A NOTE ON PROFILE LIKELIHOOD, LEAST FAVOURABLE FAMILIES AND KULLBACK-LEIBLER DISTANCE

Robert Tibshirani and Larry Wasserman

SUMMARY

We consider several methods for reducing high dimensional models to one dimensional models for the purpose of simplifying likelihood inferences. The equivalence between these methods is investigated.

Some Key Words : nuisance parameters, likelihood, exponential families.

1. INTRODUCTION

Consider a statistical model Γ consisting of a class of densities $\{f(x|\eta)\}$ where $\eta \in \Omega \subset \mathbb{R}^k$ is a vector-valued parameter of dimension greater than one. Often we are interested in a real valued function $\theta \equiv \theta(\eta)$. Many useful inferential techniques involve ession For the log-likelihood function defined by

П

TAB

$$L(\eta) = a + \sum_{i} \log(f(x_i | \eta))$$

where x_1, x_2, \dots, x_n are independent observations from the true density and a is an arbiribution/ ilability Codes trary real constant which, for convenience we shall take to be zero. In general, a one-Avail and/or

dimensional likelihood function is not available for the parameter of interest θ . The problem of constructing such a likelihood function is discussed at length by Kalbfleisch and Sprott (1970).

The method that we discuss here for dealing with this problem is to strategically choose a sub-family of densities from Γ indexed by θ . We then construct a likelihood function based on the new reduced model. Specifically, let $\Gamma_{\theta} = \{f(x | \theta)\}$ denote the reduced model. (When convenient, Γ_{θ} will also refer to the corresponding curve in the parameter space Ω). We then take $L(\theta) = \sum log(f(x_i | \theta))$. (Unqualified sums are to be taken from i=1 to n).

We shall consider several such techniques for choosing Γ_{θ} and investigate certain equivalences between them. We note that some of the methods of model reduction that we discuss were originally proposed for reasons other than constructing likelihood functions.

2. DEFINITIONS

The first reduction technique we consider is used to construct the profile likelihood (see Kalbfleisch and Sprott, 1970). Let $f(x|\theta)$ be the density which maximizes the probability of the observed data subject to $\theta(\eta) = \theta$. This defines a family indexed by θ which we will denote by Γ_{θ}^{PL} . The resulting log-likelihood function will be denoted by $L^{PL}(\theta)$. Note that $L^{PL}(\theta)$ passes through the global maximum of $L(\eta)$.

Another method of defining a one parameter family is what Stein (1956) calls the "least favourable family" given by

$$\eta(\tau) = \hat{\eta} + \tau I_{\eta}^{-1} \nabla \theta(\hat{\eta})$$

where L_{η} is the observed Fisher information at η and $\nabla \theta(\eta)$ is the vector whose ith component is $\partial \theta / \partial \eta_i$. This traces a straight line through η having direction $I_{\eta}^{-1} \nabla \theta(\eta)$. Denote this family by Γ_{θ}^{S} and the corresponding log-likelihood by $L^{S}(\theta)$. This family has the property that the observed Fisher information for θ is the same as in the full family $f(x|\eta)$ (Stein, 1956). Furthermore, any other (linear) sub-family through η has greater Fisher information for θ . (Note that Stein used expected information in his definition. Here we follow Efron (1984) and use the observed information).

Still another reduction method is employed by Efron (1981,1984) for the purpose of constructing confidence intervals in multi-parameter and non-parametric settings. Let

$$C_{\theta_0} = \{\eta : \theta(\eta) = \theta_0\},\$$

the level surface of constant θ . Efron selects the value of η from C_{θ_0} such that the Kullback-Leibler distance

$$K(\bar{\eta},\eta) = \int f(x | \bar{\eta}) \log(f(x | \bar{\eta}) / f(x | \eta)) \mu(dx)$$

is minimized, where μ is a dominating measure for the family Γ . As θ_0 varies, this defines a one parameter family. Since Kullback-Leibler distance is not symmetric, one can create a "forward" or "backward" family using $K(\hat{\eta}, \eta)$ or $K(\eta, \hat{\eta})$, respectively. The corresponding families will be denoted by Γ_{θ}^{F} and Γ_{θ}^{B} and their log-likelihoods by $L^{F}(\theta)$ and $L^{B}(\theta)$.

