SUMMARY

A computer program which simulates life and reliability of helicopter transmissions is presented. The helicopter transmissions may be composed of spiral bevel gear units and planetary gear units - alone, in series or in parallel. The spiral bevel gear units may have either single or dual input pinions, which are identical. The planetary gear units may be stepped or unstepped and the number of planet gears carried by the planet arm may be varied. The reliability analysis used in the program is based on the Weibull distribution lives of the transmission components. The computer calculates the system lives and dynamic capacities of the transmission components and the transmission. The system life is defined as the life of the component or transmission at an output torque at which the probability of survival is ninety percent. The dynamic capacity of a component or transmission is defined as the output torque which can be applied for one million output shaft cycles for a probability of survival of ninety percent. A complete summary of the life and dynamic capacity results is produced by the program.

INTRODUCTION

In the helicopter industry, experimental testing programs are used to measure the relative merits of different transmissions [1,2,3]. These tests are costly in terms of time and resources. The tests should be complemented with computer simulations of many possible designs, so that only optimal designs are brought forward to the testing stage in helicopter transmission development.

This report describes a computer simulation program which models the life and reliability of a helicopter transmission. The computer program uses the lives and reliabilities of the individual components to compute the life and reliability of the transmission.

The life and reliability models are based on the assumption that the transmission is adequately lubricated and well designed. This means that its gears have sufficient rims and are made of adequate materials so that premature tooth breakage will not occur. Also, it is assumed that the tooth form geometry and lubricant have been selected to prevent tip scoring. Both of these failure modes can be prevented [4].

However, surface pitting is not preventable due to the lack of a surface fatigue endurance limit for high strength gears. As with rolling element bearings, gear teeth will fail eventually in surface pitting even in a well designed, well lubricated transmission,

regardless of the loads [5-11]. Thus, the life and reliability models for spiral bevel gear reduction and planetary gear units are based on the pitting fatigue life and reliability models for the bearings and gears in the transmission.

In this program, a modular approach is used in which the force and motion analyses of the reduction are separated from the life and reliability analyses. The dynamic capacity models are also separated algebraically from the prior calculations. In this way, the calculations can be performed sequentially and the complexity and diversity of the analyzed transmissions can be increased greatly.

The computer program can simulate a number of configurations of spiral bevel gear units, dual spiral bevel gear units, planetary gear units and combinations of units. The eight transmission configurations analyzed by this program are shown in figure 1. Configuration 3 is found in the OH-58 light duty helicopter and consists of a spiral bevel gear unit combined with a planetary gear unit. Configuration 8 is found in the Black Hawk helicopter and consists of parallel spiral bevel units combined with a dual spiral bevel gear unit. The power is then transmitted to the rotor through a planetary gear unit. The power inputs to the two input pinions of the dual spiral bevel gear unit do not have to be equal, so that the loss of power in one engine can be simulated. The program also allows the planetary gear unit to be composed of stepped or unstepped planet gears. The program can simulate transmissions at different power levels and load duty cycles. The program can calculate the lives and dynamic capacities of a single unit or the transmission as a whole.

TRANSMISSION POWER FLOW

In a helicopter, power is typically produced by a turbine engine oriented horizontally and close to the main rotor shaft. The rotor shaft is nearly vertical and the power from the turbine must be transmitted through approximately ninety degrees. The transmission must handle a speed reduction from the turbine engine to the rotor shaft in the range of 80:1. To accomplish this in a small amount of space, spiral bevel gear units are used in conjunction with planetary gear units.

In the analysis, the spiral bevel gear units and planetary units are treated separately. Even though the units are treated separately, they must have a common counting base to allow combinations of lives and reliabilities. In helicopters, a significant part is the output rotor shaft. Therefore the common counting base in this program is the output torque and speed of this rotor shaft which is unchanged from design to design.

In helicopters, a common configuration is a spiral bevel gear unit from the turbine followed by a planetary unit along the output shaft. There may be more than one spiral bevel gear unit in series or parallel and there may be more than one planetary gear unit in series

along the output shaft. The couplings between the units are assumed to be splined, only able to transmit torque loads between the units.

Spiral Bevel Gear Unit

For the spiral bevel gear unit there are many inputs which define the geometry [12]. In figure 2, the geometry which is required for analysis of the gear mesh is shown. The main measure of bevel size is the cone distance, A_o . The cone distance is the distance from the apex of the bevel cones to the back edge of the tooth face. This distance is measured along the pitch line of the two pitch cones of the mating gears. The contact face width of the gear set, f , is measured along the same pitch line.

To define the geometry of the pitch cones, the following inputs are required, number of teeth on the pinion, N_p , number of teeth on the gear, N_g , and the shaft angle. The shaft angle is the angle between the input pinion shaft and the output gear shaft. The pitch angles, which are half the cone angle of the gear, are related by these inputs in the following equations.

$$\tan \Gamma_g = \frac{\sin \Sigma}{(N_p/N_g) + \cos \Sigma} \quad (1)$$

$$\tan \Gamma_p = \frac{\sin \Sigma}{(N_g/N_p) + \cos \Sigma} \quad (2)$$

Figure 2

Spiral Bevel Gear Pitch Cone Geometry

The point of gear contact used in the analysis is the pitch point. The distance from the apex to the midpoint of the face locates the pitch point.

$$D_o = A_o - \left(\frac{f}{2} \right) \quad (3)$$

The pitch diameters of the equivalent spur gear for the spiral bevel pinion and gear can be found by:

$$D_p = 2 * D_o * \sin \Gamma_p \quad (4)$$

$$D_g = 2 * D_o * \sin \Gamma_g \quad (5)$$

Also in this analysis, the teeth in the mesh at the pitch point are modeled as planar spur gears. Figure 3 is a composite drawing showing the bevel and reference spur gear. The diameter of the reference planar spur gear is double the backcone distance. The backcone distance is defined as the perpendicular distance from the pitch point at the midpoint of the gear face to the centerline of the gear shaft. The backcone distance of the pinion and gear are calculated by:

$$B_{cp} = \tan \Gamma_p * D_o \quad (6)$$

$$B_{cg} = \tan \Gamma_g * D_o \quad (7)$$

In addition to the size and shape of the pitch surface, the gears are defined by the geometry of the meshing gears. In figure 4 one sees a spiral bevel gear in the pitch plane which is tangent to the pitch cones at the line of contact.

