ABSTRACT

This thesis presents a fully developed, tactically oriented computer aided mission planning system for the A-7E aircraft. The system is designed to be extremely easy to operate by someone with no computer experience, and is a replacement for 53 NATOPS performance charts that are most applicable to flight and mission planning. High altitude performance, as well as low altitude and maximum range performance, are available. Tactical navigation routes may be entered, edited, and saved in a disk file. Navigation computations are linked with aircraft performance to provide printout of a completed mission planning jet log.

Numerical techniques for obtaining analytical expressions from chart and tabular data included multiple linear regression analysis, curve fitting, and cross plotting of regression coefficients. The computer program results have been correlated with NATOPS data and actual flight test, and have been found to be highly accurate. The program is designed to be run on the IBM PC/XT/AT and compatible computers with a minimum of 256K memory available.

THESIS DISCLAIMER

Neither the U.S. Navy nor anyone else who has been involved in the creation, production, or delivery of this program shall be liable for any direct, indirect, consequential, or incidental damages arising out of the use, the results of use, or inability to use such product. Complete and thorough preflight and tactical planning is the responsibility of the officer in charge of such activities, and should be accomplished using accepted techniques and the appropriate officially approved publications. This program is a planning aid and all computed solutions should be carefully validated.

ACKNOWLEDGMENT

My thanks to Professor D.M. Layton for his professional assistance and support in the pursuit of this thesis. My thanks also to CDR. W.M. Siegel, USN (Ret), and to CDR. R.G. Bettinger, USN, for their professional leadership and support.

I. INTRODUCTION

The objective of this thesis was to produce a fully developed and correlated, computer based mission planning system. Current mission planning computations are done by hand calculation with aircraft performance data derived from graphical interpretation of NATOPS chart presentations. That method is slow and generates solutions which may contain significant errors. A class of sixteen prospective squadron commanding officers attending a one-week Command Safety Course at the School of Aviation Safety, Naval Postgraduate School, Monterey, California, was asked to complete a typical mission planning problem. The results were that the correct answer was not achieved by any member of the class. The range of solutions was 336 nm to 868 nm, spread about the correct answer of 538 nm. The correct answer was achieved only by the class instructor after a measured 16 hours of effort with the NATOPS manual [Ref. 1].

A study by the Vought Corporation to evaluate the feasibility of a computer based flight planning system resulted in a recommendation to the Naval Air Development Center (NADC), Warminster, Pennsylvania, that such a system would be feasible and would result in fuel savings as well as increased accuracy in the mission planning

areas [Ref. 2]. In addition, Hill [Ref. 3] clearly defines the need for accurate aircraft performance data to be available in order for strike planners to plan safe and tactically effective long range missions of 800 to 1200 nm radius. These missions are complex evolutions and may be significantly compromised by a false need for additional support aircraft such as electronic countermeasures, radar surveillance, and tanker assets. A recent article [Ref. 4:pp.69-73], detailing a report on the differences between Navy and Air Force aviation operations was completed in May 1985 as a result of a study directed by the Vice Chief of Naval Operations on this subject. This report directly addressed a major difference regarding aircrew duties and aircrew fatigue:

The familiar complaint of excessive collateral duties was of major interest to the exchange pilots. There was unanimous agreement that in the Navy these non-flying tasks impede the development of flying skills, particularly in the junior ranks, while contributing to fatigue, hasty flight planning, and sketchy briefings and debriefings. In the Air Force, collateral duties are directly related to flying and help fulfill requirements for professional development of the officer and the aviator. . . . Navy aircrews devote less time to flight planning than Air Force fliers. Although briefings and post-flight debriefings are valued in both services, Navy briefings were considered non-standard when compared to those in the Air Force. Again, collateral duty responsibilities were believed to detract from better fight planning and briefing in the Navy. The Air Force is more strictly regulated than the Navy. The Navy system fosters the bending of rules to fit operational commitments, a practice which compromises safety, and promotes a side effect--tacit approval of nonadherence to regulations.

NATOPS was created in 1961 and is credited with being a milestone in naval aviation safety improvement. Yet, the study group found that NATOPS is less effective

in promoting safety than the Air Force's Standardization and Evaluation (Stan/Eval) program. Overall, the NATOPS program is sound, but enforcement of the procedures is occasionally weak. Furthermore, the Air Force's Eval checks are more stringent than the Navy's NATOPS checks.