In section 3 we find the directions of the families at η . Conditions under which the families are equivalent will be derived. In section 4 we consider two examples.

3. LOCAL EQUIVALENCE OF FAMILIES

The directions of the families can be found using the following lemma.

Lemma: Let $g: \mathbb{R}^k \to \mathbb{R}$ be three times differentiable with invertible Hessian $\nabla^2 g$ and global minimum at $\hat{\eta} \in \mathbb{R}^k$. Let $\theta: \mathbb{R}^k \to \mathbb{R}$ be continuously differentiable with non-zero gradient on a neighbourhood of $\hat{\eta}$. Define a curve c(t) implicitly by

 $g(c(t)) \equiv \min_{\Omega} g(\eta)$

where $C_t = \{\eta: \theta(\eta) = t\}$ and let $c(t_0) = \hat{\eta}$. Then

$$D(c(t))|_{t_0} \equiv \frac{dc(t)}{dt}|_{t_0} = \lambda_0 (\nabla^2 g(\hat{\eta}))^{-1} \nabla \vartheta(\hat{\eta})$$

where

$$\lambda_0 = [(\nabla \theta(\hat{\eta}))^{t} (\nabla^2 g(\hat{\eta}))^{-1} (\nabla \theta(\hat{\eta}))]^{-1}.$$

Proof: First note that c(t) is differentiable by the implicit function theorem (Spivak, 1965, p. 41). Now, since c(t) is defined as a minimum we have (using Lagrange multipliers)

$$\nabla \mathbf{g}(\mathbf{c}(t)) = \lambda(t) \nabla \boldsymbol{\theta}(\mathbf{c}(t)).$$

Differentiation with respect to t gives

$$(\nabla^2 \mathbf{g})\mathbf{D}(\mathbf{c}(t)) = \lambda(t)(\nabla^2 \theta)\mathbf{D}(\mathbf{c}(t)) + \lambda(t)\nabla \theta$$

where $\nabla^2 h$ is a matrix with i, jth entry $\partial^2 h/\partial \eta_i \partial \eta_j$ for a function h. Evaluating this expression at t_0 gives the form of $D(c(t))|_{t_0}$. (Note that $\lambda(t) = 0$ at $t = t_0$). The constant is determined by differentiating the Lagrange equation with respect to λ then t.

Now let D_{η}^{a} be the direction vector of a particular family at $\hat{\eta}$ where a = PL,S,F or B to indicate the appropriate family. We have

Theorem:
$$D_{\eta}^{PL} = D_{\eta}^{S} = \alpha(I_{\eta})I_{\eta}^{-1} \nabla \theta(\hat{\eta}) \text{ and } D_{\eta}^{F} = D_{\eta}^{B} = \alpha(i_{\eta})i_{\eta}^{-1} \nabla \theta(\hat{\eta}) \text{ where}$$

$$\alpha(A) = [(\nabla \theta(\hat{\eta}))^{t}A^{-1}(\nabla \theta(\hat{\eta}))]^{-1}.$$

Proof: The direction of Γ_{Θ}^{S} is $(\Gamma^{-1}\nabla\Theta)\partial\tau/\partial\Theta$ which equals $\alpha(I_{\eta})I_{\eta}^{-1}\nabla\Theta(\hat{\eta})$ since $\partial\tau/\partial\Theta = \alpha(I_{\eta}^{-})$. The direction of Γ_{Θ}^{PL} follows from the lemma by taking g to be minus the log-likelihood and assuming the usual regularity conditions. The directions of Γ_{Θ}^{F} and Γ_{Θ}^{B} are obtained by noting that to second order terms

$$\hat{K(\eta,\eta)} = K(\eta,\eta) = \frac{1}{2}(\eta-\eta)\hat{i_{\eta}(\eta-\eta)}$$

(see Kullback (1959, p. 28)). Applying the lemma yields the result.