Figure 3
 Composite Section of Spiral Bevel Gear and
 Reference Planar Spur Gear

Figure 4
Spiral Angle

In the figure, the spiral angle, Ψ , is shown as the angle between the pitch ray and a tangent to the circular cutter at the mid-point of the tooth. This angle is positive for right hand advance of the spiral along the axis of the gear toward the cone apex. The figure shows a right hand spiral. In the spiral bevel mesh the pinion and the gear must have the same spiral angle but the hands of the meshing gears must be opposite.

The diametral pitch of the teeth is defined at the mid-tooth radius.

$$P_d = \frac{N_g}{2 * D_o * \sin r_g} \quad (8)$$

It can be noted that the pitches are direct functions of the numbers of teeth on the gears and the pitch cone geometry. Figure 5 shows the normal tooth geometry at the mid-plane of the tooth. Figure 5 corresponds to section AA in figure 4. The normal pressure angle ϕ_n , addendum a_b , and dedendum d_b , are shown at the mid-plane of a bevel tooth.

The direction of rotation of the pinion is required to define the loads transmitted at the point of gear contact. In this paper, clockwise rotation is defined looking at the back of the pinion along the pinion shaft toward the cone apex.

One must also specify the bearing supports of the gears. The two bearing configurations most commonly used, straddle and overhung, are shown in figure 6. In both cases distance A is the distance from

Gear Tooth

Figure 5
Normal Tooth Geometry

a) Straddle

b) Overhung

Figure 6

Bearing Mounting Configuration

the gear to the bearing closest to the apex. In case 2, distance A takes on a negative value. Distance B is defined as the distance from the gear to the bearing furthest away from the apex. All distances are measured from the mid-point of the gear to the mid-point of the bearing. One bearing on each shaft must be identified as a thrust bearing to take the axial thrust loads produced by the bevel gear mesh.

In the case of dual inputs, the pinions and their mounting are considered to be identical. The only difference can be the load levels applied by the pinions. Figure 7 shows the twin input bevel in the plane of the two input shafts.

Planetary Gear Unit

For the planetary gear unit one must define whether the unit is stepped or non-stepped and the number of planets carried by the planet arm. Figures 8 and 9 show an unstepped and stepped planetary gear unit, respectively, with three planet gears. For the planetary units, the sun gear is the input shaft, the ring gear is fixed and the planet arm is the output shaft. In the case of the non-stepped planetary unit, the number of teeth of the sun gear, planet gear, and ring gear are required. Figure 10 shows a mesh of an unstepped planetary gear unit. In the case of a stepped planetary unit, the number of teeth on the sun gear, planet-sun gear, planet-ring gear, and the ring gear are required. The planet-sun gear is defined as the planet gear meshing with the sun gear in a stepped planetary gear unit. The planet-ring gear is the planet gear meshing with the ring gear in a stepped planetary gear unit. Figure 11 shows a mesh of a stepped planetary

Figure 7

Figure 8
Unstepped Planetary Gear Unit

Figure 9

Stepped Planetary Gear Unit

Figure 10

Unstepped Planetary Gear Unit Gear Mesh

Figure 11

Stepped Planetary Gear Unit Gear Mesh

gear unit. The diametral pitch of the gears in each mesh must be known to define the size of the planetary transmission. The diameter of the gears is found from the diametral pitch, P_d and number of teeth, N .

$$D = N / P_d \quad (9)$$

Due to the motion of the planetary arm carrying the planet gears, each component will not see the same number of load cycles as it would in a fixed axis reduction. Table 1 gives the relationship between one output revolution and the load cycle of each component [13]. The ratios in this table are found by a standard planetary gear motion analysis.

In all units, the mesh material strength must be known to calculate the dynamic capacity of the gear tooth. In the case of the bearings, catalog values of the dynamic capacities must be given. The Weibull exponents must be specified for each component. The load-life exponent must be specified for each gear. The program automatically assumes an exponent of 3.0 for ball bearings and an exponent of 3.333 for roller bearings [14].

COMPONENT LOADING

The load on each component can be calculated from the applied input torque and the geometry of the components. Due to the many configurations of bearing and gear location, no single formula can be used to calculate the component load. Instead, a series of steps is required to obtain the component load.

Spiral Bevel Gear Unit Loading

The loading on the spiral bevel gear units can be analyzed by calculating the force developed in the gear teeth. This force can be divided into three orthogonal components shown in figure 12.

These forces are the tangential load, W_t , which is produced by the torque on the gear shaft [12,14]. The radial load, W_r , and the axial load, W_a , are produced by the geometry of the gear teeth transmitting the tangential load. These loads are

$$W_t = \frac{T_o}{D_o * \sin \Gamma_g} \quad (10)$$

$$W_r = \frac{W_t * (\tan \phi_n * \cos \Gamma_g + \sin \psi * \sin \Gamma_g)}{\cos \psi} \quad (11)$$

Figure 12
Spiral Bevel Gear Forces

$$W_a = \frac{W_t * (\tan \phi_n * \sin \Gamma_g - \sin \psi * \cos \Gamma_g)}{\cos \psi} \quad (12)$$

In equation 11 and 12, the sign of the last term changes with respect to the spiral hand, direction of gear rotation and whether the gear is driving or being driven. These equations are valid for a driving gear with a right hand spiral which is rotating clockwise. The equations are also good for a driving gear with a left hand spiral which is rotating counterclockwise. For a driven gear, the equations are valid for a right hand spiral gear driven counterclockwise and a left hand spiral gear driven clockwise. For the four other conditions with power flow in the opposite direction, the signs of the equations are switched.

$$W_r = \frac{W_t * (\tan \phi_n * \cos \Gamma_g - \sin \psi * \sin \Gamma_g)}{\cos \psi} \quad (13)$$

$$W_a = \frac{W_t * (\tan \phi_n * \sin \Gamma_g + \sin \psi * \cos \Gamma_g)}{\cos \psi} \quad (14)$$

For a shaft angle of 90 degrees, the radial load of the pinion will be equal to the axial load of the gear. Also the axial load of the pinion will be equal to the radial load of the gear. Regardless of shaft angle, the tangential force will be equal on pinion and gear. Also, the total resultant tooth load on the pinion and the gear must be equal in all cases. The total resultant tooth load is given by:

$$W_n = \sqrt{W_t^2 + W_r^2 + W_a^2} \quad (15)$$

The three force components of the gear will transmit forces to the support bearings. In this analysis one bearing will take the thrust load, transmitted axially from the gear.

$$F_t = W_a \quad (16)$$

The radial forces on the bearings are a result of the moment produced by the axial load on the gear, and the radial and tangential loads. Bearing 1 is the bearing closest to the gear cone apex. Bearing 2 is the bearing furthest away from the cone apex.

