NOTICE

When U.S. Government drawings, specifications, or other data are used for any purpose other than a definitely related government procurement operation, the government thereby incurs no responsibility nor any obligation whatsoever, and the fact that the government may have formulated, furnished, or in any way supplied the said drawings, specifications, or other data is not to be regarded by implication or otherwise, as conveying any rights or permission to manufacture, use, or sell any patented invention that may in any way be related thereto.

FOREWORD

This special report comprises the presentations provided by speakers at the Antiproton Technology Workshop held at Brookhaven National Laboratory (BNL) 10 may 1989 jointly sponsored under the Astronautics Laboratory (AFSC) / Department of Energy-BNL Memorandum of Agreement for support of Applied Research In Energy Storage (ARIES). This special report has been reviewed and approved in accordance with the distribution statement on the cover an on the DD form 1473.

19. ABSTRACT (Continue on reverse if necessary and identify by block number)

This workshop, held at Brookhaven National Laboratory, 10 May 1989, was a follow-on to the Antiproton Science and Technology Workshops held at the RAND Corporation in Santa Monica through October 1987 following the Air Force Project Forecast II initiative in Antiproton Technology. The workshop was attended by about 50 researchers from a wide variety of disciplines, including medicine, particle physics, and the aerospace industry. New, more efficient technology for a variety of scientific, medical, and industrial uses could result from antiproton experiments proposed by workshop participants. Antiprotons are particles of antimatter which release highly penetrating radiation when they are stopped in normal matter. According to presentations at the Antiproton Technology Workshop this radiation can be used, in very small quantities, to image objects and determine their composition and density. In larger amounts, the radiation could be used to kill cancer tumors or produce highly localized heating and shock waves. DOE plans are contingent on potential user support.

PROCEEDINGS OF THE ANTIPROTON TECHNOLOGY WORKSHOP*

HELD AT BROOKHAVEN NATIONAL LABORATORY 10 MAY 1989

EXECUTIVE SUMMARY

1. Background

New, more efficient technology for a variety of scientific, medical, and industrial uses could result from antiproton experiments proposed by a workshop of government, industry and academic researchers at Brookhaven National Laboratory, Wednesday 10 May 1989. Antiprotons are particles of antimatter which release highly penetrating radiation when they are stopped in normal matter. According to presentations at the Antiproton Technology Workshop this radiation can be used, in very small quantities, to image objects and determine their composition and density. In larger amounts, the radiation could be used to kill cancer tumors or produce highly localized heating and shock waves. The Alternate Gradient *Synchrotron, or "AGS", located at Brookhaven* is one of the few particle accelerators in the world capable of making the number of antiprotons needed to perform the experiments.

The workshop was a follow-on to the Antiproton Science and Technology Workshops held at the RAND Corporation in Santa Monica through October 1987 following the Air Force Project Forecast II initiative in Antiproton Technology. The workshop was attended by about 50 researchers from a wide variety of disciplines, including medicine, particle physics, and the aerospace industry.

2. Workshop Results

Aerospace uses include the detection of physical or chemical flaws in the manufacture of composite materials, with implications for increased aviation safety and lighter, less expensive rockets.

An existing market of about $100 billion a year in medical imaging and radiotherapy has attracted the interest of private investors. Demonstrations of rapid, low radiation imaging of hard tissues and killing cancer tumors might prove the viability of a new, privately funded accelerator to provide antiprotons for medical and industrial uses.

Atomic chemists want to make antihydrogen to see if it obeys the same physical rules as ordinary hydrogen. Antihydrogen would be made by combining antiprotons with the anti-electron, or positron, the first form of antimatter discovered back in 1935.

Physical scientists are interested in radiation effects and small but intense shock waves that could be produced by pulsed antiproton beams. Protection of spacecraft from solar storms and meteor impacts are among many uses of radiation and shock data.

Particle physicists are interested in broken symmetries in particle reactions which one might expect to have identical outcomes, but don't. Such reactions help tell us how the universe was made and what its ultimate destiny might be.

Antiproton Workshop members came from organizations as diverse as the Lahey Clinic in Boston, the Astronautics Laboratory at Edwards Air Force Base, General Dynamics Corporation in Fort Worth, and the University of Illinois. The workshop agenda is provided as table 1. Workshop attendance is provided as table 2.

The only source of antiprotons suitable for many of the experiments discussed is the European accelerator in Switzerland, which has long waiting lines for experimenters. The researchers generally agreed that an antiproton source in the United States, perhaps based on the Brookhaven AGS accelerator, Fermilab's accelerator, or the booster ring planned for the Superconducting Supercollider will make United States science and technology significantly more competitive in areas discussed. Significant informational activities concerning antiproton technology continue within DOE. Potential user interest expressed as serious proposals is a significant determinant of DOE support.

*The workshop was jointly sponsored by the Astronautics Laboratory and Brookhaven National Laboratory (DOE).

RECENT SIMULATION RESULTS OF ASTER

Robert Muratore

Department of Physics, Syracuse University

201 Physics Building, Syracuse, New York 13244-1130 USA

Abstract. ASTER, an imaging technique proposed several years ago, is now ready to be built. ASTER uses antiprotons to form direct three dimensional images of the target density profile. Useful images can be obtained with less than one million antiprotons, well within current production levels. ASTER has potential advantages over other imaging techniques, including flexibility, speed, lower dose, and less ambiguity. Simulations show that the scattering of antiprotons by target nuclei reduces the correlation of image and target, but increasing the number of antiprotons used by less than an order of magnitude overcomes this effect.

WHEN COMPLICATED TECHNOLOGY is used in medicine, reassuring names are attached to the machines and techniques. One speaks of CAT scans, PET, and MRI (née NMR). Today I will talk about an imaging technique which has been discussed before at these meetings, ASTER, named after the wildflower. Since I am limited to about ten minutes, I will keep my talk simple. Here is the outline:

I. ASTER is ripe.

It is my contention that this flower has formed its fruit, and that not only is this fruit ripe for picking, but neither is it spoiled, as some have suggested.

A. ASTER uses antiprotons to image densities, and enough antiprotons are currently produced.

I will begin by reviewing ASTER.[1,2,3,4,5] ASTER is an acronym for Antiprotonic STERiography. In the ASTER imaging technique, still on the drawing board, a beam of antiprotons are sent into a target. Collisions with electrons slow the antiprotons down, according to the well known stopping power

$$\frac{dE}{dx} = D\rho \frac{Z}{A}\frac{1}{\beta^2}\left[\ln \frac{2m_e c^2 \beta^2}{I(1-\beta^2)} - \beta^2\right],$$

where E is the kinetic energy of the particle, x is the distance traversed, Z is the proton number, A is the atomic mass, β is the speed relative to the speed of light, D is a constant approximately equal to 0.30707 MeV cm^2/g, ρ is the density, m_e is the electron mass, and I is an empirical function of Z which represents the average ionization potential of *all* electrons in an atom.[6]

The important features are the inverse square relation of the stopping power and the speed, which results in the Bragg peak, and the direct dependence on the density.

ASTER (a third definition here) means star (as in *). When the antiprotons have come to rest, they annihilate on a nucleon. Outward from the annihilation site stream various particles. In a bubble chamber photo, this event looks like a star (Fig. 1). Among the particles produced are charged pions. These are of sufficient energy to exit a target the size of the human body, and of sufficient mass to be deflected just a small amount before emerging. By detecting the directions of these pions and tracing their paths back to the intersection point with the antiproton path, the annihilation site can be determined precisely.

In this way, the range as a function of energy, $R(E)$, can be determined for the target, and $R(E)$ can be mapped to $\rho(R)$, a density profile.

Simulations of ASTER imaging confirm the estimates of the number of antiprotons needed for a scan, N:

$$N \sim \frac{\text{volume}}{\Delta x \Delta y \Delta z} \times \left(\frac{\sigma_V}{\Delta x}\frac{\rho}{\delta\rho}\right)^2$$

where the antiprotons are assumed to be travelling initially in the x direction, Δx, Δy, and Δz are the step sizes with which the beam is incremented in the various directions, σ_V is the error in determining the vertex, and $\delta\rho/\rho$ is the contrast resolution. To image a slice of $10 \times 10 \times 0.5$ cm^3 requires 2×10^5 antiprotons, for 1% contrast resolution and 1.5 mm spatial resolution within the slice. To image a whole organ might require 20 slices, or 4×10^6 antiprotons, well within current production levels. The corresponding dose is about 200 μGy = 0.02 rads. Considering the biological effect of protons, the dose is about a tenth of the natural average annual background in the United States.[6]

B. ASTER has advantages over other imaging techniques.

ASTER appears to be lower in dose for comparable images than x-ray CT, as shown in a comparison of an ASTER simulation (Fig. 2) of the imaging of a Plexiglas and water phantom and the actual x-ray CT image of the same phantom. The phantom is an 8 cm diameter Plexiglas disk inside a 10 cm diameter Plexiglas cylinder filled with water. In the 3 mm thick disk the letter E is engraved to a depth of 1.5 mm. In the simulation, this cylinder was immersed in a rectangle filled with water. An x-ray CT scan (Fig. 3) was made of the cylinder in the plane containing the engraved disk. The dose imparted by the ASTER simulation was 100 μGy, over two orders of magnitude less than that imparted by the CT scan, approximately 30 mGy.

The table in Fig. 4 gives an overview of ASTER with other techniques. No one technique seems better than all the others for every situation. Similarly, ASTER will be complementary to the other techniques. Nonetheless, ASTER has potential for lower dose, higher resolution, faster scans, and imaging of elements as well as density. Perhaps most importantly, ASTER avoids the uncertainties introduced by back-projection techniques. Finally, ASTER is a flexible technique, as the following discussion shows.

C. The scattering of antiprotons does not spoil the image quality.

There has been some question as to whether the scattering of the antiprotons off the nuclei will irretrievably lower the resolution of ASTER. In water, the antiproton beam spreads out with a width of $\sigma_y = 0.0195R^{0.966}$. There is a well defined centroid, so resolution can be maintained by increasing the number of antiprotons used. In heterogeneous media, one can imagine that some of the antiproton paths will sample regions of different density, hopelessly convoluting the relation of stopping position to density profile. However, this is not the case, as I will show by considering individual antiproton paths in water, and by showing successful images of highly heterogeous targets.

In terms of individual paths, it is reasonable that transverse scattering will not ruin ASTER images. This is because the average density in a small region is obtained from the difference in the mean stopping positions of two cohorts of antiprotons with nearly the same energy. In engineering terms, one would say that one is looking at the difference between two integrals, and integration suppresses the noise.

Fig. 5 shows the paths of many antiprotons in water. The horizontal (longitudinal) and vertical (transverse) scales are the same, and the three dimensional paths have been projected onto the plane. Next, I considered only the antiprotons stopping in a small transverse bin. If the initial energy of the antiprotons is varied just a bit, the antiprotons still sample the same region in space. That is, a group of paths stopping about R tends to sample the same portion of the target as a group of paths stopping about $R + \Delta R$. This is shown in Figs. 6, 7, 8, and 9. This is true even though I have included the finite beam width in the Monte Carlo.

The sampling of the same region in space by the antiprotons is a statistical phenomenon. Therefore, it suggests that the scattering problem can be overcome by increasing the number of antiprotons, a method already required by the straggling. To test this, I simulated the imaging of a "random" target, which was the most heterogeneous thing I could think of. ASTER is a very flexible tool, and the imaging can be oriented to best advantage. I imaged this random slice longitudinally, so that each antiproton travelled in the slice. And I imaged the random slice transversally, so that the antiprotons travelled through a centimeter of water before encountering the slice perpendicular to the plane. The transverse orientation is shown in Fig. 10, the random target in Fig. 11, and the transverse image in Fig. 12.

The heterogeneous nature of this target convolutes the longitudinal image more than the transverse image. So for a given number of antiprotons, the transverse image will be better.

The quality of the image can be shown by correlating the image and the target. I define a correlation number C^{-1}, where

$$C^2 \equiv \sum_j \sum_k (\rho_{1jk} - \rho_{2jk})^2 / n,$$

ρ_{1jk} and ρ_{2jk} are the densities of the target and image at the jkth pixel, and n is the number of pixels used for comparison. The correlation increases as the number of antiprotons increases for both the transverse and longitudinal imaging (Fig. 13). The correlations match when about four to nine times as many antiprotons are used in the longitudinal case as in the transverse case. So increasing the number of antiprotons by an order of magnitude will overcome severe heterogenous effects. After this increase is made, ASTER still imparts an order of magnitude less dose than x-ray CT.

If the decrease in correlation is due to the heterogeneous convolutions, than the effect will begin to show up in the transverse case as the slice is lowered deeper into the water, so that the antiproton beam is more spread out when it reaches the slice. This is shown in Fig. 13 by the decrease in correlation between transverse image and target as the depth increases.