II. APPROACH TO THE PROBLEM

A. BACKGROUND

Development of a computer based mission planning system required examining constraints in hardware/software performance and availability, and in deriving the necessary mathematical equations and algorithms. Until 1984, the primary consideration in development of a computer based system was the high cost and limited performance of hardware. Since 1984, these problems have been eliminated due to the advance in micro computer technology. Central processing units have tremendous speed and capability, and additional memory chips have become so inexpensive that one megabyte of Random Access Memory (RAM) is common on many personal computers. As a result of application programs written for users with a broad range of technical backgrounds, and development of very powerful languages, software for personal computers has become, in many ways, more usable than main frame programs. Many main frame capabilities now reside also with the personal computer.

Several attempts at deriving adequate mathematical equations that represent the NATOPS curves have resulted with only partial success. Koger [Ref. 5] employed an extension of the technique developed by Siegel [Ref. 1] to derive mathematical expressions through a least squares

fit modeling method for takeoff, maximum range, maximum endurance, and low level aircraft performance. These equations, however, do not fully describe the entire NATOPS chart for which they were developed. Koger [Ref. 5] explained the difficulties encountered with charts containing different families of curves, non-linear coefficients required in regression analysis, and regression of curves that were not well behaved. Consequently, these equations may only be accurately applied over a limited range of mission parameters. Hill [Ref. 3] developed equations and software for computing aircraft performance during the climb, cruise, and descent mission phases. One of the two primary limitations to Hill's program is its reliance on some equations applicable only to limited areas of the chart for which they were intended to describe. A second primary limitation is the program's dependence on published NATOPS drag count data, computed as a function of very specific aircraft loading information which must be looked up and supplied by the user. Obtaining this input data is a time intensive exercise, the results of which are frequently not completely accurate. Recent investigation of NATOPS drag count data by Naval Weapons Center, China Lake, and the Vought Corporation has revealed an underprediction of the actual drag counts by 25 to 30 counts, or approximately 25% error in total drag. Actual aircraft

installations with flight test data show higher drag and fuel requirements than those computed from NATOPS [Ref. 6].

In support of a contract between NADC and Vought Corporation to develop the Flight Performance Advisory System (FPAS) for Navy A-7E aircraft, Vought undertook a two year program, from December 1980 until January 1982, designed to develop flight performance algorithms and equations which could be programmed into the TC-2A Navigation and Weapons Delivery Computer (NWDC) on-board the A-7E aircraft [Ref. 7]. The study utilized actual aerodynamic and propulsion data bases, accounted for nonstandard atmospheric conditions, included algorithms for computation of cockpit instrument readings (indicated altitude, airspeed, and mach number), and allowed computations for partial power climbs and descents. Results from the generated equations and algorithms were correlated and verified within 1% of those from a more precise program running on the Cyber 175 computer. This study did not evaluate takeoff performance.

As a foundation for the mission planning system, accurate equations were required which described the full range of each applicable NATOPS chart for all mission areas. These mission planning areas were the takeoff, climb, high and low level cruise, descent, maximum range profile at maximum range altitude, maximum range possible

at an alternate altitude, high and low level navigation route computations, and the means to edit and store tactical navigation route structures. Complete aircraft performance data for each mission area, and coupled with the navigation route data to produce completed flight log cards, was the goal of this study.

B. EQUIPMENT

The work in obtaining satisfactory equations from NATOPS data and charts was performed on an IBM PC personal computer using relatively sophisticated multiple regression software [Ref. 8], and on the Hewlett-Packard HP-41 hand calculator using a set of four statistical regression programs written by the author. The mission planning software was developed with the author's equations obtained from statistical regression analysis of 20 NATOPS graphs for the takeoff, climb, and optimum performance mission phases. Each graph contained up to 9 curves and each curve was a function of primarily four independent variables. Additional equations were obtained from statistical regression and aerodynamic analysis by Vought [Ref. 7] which included another 33 NATOPS graphs for the cruise, descent, and optimum performance mission phases.

III. SOLUTION

A. PROCEDURE

The general procedure for statistical analysis of NATOPS graphical data is multiple regression. Each curve on a chart is regressed according to the same family of curves. The coefficients obtained in the equations are plotted against a common parameter of significance present in the initial graph. Equations are obtained to solve for the coefficients as a function of independent variables, which are then inserted into the equation of the family of original curves containing other independent variables. The result is a single equation to compute a dependent variable, and which contains all the other independent variables present in the original plots. This technique was investigated by Siegel [Ref. 1] and is clearly described by Koger [Ref. 5]. The technique is one of many numerical methods that may be applied to the problem of multiple regression of graphical data, however, this technique is not clearly presented in texts and is not a common or popular method of analysis. The requirement for application of computer methods in the analysis has been a factor in its lack of popularity. The multiple regression model used is a standard model and is described in Park [Ref. 8] and Ott/Hildebrand [Ref. 9]. Complete descriptions of this basic model and other techniques are

contained in an excellent text by Draper and Smith [Ref. 10].