Bearing 1

Tangential load

$$F_{t1} = \frac{W_t * B}{A + B} \quad (17)$$

Radial Load

$$F_{r1} = \frac{(W_a * N_g / (2 * P_d)) - W_r * B}{A + B} \quad (18)$$

Combined Radial Load

$$F_{rT1} = \sqrt{F_{t1}^2 + F_{r1}^2} \quad (19)$$

Bearing 2

Tangential load

$$F_{t2} = \frac{W_t * A}{A + B} \quad (20)$$

Radial Load

$$F_{r2} = \frac{(W_a * N_g / (2 * P_d)) + W_r * A}{A + B} \quad (21)$$

Combined Radial Load

$$F_{rT2} = \sqrt{F_{t2}^2 + F_{r2}^2} \quad (22)$$

These equations are good for any pinion and a gear loaded by one pinion. In the case of straddle mounted gear, distance A is considered to be positive. In the overhung case, distance A is considered negative. For the case of dual pinion input, each bearing carries two sets of tangential and radial loads which can be reduced into one tangential and radial load. The direction of the combined tangential and radial loads is taken to be the direction of the load from the contact with the right pinion. The resultant of these two orthogonal components is the total radial load on the bearing. The vectoral combination of the forces into one total radial load is shown in figure 13. The axial load on the bearing is the sum of the reactions of the right and left pinion axial gear forces. The total torque output from the gear is also the sum of the two pinion gear torques on the output gear.

Combined Radial Load

$$F_R = F_{rr} + F_{r1} * \cos \Lambda - F_{t1} * \sin \Lambda \quad (23)$$

Combined Tangential Load

$$F_T = F_{tr} + F_{r1} * \sin \Lambda + F_{t1} * \cos \Lambda \quad (24)$$

Figure 13
Dual Spiral Bevel Gear Forces

Total Radial Load

$$F_{RT} = \sqrt{F_R^2 + F_T^2} \quad (25)$$

Planetary Gear Unit Loading

In the planetary gear unit all loads on the components are either tangential or radial. All loads are assumed to be acting in the same plane. It is assumed that each planet gear carries an equal amount of the input torque of the sun gear.

For the sun or planet gear, the tangential force on a tooth at each sun-planet gear mesh is :

$$F_S = \frac{T_i}{n * R_S} \quad (26)$$

The tangential force on a tooth of the ring or planet gear in each ring - planet mesh is :

$$F_R = \left(\frac{R_{ps}}{R_{pr}} \right) * \left(\frac{T_i}{n * R_S} \right) \quad (27)$$

Figure 14 shows the loading on the planet gear from the sun - planet and ring - planet gear meshes. The total tangential force on the planet gear bearing is :

$$F_t = F_R + F_S \quad (28)$$

Figure 14
Planet Gear Forces

The bearing may also see a radial load due to the radial components produced by the pressure angle of the gear meshes.

$$F_r = F_R * \tan \phi_r - F_S * \tan \phi_s \quad (29)$$

The total load on the bearing is :

$$F_T = \sqrt{F_t^2 + F_r^2} \quad (30)$$

LIFE AND DYNAMIC CAPACITY

Life and Dynamic Capacity Models

Surface pitting fatigue from cyclic loading is the mode of failure for the components considered in this simulation program for the life of a helicopter transmission. Loaded surfaces of rolling element bearings and the gears, will fail due to surface pitting after a number of repeated loadings. The model used to predict failure which relates the number of load cycles at failure to the applied load is Palmgren's model. Palmgren's model was originally developed for rolling element bearings. It has also been applied to gear teeth in this computer simulation program. The Palmgren model is:

$$l_{10} = \left(\frac{C}{F} \right)^p \quad (31)$$

l_{10} is the life of the component in millions of load cycles for a 90 percent probability of survival [15,16]. F is the equivalent load on the component. C , the basic dynamic capacity, is the reference load for which 90 percent of a large sample of the components will survive one million load cycles. The exponent p is called the load-life factor.

Equation 31 is the analytical expression for a load verses life diagram in which there is no endurance limit. Using the Palmgren-Minor linear damage rule and equation 31 an equivalent nominal load for a component in terms of a mission spectrum of loads can be obtained as:

$$F = \left(\frac{F_a^p * L_a + F_b^p * L_b + \dots}{L_a + L_b + \dots} \right)^{1/p} \quad (32)$$

Where L_a is the life at load F_a .

The model for component life as a function of load has been combined with the Weibull distribution for probability of survival as a function of life at a given load for ball and roller bearings [15,16] and for gear teeth [5-9]. The equation resulting from the combination describes the life and reliability as a function of the applied equivalent load. The two parameter Weibull distribution is:

$$\log \left(\frac{1}{S} \right) = \log \left(\frac{1}{0.9} \right) + \left(\frac{1}{l_{10}} \right)^e \quad (33)$$

Here, S is the reliability which is also the probability of survival. l is the component life at the reliability S . l_{10} is the component life at 90 percent reliability, and e is the Weibull slope.

The transmission life and reliability models used in this program combine these models for the components with a strict series probability law that states that the probability of survival of the transmission is the product of the probabilities of survival of the components:

$$S_T = S_1 * S_2 * S_3 * \dots \quad (34)$$

This strict series probability law is justified on the basis of the high speed of the transmission components and the effect of loose debris. If any component fails, debris present in the transmission can accelerate wear damage of other components of the transmission. In the case of a transmission run until failure occurs in one component, a complete transmission overhaul is required. The complete overhaul is recommended to repair all components which could have been damaged by debris of the failed component. The overhaul would return the transmission to a high state of reliability.