Pbar TESTING OF HYDROGEN EFFECTS IN SEALED CARBON-CARBON COMPOSITES

HARRIS CARTER

GENERAL DYNAMICS FORT WORTH
FORT WORTH, TX

PRESENTED AT THE ANTIPROTON TECHNOLOGY WORKSHOP
HELD AT BROOKHAVEN NATIONAL LABORATORY
10 MAY 1989

Rationale and Concept for NDE Application of Antiprotons (u)

- Early applications might include non-destructive evaluation (NDE) of aerospace materials
- Advanced carbon-carbon structures present
  - ✔ Special NDE problems (e.g. need for "backscatter" rather than transmission)
  - ✔ Special features suggesting $\bar{p}$'s for NDE (vs ultrasound or x-rays)

Assumption: Useful Sources will be $\bar{p}$'s trapped at ≤ Kev energies or stabilized in chemical complexes

Suggested NDE mode: Use low energy $\bar{p}$'s as portable source of Π^- mesons

Purpose: Determine atomic ratios O/C and H/C deep in Carbon - Carbon structures

Annihilation at source: $\bar{p} + p \rightarrow \Pi^0 + \Pi^+ + \Pi^-$ (K.E. ~ 250 Mev)

Reactions:

Reactions in Target: Π^- (stopped) + p → n + γ (129 Mev)

Π^- (stopped) + O → Π^- O mesic atom + 178 Kev x-ray

UNCLASSIFIED

BN06752

ADVANCED CARBON-CARBON: EDGE VIEW SHOWING CRACKS AND VOIDS

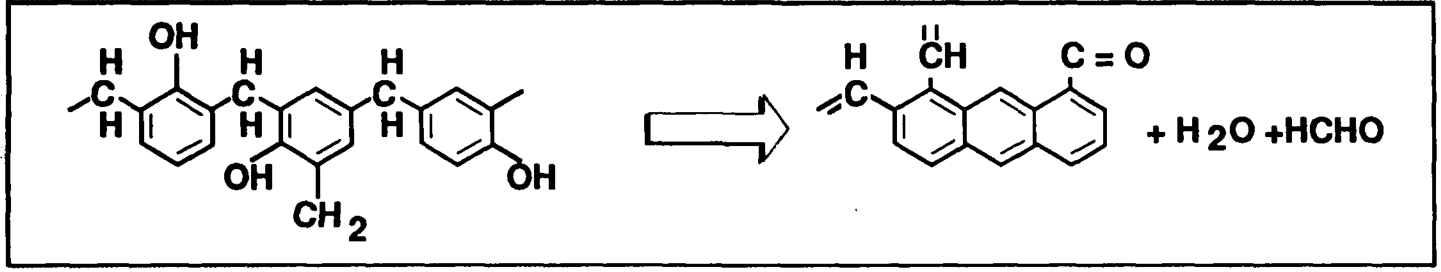
B18084

ADVANCED CARBON-CARBON: HIGHER MAGNIFICATION SHOWING INCOMPLETE REACTION IN CONVERSION COAT

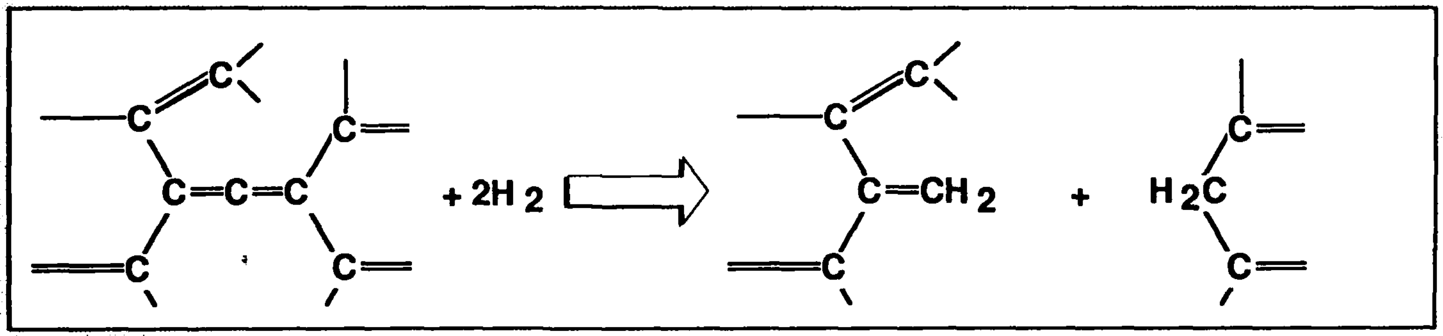
B18087

Need for NDE to Sample Atomic Ratios in Thick C-C Structures (u)

a) Residual Oxygen and Hydrogen indicate incomplete pyrolysis



b) Hydrogenation of C-C in high temp H_2 environment is possible reversion mechanism

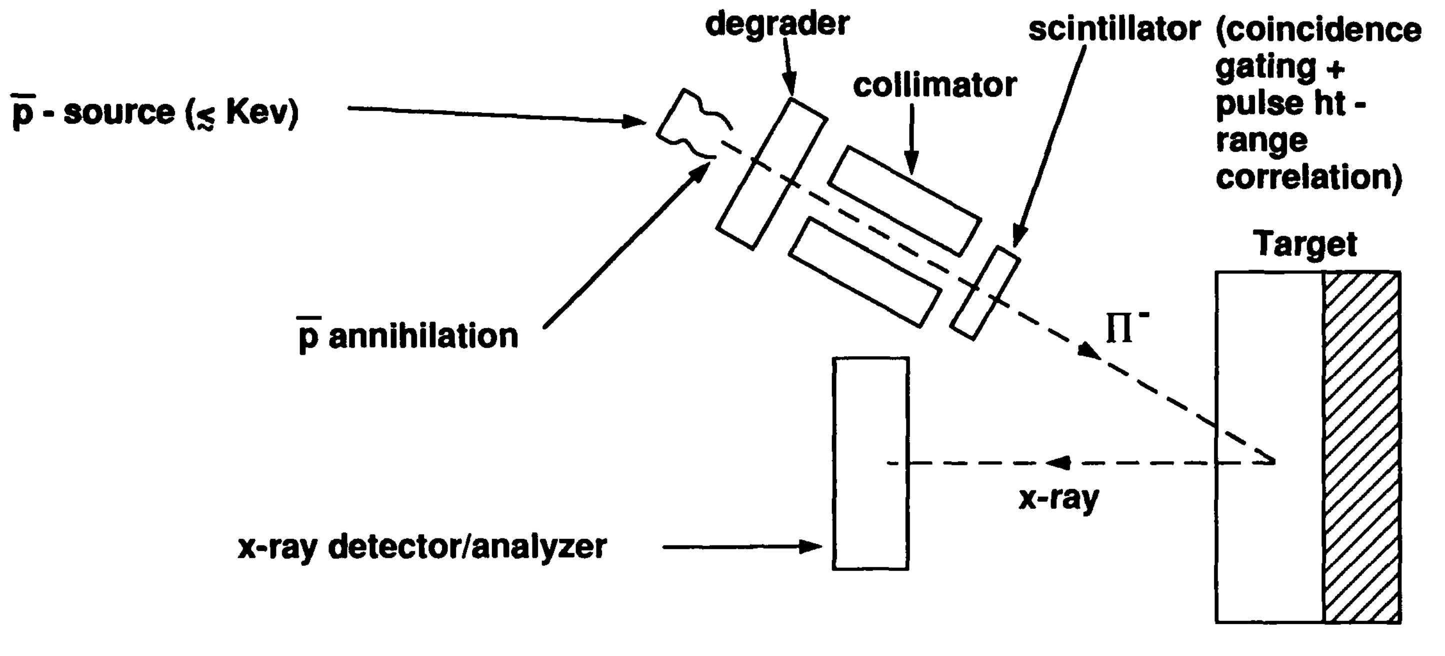


- Energetic Π^- from $\overline{p}$ + p annihilation could reveal (a) poor cure or (b) in use hydrogenation at points deep in Carbon-Carbon structure by γ and x-ray backscatter

UNCLASSIFIED

BN06753

Proposed Deep-Target Chemical Diagnostics using Π^- from $\bar{p}$ Annihilation (u)



- In practical case, x-ray counts from 10^8 $\bar{p}$ might not exceed 10^3 ; but:
  - ✔ Effective clutter would be low due to gating & low count rate
  - ✔ X-rays from, say, Π^- O could be easily counted and identified

UNCLASSIFIED

X-Rays from 2 P→IS Transitions in Π^- Mesic Atoms and Attenuation in Carbon-Carbon (u)

Π^- Atom	X-ray energy (KEV)	Mass abs coef in C-C (ρ = 1.5 gm/cc): $\mu(cm^{-1})$
H	2.4	~ 150
C	100	.23
O	178	.19
(Fluorescent X-ray fom normal O atom)	(.65)	(~1000)

X-ray line degradation through 5 cm of C-C:

C(100 Kev) = 1/3.1

O(178 Kev) = 1/2.6

- Oxygen, implying poor cure, could be identified in thick (e.g., 5 cm) C-C structures
- X-rays from Π^- H would not be observed; presence of H might be inferred from Π^- C reduction due to competitive orbital capture of Π^- by H

THEORETICAL POTENTIAL OF ANTIPROTONS IN RADIATION ONCOLOGY

Mark H. Liebenhaut, M.D.

Department of Radiation Therapy
Lahey Clinic Medical Center
Boston MA

PRESENTED AT THE ANTIPROTON TECHNOLOGY WORKSHOP
HELD AT BROOKHAVEN NATIONAL LABORATORY
10 MAY 1989

Potential Radiation Damage

A) Direct Effects - Damage DNA Itself

B) Indirect Effects - Form Free Radicals

$OH\cdot$

$DNA\cdot$

$DNA\cdot + O_2 \longrightarrow DNAOO\cdot$

$$\text{Oxygen Enhancement Ratio} = \frac{\text{Dose Hypoxic}}{\text{Dose in Oxygen}}$$

x-rays OER = 2.5-3
neutrons OER = 1.6

$$\text{Relative Biological Effect} = \frac{\text{Dose}_{250}}{\text{Dose}_{r}}$$

RBE varies with:
1) system or tumor studied
2) amount of damage in that system

FIG. 6–11. Variation of the OER and the RBE as a function of the LET of the radiation involved. The data were obtained by using T_1 kidney cells of human origin, irradiated with various naturally occurring α-particles or with deuterons accelerated in the Hammersmith cyclotron. Note that the rapid increase of RBE and the rapid fall of OER both occur at about the same LET, namely about 100 keV/μ. (Redrawn from Barendsen GW: in Proceedings of the Conference on Particle Accelerators in Radiation Therapy. US Atomic Energy Commission, Technical Information Center, LA-5180-C, October 1972, pp 120–125)

Figure 9.3. Central axis depth dose distribution for different quality photon beams. Field size, 10 × 10 cm; SSD = 100 cm for all beams except for 3.0 mm Cu HVL, SSD = 50 cm. Data are from Reference 13 and the Appendix.

Source: Khan, Faiz M., The Physics of Radiation Therapy, Williams & Wilkins, Baltimore, pg. 161.

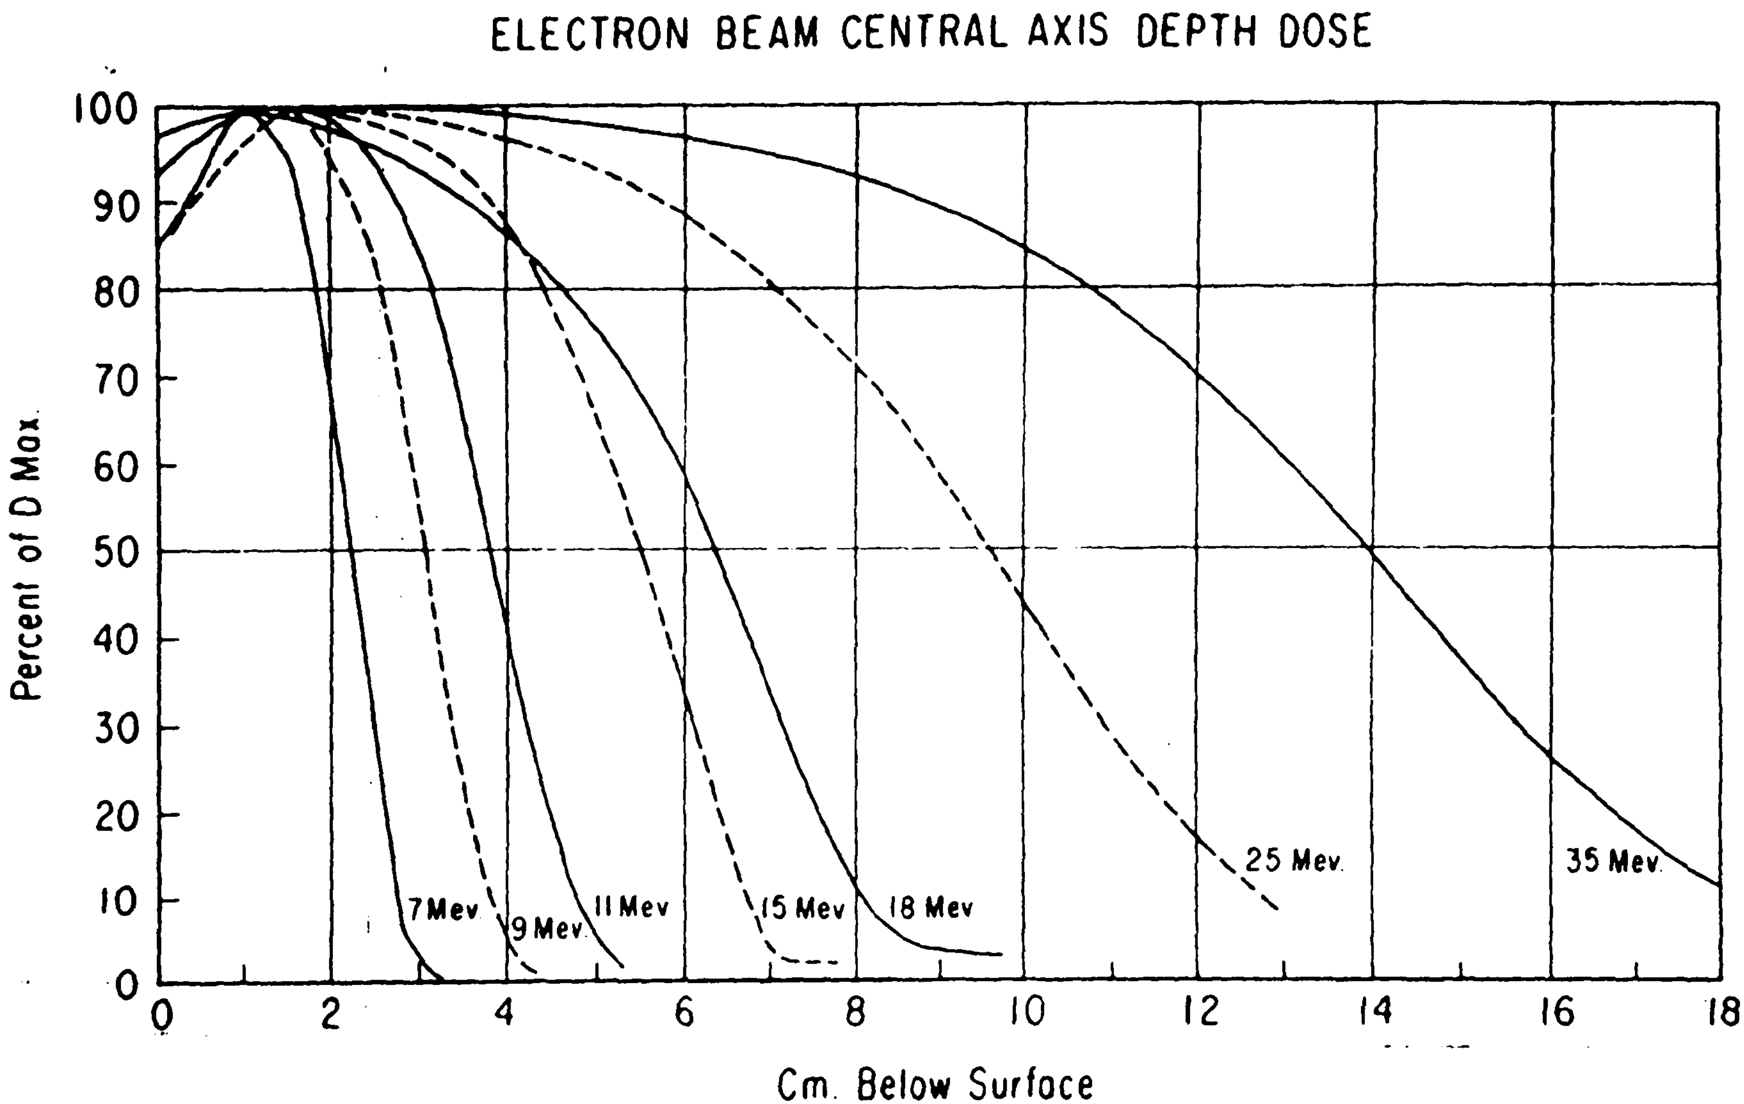

Figure 14.8. Comparison of central axis depth dose distributions of the Sagittaire linear accelerator (continuous curves) and the Siemen's betatron (dashed curve). [Reprinted with permission from: Tapley (35).]