Many of the NATOPS charts are plots of a dependant variable as a function of up to four independant variables. This complicates the multiple regression procedures, but is quite manageable. A number of technical difficulties can, however, significantly reduce the effectiveness of this method of analysis. The most prevalent problem is a plot of data in which all curves are not of the same family. This is evident in the maximum refusal speed chart for takeoff factor shown in Figure 1, in which the nature of the plotted data is clearly not consistant or of the same family. In these curves, additional numerical and statistical analysis is applied using computer methods, and a family is found for the curves that adequately describes them entirely. One method is to plot the graphical data using a reversed coordinate system and carefully chosen unit gradations, then to apply the multiple regression procedure to this "new" graph. Occassionally this resulted in a set of original curves more well behaved for analysis and closer to a common family of curves. Simply adding terms to the initial regression model is not satisfactory and, in fact, complicates the statistical analysis by positively influencing computed parameters indicative of how good a

model is. This results in a final set of equations which do not describe the original graphical data.

Obtaining accurate mathematical equations was a basic and preliminary requirement for addressing the problem which was the objective of this thesis. Developement of a fully functional computer aided mission planning program required accurate equations for the entire range of possible aircraft configurations, and the entire range of 53 NATOPS graphical plots.

IV. RESULTS

A. DISCUSSION

The final equations obtained from the author's analysis and the work by Vought [Ref. 7] were used in the programming effort, and are accurate within 1% of NATOPS results for most operational aircraft configurations. At extremes of either environmental or aircraft parameters, the final mission planning program yields results within 2% of NATOPS results. It should be pointed out that most of the NATOPS charts for the A-7E aircraft can not be read to within 2% and that this degree of accuracy over the entire operating range of the aircraft is considered acceptable.

The result of the programming effort is a mission planning system which enables pilots with no experience in computers to obtain complete aircraft performance for all mission phases. Navigation routes may entered, edited, and stored on disk. These may be called later to speed the planning process. High or low navigation route data is combined with the appropriate performance computations, and the system will produce a completed jet log for the high and low mission areas. The experimental planning exercise described by Siegel [Ref. 1] required 16 hours of work with the NATOPS charts to obtain a correct solution. This same problem can be solved using the mission planning

system software developed in this thesis, and requires approximately 30 minutes. This is a decrease in mission planning time of 96.9 percent. All results can be printed manually or automatically, an option selected by the user.

In order to fully describe the software to users, and explain each of the program's features, options, and logic flows, a complete user manual has been written as Appendix B. A feature of this manual is a quick start card which allows users to immediately begin planning without reading the documentation. The program has been written with on-screen help in order to accomodate this user approach. Each data input/output screen is detailed in Appendix B.

B. CORRELATION

Computed numerical results have been compared with four separate sources and have been found to be very accurate to over the entire operating envelope of the aircraft. Program computations were verified with numerical examples in the Vought work [Ref. 7], manual data extraction from the NATOPS charts, performance computations made with the Navy's Optimum Path Aircraft Routing System (OPARS) [Ref. 11], and fight test data obtained from an informal analysis conducted by a U.S. Navy test pilot and Naval Weapons Center, China Lake, California.

V. CONCLUSIONS AND RECOMMENDATIONS

This mission planning system software reduces planning time significantly, and allows missions to be planned with increased safety and mission effectiveness. A broad range of tactical options can be studied for tradeoffs in mission requirements, and can enable the planner to quickly compute requirements and a jet log for any of the input routes, or any of the routes on file. These tactical options may be required for consideration due to changes in the assigned targets, current intelligence regarding enemy target location or defensive placement of anti-aircraft weapons, or last minute changes in political cooperation or policy which may dictate severe changes to operational planning.

This program will allow pilots and aircrews to spend more time studying the target, briefing the mission, and reviewing complex aircraft emergency procedures, and significantly less time tracing through NATOPS charts for basic aircraft and mission performance data.

A single recommendation is necessary. Computed performance data under a broad range of aircraft configurations and environmental conditions should be verified. This can be most economically accomplished if each A-7E squadron and each functional wing were given a

copy of the program and the user manual, and kept a record of computed performance versus actual performance. The program should also be distributed to Air Force Tactical A-7D units, and Air National Guard A-7D units. Although the Air Force A-7D is lighter than the Navy A-7E, the program is written to accomodate input weights, therefore, computed aircraft performance should be very close to that actually experienced by Air Force and Air National Guard units.