Component Dynamic Capacity

Each bearing and gear in a transmission has a load which will cause ten percent of a large sample of these components to fail by pitting at or before one million load cycles. This is the component dynamic capacity.

The dynamic capacity for bearings, C_b , can be obtained from the manufacturer of the bearing. The load-life exponent for rolling element

bearings are normally taken as $p_b=3.0$ for ball bearings and as $p_b=3.33$ for cylindrical and tapered roller bearings [19].

For gears, the dynamic capacity is not tabulated directly. The dynamic capacity of a gear tooth is proportional to the Hertzian contact pressure squared for applications in which the major axis of the contact ellipse is significantly larger than the minor axis. In spur gears there is line contact. With this proportionality, the dynamic capacity of a gear tooth, C_t , can be expressed as:

$$C_t = \frac{B_1 * b}{\sum \rho} \quad (35)$$

Where B_1 is the material constant, b is the length of the major axis of the contact ellipse or line contact and $\sum \rho$ is the curvature sum in the direction of gear tooth rotation. The material constant, B_1 , is the experimental load-stress factor, K_1 of Buckingham [17].

Component System Lives - Gears

To obtain the system life of a gear in a transmission the component life of a single tooth of the gear has to be calculated. The load cycles it sees must be adjusted to the output shaft rotations [18,19,20]. Gears with more than one loading are treated separately.

Using a strict series reliability model we can convert the reliability of a single gear tooth to the reliability of a gear.

$$S_g = S_t^{N_g} \quad (36)$$

Where, S_g , is the probability of survival of the gear, S_t is the probability of survival of the gear tooth, N_g is the number of teeth on the gear. If the reciprocal of this equation is taken, the result is:

$$\left(\frac{1}{S_g}\right) = \left(\frac{1}{S_t}\right)^{N_g} \quad (37)$$

Taking the natural logarithm of the equation :

$$\log \left(\frac{1}{S_g}\right) = N_g * \log \left(\frac{1}{S_t}\right) \quad (38)$$

Substituting equation 33, which relates reliability to l_{10} life, into equation 38 yields :

$$\log \left(\frac{1}{0.9}\right) * \left(\frac{L_g}{L_{g10}}\right)^{e_g} = N_g * \log \left(\frac{1}{0.9}\right) * \left(\frac{L_t}{L_{t10}}\right)^{e_g} \quad (39)$$

Where, L_g is the life of the gear, L_{g10} is the 90 percent reliability of the gear, L_t is the life of the gear tooth, L_{t10} is the 90 percent reliability life of the gear tooth, and e_g is the Weibull exponent of the gear. Cancelling terms and taking the equation to the $(1/e_g)$ power yields :

$$\left(\frac{l_g}{l_{g10}}\right) = N_g^{(1/e_g)} * \left(\frac{l_t}{l_{t10}}\right) \quad (40)$$

The equation relating gear tooth dynamic capacity and load to gear tooth life is:

$$l_{t10} = \left(\frac{C_t}{W_n} \right)^{p_g} \quad (41)$$

Where, C_t is the dynamic capacity of a gear tooth and W_n is the load on the gear tooth. This equation can be substituted into equation 40 to yield.

$$\left(\frac{l_g}{l_{g10}} \right) = N_g^{(1/e_g)} \left[\frac{l_t}{\left(\frac{C_t}{W_n} \right)^{p_g}} \right] \quad (42)$$

This equation relates gear life to tooth load. W_n , is the normal tooth load on a single pinion input. When there is a dual pinion input to a gear an equivalent gear tooth load is used. Since the loads from the two pinions may differ, an equivalent load must be used to simulate the same fatigue damage as the two separate loads. To derive the equivalent load we use equation 32.

$$F = \left(\frac{F_a^p * L_a + F_b^p * L_b}{L_a + L_b} \right)^{(1/p)} \quad (43)$$

Substituting W_{n1} , the right pinion normal load, and W_{n2} , the left pinion normal load, and substituting, L , for the number of cycles for each pinion.

$$W_{ne} = \left(\frac{W_{n1}^p * L + W_{n2}^p * L}{L + L} \right)^{(1/p)} \quad (44)$$

Cancel terms:

$$W_{ne} = \left(\frac{W_{n1}^p + W_{n2}^p}{2.0} \right)^{(1/p)} \quad (45)$$

This equivalent load is a weighted average of the two loads. W_{ne} is substituted for W_n in the dual input.

In equation 42 the gear tooth load cycles will not always equal the number of gear rotations. Also the gear rotations will not always equal the output shaft rotations. To get all components on the same counting base, a factor must be inserted. The relationship between output rotations, l_g , and tooth load cycles, l_t , is:

$$l_g = \left(\frac{1}{m_g} \right) * l_t \quad (46)$$

The factor m_g is a combination ratio:

$$m_g = m_1 * m_{g2} \quad (47)$$

Where, m_1 is the gear ratio from the unit output shaft to the final output shaft of the transmission, and m_{g2} is the ratio from tooth load cycles to the unit output shaft. m_{g2} can be found in table 2.