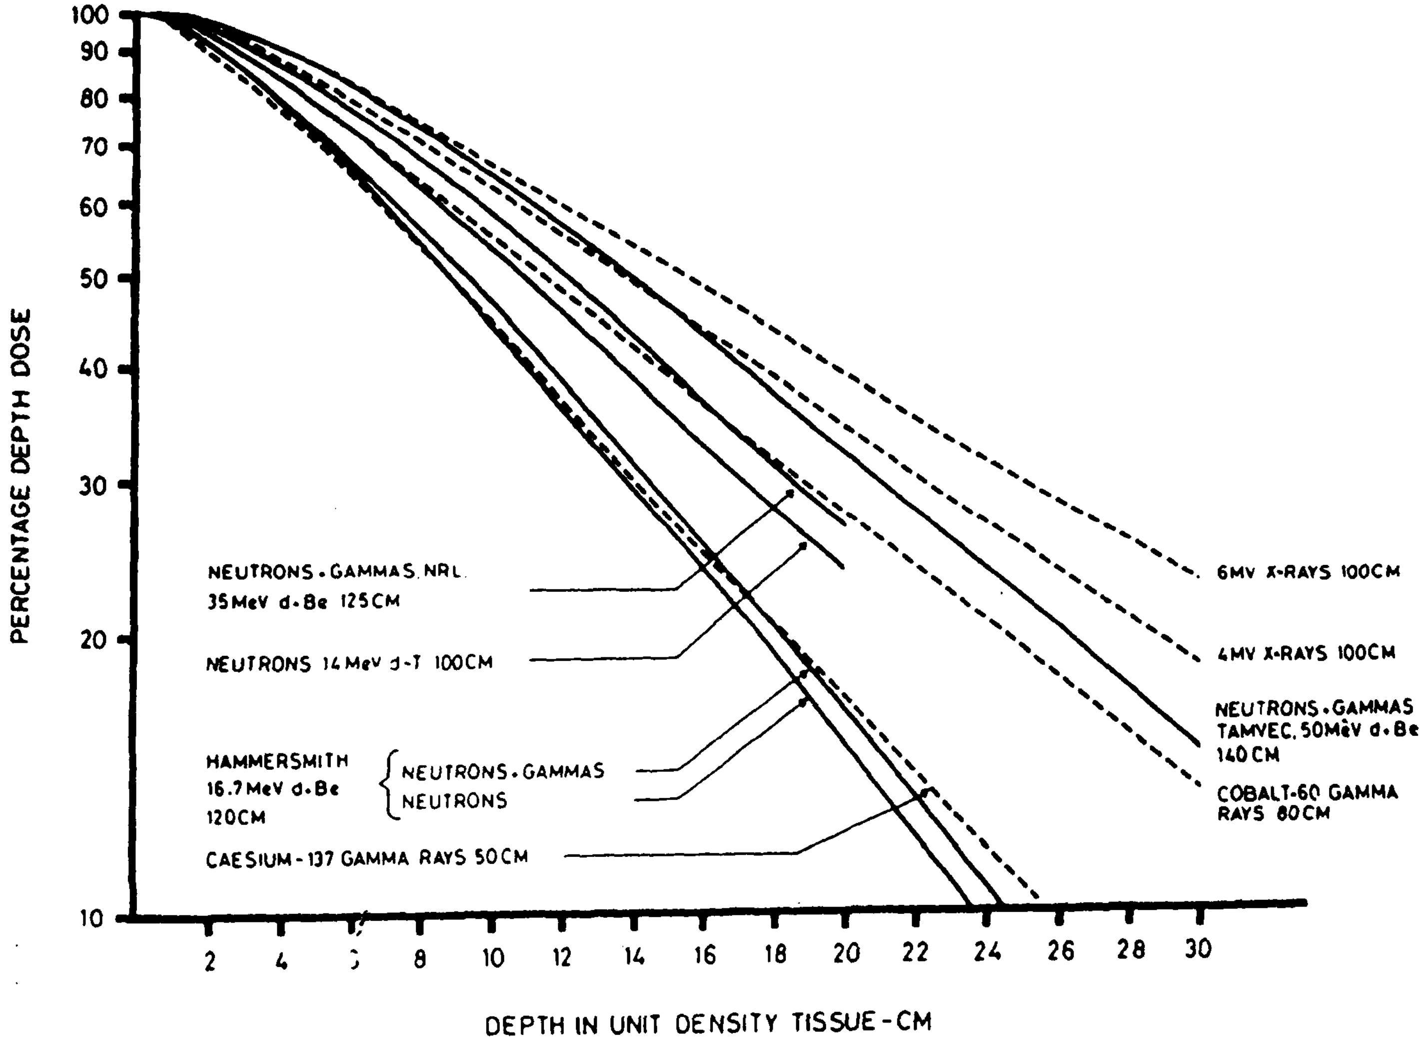
Source: Khan, pq. 314.



Source: Hall, pg. 296.

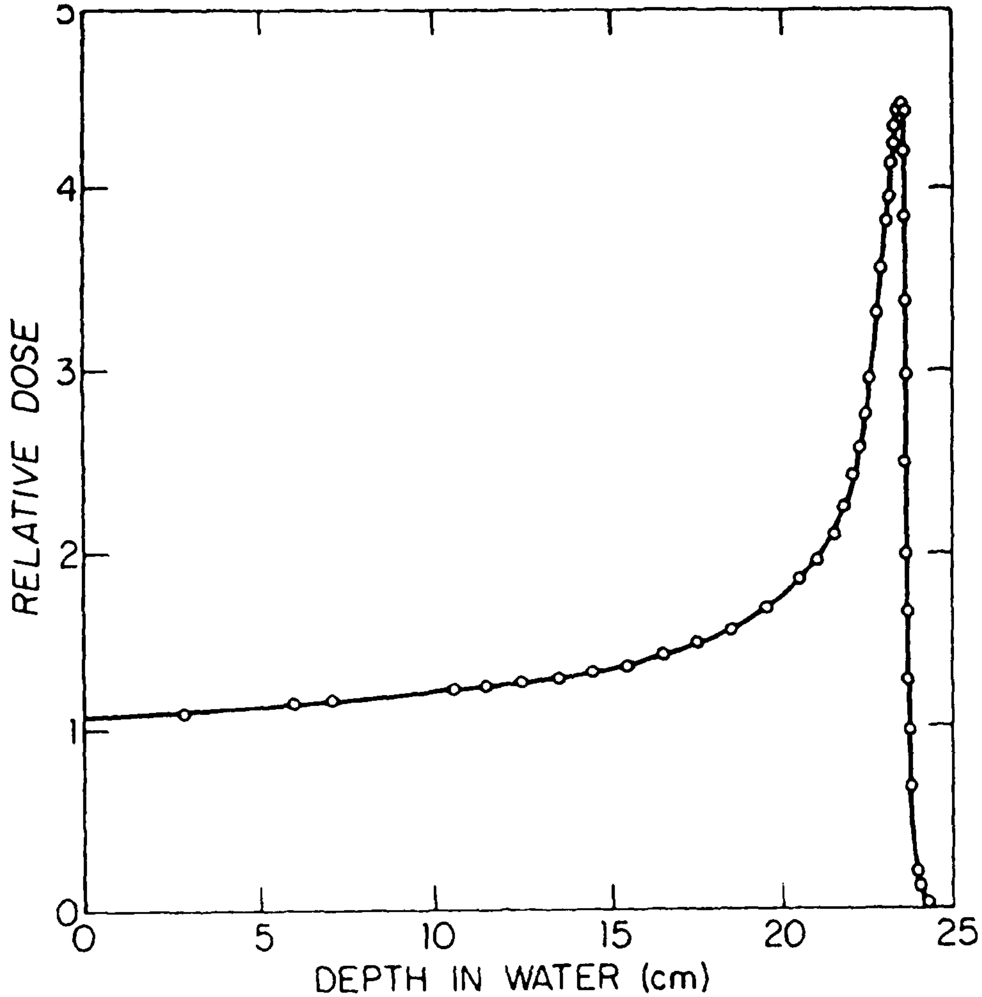


FIG. 15–6. Depth-dose curve for 187-MeV protons from the Uppsala synchrocyclotron. The dose reaches a sharp peak at a depth of about 23 cm. (Redrawn from Larsson B: Br J Radiol 34:143–151, 1961)

Source: Hall, pg. 311.

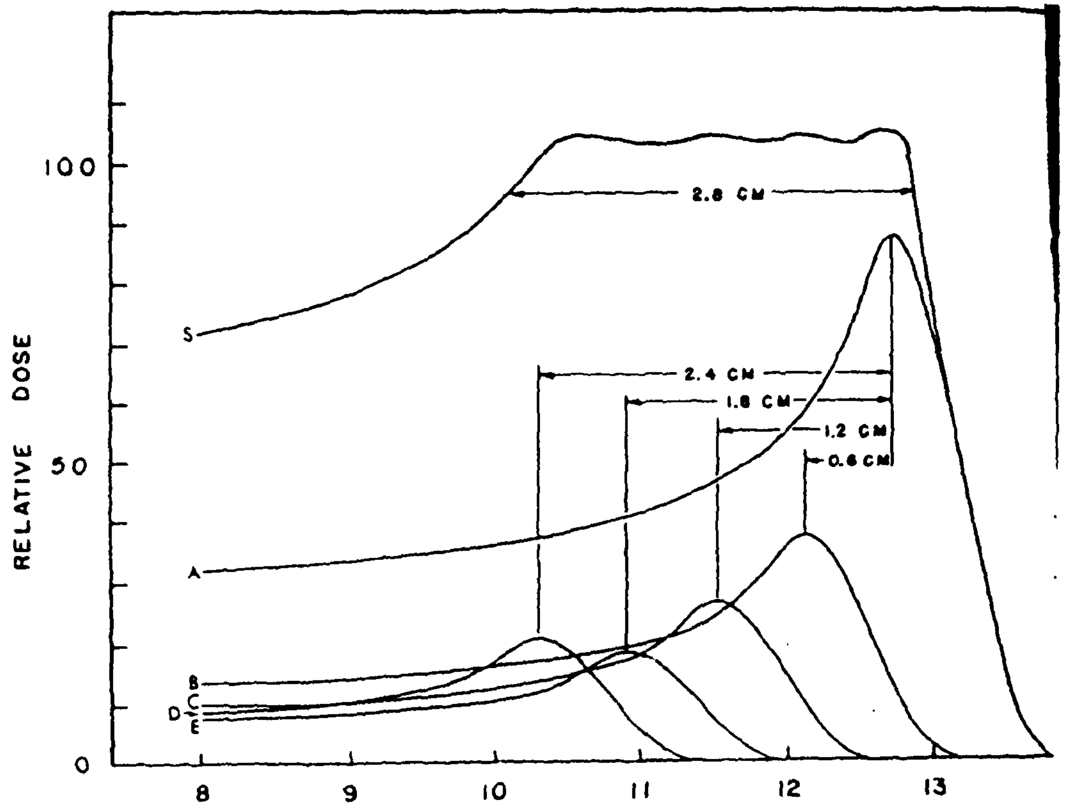

FIG. 15-7. Illustrating the way in which the Bragg peak for a proton beam can be spread out. Curve A is the depth-dose distribution for the primary beam of 160-MeV protons at the Harvard cyclotron, which has a half-width of only 0.6 cm. Beams of lower intensity and shorter range, as illustrated by curves B, C, D, and E, can be added to give a composite curve *S*, which results in a uniform dose over 2.8 cm. The broadening of the peak is achieved by passing the beam through a *rotating wheel with sectors of varying thickness.* (Redrawn from Koehler AM, Preston WM: Radiology 104:191–195, 1972)

Source: Hall, pg. 312.

