows the command. This signal can then be used to trigger a relay in the trigger line to cut off the trigger pulse to the experiment.

USER CAPABILITIES

The user subroutines have been written to enable the user to perform a wide variety of tasks, the most important being the logging of experimental data. The intent is to measure various voltages of interest in a pulsed experiment, typically 1-30 microseconds in duration. There are two types of voltage data to be recorded. First are the channels for which the entire wave form is to be recorded, such as the cathode voltage or the collector current. Second are the channels for which a single point during the pulse is desired. An example of this type of data is the current in any of the magnetic field coils or the calorimeter voltage.

The second type of data is taken with the use of a multi-channel sample and hold unit fed into a Data Translation DT2801 multi-channel data acquisition card plugged into one of the expansion slots in the IBM PC-XT. The sample and hold unit can be triggered simultaneously so that the data that the computer retrieves all correspond to the same point in time. The DT2801 then reads the data one channel at a time from the sample and hold unit into the memory of the IBM PC-XT. A maximum of 16 channels have been developed for this type of data.

A Transiac 2008F transient digitizer is used to record the total waveform of the appropriate data. Currently there are three actual channels of hardware, but the software is set up for as many as 5 channels and can easily be expanded. During the experimental pulse the data is stored in the internal memory of each transient digitizer, which resides physically in a CAMAC crate. The data can then be read into the memory of the IBM PC-XT through an interface card in an expansion slot of the computer which is connected to a controller in the crate itself. This data transfer is set up to proceed in the DMA mode.

In addition to the transient digitizers, there is also a LeCroy 8102 six channel variable attenuator in the CAMAC crate. By telling the computer which data points are connected to each attenuator channel, the computer can calculate the correct voltages for the various data. The attenuator values are read by the computer through the crate controller each time an experimental run is started.

Besides the attenuators there is a single channel Transiac 1020 differential amplifier which can also be read by the computer through the crate controller. This allows amplification of weak signals to voltages appropriate to be measured by the various analog to digital converters.

Once the data is in the memory of the computer it is desirable to store it on the 10 MB hard disk of the IBM PC-XT. This is accomplished in the PICAX program by first opening a file for data storage. When the write data command is given, all information including data as well as user programable variables is written into the file. The data can then be transfered to floppy disks for future analysis. There are, of course, analagous routines for reading data from a file into the computer memory.

The data can be analyzed any time that it is in the memory of the computer, whether it was just taken from the experiment or read from a disk file. In this manner the experimental data can be taken and quickly stored, then analyzed at a later time. At present the peak microwave power as well as the efficiency can be derived from the data.

Another convenient feature of the PICAX program is the ability to immediately plot the experimental data. The first type of plot is simply the voltage versus time plot of one of the transient digitizers for either a single pulse or an average over a number of pulses. A second type of plot that is desirable is a graph of one parameter as a function of a second, for example, peak microwave power as a function of average magnetic field. The data presented in this type of plot will typically be averaged over many pulses.

Finally, it would be desirable to control various experimental parameters through the PICAX program. Only a small part of the software has been completed and some of the necessary hardware has been acquired. The Data Translation DT2801 has two channels of digital to analog converters as well as sixteen channels of digital input or output. One channel of the digital output has been programmed to respond to the trigger on/off command. Also available is a Transiac 3016 sixteen channel digital to analog conveter that resides in the CAMAC crate. Two of these channels have been programmed to set the superconducting magnet coil currents to the values specified by the user programmable variables. With this hardware combined with varying amounts of interface, it should be possible to control many more of the experimental parameters such as the electron gun magnetic field and the cathode voltage.

USER SUBROUTINE FLOW

The user subroutines are collected into the files USERR.QO, USER1.QO, USER2.QO, USER3.QO, USER4.QO, and USER5.QO. Each subroutine is well commented and the user is refered to the individual routine for more detailed information than is presented here. USERR.QO contains the plotting subroutines, and USER1.QO holds the initializing subroutine as well as the data analysis, disk file input and output routines and the data array zeroing routine. USER2.QO has the user command subroutines in addition to the user variable listing routine, while USER3.QO contains the online help package for the user written subroutines. USER4.QO holds both the routines to control the experiment as well as the routines to convert the raw data collected by the computer into real world units, and USER5.QO has all of the routines necessary for the actual data acquisition.

Immediately upon starting the PICAX program many variables need to be initialized. This is accomplished for the user written subroutines in the subroutine UINIT. Here such parameters as the memory address of the CAMAC crate controller are set. This subroutine is called only once, so that only parameters that will not change are set here.

To start the experiment and take data, the "S" command is used. This calls the subroutine USTART which sets up the computer to collect the data. The type of data to be acquired, number of shots to average over, etc. are all determined by the previously set USER VARIABLES. Data is then actually collected in subroutine UPDATE, which is called automatically. The raw data is first summed and then averaged here before being converted into real world units. After each data pulse, control is returned to PICAX to check for any keyboard input. If any input exists, the experiment is suspended and the input interpreted. The experiment may be resumed by using the PICAX command "PR" which calls the subroutine UPROCD. New attenuator values will be read before restarting the experiment, so care must be used when interpreting the results of such restarted experiments. Upon completion of the experiment and conversion of the data, program control is returned to PICAX.