TABLE 2
Ratio Relating Gear Tooth Load Cycles to
Unit Output Shaft Rotations

spiral bevel	single input	dual input	
-----+-----+-----+			
pinion	$\frac{N_g}{N_p}$	$\frac{N_g}{N_p}$	
-----+-----+-----+			
gear	1.0	2.0	
-----+-----+-----+			
planetary	non-stepped	stepped	
-----+-----+-----+			
sun	$\frac{n \cdot R_r}{R_s}$	$\frac{n \cdot (R_r \cdot R_s)}{(R_s \cdot R_{pr})}$	
-----+-----+-----+			
planet	$\frac{R_r}{R_p}$	$\frac{R_r}{R_{pr}}$	
-----+-----+-----+			
ring	n	n	
-----+-----+-----+			

If the factor m_g of equation 46, is substituted into equation 42 a relation to calculate gear life in output rotations from the gear tooth load is obtained.

$$l_{g10} = \left(\frac{1}{N_g} \right)^{(1/e_g)} \left(\frac{1}{m_g} \right)^{P_g} \left(\frac{C_t}{W_t} \right) \quad (48)$$

There is one exception to this equation. In the case of a non-stepped planet gear in a planetary unit, the gear will mesh with two different gears. Since the planet gear meshes with two different gears, the life analysis must take into account the different levels of damage done in each gear mesh [19]. The probability of survival for the planet gear, S_p , is the product of the probability of survival of the teeth in the planet-sun mesh, S_{ps} and the probability of survival of the teeth in the planet-ring mesh, S_{pr} .

$$S_p = S_{ps}^{N_p} * S_{pr}^{N_p} \quad (49)$$

The probabilities can be combined under one power, since the power of the two probabilities is the same.

$$S_p = (S_{ps} * S_{pr})^{N_p} \quad (50)$$

Take the reciprocal of the equation

$$\frac{1}{S_p} = \frac{1}{(S_{ps} * S_{pr})^{N_p}} \quad (51)$$

Take the logarithm

$$\log \frac{1}{S_p} = N_p * \log \left[\frac{1}{(S_{ps} * S_{pr})} \right] \quad (52)$$

By expanding equation 52, the relation is seen to be similar to the Weibull distribution, equation 33:

$$\log \left(\frac{1}{S_p} \right) = N_p * \left[\log \left(\frac{1}{S_{ps}} \right) + \log \left(\frac{1}{S_{pr}} \right) \right] \quad (53)$$

Substitute equation 33, relating reliability to L_{10} life into the expanded equation to yield:

$$\log \left(\frac{1}{0.9} \right) * \left(\frac{L_p}{L_{p10}} \right)^{e_g} = N_p * \left[\log \left(\frac{1}{0.9} \right) * \left(\frac{L_{pt}}{L_{ps10}} \right)^{e_g} + \log \left(\frac{1}{0.9} \right) * \left(\frac{L_{pt}}{L_{pr10}} \right)^{e_g} \right] \quad (54)$$

Where L_p and L_{pt} are the lives of the planet gear and planet gear tooth respectively. L_{p10} , L_{ps10} , and L_{pr10} are the 90 percent probability of survival life of the planet gear, of a gear tooth in the planet-sun mesh, and of a gear tooth in the planet-ring mesh respectively. e_g is the gear Weibull exponent. Cancel terms and factor common terms:

$$\left(\frac{L_p}{L_{p10}}\right)^{e_g} = N_p * L_{pt} * \left[\left(\frac{1}{L_{ps10}}\right)^{e_g} + \left(\frac{1}{L_{pr10}}\right)^{e_g} \right] \quad (55)$$

Combine fractions:

$$\left(\frac{L_p}{L_{p10}}\right)^{e_g} = N_p * L_{pt} * \left[\frac{\left(\frac{1}{L_{ps10}}\right)^{e_g} + \left(\frac{1}{L_{pr10}}\right)^{e_g}}{\left(\frac{1}{L_{ps10}}\right)^{e_g} * \left(\frac{1}{L_{pr10}}\right)^{e_g}} \right] \quad (56)$$

By taking the reciprocal and rearranging the terms the following relation is found:

$$L_{p10}^{e_g} = \left(\frac{1}{N_p}\right)^{e_g} * \left(\frac{L_p}{L_{pt}}\right)^{e_g} * \left[\frac{\left(\frac{1}{L_{ps10}}\right)^{e_g} * \left(\frac{1}{L_{pr10}}\right)^{e_g}}{\left(\frac{1}{L_{ps10}}\right)^{e_g} + \left(\frac{1}{L_{pr10}}\right)^{e_g}} \right] \quad (57)$$

Take the equation to the e_g th root

$$L_{p10}^{(1/e_g)} = \left(\frac{1}{N_p}\right)^{(1/e_g)} * \left(\frac{L_p}{L_{pt}}\right)^{(1/e_g)} * \left[\frac{\left(\frac{1}{L_{ps10}}\right)^{e_g} * \left(\frac{1}{L_{pr10}}\right)^{e_g}}{\left(\frac{1}{L_{ps10}}\right)^{e_g} + \left(\frac{1}{L_{pr10}}\right)^{e_g}} \right]^{(1/e_g)} \quad (58)$$

Substitute the m_g factor for relating output revolutions to tooth load cycles.

$$L_{p10} = \left(\frac{1}{N_p} \right)^{(1/e_g)} * \left(\frac{1}{m_g} \right)^{(1/e_g)} * \frac{L_{pr10} * L_{ps10}}{\left[\frac{e_g}{L_{ps10}} + \frac{e_g}{L_{pr10}} \right]^{(1/e_g)}} \quad (59)$$

Substitute equation 31 relating tooth life to tooth dynamic capacity and load.

$$L_{p10} = \left(\frac{1}{N_p} \right)^{(1/e_g)} * \left(\frac{1}{m_g} \right)^{(1/e_g)} * \frac{\left(\frac{C_{pr}}{W_{pr}} \right)^{p_g} * \left(\frac{C_{ps}}{W_{ps}} \right)^{p_g}}{\left[\frac{(p_g * e_g)}{\left(\frac{C_{pr}}{W_{pr}} \right)} + \frac{(p_g * e_g)}{\left(\frac{C_{ps}}{W_{ps}} \right)} \right]^{(1/e_g)}} \quad (60)$$

Where C_{pr} and C_{ps} are the dynamic capacities of a tooth in the planet-ring gear mesh and a tooth in the planet-sun gear mesh respectively. W_{pr} and W_{ps} are the load on a tooth in the planet-ring and planet-sun mesh respectively. p_g is the load-life exponent of the gear.