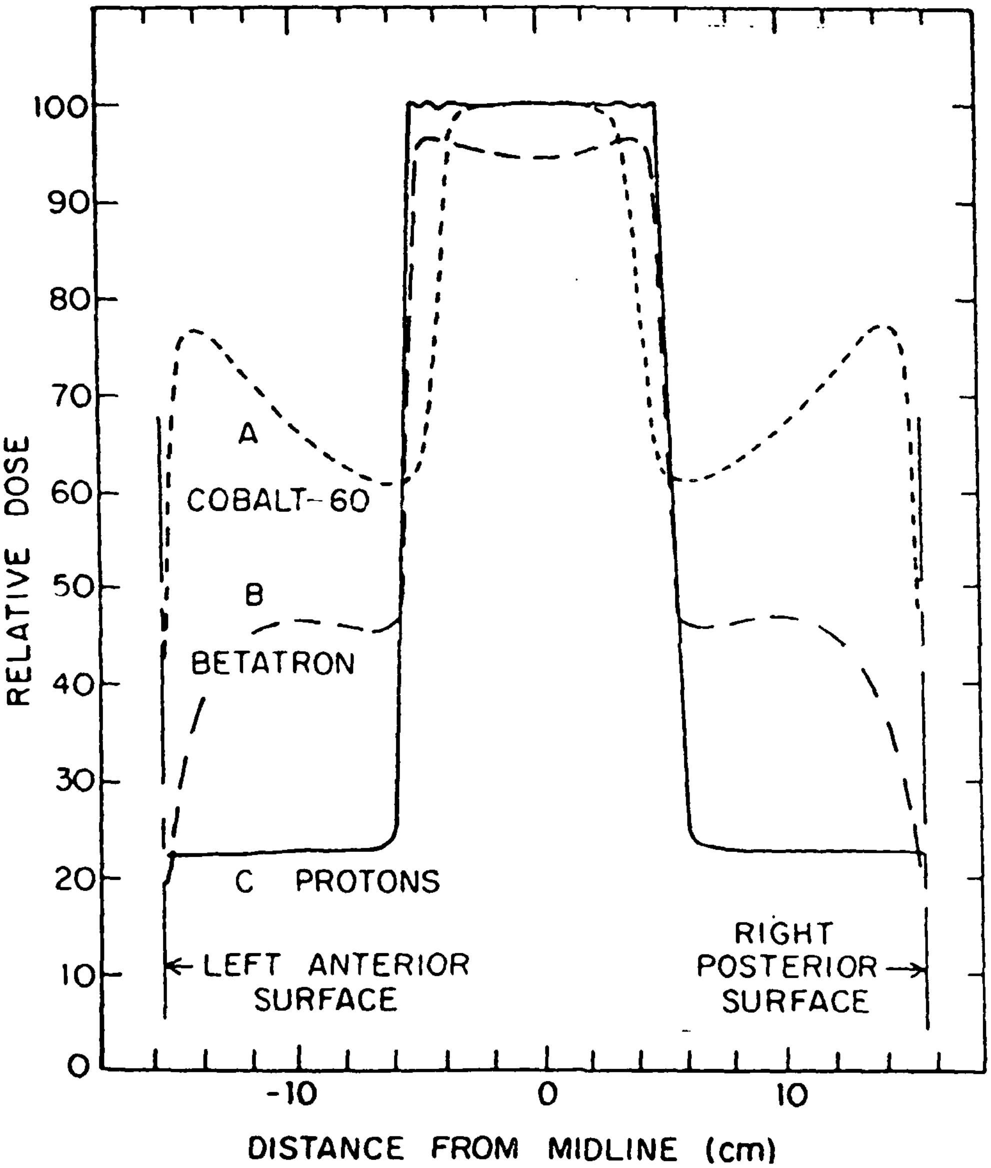

FIG. 15–8. Cross-section of the dose distribution that can be obtained in the treatment of an imaginary carcinoma of the cervix, using a four-field technique with ^{60}Co γ-rays, 11-MeV x-rays from a betatron, and 160-MeV protons from the Harvard cyclotron. (From Koehler AM, Preston WM: Radiology 104:191–195, 1972)

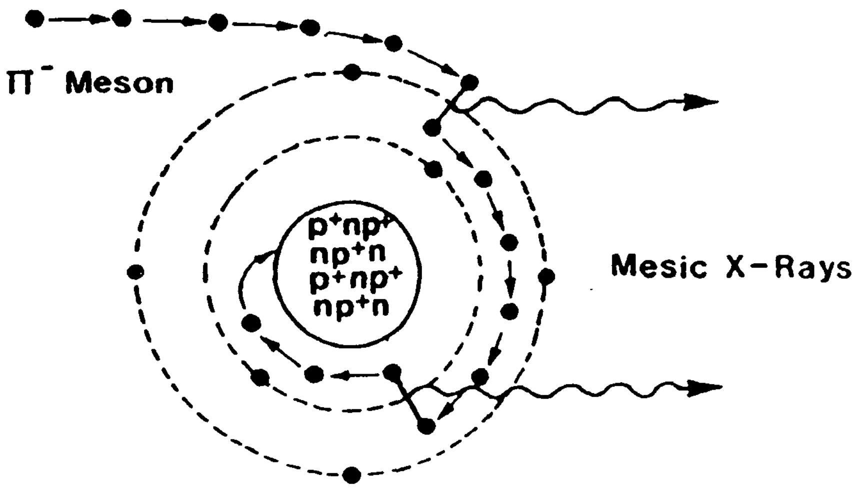
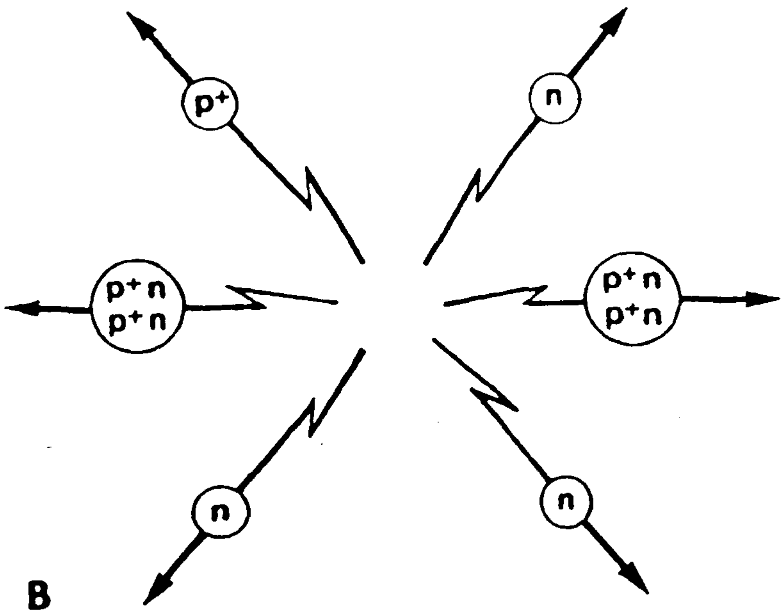
Source: Hall, pg. 313.



A



B

Source: Hall, pg. 24.

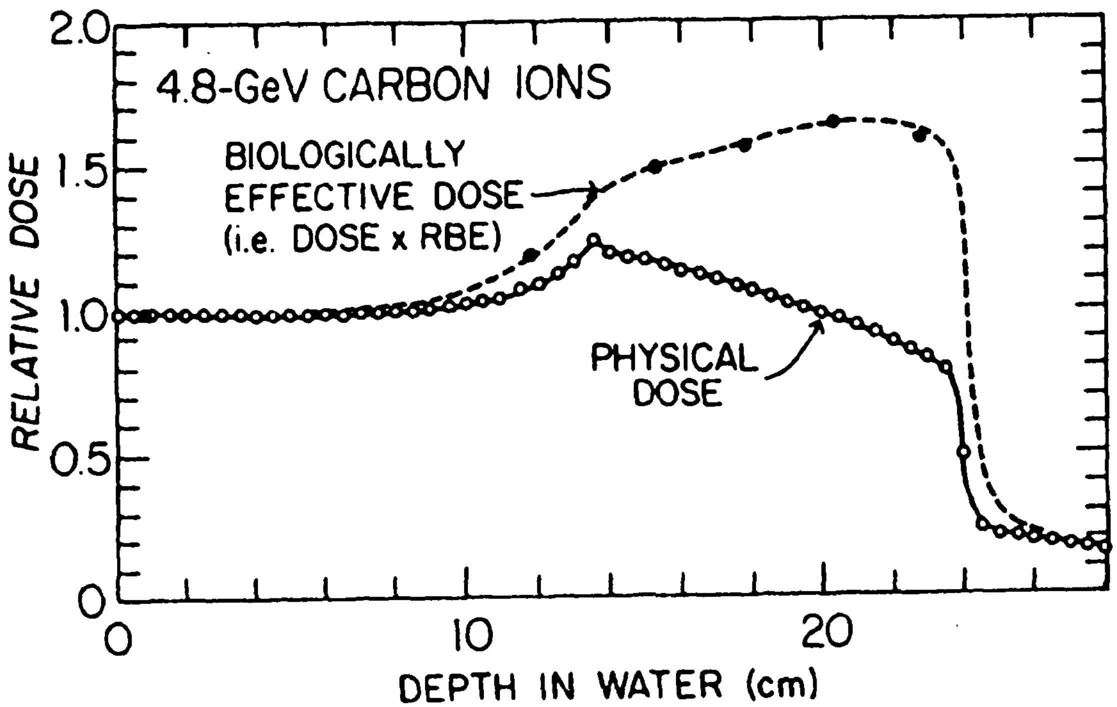


FIG. 15–10. Depth-dose curve for carbon ions in which the Bragg peak has been spread out over 10 cm by the use of a ridge filter. The ions had an initial energy of 400 MeV/nucleon, corresponding to a total energy of 4.8 GeV. The spread-out peak is located between 12 and 22 cm deep. The lower curve represents the physical absorbed dose. The upper curve represents the biologically effective dose; it is, in fact, the product of dose and RBE, calculated at the level of 50% cell survival. (By courtesy of Dr. J.D. Chapman)

Source: Hall, pg. 318.

PROSPECTS FOR A COMMERCIAL ANTIPROTON SOURCE

BRIAN VON HERZEN

ANTIMATTER TECHNOLOGY CORPORATION
HILO, HI

PRESENTED AT THE ANTIPROTON TECHNOLOGY WORKSHOP
HELD AT BROOKHAVEN NATIONAL LABORATORY
10 MAY 1989

Prospects for a Commercial Antiproton Source

Brian Von Herzen, Ph.D.

Antimatter
TECHNOLOGY CORPORATION

Objective:

To develop the production facilities, transport systems, and equipment needed to apply antimatter to problems in medicine, aerospace, and academic research.

Antimatter
TECHNOLOGY CORPORATION

Current Efforts

- to obtain complete funding for the production, distribution, and application of antimatter.

- to develop a cost-effective source for antiprotons.

- to develop a portable system capable of storing antiprotons and delivering them to remote sites.

- to develop the necessary imaging, diagnostic and therapeutic equipment for medical applications.

Antimatter
TECHNOLOGY CORPORATION

Funding Being Sought

$195 million for a dedicated production facility, or an extension of an existing facility

$15 million to develop a portable storage device capable of transporting antiprotons to remote sites.

$35 million for medical applications, including imaging, diagnosis, medical clinics, and development.

$245 million needed for commercial break-even

Antimatter
TECHNOLOGY CORPORATION

Possible Antiproton Sources

- Collaboration with Brookhaven
- Collaboration with Fermilab
- Collaboration with a future facility
  - Advanced Hadron Facility at Los Alamos
  - Triumf in Canada
  - SSC Collaboration
- Dedicated production facility

Antimatter
TECHNOLOGY CORPORATION

Transport and Storage Systems

- Medical Tabletop ring by Prof. Robert Wilson
- Design studies in RAND proceedings by researchers at UCLA and Los Alamos
    - Penning traps
    - Superconducting storage rings
- Molecular storage of antimatter

Antimatter
TECHNOLOGY CORPORATION

Imaging and Treatment

- Proton therapy at Harvard Cyclotron, and Mass General Hospital (4500 patients treated).
- Antiprotons are thought to be much more effective than protons, leading to reduced mortality.
- Imaging experiments at BNL (Kalogeropoulos *et al.*)
- Acceptance of particle treatment by the medical community (Loma Linda medical cyclotron installed).

Antimatter
TECHNOLOGY CORPORATION

Potential Markets

- Cancer Treatment
- Medical Imaging
- Non-destructive Testing

Antimatter
TECHNOLOGY CORPORATION

Cancer Treatment

- $40 billion spent per year on cancer treatment
- 1 million new cases of cancer each year
- Over half of the patients receive radiation therapy.
- Antiprotons are the most selective particles in being able to deliver radiation to the tumor while leaving overlying tissues unharmed.
- A ten percent market penetration in the short-term could be expected to produce revenues of over $1 billion per year.

Antimatter
TECHNOLOGY CORPORATION

Medical Imaging Market

- The medical imaging market is even larger than the cancer market ($50 billion).
- CT scans produce too much radiation.
- Magnetic resonance imaging has limitations to certain types of tissue.
- Benefits from combined imaging and therapy.
- No really satisfactory techniques exist for mammography.