APPENDIX B

TACTICAL COMPUTER AIDED MISSION PLANNING SYSTEM USER MANUAL

WHAT IS COMPUTER AIDED TACTICAL PLANNING?

INTRODUCTION

This program was designed to assist pilots with tactical mission planning in three ways:

1. Compute aircraft performance parameters for all phases of the mission, both high and low altitude. This includes display of the maximum range profile and the maximum range performance for a selected altitude, and allows a side by side comparison of maximum range mission requirements.
2. Provide the ability to enter, edit, and store on disk, many different low level routes, each defined by up to a maximum of nine (9) lat/long navigation points. These routes may later be recalled for performance computations. Routes of more than nine points can be planned in one of two ways:
 - A. Make two separate runs of the entire program.

B. Following jet log completion, select the option to calculate another route, then enter the route and continue with the program. Low level performance will be computed using previously input aircraft performance parameters and computed performance.

3. Combine the low level performance computations with lat/long route data, and automatically prepare a completed jet log for the low level route.

The program supplants the time consuming requirement to trace through NATOPS charts to obtain aircraft performance data, compute aircraft performance and mission requirements, measure low level route navigation data, and finally compute a jet log.

USES FOR COMPUTER AIDED TACTICAL PLANNING

The primary uses for a computer based mission planning system are to save time and allow a range of tactical options for consideration that would not be possible with manual calculation. Additionally, computed aircraft performance data must be at least as accurate as data obtained from the NATOPS charts, offering these tactical options with complete and consistent accuracy. Accurate fuel management, beginning at the mission

planning phase, results in more training per flight hour and more tactical options available per mission than is presently available with manual calculations. With this program, planners could build a file of low level routes to a target. Current intelligence information could be collected and utilized much longer, with tactical decisions regarding route, altitudes, and target selection made much later and closer to actual launch times. These tactical decisions could be based upon weather considerations, target options, information regarding enemy defenses, or political considerations. Additionally, accurate launch position information could be used to compute more accurate mission fuel requirements. For the training environment, use of this program can provide significantly better fuel management, reduced costs per flight hour, and thus more effective training per flight hour. Tradeoff studies in mission requirements, based on altitude, speed, fuel required, and time, may also be easily conducted.

SYSTEM REQUIREMENTS

1. An IBM PC, PCXT, PCAT, Portable or any true compatible.
2. 256K RAM.
3. A double density disk drive or a hard disk drive.
4. Any 80 column display, color or monochrome.
5. DOS 2.0 or higher.

WARNING: Always run this program with no other memory resident software installed. The only exception to this is running the program from a RAMDISK. The RAMDISK must be

created BEFORE copying this program to the disk and
running this program.

RUNNING THE PROGRAM FROM A RAMDISK

1. System RAM of 640K total is required.
2. Create the ramdisk of size at least 360K.
3. Copy the program disk to the ramdisk using the *.* method.
4. On the ramdrive prompt C> type the batch filename to start the program, RAMPLAN.
5. Be sure to file route data using B:filename

HOW DOES THE PROGRAM WORK?

There are four (4) sections to the complete program.

1. The MAXIMUM RANGE COMPUTER section.
2. The TAKEOFF and HIGH ALTITUDE CRUISE section.
3. The LOW LEVEL CRUISE AND JET LOG section.
4. The LAT/LONG COORDINATE EDITOR section.

MAXIMUM RANGE COMPUTER SECTION

This section requires 6 inputs, and is a stand alone program. This means that the program is run completely separate from the other programs, and results from this program are not automatically transfered to any other program. In contrast, all the remaining sections are interconnected.

Following the data inputs, aircraft maximum range performance is computed at the altitude for maximum range, and at an alternate altitude which the user specifies. Mission time, fuel, and speeds are computed for a mission distance the user specifies. Results can be compared side by side. Maximum endurance performance is also presented. This information can be used to select actual mission altitudes, and input to the other sections.

TAKEOFF AND HIGH ALTITUDE CRUISE SECTION

This section requires 11 inputs regarding aircraft and desired operational parameters. Aircraft performance is then computed and displayed. The program is designed to output this performance in a form most easily utilized by pilots. There is no attempt made to "micro-manage" the planning process by completely computerizing the entire navigation route. The program is intended to be tactically utilized, to be useful in any environment which may precede the low level ingress route. Carrier based Navy and Marine Corps aircraft often launch and complete a rather lengthy procedure of rendezvous, tanking, and tactical formation. Much of the high altitude navigation route may be open ocean, thereby negating the usefulness of any high altitude route planner. A feature such as this would complicate the user interaction and result in a less useful program.