Therefore Stein's family and the profile likelihood family are locally equivalent as are the two Kullback families. A sufficient condition for $i_{\eta}=I_{\eta}$ is that the model be a member of the exponential family. Hence in this case all four families are locally equivalent. It can also be shown, using Hoeffding's lemma (Efron, 1978) that in the exponential family, the profile family and the forward Kullback family are globally equivalent.

Outside of the exponential family, I_{η} and i_{η} are in general different; their difference can be expressed as a function of statistical curvature (Efron, 1975 and Skovgard, 1985).

The theorem suggests that inferential techniques based on the local properties of the likelihood function will be similar for all four methods. In particular, note that the second derivative (at $\hat{\eta}$) of the log-likelihoods is $(D_{\eta}^{a})^{t} I_{\eta}^{-1}(D_{\eta}^{a})$ for a = PL and a = S and is $(D_{\eta}^{a})^{t} i_{\eta}^{-1}(D_{\eta}^{a})$ for a = B and F. Hence $L^{PL}(\theta)$ and $L^{S}(\theta)$ have the same second derivatives as do $L^{F}(\theta)$ and $L^{B}(\theta)$. Agreement of the third derivatives can be shown by a simi-

lar calculation. One application of this result would be the approximation of $L^{PL}(\theta)$ by $L^{S}(\theta)$. This can provide considerable simplification since $L^{S}(\theta)$ requires only the computation of I_{η} and $\nabla \theta(\hat{\eta})$ while $L^{PL}(\theta)$ requires a restricted maximization at each value of θ . This will be difficult if $\theta(\eta)$ is a complicated function of η . However, the quality of such an approximation is still an open question.

4. EXAMPLES

Example 1.

Let x be bivariate normal with mean η and covariance equal to the identity matrix. Suppose the parameter of interest is $\theta = \eta_1/\eta_2$. Note that θ is constant over rays through the origin in E^2 . It is easy to show that $K(\hat{\eta}, \eta)$ reduces to 1/2 times the squared Euclidean distance between $\hat{\eta}$ and η so that the forward and backward Kullback-Leibler families and the profile likelihood based family all correspond to the circle passing through the origin and $\hat{\eta}$ (see Figure 1a). The corresponding likelihood functions are plotted in Figure 1b.

Example 2.

This example is motivated by Efron's (1984) use of the least favourable family in computing bootstrap confidence intervals. The data $x_1, x_2, ..., x_n$ are fixed and the family of rescaled multinomial distributions $M(n, \omega)/n$ is considered. The parameter of interest is a functional $\theta(\omega)$. The natural parameter is $\eta = \log \omega$. A least favourable family is drawn through the m.l.e $\omega_0 = e^{\hat{\eta}} = (1/n, 1/n, ... 1/n)$. We illustrate this in Figure 2 for n = 3 with $\theta(\omega) = \bar{x}_{\omega} = \sum \omega_i x_i$ and $(x_1, x_2, x_3) = (-1, 0, 1)$. The triangle represents the simplex

$$S_3 = \{\omega \mid \omega_i \ge 0, \sum_{i=1}^{3} \omega_i = 1\}.$$

The least favourable family and backward Kullback-Leibler family agree while the profile likelihood and forward Kullback-Leibler families coincide. Also shown are the level curves C_{θ_n} .

ACKNOWLEDGEMENTS

We would like to thank the referees for their helpful comments. We would also like to thank Penny Brasher for her help with the illustrations, a previous referee for suggesting the general form of the lemma and Tom DiCiccio for helpful discussions.

 DISTRIBUTION STATEMENT (of the observed monod is Plost 20, 11 different base Report) SUPPLEMENTARY NOTES Survey of the server of the necessary and identify by Need matery Nuisance parameters, likelihood, exponential families. ABSTRACT (Continue in reverse of the necessary and identify by Need matery) Several methods exist for reducing higher dimensional problems to a single arameter. These include the profile likelihood, least favourable families and extra the needed on the Kullback-Leibler distance function. We demonstrate that at east in a neighborhood of the maximum likelihood estimate, these are equivalent 		TTED