Antimatter
TECHNOLOGY CORPORATION

Non-Destructive Evaluation

- Aerospace applications for critical components
  - Turbines
  - Composites
  - Structural members
  - *Inspection of aging aircraft*
- Aerospace spends 2% of sales on non-destructive test
- Aerospace sales amount to over $50 billion per year
- Aerospace NDE is already a billion dollar market
- Electronic Industry
  - Inspection of solder joints
  - Automated annealing of cold solder joints

Antimatter
TECHNOLOGY CORPORATION

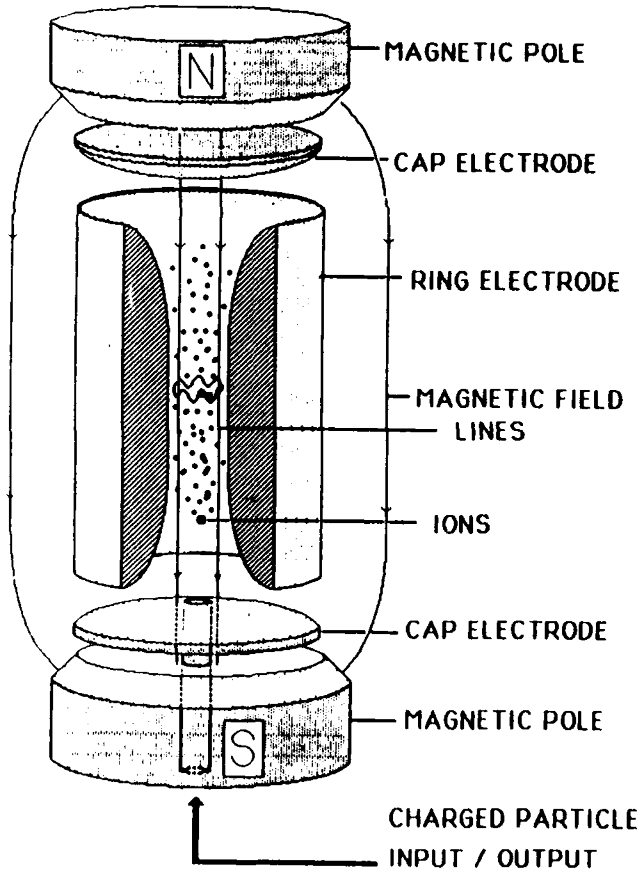
PENNING TRAP

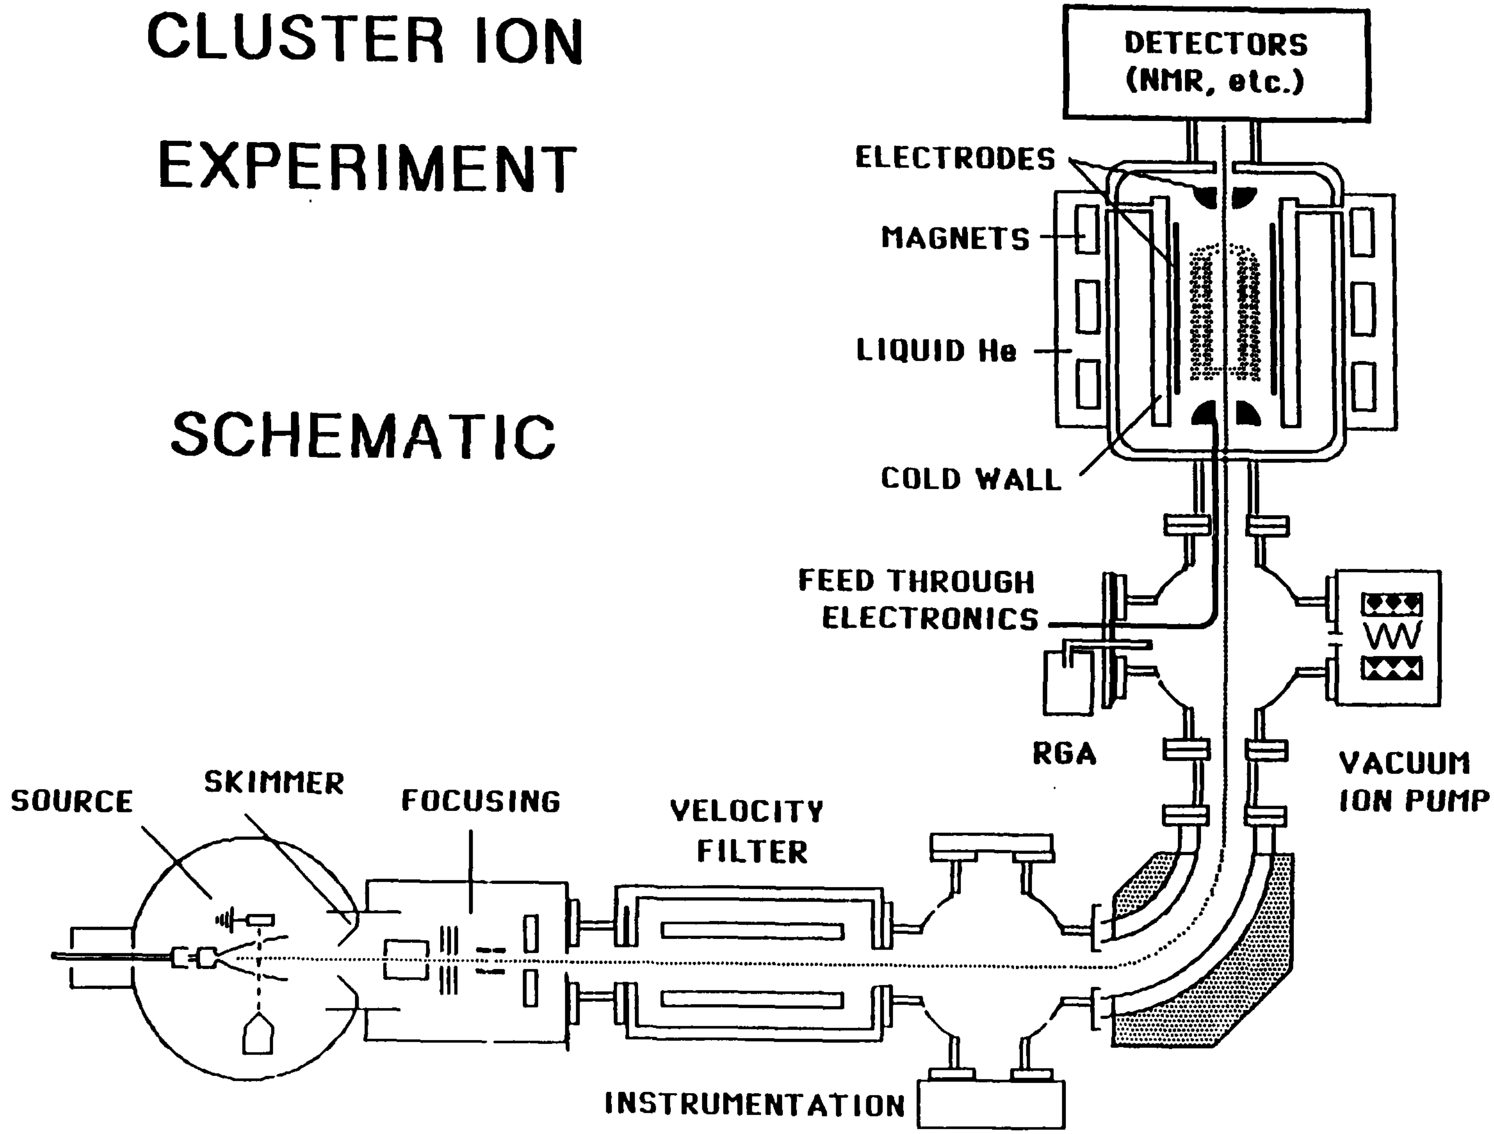
ION TRAPS: PENNING TRAP



TR538a

CLUSTER ION EXPERIMENT

SCHEMATIC



HYDROGEN CLUSTER ION PROJECT AFAL/AFOSR

SCIENTIFIC OBJECTIVE

o Determine Associative and Dissociative Pathways for Trapped Cluster Ions

- Initially, develop technique to follow reaction pathways for H_5^+ systems using a dense non-neutral plasma as a "pseudo-wall" to absorb the energy of association:

$$M^+ + H_3^+ + H_2 \Rightarrow H_5^+ + M^{*+}$$

$$M^+ + H_5^+ + H_2 \Rightarrow H_7^+ + M^{*+}$$

- Larger H_n^+ systems as experience is gained

o Assess Potential of Bulk Antihydrogen Nucleation via Cluster Ions

APPROACH

1. Fill the trap with cluster ions of a selected size
2. Introduce molecular hydrogen, allowing it to interact with the trapped ions
   - use proven electromagnetic cooling techniques to maintain temperature
3. Measure size and radial distribution of products through NMR and/or mass spec

PAYOFF/POTENTIAL APPLICATIONS

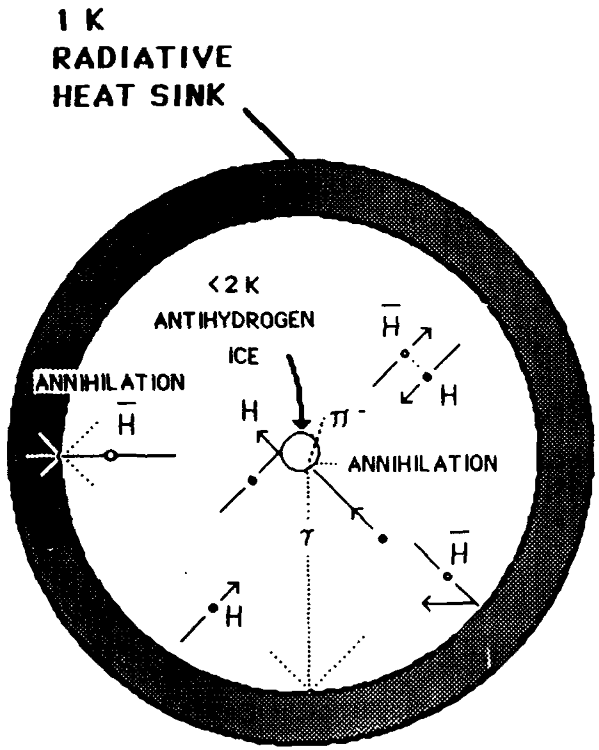
- Bridge between theory and experiment on cluster ion formation & growth
  - Explain semi-empirical models for free expansion nozzles
  - Create new models for contact free processes

- Illuminate third body cooling processes in non neutral plasmas (pseudo walls)

- Provides versatile experimental apparatus in an active field
  - Cluster Ion Beam Experiments (Y.T. Lee et al., UCB)
  - Models for anti-cluster ion nucleation and growth (Saxon, SRI; Turner, AFIT)
  - Contribute to understanding cluster ion formation and deposition processes relevant to ion-matrix HEDM systems (Bae and Cosby, SRI)
  - Related to surface impact studies (Friedman, BNL and others)

- Explore measurement techniques in ion trap environment

ANTIHYDROGEN ICE STORAGE



U. HAWAII (DR JIM GAINES)
BROOKHAVEN NL (DR JIM POWELL)

- Preliminary results

- HOW STABLE IS SOLID ANTIHYDROGEN EXPOSED TO ANNIHILATION REACTION ?
  - 10 mg iceball will withstand 300 Annihilations/s

- WHAT TYPE OF VACUUM DOES THIS IMPLY ?
  - Number density Similar to Interstellar Space
    Based on: 100m/s atom velocity
    100% cross section
    Classical law

- WHAT ELSE DO WE NEED TO KNOW ?
  - Real cross sections
  - Very high Vacuum Material Behavior
  - Synergistic effects

Electromagnetic Traps for Atomic Antihydrogen (or Hydrogen)

Isaac F Silvera
Dept of Physics
Harvard University
Cambridge Ma 02138

Three types of traps:

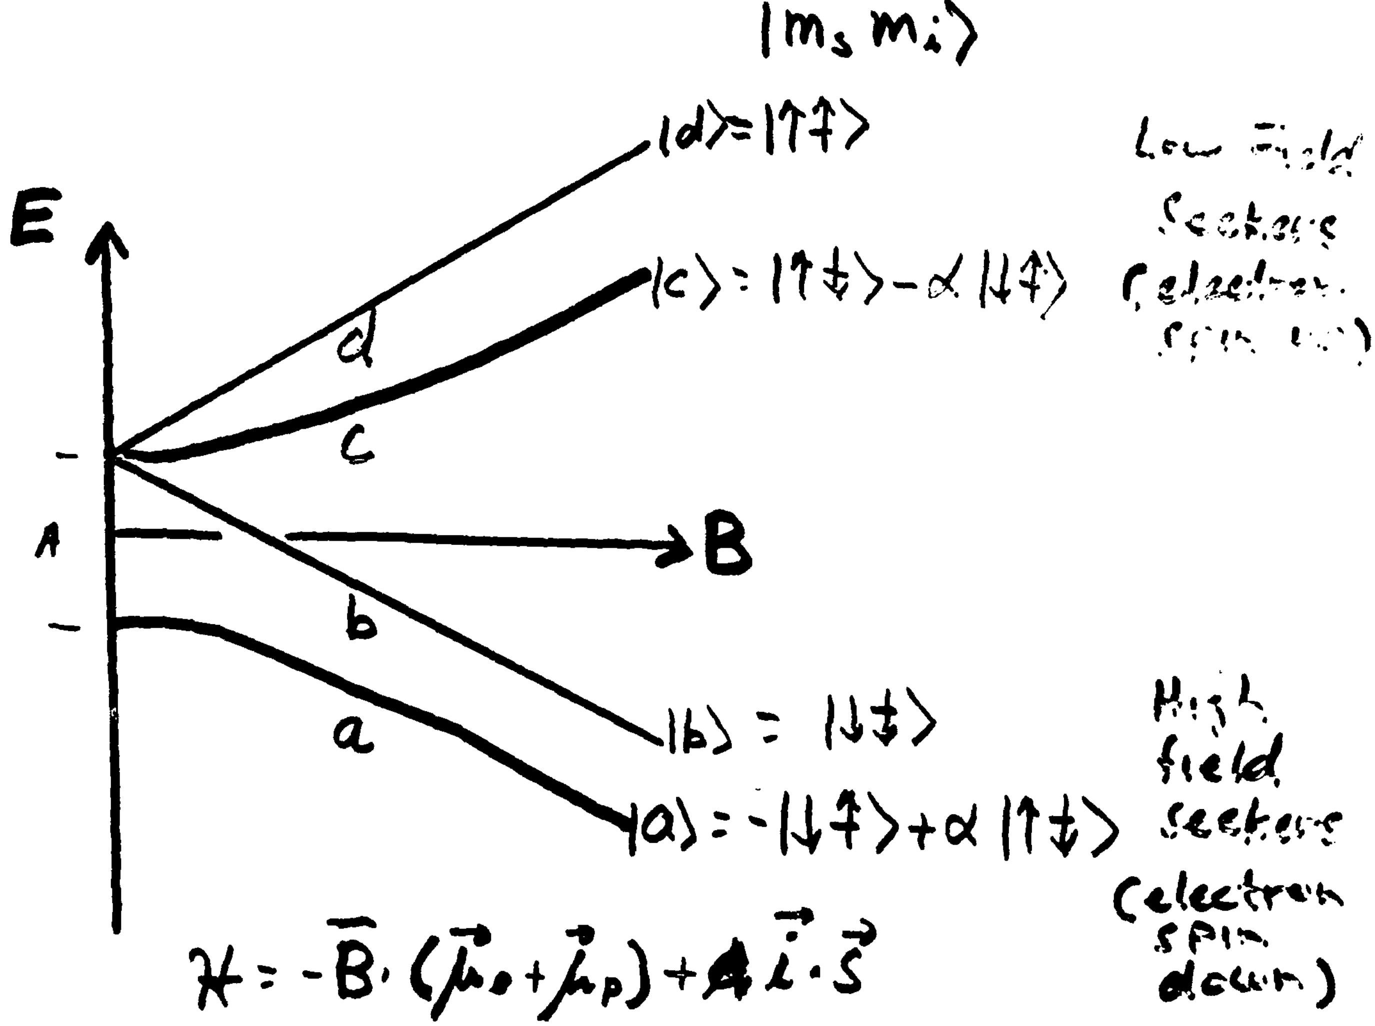
1. Static Magnetic Trap

2. Laser Trap

3. Microwave Trap

I shall discuss hydrogen as the problems are the same for antihydrogen

Hyperfine States of Hydrogen



$$\mathcal{H} = -\vec{B}\cdot(\vec{\mu}_e + \vec{\mu}_p) + A\,\vec{i}\cdot\vec{S}$$