Following the data inputs, aircraft performance is computed for the TAKEOFF, CLIMB, CRUISE, and DESCENT mission phases.

LOW LEVEL CRUISE AND JET LOG SECTION

This section embraces three (3) low level operational features.

1. Lat/long coordinate editor.
2. High or Low level performance computations.
3. Completed jet log.

The user may choose to enter lat/long data manually or from a file. With manual entry, latitude and longitude are entered, along with magnetic variation at each navigation point. The route may then be filed. The user may choose to build another route, or continue with performance calculations for the route just entered. Computed high or low level performance is combined with the navigation route information, high or low level, to produce a completed jet log.

LAT/LONG COORDINATE EDITOR

This section, while included in the LOW LEVEL CRUISE AND JET LOG section, may also be selected independently from the low level planning section. Performance computations are not made here, however, distance and heading information are presented for each route computed. This section is primarily used to build a file of high or low level routes. Since ANY navigation route can be constructed and filed, this section is well suited to aid

the planner in the navigation computations required for the high altitude routes.

GETTING STARTED

This section will describe how to start the program on either an IBM PC/XT/AT or a true compatible such as a COMPAQ, AT&T PC 6300, or ZENITH 150 or 248. Each data input/output screen will be discussed and explained. Pay particular attention to the NOTES and WARNINGS which will attempt to prevent the user from becoming frustrated with the program.

STARTING THE PROGRAM

Insert the program disk into drive A:, close the drive door, turn on the monitor, and then the computer power switch. Highlight the type of machine you are using from the menu using the arrow direction keys on the numeric keypad, followed by hitting the ENTER key to make the selection. Then highlight which group of programs you want to run, either the Maximum Range Computer or the Mission Planning programs, followed by hitting the ENTER key to make the selection.

INTRODUCTION TO THE MAXIMUM RANGE COMPUTER

There is no introductory screen for this section. The first screen displayed will ask for data entry. The second

screen displayed will contain all of the results of the computations.

WHAT YOU NEED TO GET STARTED PLANNING

The following information will be asked for in the data input screen, and therefore should be available initially upon starting the program.

- * Gross Weight At Takeoff
- * Drag count for Mach Number 0.6
- * Desired Altitude for comparison to the optimum altitude for maximum range.
- * A Cruise Leg Distance
- * Takeoff Temperature in Degrees Fahrenheit
- * Cruise Headwind or Tailwind

DATA OUTPUT SCREEN

There is only one Data Output Screen containing the following information based on the input data:

Screen #1 - Computed Performance at the optimum altitude for maximum range:

- * Optimum Cruise Altitude
 - * Max Range Mach Number
 - * Specific Range in lb/nm
 - * Cruise Leg Time
 - * Cruise Leg Fuel
 - * True Airspeed and Ground Speed
- Computed Performance for maximum range possible at the desired altitude:
- * Optimum Cruise Altitude
 - * Max Range Mach Number
 - * Specific Range in lb/nm
 - * Cruise Leg Time
 - * Cruise Leg Fuel
 - * True Airspeed and Ground Speed

- Computed performance at the altitude for maximum endurance:
 - * Optimum Endurance Altitude
 - * Optimum Endurance Mach Number
 - * Optimum Endurance Fuel Flow in lb/hr

NOTE: These optimum endurance numbers are computed for a relatively heavy gross weight. The computed performance is therefore tactically useful in determining the optimum rendezvous and join up altitude.

INTRODUCTION

This is a series of screens to explain how the program is structured. For new users, read the introduction, and select option 1: "output to the screen only", at the end of the introduction. Experienced users should select option 2 or option 3.

WHAT YOU NEED TO GET STARTED PLANNING

The following information will be asked for in the first data input screen, and therefore should be available initially upon starting the program.