Component System Lives - Bearings

Using a similar approach to the gears [18,19,20], the relationship obtained for bearings is:

$$\frac{L_{bs}}{L_{bs10}} = \frac{L_b}{L_{b10}} \quad (61)$$

Where L_b is the life of the bearing in terms of bearing cycles, L_{bs} is the life of the bearing in terms of output shaft revolutions. L_{b10} is the 90 percent reliability life in terms of bearing cycles. L_{bs10} is the 90 percent reliability life in terms of output shaft revolutions. By substituting equation 31, which relates bearing life to bearing capacity and load, the relationship becomes:

$$\left(\frac{L_{bs}}{L_{bs10}} \right) = \left[\frac{L_b}{\left(\frac{C_b}{W_b} \right)^{p_b}} \right] \quad (62)$$

In equation 62 the bearing load cycles will not always equal the number of output shaft rotations. To get all components on the same counting base a factor must be inserted. The relationship relating output rotations, L_{bs} , and bearing load cycles, L_b , is:

$$L_{bs} = \left(\frac{1}{m_b} \right) * L_b \quad (63)$$

The factor m_b is a combination ratio:

$$m_b = m_1 * m_{b2} \quad (64)$$

Where, m_1 , is the gear ratio from the unit output shaft to the final output shaft of the transmission, and m_{b2} is the ratio from bearing load cycles to the unit output shaft revolutions. m_{b2} can be found in table 3.

If one substitutes factor m_b , equation 63, into equation 62 a relation is obtained which will calculate gear life in output shaft

TABLE 3
Ratio Relating Bearing Load Cycles to
Unit Output Shaft Rotations

-----+-----+-----+					
planet		$\frac{R_r}{R_p}$		$\frac{R_r}{R_{pr}}$	
-----+-----+-----+					

rotations from the gear tooth load. The equation for the bearings becomes:

$$L_{bs10} = \left(\frac{1}{m_b} \right) * \left(\frac{C_b}{F_b} \right)^{p_b} \quad (65)$$

This equation gives the bearing life in terms of output rotations.

Component System Dynamic Capacities

The dynamic capacity of each component can now be expressed as an output torque. By taking the p^{th} root of equation 31 and replacing the ratio of the component system capacity to the component equivalent load by the ratio of component system dynamic capacity to reduction output torque, the component system lives can be used to determine the component system dynamic capacities.

$$D_i = (L_{i10})^{(1/p_i)} * (T_o) \quad (66)$$

These dynamic capacities are in units of output torque and express the output torque of the reduction at which 90 percent of a set of similar components will survive for one million rotations.

Transmission Life

To calculate the life of the transmission, the probability of survival of the transmission is expressed as the product of the probabilities of survival of the components.

$$S_T = \prod_{i=1}^n S_i \quad (67)$$

The reciprocal of the equation is:

$$\frac{1}{S_T} = \prod_{i=1}^n \left(\frac{1}{S_i} \right) \quad (68)$$

Taking the natural logarithm of this equation:

$$\log \left(\frac{1}{S_T} \right) = \sum_{i=1}^n \log \left(\frac{1}{S_i} \right) \quad (69)$$

Using the Weibull distribution equation relating life to probability of survival, equation 33, the preceding equation becomes:

$$\log \left(\frac{1}{S_T} \right) = \log \left(\frac{1}{0.9} \right) \sum_{i=1}^n \left(\frac{L_T}{L_{i10}} \right)^{e_i} \quad (70)$$

In this equation L_T is the life of each component and of the entire transmission for a transmission reliability of S_T . This equation is not a strict Weibull relationship between transmission life and reliability. The equation would be a true Weibull distribution if all the Weibull exponents, e_i , were equal. This is not true since Weibull exponents for gears and bearings will differ from each other significantly. This equation can be solved for S_T as a function of the transmission life, L_T , and plotted on Weibull coordinates.

On this plot of percent probability of failure versus transmission, life a straight line can be fit to the model. Linear regression can be used to approximate the straight line. The range of this linear regression is for probability of survival between fifty and ninety-five percent. The slope of the straight line approximation is the transmission Weibull exponent e_T . The transmission life, L_{T10} , is the life calculated from the straight line approximation at a reliability $S_T=0.9$. This L_{T10} life is the life of the transmission at the given output torque. The equation using the transmission life L_{T10} and Weibull exponent, e_T is:

$$\log \left(\frac{1}{S_T} \right) = \log \left(\frac{1}{0.9} \right) \left(\frac{L_T}{L_{T10}} \right)^{e_T} \quad (71)$$

Transmission Dynamic Capacity

The basic dynamic capacity for the transmission, D_T , is the output torque which will give a transmission life of one million output shaft rotations, at a reliability of 90 percent. Setting $S_T=0.9$ in equation 69 yields:

$$\log \left(\frac{1}{0.9} \right) = \log \left(\frac{1}{0.9} \right) \sum_{i=1}^n \left(\frac{L_T}{L_{i10}} \right)^{e_i} \quad (72)$$

By canceling terms the equation becomes:

$$1 = \sum_{i=1}^n \left(\frac{L_T}{L_{i10}} \right)^{e_i} \quad (73)$$

Expressing the Palmgren load-life model in terms of component system torques and lives:

$$L_{i10} = \left(\frac{D_i}{T_o} \right)^{p_i} \quad (74)$$

Substitute into equation 73

$$1 = \sum_{i=1}^n \left[\frac{D_T / T_o^{p_i}}{D_i / T_o^{p_i}} \right] \quad (75)$$

Cancel terms and rearrange:

$$1 = \sum_{i=1}^n \left(\frac{D_T}{D_i} \right)^{p_i} \quad (76)$$

This equation can be solved by iteration to obtain the transmission dynamic capacity, D_T .

To find the load life exponent, a series of 90 percent reliability lives of the transmission are calculated at output torques between 10 and 100 percent of the dynamic capacity. The lives are plotted against torque on a log versus log plot. this curve can be approximated by a straight line. Using a linear regression, the slope and value of the function at one million cycles can be found. The negative reciprocal of the slope is the load life exponent for the

transmission. The value of the function at one million cycles will be the dynamic capacity of the transmission corresponding to the load life exponent. With the values from the linear regression, The load life relation for the transmission is given by:

$$L_{T10} = \left(\frac{D_T}{T_0} \right)^{p_T} \quad (77)$$

Where, D_T is the output torque for one million output rotations, p_T is the load-life exponent and L_{T10} is the 90 percent reliability life of the transmission.