electron spin = $1/2\,\hbar$: $\vec{S}$

nuclear spin = $1/2\,\hbar$: $\vec{i}$

Total spin : $F = i + S$ = 1 or 0

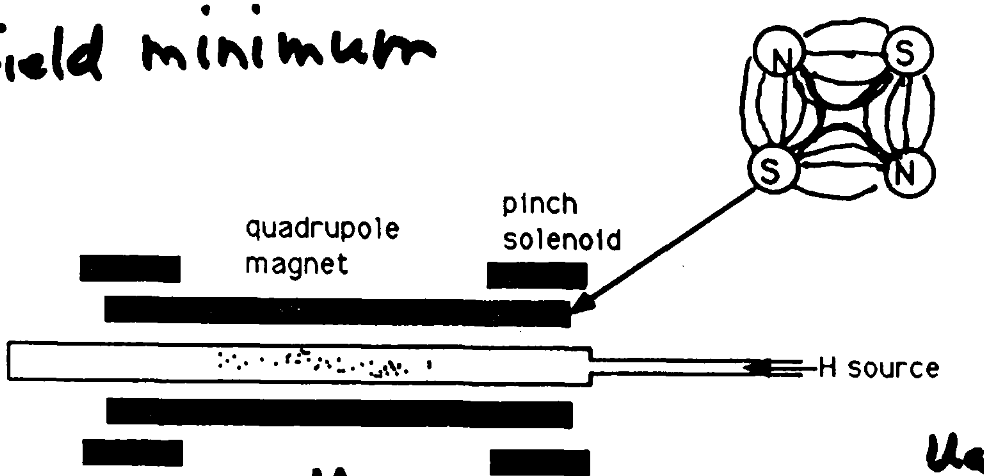
For static magnetic fields
Maxwell's equations do
not allow a field maximum
in Free space.

A Field Minimum is allowed

No restriction on AC fields
(microwave or laser)

STATIC MAGNETIC TRAP (H. Hess)

uses field minimum



Trap potential $U \gg kT$

Barrier potential

← Trapped states

relaxation : magnetic dipole
spin-exchange

$\frac{dn}{dt} = -Gn^2$ Rates are very rapid
But $n = 10^{14}/cm^3$ $\tau_{1/2} = 1 sec$

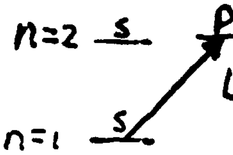
$\frac{1}{n} - \frac{1}{n_0} = -\frac{t}{\tau_{1/2}}$

$\tau_{1/2} = 1/G$

MIT (Kleppner + Greytak et al)
Amsterdam (Walraven et al)

Trap ~ 10^{10}–10^{11} atom
Densities 10^{12} - $10^{13}/cm^3$

Laser cooling of hydrogen



Lyman-alpha at 1216 Å

Laser light can cool and trap (Phillips et al; Chu et al; Pritchard) ENS group)

Cool to quantum limit $T_{min} \simeq \frac{\Gamma}{2} = 2.2\,mK$ Lyman-α

$\Gamma \equiv$ spontaneous emission rate

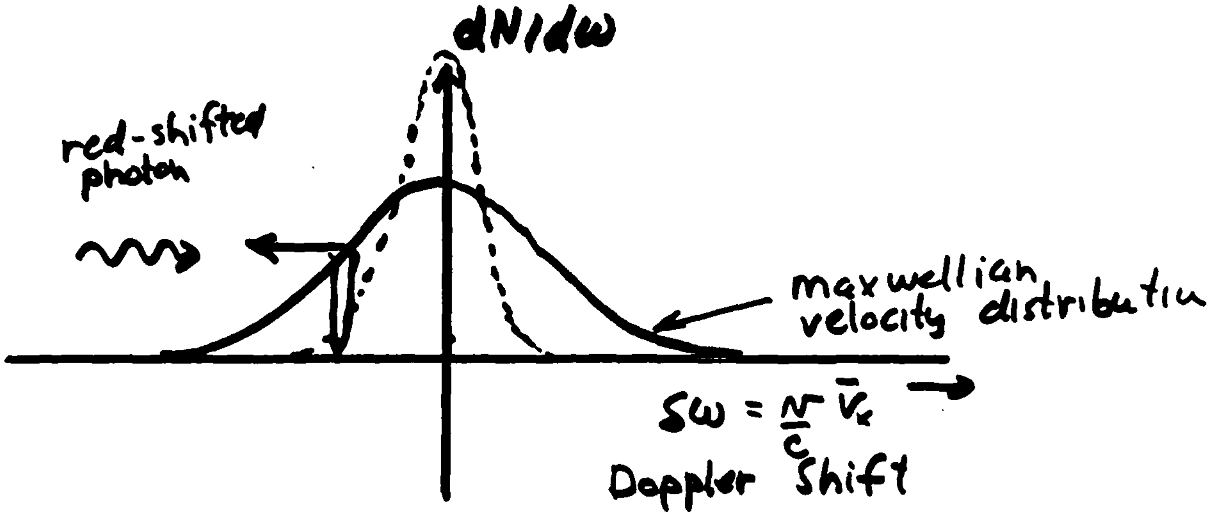
Dipole Trap Potential U

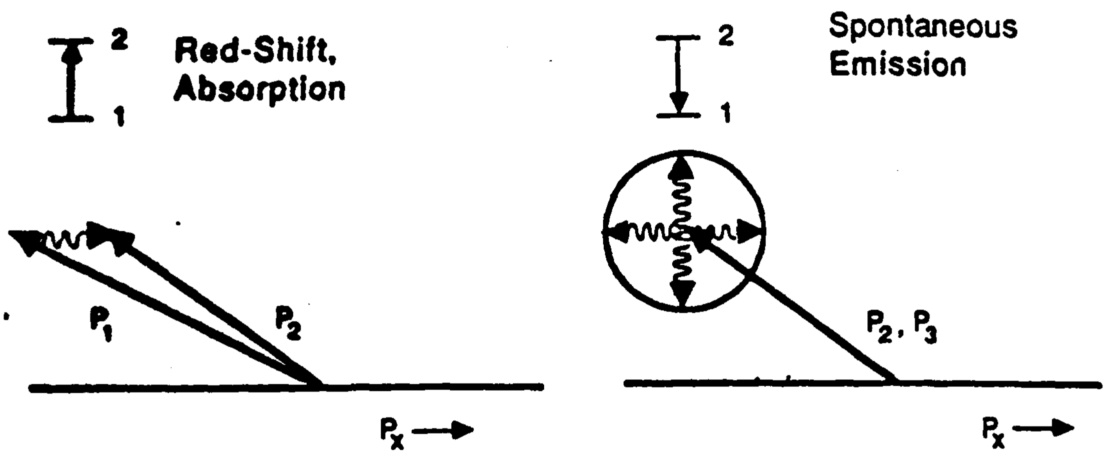
ω_0 = transition frequency
ω = laser frequency

detuning $\delta = \omega - \omega_0$

↑ Deepest potential at $\delta \doteq -\Gamma$
But severe heating of gas due to spont. emission

For Na Chu et al used $\delta \geq 10^3 \Gamma$ to minimize heating
but potential well - few mK





LASER SPONTANEOUS COOLING

Laser power is a major problem

For 1216 Å sources are pulsed, non-linear harmonic generators

Current sources $\sim 10^{10}\frac{\text{photons}}{\text{sec}}$ $\left(1\ \text{Watt} = 6\times10^{17}\frac{\text{photons}}{\text{sec}}\right)$

Very Large improvements possible
but still pulsed at ~30 hz

$t_{off} = 33\text{msec}$

Trapped atoms rapidly expand during off time
trap dimensions ~ microns
$\bar{v}$ at 2.2 mk ~ 3 meters/sec

off time expansion

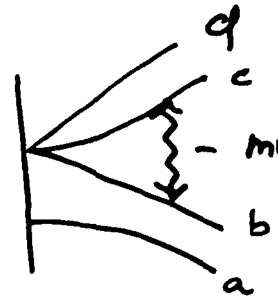
$\Delta x = \bar{v} \times t_{off} = 3\ \text{m/sec} \times 33\ \text{msec}$

$\approx 10\ \text{cm}$!

New Trap: Microwave Trap

Agosta, Silvera, Verhaar + Stoof

Just like laser trapping, but no spontaneous emission



Dressed atoms: Diagonalize atomic states and radiation field (N-photons)

Dressed states

low field seeker

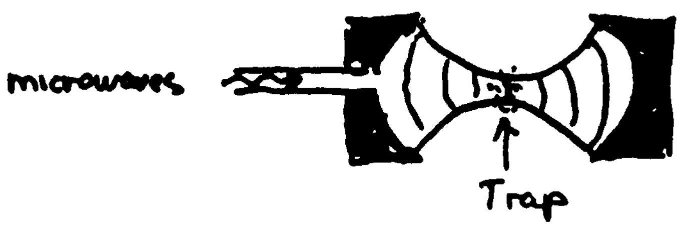
$$|1\rangle = \cos\theta\,|c, N-1\rangle + \sin\theta\,|b, N\rangle$$

$$|2\rangle = -\sin\theta\,|c, N-1\rangle + \cos\theta\,|b, N\rangle$$

high field seeker

State $|2\rangle$ seeks highest microwave field

Confocal resonator cavity



$$U_{trap} = \frac{\hbar}{2}\,\omega_{rabi}$$

$$\omega_{rabi} \simeq \mu_{bc} B_{microwave}$$

$$\therefore\quad U_{trap} = \frac{\hbar}{2}\,\mu_{bc} B_{microwave}$$

$\overline{\mathrm{H}}$ APPLICATIONS

1. TCP Tests

   Hyperfine Structure

   Lamb Shift

   Fine Structure

   Electronic Structure ($\overline{\text{Rydberg}}$) and $m_{\bar{p}}$ (inertial), $\mu_{\bar{p}}$

2. Production of Polarized $\bar{p}$

   i. Transfer of Polarization from an Initially Polarized e^+ Beam -

   $e^+(\uparrow) + \bar{p} \rightarrow \overline{H}(\uparrow) \rightarrow e^+(\uparrow) + \bar{p}(\uparrow)$

   ii. Optical pumping, Resonant Ionization, Lamb Shift Spin Filter -

   $e^+ + \bar{p} \rightarrow \overline{H}; \quad \overline{H} + nh\nu \rightarrow \overline{H}(\uparrow) \rightarrow \bar{p}(\uparrow) + e^+(\uparrow)$

3. Astrophysics

   $\overline{H} + H \rightarrow [\bar{p}p + Ps; \quad \bar{p} + p + Ps; \quad \bar{p}p + e^+ + e^-; \quad \bar{p} + p + e^+ + e^-]$

   $\overline{H} + H \rightarrow \overline{H} + H$

4. $\overline{H}$ - Gravity Interaction

   $m_{\bar{p}}$ *(inertial)*/m_p *(inertial)* - $[\omega(\overline{H} - hfs)/\omega(H - hfs)]$

   $m_{\bar{p}}$ gravitational -

5. Atomic Physics

   $\overline{H}$ + Matter $\longrightarrow$ $\bar{p} + e^+$ + Matter (stripping)

   $\overline{H}$ + Matter $\longrightarrow$ $\overline{H}$ + Matter (elastic and inelastic scattering)

6. $\overline{H}$ - Energy storage

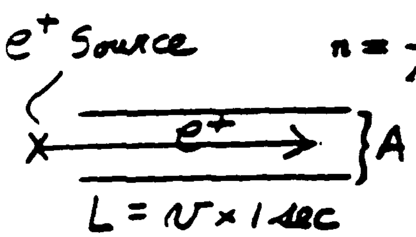
$\bar{H}$ Production by Radiative Recombination – Projected Rates (1 pass)

Assume equal area, non-relativistic, $\bar{p}$ and e^+ beams. Then

$$R(e^+ + \bar{p} \rightarrow \bar{H} + h\nu) \approx n(e^+) \langle \sigma v_T (e^+ - \bar{p}) \rangle (N(\bar{p})\eta)$$

where: $n(e^+) = e^+/cm^3$ in $(e^+, \bar{p})$ overlap region

10 Ci - ^{22}Na   1 Remoderation



$$n = \frac{R(e^+/s)}{A(L = v \times 1\ \text{sec})} \sim \frac{(4 \times 10^{11}) \times (10^{-4})}{\underbrace{10^{-2}\ \text{cm}^2}_{A} \times \underbrace{10^{10}\ \text{cm}}_{L}} \sim 1\ \text{cm}^{-3}$$

$$\frac{\alpha}{c^2}\omega^3 a_0^2 = \frac{\alpha}{c^2}\left(\frac{\alpha c}{a_0}\right)^3 a_0^2 = \alpha^4 c / a_0$$

γ ← ; $\Delta T \rightarrow a_0 / v_r$

$$\sigma_1(\infty \rightarrow 1) = 2\pi\left[(\pi a_0^2)\left(\frac{\alpha^4}{\beta_r}\right)\left(\frac{\alpha}{\beta_r}\right)\right] = \frac{2\pi^2 \alpha r_e^2}{\beta_r^2}\ \text{cm}^2$$

$$\sigma = \sum \sigma_i \sim 3\sigma_1 \sim 0.5 r_e^2 / \beta_r^2$$

$$\underbrace{\langle \sigma v_T \rangle}_{\alpha_T} \sim \frac{0.5 r_e^2 c}{\langle \beta_T \rangle} \sim \frac{(4 \times 10^{-26}) \times (3 \times 10^{10})}{6 \times 10^{-4}} \sim 2 \times 10^{-12}\ \text{cm}^3/\text{s}$$

$T_T \sim 0.1$ eV

$N(\bar{p})$ = number of $\bar{p}$ stored in LEAR $\approx 10^{11}$ (Cooled - 10^{10})

η = fraction of $\bar{p}$ ring overlapped by e^+ beam $\approx$ 4m/80m $\simeq$ 0.05

$$R \sim 1 \times (3 \times 10^{-12}) \times (5 \times 10^9) \sim 10^{-2}/\text{s} \sim 30\text{hr}^{-1}\ (3\ h^{-1})$$

7.