- * Runway Takeoff Temperature in Degrees Fahrenheit.
- * Runway Pressure Altitude
- * Takeoff Gross Weight
- * Runway Length
- * Drag Count for Mach Numbers 0.6, 0.7, 0.8, 0.9.
- * Desired Cruise Mach Number
- * Desired Cruise Altitude
- * Headwind or Tailwind
- * Altitude at Start of Descent in MSL
- * Altitude at End of Descent in MSL
- * Takeoff Fuel Load

DATA INPUT SCREEN

Enter the above data for your flight by typing in a value, then pressing the ENTER key, repeating this for all the values. Default values are displayed, and you may select these by simply putting the cursor on the value, and pressing the ENTER key. Drag count data may be found in NATOPS section 11, or in Appendix A of this user guide. To use Appendix A, compute the drag count for mach number 0.6 only from the NATOPS tables. Then proceed to Appendix A and simply read the drag count for the mach numbers 0.7 through 0.9. Input these drag counts to the Data Input Screen.

DATA OUTPUT SCREENS

There are five (5) Data Output Screens containing the following information based on the input data:

Screen #1 - Takeoff Configuration of the aircraft.

Screen #2 - Computed Takeoff Performance with and without double datum:

- * Ground Roll Distance
- * Takeoff Speed
- * Refusal Speed

Screen #3 - Computed Climb Data using the NATOPS maximum range profile approximations:

- * Climb Speed
- * Climb Mach
- * Climb Time
- * Climb Fuel Required
- * Distance Covered in Climb

Screen #4 - Computed Cruise Data for the input parameters:

- * Ambient Temperature
- * Fuel Flow
- * Specific Range in lb/nm
- * Ground Speed
- * True Air Speed

Screen #5 - Computed Descent data for the input parameters and for a minimum fuel profile:

- * Descent Fuel Used
- * Distance Covered
- * Descent Time
- * Descent Speed

MISSION PLANNING OPTIONS

Select one of the three options:

- LOW LEVEL ROUTE PLANNER -
 - * Manually enter a route, edit the route, file the route, compute performance and a jet log for the route.
 - * Load a route from a file, and compute performance and a jet log for the route.
NOTE: CAN NOT EDIT ROUTES LOADED FROM A FILE.
- ENTER ONLY LAT/LONG DATA -
 - * Manually enter, edit, and file a route.
 - * May repeat this procedure for multiple route entry and filing.
 - * Distance and Heading information is presented.
 - * NOTE: NO AIRCRAFT PERFORMANCE OR JET LOG IS COMPUTED.
- EXIT TO DOS -
 - * NOTE: BE SURE TO SAVE THE ROUTE BY FILING IT BEFORE YOU EXIT THE PROGRAM!

LOW LEVEL ROUTE PLANNER

This section will be discussed here in more detail, and will include discussions of the other options in this section.

Screen #1 - Low level data input form:

* Type in a value, followed by pressing the ENTER key. Three values are requested.

1. Low Level Altitude in MSL
2. Low Level Speed (Kts. Ground Speed)
3. Beginning Fuel State for the Route

* WARNING: BE SURE TO ENTER LOW LEVEL ALTITUDE AS MSL!

* NOTE: The Low Level Altitude may be as high as 45000 feet MSL. Therefore, typical cruise altitudes may be entered. When combined with a high altitude navigation route entered in the next section, a cruise leg jet log may be produced. Simply run the Mission Planning program again to compute the low level route portion.

Screen #2 - This shows the format for lat/long data entry as DEG.MIN.SEC and requests the following:

- * North or South Latitude (N or S)
- * East or West Longitude (E or W)
- * East or West Magnetic Variation (E or W)
- * Number of points to enter (2 to 9)

Screen #3 - Lat/Long data input uses the following sequence:

- * Type the value of the latitude DEGrees, then press the ENTER key.
- * Type the value of the latitude MINutes, then press the ENTER key.
- * Type the value of the latitude SEConds, then press the ENTER key.
- * Repeat this sequence for the longitude values.
- * Type the value of the magnetic variation as simply a number. NO PLUS OR MINUS SIGNS. NO EAST (E) or WEST (W).

- EDITING DATA BEFORE PRESSING THE {ENTER} KEY:

- * Position the cursor over the incorrect value, type the correct value, press the ENTER key.

- EDITING DATA AFTER PRESSING THE {ENTER} KEY:

- * Continue entering the remaining points. Following this, you will be given the opportunity to edit any incorrect points.

- FILING DATA -

- * Respond to program requests.
- * WARNING: Provide only filenames of 8 characters or less. DO NOT TYPE ANY EXTENSIONS (example: .DAT) WITH ANY FILENAMES.
- * See the following Note To Experienced Users for more filing details.