PROGRAM USE

To use the program one must define the geometry of the transmission. One can run the program interactively or by batch file. To run the program interactively, one will have to answer the prompts (questions) with the proper information. If a mistake is made entering the information according to the prompts, all is not lost. After a series of questions, the value of the last few will be printed out. A prompt will ask if you wish to change any of the previous answers. If one answers yes, the program will return to the beginning of the section and then one can input the correct information.

The program will prompt the user with a list of eight types of transmissions which can be analyzed. The eight types of transmissions are shown in figure 15. Any one of these eight types can be analyzed. Once the type of transmission is chosen, the program will ask for information to define each gear unit making up the transmission. The inputs for spiral bevel gear units are asked for separately from the inputs for the planetary gear units.

The inputs required for the spiral bevel gear unit are divided into three main parts: the geometry of the gear mesh, the mounting of the bearings and gears, and the characteristics of the bearings. These three sets of inputs can be found in table 4, 5, and 6 respectively.

2. Distance A - Gear to bearing closest to the gear mesh apex
3. Distance B - Gear to bearing furthest from the gear mesh apex
4. The bearing which takes the thrust load

TABLE 6

Inputs to Define the Characteristics of the
Spiral Bevel Gear Unit Bearings

The bearings can be of the following types:

1. Single row ball bearings
2. Double row ball bearings
3. Single row roller bearings
4. Double row roller bearings
5. Single row tapered roller bearings
6. Double row tapered roller bearings

For types 1 and 2 - Single and Double row ball bearings the inputs required are :

1. Number of rolling elements in the bearing
2. Diameter of the rolling elements in the bearing (in)
3. Bearing contact angle (deg)
4. Basic dynamic capacity (lbs)
5. Rotational factor (inner race or outer race rotation)
6. Weibull exponent
7. Life adjustment factor

For types 3 and 4 -Single and Double row roller bearings the inputs required are :

1. Basic dynamic capacity (lbs)
2. Rotational factor (inner race or outer race rotation)
3. Weibull exponent
4. Life adjustment factor

For types 5 and 6 -Single and Double row tapered roller bearings the inputs required are :

1. Thrust ratio
2. Basic dynamic capacity (lbs)
3. Weibull exponent
4. Life adjustment factor

In the planetary gear unit, the inputs will be for either an unstepped planetary or a stepped planetary. The stepped planetary gear unit will require extra inputs to define the stepped planet gears. Inputs for a planetary gear unit are found in table 7.

In the program, the spiral bevel gear unit and planetary gear unit analysis are done in separate parts. The method of analysis is the same in both parts. First the geometry of the gears is completed from the information given and the geometric relations. Next the loads on each component of the unit are calculated. The life of the component is calculated from the load on the component and the load cycle ratio of the component. The dynamic capacity is then calculated for each component. From the calculated lives of the components, the life and the Weibull exponent of the transmission is found by iteration. The program next figures a series of transmission lives verses output torques between 10 and 100 percent transmission dynamic capacity. Using a linear approximation of the output load verses life of the transmission, the transmission dynamic capacity and load-life exponent is found. Figure 16 is a basic flow chart of the program. Appendix C contains the computer listing for the program.

In the output of the program one will find the complete dimensions of the gear meshes and the forces on the components. Also the component system lives and dynamic capacities are in the output. The transmission life and dynamic capacity are the final results produced by the program. Table 8 lists the format of the transmission analysis results.

TABLE 8

Output of the Program

For each gear unit the following will be output:

1. The gear mesh geometry
2. The gear mounting geometry
3. The forces on the gears and bearings

For each component the following will be output:

1. Component system dynamic capacity
2. Component system load-life exponent
3. Component system life in output shaft rotations
4. Component system life in hours
5. Component system Weibull exponent

For the transmission the following will be output

1. Transmission system dynamic capacity
2. Transmission system load-life exponent
3. Transmission system life in output shaft rotations
4. Transmission system life in hours
5. Transmission system Weibull exponent

NUMERICAL EXAMPLE

In the design of a transmission the components are sized from the power transfer requirement. The initial design does not consider the effects of the components on one another. The initial design contains some overdesigned and weak parts. One can change the parameters on the overdesigned and weak components to see the overall effect in the transmission.

In this example, the transmission being designed is a 320 horsepower single input helicopter transmission. The input speed is 6180 rpm and the output speed is 354 rpm. The L_{10} life of the transmission is to be approximately 3500 hours at the rated power level.

The layout chosen for this transmission is a spiral bevel unit followed by an unstepped planetary unit, figure 17. The spiral bevel unit will produce a gear reduction of 3.736 : 1. The input torque will be transferred through 95 degrees from an approximately horizontal input to a vertical output shaft. Table 9 lists the geometry of the spiral bevel unit. The planetary unit will produce a gear reduction of 4.66 : 1 along the output shaft. Table 10 lists the geometry of the planetary unit. Appendix A shows how the input is entered into the program for this original design.

The program was run with the geometry described in table 9 and 10. The output of the program can be found in appendix B. The program first calculates the loading on each component in the transmission. This intermediate step of calculating the life of the components is useful to a designer. If the designer changes the geometry of the transmission the loads on the components will change. The change in loading of the component will change the life of the component without changing the dynamic capacities of the components.

After the intermediate step of calculating the loads, the program computes the life of each component. The dynamic capacity of each component is calculated next. The life and Weibull exponent is then calculated for the spiral bevel unit, planetary unit, and the total transmission. Finally the dynamic capacity and load life exponent is calculated for the spiral bevel unit, planetary unit, and the total transmission.

The intermediate calculation of life and dynamic capacity of the spiral bevel unit and the planetary unit are valuable since a change within one unit will not effect the components in the other unit. Therefore the effects of design change within a unit are readily observed.