$\bar{H}$ Production by Radiative Recombination Using Recirculating e^+

$$R_S(e^+ + \bar{p} \rightarrow \bar{H}) \approx n_S(e^+)\,\alpha_r\,(N(\bar{p})\eta)$$

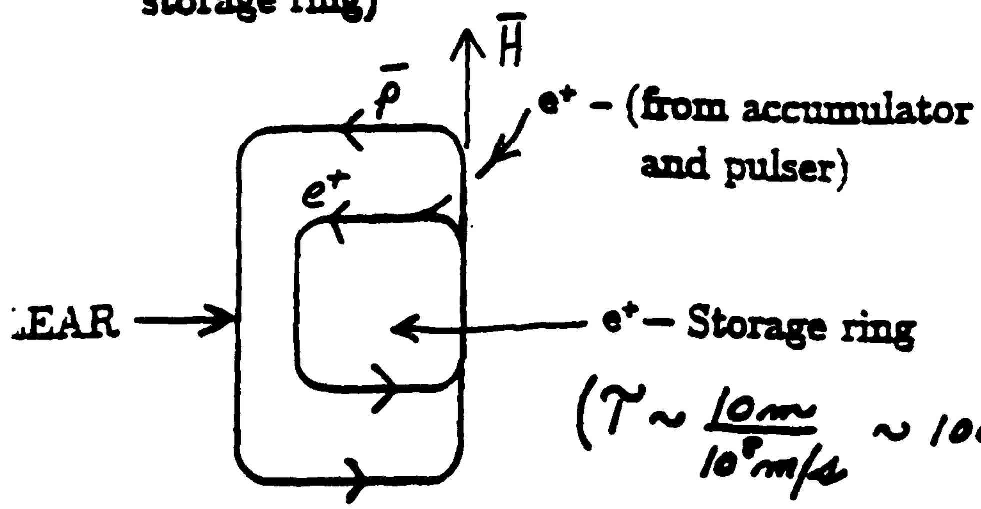
3×10^{-12} 10^{11} 0.05 (fraction of $\bar{p}$ ring occup. by e^+)

$$\alpha_r \equiv \langle \sigma v_r \rangle \simeq \frac{r_e^2}{\beta_r^2}\, v_r \sim 10^{-19} \times 10^{7}$$

10 Ci   Remoderate and store-ls

$$0.1\,eV \quad n_S \equiv \frac{R(e^+/s)}{A(L = 10^3\,\mathrm{cm})} = \frac{(4\times10^{11})\times10^{-5}}{10^{-2}\times10^{3}} \sim 4\times10^{6}\ \mathrm{cm}^{-3}$$

e^+ - accumulated, cooled, pulsed and recirculated (10 m e^+ storage ring)



$$\left(\tau \sim \frac{10\,m}{10^{8}\,m/s} \sim 100\,ns\right)$$

$$R_S(e^+ + \bar{p} \rightarrow \bar{H}) = \underbrace{(4\times10^{6})}_{n_S} \times \underbrace{(3\times10^{-12})}_{\alpha_r} \times \underbrace{(5\times10^{9})}_{N(\bar{p})\eta} \sim 6000\ /s$$

$\bar{H}$ Production by Radiative Recombination : Recirculating e^+ and Stimulated Recombination

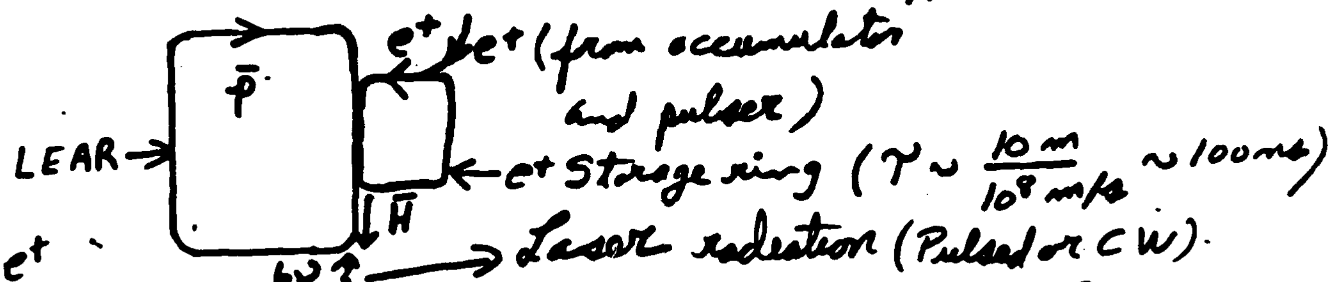
3×10^{-12} 5×10^{7} Laser recomb. gain factor

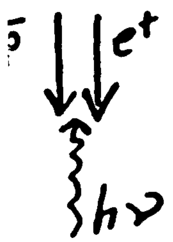
$$R_S(e^+ + \bar{p} \to \bar{H}) \approx n_S(e^+)\alpha_R(N(\bar{p})\eta)G$$

Recomb. and storage for 1 sec

e^+ storage: $$n_S \equiv \frac{R(e^+/s)}{A(L = 10^3 cm)} = \frac{(4\times10^{11})\times10^{-5}}{10^{-2}\times10^{3}} \sim 4\times10^{5}\ cm^{-3}$$

e^+ - accumulated, cooled, pulsed and recirculated (10 m e^+ storage ring)

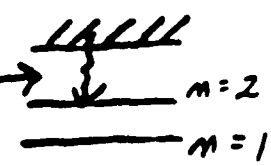




G = Stimulated recombination gain factor $(e^+ + \bar{p} + h\nu \to \bar{H} + 2h\nu) =$

$$= \frac{n^3}{2}\frac{I(MW/cm^2)}{(T_e/0.1eV)}$$

If $\lambda_{Lab} = 521$ nm$(\lambda_{CM} = \lambda_L(1-\beta)\gamma = 364$ nm for $\infty \to 2)$



then $G \sim 16\ I$ for $T_e \sim 0.1$ eV

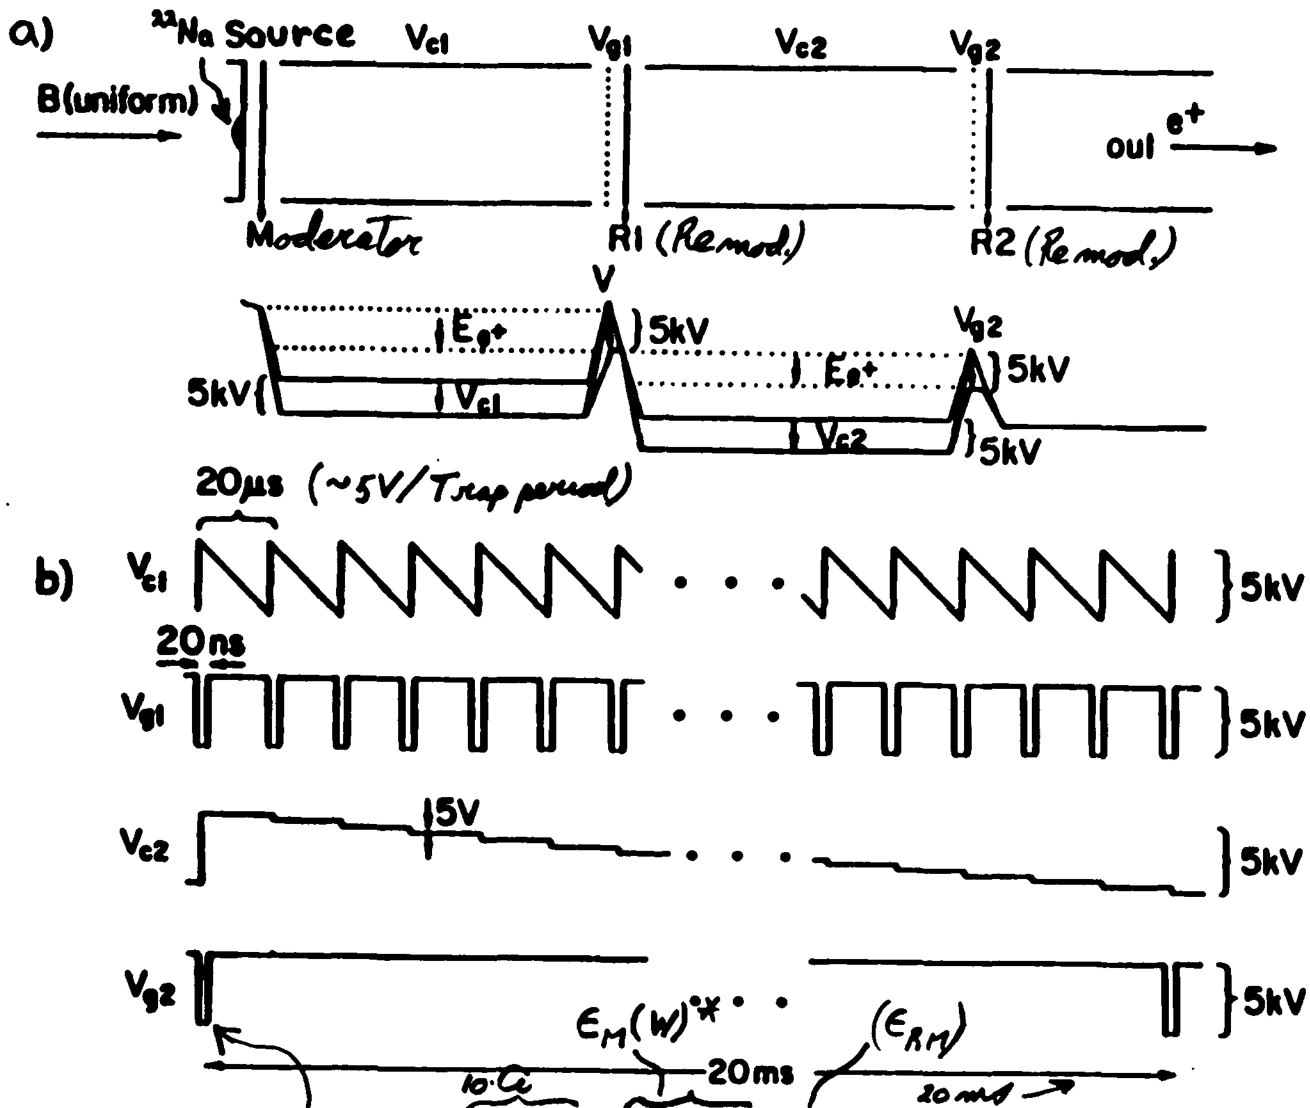
Commercial 20 MW/cm² excimer laser (250 Hz, 20 ns pulse) $G \sim 10^2$

Finally - If pulsed e^+ matches laser (stored pulse)

$$R_S(e^+ + \bar{p} \to \bar{H}) = \underbrace{(4\times10^{5})}_{n_S}\times\underbrace{(3\times10^{-12})}_{\alpha}\times\underbrace{(5\times10^{9})}_{N_{\bar{p}}\eta}(G) \sim 6000\ G/s$$

CW - (CO/CO$_2$ ~ 20 W), $n > 10$, $G \sim 10^3$ but re-ionization and field ionization problems

Positron Accumulator and Pulser



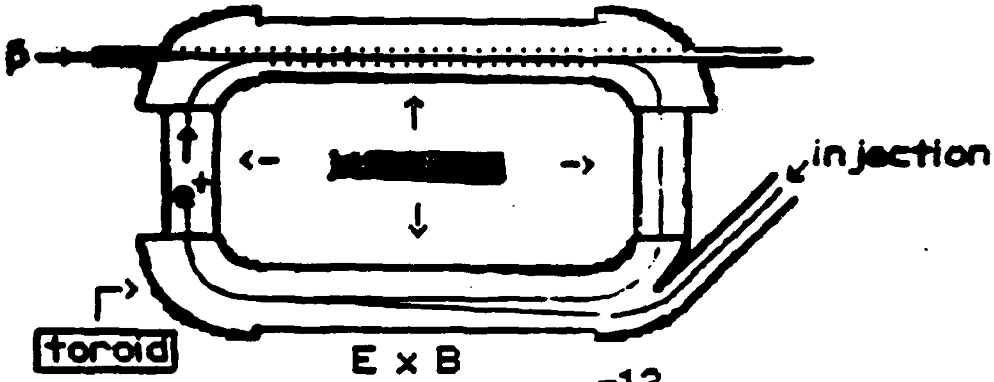
$\#$ of e^+/pulse $\sim 4\times10^{11} \times (3\times10^{-4}) (\frac{1}{3})^2 \times 20\times10^{-3} \sim 2\times10^5$/pulse

" /sec $\sim 2\times10^5\times 50 \sim 10^7$/s

$^*\epsilon_M(Ne) \sim 10^2 \epsilon_M(W)$

Positron recirculator

a) circular device

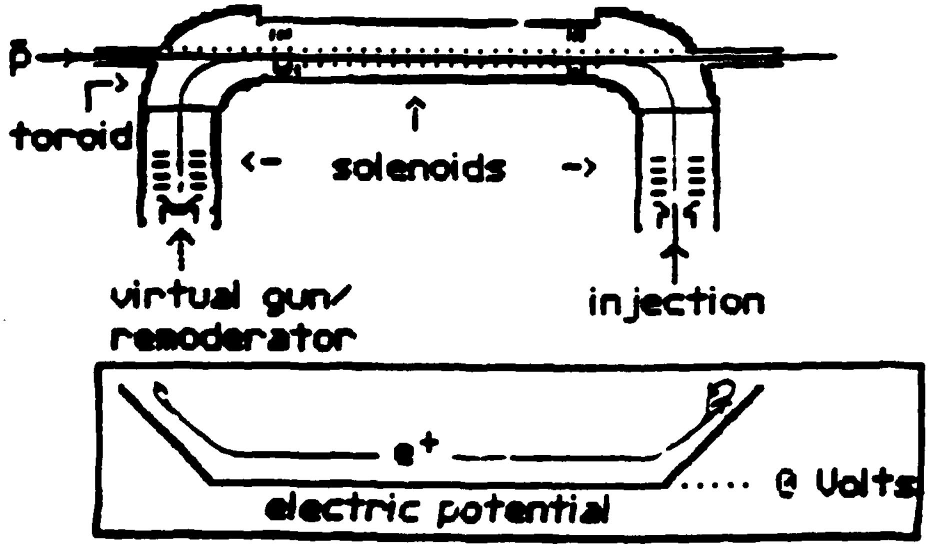


circumference: 15 m, vacuum: 10^{-12} Torr

magnetic field 200-600 G, e^+ energy: 20-100 keV

---

b) linear device



$\overline{\text{H}}$ APPLICATIONS

1. TCP Tests

   Hyperfine Structure
   Lamb Shift
   Fine Structure } $N \sim$ 10 cycles/m at $\beta \sim 0.3$