NOTE TO EXPERIENCED USERS

Data is filed according to the fully qualified filename definition, however, in NO CASE SHOULD A USER SPECIFY A FILENAME THAT INCLUDES AN EXTENSION. Data may be filed on the B: drive to a separate data disk. Route files are very small, approximately 1K in size, and there is approximately 20K of disk space available on the program disk which can store about 20 route files. The user may desire to store classified or otherwise sensitive routes on a separate data disk in the B: drive, which then may be afforded the appropriate degree of security, or to store all route files on a separate data disk. To accomplish this, simply respond to the requests for filenames with a more complete filename. For an example, the user would type B:IR203 in response to the requests, instead of simply IR203. To erase files from the program disk, use the DOS command { ERASE filename.* } and substitute the actual name of the route for the filename.

Screen #4 - Output screen of computed navigation data.

Screen #5 - Computed low level aircraft performance data.

Screen #6 - Completed low level jet log.

FINAL OPTIONS

To compute a return profile, the program will begin at the beginning, with the data input form. All values must be entered, even though there is no takeoff to be made. The user must tolerate the takeoff computations and display, in order to obtain accurate return profile performance. This method actually allows re-entry of important aircraft configuration, weight, drag, and fuel information that most certainly has changed from the ingress parameters. The result is very accurate return profile performance data.

Calculation of another route will use the input data already provided and performance data already computed in completing the navigation data and jet log.

ERRORS

Most errors will be intercepted, allowing the user to repeat some action correctly and continue with the program. Two most common errors may occur:

1. Responding to a request for a letter by typing a number. In this case, the number will be accepted, however, the program will probably fail shortly thereafter. In this case, start the

program again by pressing the CTRL-ALT-DEL keys simultaneously.

2. Responding to a request for a number by typing a letter. In this case, the user will see the following message on the monitor screen:

?Redo from start

Although this looks bad, there is an easy solution. Simply type the correct response, press the ENTER key, and continue with the program. If the screen display and cursor location do not line up for proper data entry, or the program isn't running correctly, then press the CTRL-ALT-DEL keys simultaneously to start the program over from the beginning.

QUICK START REFERENCE INSTRUCTIONS

Many people would like to start using a program without reading the instructions, or bothering with the details of program operation. This quick reference guide has been prepared for this purpose.

LOADING AND STARTING THE PROGRAM

Insert the program disk into drive A:, close the drive door, turn on the monitor, and then the computer power switch. Highlight the type of machine you are using from the menu using the arrow direction keys on the numeric keypad, followed by hitting the ENTER key to make the selection. Highlight the MAX RANGE COMPUTER, followed by hitting the ENTER key to make the selection. Follow the on screen instructions. After returning to the main program selection menu, highlight the MISSION PLANNING option followed by hitting the Enter key to make the selection. Then hit the ENTER key again to select the "READ A SHORT INTRO TO THE PROGRAM" option from the mission planning menu. Follow the on-screen instructions carefully. Proceed slowly and patiently the first time through, taking time to read each screen fully, and to read the associated help screens that appear as different options are highlighted with the arrow direction keys on the numeric keypad to the right of the keyboard. Decide on

an option, highlight the option, then hit the ENTER key to make the selection.

DATA ENTRY FORMS

Type in the correct value asked for in a block, followed by pressing the ENTER key. Some blocks, when they are filled, will automatically enter the value and place the cursor at the next block, waiting for data to be entered. If this occurs, simply continue entering the data for the block containing the cursor, and go on with the program. This is designed to save time. Repeat for all the blocks.

LAT/LONG DATA ENTRY

Type in a value for the DEGRees, then press the ENTER key.
Type in a value for the MINutes, then press the ENTER key.
Type in a value for the SECONDS, then press the ENTER key.
Type in a value for the MAGnetic VARIation, then press the ENTER key.

Repeat for all the data points.

EDITING

- EDITING DATA BEFORE PRESSING THE {ENTER} KEY:
 - * Position the cursor over the incorrect value, type the correct value, press the ENTER key.

- EDITING DATA AFTER PRESSING THE {ENTER} KEY:
 - * Continue entering the remaining points.
Following this, you will be given the opportunity to edit any incorrect points.
- FILING DATA -
 - * Respond to program requests.
 - * WARNING: Provide only filenames of 8 characters or less. DO NOT TYPE ANY EXTENSIONS (example: .DAT) WITH ANY FILENAMES.

FINAL OPTIONS

To compute a return profile, the program will begin at the beginning, with the data input form. All entries must be made, even though there is no takeoff to be made. The user must tolerate the takeoff computations and display, in order to obtain accurate return profile performance. This method actually allows re-entry of important aircraft configuration, weight, drag, and fuel information that most certainly has changed from the ingress parameters. The result is very accurate return profile performance data.