The values of the total transmission life and dynamic capacity will help the designer determine the critical elements in the transmission by comparing the values for the transmission to the life and dynamic capacity of each unit. Table 11 shows the values of dynamic capacity, load-life exponent, life in output rotations, life in hours, and Weibull exponent for the initial design. By checking the values of

Table 11
Life and Dynamic Capacity of Transmission

Planet-Sun Gear	4,433,816	4.3	668*10E12	31*10E9	2.5
Total Transmission	76,841	3.966	16*E6	758	2.2

the spiral bevel unit and planetary unit against the values for the total transmission, it can be seen that the spiral bevel unit values are very close to the transmission values. This is also illustrated in figure 18. The spiral bevel unit dominates the life and dynamic capacity of the total transmission. Therefore it is the weakest part of the transmission. By further examination it can be seen that the life and dynamic capacity of the spiral bevel unit is dominated by the input pinion and output gear. The value of these components are much lower than any other component in the system, therefore a redesign of the gear mesh would be recommended.

In this example the size of the spiral bevel gear mesh was increased. The size of the cone distance, A_o , was increased from 5.199 inches to 8.5 inches, and the face width, f , was increased from 1.8 inches to 3.5 inches. This redesign causes an increase in spiral bevel unit life of 400 percent and an increase in transmission life of 300 percent. The results of this redesign are shown in table 12. The life verses probability of failure graph for this case is shown in figure 19.

The life of the transmission is still less than the life required in the specifications. Since the life of the spiral bevel unit and planetary unit are about equal, the lives of both units will have to be increased. In the spiral bevel unit, the output bearings have the lowest life. In this case the dynamic capacity of the bearings are increased. For the planetary unit the planet bearings have the lowest life. There are two choices to increase the life of the planet bearing, either increase the number of planet bearings or

Figure 19

Life Versus Probability of Failure Re-Design 1

increase the dynamic capacity of the bearings. In this case the number of bearings is increased. The life of the bearings will increase because the load on each bearing will be lower. This also increases the life of the other components in the planetary since the loads transmitted by each planet gear will be lower.

The results of this redesign are shown in table 13. The life verses probability of failure graph for this case is shown in figure 20. The modifications doubled the life of each unit. The life of the total transmission increased to 4500 hours which is above the design requirement of 3500 hours. By examining the Weibull and load-life exponents one can see that the design is dominated by the life of the bearings. The Weibull and load-life exponents are very close to the most common exponent values of bearings. This indicates that the life and dynamic capacity of the transmission are dominated by the bearings. This is a good test to find which components dominate the life of the transmission or any unit in the transmission.

The results of each following design run will give a great deal of information on which design changes can be based. These design changes will allow the designer to approach an optimal transmission design.

Life Versus Probability of Failure Re-Design 2

DISCUSSION OF RESULTS

This computer program was developed to model the life and reliability of helicopter transmissions. The calculation of the life of a transmission is based on a strict series probability law. The strict series probability law states that the probability of survival of a transmission is the product of the probabilities of survival of all the components. The relationship between the probability of survival of a component and its life is the two parameter Weibull distribution. The resulting reliability model for the transmission is also a two parameter Weibull distribution.

The computer program is written in a modular form to model many different types of transmissions. In addition to results for the overall transmission, intermediate results for modules of the transmission are given.

Input to the computer program is to be given in an interactive format. The program prompts the user with questions which ask for the parameters required to describe the transmission. In this interactive format, a screen by screen review of the input data is provided to the user. If any data on the screen is incorrect, the user may return to the input stream at a point just prior to this screen to input this data correctly. If more than one design is to be

modeled at a time, an input data file may be used to speed up the use of the program. The user can change one parameter in a data file and quickly run the program again to determine the effects of this change on the components and the transmission.

The output of the computer program gives a complete overview of the transmission analysis. The geometry of the components entered into the program and the geometry calculated for the components are both printed out. Lives and dynamic capacities of the components are printed out in terms of component cycles and loads and in terms of system cycles and load. Each result listed in the output includes a title and the proper units.

By using the program in a systematic manner, a user can approach an optimal design. An example of this use is given in the proceeding chapter to illustrate the use of the program. Sample input and output listings are included in the first two appendices. The third appendix is a listing of the fortran source code for the program.

SUMMARY OF RESULTS

This report describes a computer simulation program which models the life and reliability of a helicopter transmission. The computer program uses the lives and reliabilities of the individual bearings and gears in the transmission to compute the life and reliability of the transmission. This model is a strict series probability model which is based on the pitting fatigue life and reliability models for the components of the transmission.

In this program, a modular approach is used in which the force and motion analyses of the transmission are separated from the life and reliability analyses. The dynamic capacity models are also separated algebraically from the prior calculations. In this way, the calculations can be performed sequentially and the complexity and diversity of the analyzed transmissions can be increased greatly.

The computer program can simulate a number of transmission configurations built up from spiral bevel gear units, a dual spiral bevel gear unit and stepped or unstepped planetary gear units. The eight transmission configurations analyzed by the program are:

- 1) a spiral bevel reduction,
- 2) a planetary reduction,
- 3) a spiral bevel reduction followed by a planetary reduction,

- 4) a spiral bevel reduction followed by two planetary reductions in series,
- 5) a dual spiral bevel reduction with two input pinions of equal size,
- 6) a dual spiral bevel unit followed by a single planetary reduction,
- 7) a dual spiral bevel unit followed by two planetary reductions in series, and
- 8) a dual spiral bevel unit followed by a planetary reduction and proceeded by two spiral bevel input reductions.

The program allows any planetary unit to be composed of stepped or unstepped planets. It can simulate transmission designs at different power levels and load duty cycles. The program can calculate the lives and dynamic capacities of a single unit or the transmission as a whole.

This report includes a development of the theory behind the program model, a listing of the program in fortran source code and examples illustrating the use of the program.

16. Abstract → A computer program which simulates life and reliability of helicopter transmissions is presented. The helicopter transmissions may be composed of spiral bevel gear units and planetary gear units, alone, in series or in parallel. The spiral bevel gear units may have either single or dual input pinions, which are identical. The planetary gear units may be stepped or unstepped and the number of planet gears carried by the planet arm may be varied. The reliability analysis used in the program is based on the Weibull distribution lives of the transmission components. The computer calculates the system lives and dynamic capacities of the transmission components and the transmission. The system life is defined as the life of the component or transmission at an output torque at which the probability of survival is 90 percent. The dynamic capacity of a component or transmission is defined as the output torque which can be applied for one million output shaft cycles for a probability of survival of 90 percent. A complete summary of the life and dynamic capacity results is produced by the program.
