CONVERGENCE RATE OF CODES FOR NUMERICAL QUADRATURE TECHNIQUES FOR CLASSICAL RAY TRACING

> Edward R. Floyd Arctic Submarine Laboratory

ray described by the constant of motion (vertex velocity) C<sub>m</sub>. How accurate? By classical ray tracing, determine range over a single Riemann sheet for a

STATES - STATES

1222222223, 16464444

Range Integral:

$$R_{s} = \int_{z_{0}}^{z_{v}} \frac{C(z)}{[C_{m}^{2} - C^{2}(z)]^{1/2}} dz$$
$$= \int_{z_{0}}^{z_{v}} W(z) f(z) dz$$

 $J_{z_0}$ 

W and f are convenient functions of z. [W dz] becomes a Stieltjes measure and f(z), the Stieltjes integrand.

Trick: Choose W(z) to incorporate any poor behavior (singularities or zeros) into W leaving f(z) well behaved. Thus the Gaussian quadrature

$$R_s \approx (z_v - z_o)^m \sum_{i=1}^n w_{i,n} f(z_{i,n})$$

where:

n is the order of the approximation;

m is determined by W;

W<sub>i,n</sub> is a Gaussian weighting coefficient
 determined by W;

z<sub>i,n</sub> is a Gaussian sample point determined by W.L The Gaussian error is given by

$$\eta_{n} = \frac{f^{(2n)}(\xi)}{(2n)!} \int_{z_{0}}^{z_{v}} W(z) [\prod_{i=1}^{n} (z - z_{i,n})]^{2} dz$$
where  $z_{0} \leq \xi \leq z_{v}$ .

For underwater acoustics

$$W = (z_v - z)^{-1/2}$$
.

Factors out branch point singularity at vertex depth.

Therefore

$$\eta_{n} = \frac{\pi^{1/2} (z_{v} - z_{o})^{2n+1}}{4n+1} \frac{[(2n):]^{2}}{[(4n):]^{2}} f^{(2n)}(\xi),$$

$$z_{o} \leq \xi \leq z_{v}.$$

, , ,

$$\eta_{n} = \frac{\pi^{1/2} (z_{v} - z_{0})^{2n+1}}{4n+1} \frac{[(2n)!]^{3}}{[(4n)!]^{2}} f^{(2n)}(\xi),$$

$$z_{0} \leq \xi \leq z_{v}.$$

This expression has several deficiencies;

÷

- Usually impractical to evaluate f<sup>(2n)</sup>.
- f(i) for i < 2n may be discontinuous.</li>
- C(z) is often known only in tabular form.

$$\eta_{n} = \frac{\pi^{1/2} (z_{v} - z_{o})^{2n+1}}{4n+1} \frac{[(2n)!]^{3}}{[(4n)!]^{2}} f^{(2n)}(\xi),$$

$$z_{o} \leq \xi \leq z_{v}.$$

Analytic (hypothetical) C(z):\*

- Rapid convergence with increasing n.
- Only limited by round-off error.
- Thumb rule for maximum effective n:

 $n_{max} \approx ("number of signifcant figures")/2$ 

\* E. R. Floyd, J. Acoust. Soc. Am. <u>49</u>, 1580-1590 (1971)

$$\eta_{n} = \frac{\pi^{1/2} (z_{v}-z_{0})^{2n+1}}{4n+1} \frac{[(2n)!]^{3}}{[(4n)!]^{2}} f^{(2n)}(\xi),$$
$$z_{0} \leq \xi \leq z_{v}.$$

Observed (nonanalytic) C(z):\*

- C(z) tabled at discrete depths.
- Cubic spline fit → d<sup>3</sup>C/dz<sup>3</sup> discontinuous. Nevertheless still rapidly convergent over an assembly of 116 observed C(z)'s. MOE --- η reduced by a factor of 0.763 for each additional sample point per Riemann sheet.
- Thumb rule for maximum effective n:

 $n_{max} \geq$  "number of significant figures".

\* E. R. Floyd and J. D. Pugh, J. Acoust. Soc. Am. 61, 682-687 (1977). Present Status:

- Even for analytic functions, quadrature errors are difficult to estimate because higher order derivitives are generally complicated.
- While we have convergence rates for an assembly of observed profiles, the discontinuity of higher order derivatives confounds our estimate of convergence for a particular observed profile.
- Desire an estimate expressed in terms of the first derivative of the Stieltjes integrand.