APPENDIX D

SAMPLE TACTICAL PLANNING PROBLEM

A-7 NATOPS PROBLEM

An international incident has occurred which necessitates the rapid protection and extraction of U.S. military personnel within the strife stricken country.

You are the Commander of an A-7E squadron and have been given the task of planning and conducting the missions in support of the extraction of the U.S. personnel. Given the following information, determine the greatest distance from the target at which you could launch and return to the same take-off point.

1. Fuel Load - 14,000# (2,000# in each aero I D)
2. Ordnance Load
 - a. 1 AGM-45 (Skrike) on Sta #1 and Sta #8
 - b. 3 MK-20 (Rockeye) on Ter on Sta #2
 - c. 1 Aero I D (Full JP5) on Sta #3 and Sta #6
 - d. 1 AIM 9D (Sidewinder) on Sta #4 and Sta #5
 - e. 3 MK-83 (LDGP) on Ter on Sta #7
3. Basic Aircraft Weight - 21,000#
4. Area temperature at sea level - 30°C
5. Use 300# fuel for Start/Taxi/Catapult
6. Rendezvous at 10,000' and 25 NM - use 800# fuel during rendezvous
7. Descend from cruise altitude to target
 - a. Descend to 12,000'
 - b. Use 2,700#/Hr fuel flow
 - c. Maintain 370 Kts ground speed
 - d. Begin descent at 40 NM
8. Enroute winds are forecast
 - a. To the target - 40 Kts headwind
 - b. Return to ship - 70 Kts tailwind
 - c. Descents - no wind
9. Use 2,000# fuel in target area
10. Expend the following ordnance
 - a. 2 AGM-45
 - b. 3 MK-20
 - c. 3 MK-83
 - d. Retain all other racks, ordnance, tanks
11. Climb to cruise altitude for return will be from sea level.
12. Plan for Charlie on arrival with 1,000# internal fuel on the ball.

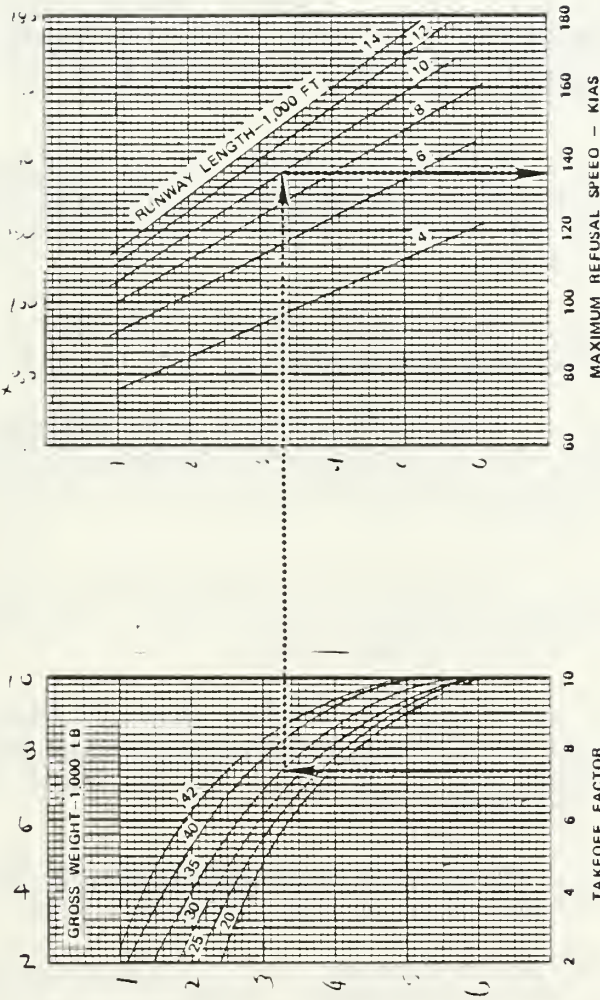

MAXIMUM REFUSAL SPEED

WITH ANTI-SKID

MODEL: A-7E
DATA BASIS: FLIGHT TEST
DATE: NOVEMBER 1971

CONDITIONS:
MILITARY RATED THRUST
HARD SURFACE RUNWAY
LANDING CONFIGURATION
TE FLAP 40°; FOH
20° TE FLAP, SUBTRACT
3 KNOTS

ENGINE: TF41-A-2
FUEL GRADE: JP-5
FUEL DENSITY: 6.8 LB/GAL

76E291-04 81