The subroutines UPLOT, UREAD, and UWRITE are simply called by PICAX in response to the "P", "R", or "W" commands to either plot, read from a disk file or write the data to a disk file, respectively. The subroutine UANLYZ is called in when the "AN" command is executed and is designed to provide data analysis. UVLIST is the subroutine called by the command "LV" and will list the USER VARIABLES. These commands all execute a single function and then return complete control to PICAX.

BUILDING PICAX

To build the PICAX program, the following steps should be taken:

1) Collect all of the necessary source files onto the directory to be used. A list of the needed files can be found in the link file PICAX (see below).

2) Compile each of the source files. The FORTRAN files can be compiled by using the batch file FORT.BAT which calls the appropriate Microsoft Fortran compiler programs (see the listing below). To execute type:

   FORT (filename)

   The ASSEMBLY language routines must be compiled by the Microsoft Assembler MASM. At the completion of this step the source files are no longer needed, but the object files must all reside on the directory being used.

3) Link the object files together to produce the executable file PICAX.EXE. This requires the presence of the necessary libraries (again see the link file PICAX). The Microsoft link command is:

   LINK @PICAX

   where PICAX is the input file to the linker.

4) Retain the file PICAX.EXE. All other files may be deleted. The program is started by typing PICAX (and then a return).

BATCH FILES

FORT.BAT

```
forl %1;
pas2
```

PICAX

```
picaxr+ittinr+user5+camv3+dtinpl+waitl+inp+out+
picaxl+picax2+picax3+userr+userl+user2+user3+
user4,picax,,dos2for+fortran+grafsub+grafms2
```

The filenames before the first comma (on the third line) are the necessary object files and the filenames after the third comma are the needed library files (for example: DOS2FOR.LIB).

      PROGRAM PICAX
C
C-----------------------------------------------------------------------
C
C       P I C A X   -   PROGRAM FOR INTERACTIVE CONTROL AND
C                        ACQUISITION FOR EXPERIMENTS
C
C-----------------------------------------------------------------------
C
C       ROOT MODULE
C
C-----------------------------------------------------------------------
C
C       PICAX IS A SET OF ROUTINES DESIGNED TO PROVIDE THE USER WITH
C       MANY OF THE OPERATIONS REQUIRED IN A GENERAL LABORATORY DATA
C       ACQUISITION AND ANALYSIS ENVIRONMENT.  PICAX PROVIDES A
C       HIGH-LEVEL INTERACTIVE COMMAND LANGUAGE WHICH CALLS
C       USER-WRITTEN SUBROUTINES WHICH IN TURN CALL ROUTINES IN
C       THE PICAX LIBRARY.  FOR MORE INFORMATION SEE THE PICAX
C       USER'S GUIDE.
C
C       WRITTEN BY ROBERT WALRAVEN

C
      SUBROUTINE UANLYZ
c
c-------------------------------------------------------------------------
c
c     This routine will calculate the peak power as well as the
c     efficiency using the calorimeter data as well as the pulse
c     shape, voltage, and current data from the transient recorders.
c     If the transient recorder data is unavailable, the routine will
c     prompt for the pulse width, and will use the voltage and current
c     data from the Data Translation card.
c
c     cvar (1) = 0      Prompt user for rep rate.
c              > 0      Rep rate.
c
c-------------------------------------------------------------------------
c
      COMMON /U VAR    / N U VAR, U VAR (150)
      common / p c var  / n c var, cvar (4)
      common / data / atten (20), datran (16,2), trrec (1000,10),
     c          freq (1000,2), data (100,10)
c
c     Calculate the area under the microwave diode curve and the
c     corresponding pulse width for the peak power.  If the data
c     is not available from the transient recorder, then ask the
c     user for the pulse width.
c
c     Note: It is assumed that the diode is working in the linear
c           regime.
c
      p width = 0.0
      p max = 0.0
      total = 0.0
      n max = 0

c
c
$storage:2
c
c
      subroutine sc b set (b,taper,func)
c
c---------------------------------------------------------------------
c
c      This routine services the superconducting magnet.
c
c      func = 0      Set the magnet currents.
c      func = 1      Check to see if the magnet has charged
c                  to full current yet. Set:
c                  func = 0      if done.
c                  func = 1      if not yet done.
c
c---------------------------------------------------------------------
c
c    See the addendum to the users manual for the derivation of
c    the formulae for the two current values.
c    This routine makes use of the following facts:
c
c    1) For a level field at 50 kG:
c              top coil current    = 118.8 amps
c              bottom coil current = 121.4 amps
c
c    2) The power supply level is programmed as:
c              0 volts =>   0 amps
c             -6 volts => 150 amps
c
c    3) The minutes full scale is still programmed at the power supply.
c       See section III, figure 5a in the IGC magnet manual.
c
c    4) The Transiac 3016 DAC has a resolution of + or - 3 millivolts
c       which corresponds to + or - 75 milliamps at the magnet.