   Electronic Structure ($\overline{\text{Rydberg}}$) and $m_{\bar{p}}$ (inertial), $\mu_{\bar{p}}$

2. Production of Polarized $\bar{p}$

   i. Transfer of Polarization from an Initially Polarized e^+ Beam -

   $e^+(\uparrow) + \bar{p} \rightarrow \overline{H}(\uparrow) \rightarrow e^+(\uparrow) + \bar{p}(\uparrow)$

   $P_i(e^+)$ $\quad$ $P_f(e^+) \sim \frac{1}{2} P_i(e^+)$; $P(\bar{p}) \sim \frac{1}{2} P_i(e^+)$

   ii. Optical pumping, Resonant Ionization, Lamb Shift Spin Filter -

   $e^+ + \bar{p} \rightarrow \overline{H}$; $\quad \overline{H} + nh\nu \rightarrow \overline{H}(\uparrow) \rightarrow \bar{p}(\uparrow) + e^+(\uparrow)$

3. Astrophysics

   $\overline{H} + H \rightarrow [\bar{p}p + Ps; \quad \bar{p} + p + Ps; \quad \bar{p}p + e^+ + e^-; \quad \bar{p} + p + e^+ + e^-]$

   $\overline{H} + H \rightarrow \overline{H} + H$

4. $\overline{H}$ - Gravity Interaction

   $m_{\bar{p}}$ *(inertial)*/m_p *(inertial)* - $[\omega(\overline{H} - hfs)/\omega(H - hfs)]$

   $m_{\bar{p}}$ gravitational -

5. Atomic Physics

   $\overline{H}$ + Matter $\longrightarrow$ $\bar{p} + e^+$ + Matter (stripping)

   $\overline{H}$ + Matter $\longrightarrow$ $\overline{H}$ + Matter (elastic and inelastic scattering)

6. $\overline{H}$ - Energy storage

Anti-Proton Polarization via $\bar{H}$ Formation with Polarized Positrons

1. $\bar{H}$ hfs $(n=1)$

Triplet → $e^+\ \bar{p}$: $\Downarrow\downarrow,\ \Uparrow\uparrow,\ \underbrace{\frac{1}{\sqrt{2}}(\Uparrow\downarrow + \Downarrow\uparrow)}_{\psi_T(m=0)}$

↓ ← ω $[1.5\,\mathrm{GHz},\ \tau \simeq 10^{-9}\,\mathrm{s},\ N \simeq 10\,L(M)]$

Singlet: $\underbrace{\frac{1}{\sqrt{2}}(\Uparrow\downarrow - \Downarrow\uparrow)}_{\psi_S}$

N = # of hfs cycles for $\beta = 0.3$ $(L(\mathrm{hfs}) \sim 10\,\mathrm{cm})$

2. $\bar{H}$ Formation from Polarized e^+ – Unpol. $\bar{p}$

$(1/2)\quad \underset{e^+}{\Uparrow} + \underset{\bar{p}}{\uparrow} \longrightarrow \underset{\bar{H}}{\Uparrow\uparrow} \longrightarrow \Uparrow \underset{1/2}{+} \uparrow$

$(1/2)\quad \Uparrow + \downarrow \longrightarrow \Uparrow\downarrow \xrightarrow[t>\tau]{} \underbrace{\Uparrow + \downarrow}_{1/4}\ \text{or}\ \underbrace{\Downarrow + \uparrow}_{1/4}$

$$\psi(\Uparrow\downarrow) = \frac{1}{\sqrt{2}}\left[\psi_T(m=0)\,e^{i\omega T} + \psi_S\right] = \begin{cases} \Uparrow\downarrow & \omega T = 0 \\ \Downarrow\uparrow & \omega T = \pi \end{cases}$$

3. $\bar{p}$ Polarization

$$P(\bar{p}) = \frac{N(\uparrow) - N(\downarrow)}{N(\uparrow) + N(\downarrow)} = \frac{\left(\frac{1}{2} + \frac{1}{4}\right) - \frac{1}{4}}{1} = \frac{1}{2}\overbrace{\left(P(e^+)\right)}^{0.4}$$

Polarized $\bar{p}$ – Projected Rates

Rate

Current $N(\bar{p})\eta$ — Laser gain $(G \sim 10^2 - 10^3)$

$$R_S(e^+ + \bar{p} \longrightarrow \bar{H}) = \underbrace{(4 \times 10^5)}_{n_S} \times \underbrace{(3 \times 10^{-12})}_{\alpha_r} \times \underbrace{(5 \times 10^8)}_{N(\bar{p})\eta} G \sim 600 \text{ G/s}$$

$$(5 \times 10^9) \quad \sim 6000 \text{ G/s}$$

Future (?)

Polarization

1) If no attempt is made to maximize $P(e^+)$, $P(e^+) \sim 0.15$

2) To increase $P(e^+)$ use Be absorber to reduce low energy e^+ from beta spectrum (recall $P_{Long} = \langle v \rangle / c$)

3) Maximize $P^2 I \Rightarrow P(e^+) = 0.5$ but $n_S = 1.5 \times 10^5$ (200 G/s)
(2000 G/s)

Result

$$R_S(\bar{H}) \sim R_S(\bar{p}) \sim (2 \times 10^7 - 2 \times 10^8) \text{ G/day at } P(\bar{p}) \simeq \tfrac{1}{2} P(e^+) \simeq 0.25$$

Polarized $\bar{p}$ – Projected Rates and Uses

$$\bar{p} + p \longrightarrow \begin{cases} \bar{p} + p \\ \pi^+ + \pi^- \\ K^+ + K^- \\ \bar{n} + n \end{cases}$$

$$A_{\parallel} = \frac{1}{P_{\bar{p}}P_p}\left[\frac{\sigma_T(\uparrow_{\bar{p}}\uparrow_p) - \sigma_T(\downarrow_{\bar{p}}\uparrow_p) - \sigma_T(\uparrow_{\bar{p}}\downarrow_p) + \sigma_T(\downarrow_{\bar{p}}\downarrow_p)}{\sigma_T(\uparrow_{\bar{p}}\uparrow_p) + \sigma_T(\downarrow_{\bar{p}}\uparrow_p) + \sigma_T(\uparrow_{\bar{p}}\downarrow_p) + \sigma_T(\downarrow_{\bar{p}}\downarrow_p)}\right]$$

where $P_{\bar{p}}$ and P_p are the longitudinal polarizations of the antiproton beam and proton target, respectively, and the σ_T are the measured total cross sections with the sense of polarizations indicated by the arrows. A similar asymmetry $A_{\perp}$ could be measured for the p and $\bar{p}$ polarized transversely to the incident $\bar{p}$ direction. Each asymmetry could be measured to a precision

$$\delta(A) = \frac{1}{\sqrt{N_{event}}\, P_{\bar{p}}P_p}$$

where N_{event} is the total number of $\bar{p}$ interacting in the target. If the target thickness is chosen so that 20% of the incident $\bar{p}$ interact in the target (a sufficiently small fraction to avoid degradation of the asymmetry by multiple scattering events) and given $P_{\bar{p}} = 0.25$ and $P_p \sim 0.12$, (P_p is a typical value for the effective proton polarization in a hydrocarbon target with 70% hydrogen proton polarization) then in one day of running one can attain

$$\delta(A) = \pm\frac{1}{\sqrt{0.2 \times 3 \times 10^7}\; 0.25 \times 0.12} = \pm 0.01^{*} .$$

* $A_{\parallel}(pp) = 0.15$ ($p_{Lab} = 1.5$ GeV/c)

15.

CONCLUSIONS

I - HISTORY (e^+)

1932 - 72	HEROIC PERIOD
1972 - 85	R(slow e^+) $\sim (10^4 - 10^6)$/sec
	$n(e^+/cm^3) \sim 1$
1985 →	$R \sim 10^8/s$
	$n \sim 10^6/cm^3$

II - FUTURE

INCREASE IN R, n ⇒

1) IMPROVED QUANTUM ELECTRODYNAMICS AND SYMMETRY TESTS.

2) e^+ PLASMA.

3) e^+ IMAGING.

4) ANTI-HYDROGEN.

5) "BOSE-EINSTEIN" CONDENSATION OF POSITRONIUM.

ANTIPROTON CATALYZED FUSION

T. E. KALOGEROPOLOUS

DEPARTMENT OF PHYSICS
SYRACUSE UNIVERSITY

PRESENTED AT THE ANTIPROTON TECHNOLOGY WORKSHOP
HELD AT BROOKHAVEN NATIONAL LABORATORY
10 MAY 1989

T.E.K. / BNL / 5-10-89

$\bar{P}$ CATALYSIS

$$(\bar{P}d) + d \rightarrow \bar{p}(dd)$$

↳ Mesons + 3 NUCLEONS

Charge = +1

EXPECTED RATE (ORDER(?) ESTIMATE)

$$R_{\bar{p}}^{n} \simeq R_{\mu^-} \cdot \frac{\tau_{\bar{p}}^{n}}{\tau_{\mu^-}} \cdot \left(\frac{r_{\mu^-}}{r_{\bar{p}}^{n}}\right)^3$$

$R_{\mu^-} \rightarrow 10^2$

$\frac{\tau_{\bar{p}}^{n}}{\tau_{\mu^-}} \rightarrow (10^{-11}-10^{-13})/10^{-6}$

$\left(\frac{r_{\mu^-}}{r_{\bar{p}}^{n}}\right)^3 \rightarrow \left(\frac{m_{\bar{p}}}{m_{\mu}} \cdot \frac{1}{n^2}\right)^3 \doteq 10^3/n^6$

For $n = 2$

$$\boxed{R_{\bar{p}} \simeq (1-10^{-2})\%}$$

EVIDENCE

- COMPLETE STUDY OF 3223 $\bar{P}$ ANNIHILATIONS (PRL 33, 1631, 1974) RESULTED IN SEVEN "ZOO" EVENTS
- "ZOO" EVENTS ARE NOT:

$$\bar{P} + D \longrightarrow (\bar{p}n) + P_{vis}\ (P_{inv})$$
$$\quad \hookrightarrow \text{MESONS } (Q = -1)$$

OR

$$\longrightarrow (\bar{p}p) + n_{inv.}$$
$$\quad \hookrightarrow \text{mesons } (Q = 0)$$

- TWO INTERESTING EVENTS

$$\bar{P} + {}^4He(dd) \longrightarrow 2P + 3\pi^- + 2\pi^+ + n$$

$$\bar{P} + X \longrightarrow 3P + 3\pi^- + 2\pi^+ + \,?$$

FRAME 285126 EVENT (TWO PROTONS)

$$\bar{p} + {}^4He/2d \to 3\pi^- + 2\pi^+ + 3p + MM^2(-0.3 \pm .04\ GeV^2/c^4)$$

NOT A π!

SPECIAL SCAN FOR "ZOO" EVENTS

- FILM FROM DISTANT RUNNING PERIOD THAN THAT FOR "COMPLETE STUDY".

- TOTAL $\bar{P}$ EVENTS SCANNED 8800

  "ZOO" EVENTS FOUND 21

  $BR(ZOO) = (0.24 \pm 0.05)\%$

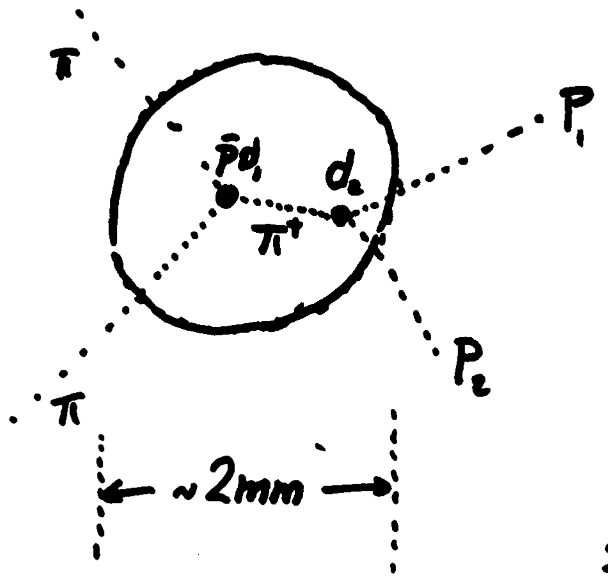
- COMPARES WELL WITH THAT OF COMPLETE SCAN:

  $BR(ZOO) = (0.22 \pm 0.08)\%$

ARE THESE EVENTS EXAMPLES OF

$\bar{P}$- FUSION CATALYSIS?

- **SECONDARY INTERACTIONS: NO!**



1) Rate of '200' events ~100 times the expected rate for secondary interactions

2) $KE(P_1) + KE(P_2) > 140$ MeV which is not satisfied in the two special events

- **CHAMBER CONTAMINANTS SUCH AS N/O ...**

—Typical results of chamber gas in %:

O_2 (0.05); D_2O (0.4); H_2O (0.04); HDO (0.06);

N_2 (0.2).

OTHERS "UNMEASURABLE".

—BUT in D_2-liquid these contaminants should freeze out!

- WHAT ABOUT ^4He?

— From The event which fits $\bar{p}+{}^4He$ we estimate from its a priori probability a Contamination from ^4He of $\sim 10\%$ (!)

— This is not in line with BR("200").

CONCLUSIONS

(1) $\bar{P}$-FUSION CATALYSIS IN LIQUID D_2 OCCURS WITH A RATE $\lesssim 1/100\bar{P}$

(2) IF POSSIBLE ^4He CONTAMINATION AT A LEVEL $\gg 1\%$ COULD BE EXCLUDED THEN A GOOD CANDIDATE EVENT FOR $\bar{P}$ D_2 FUSION INDUCED REACTION HAS BEEN OBSERVED AMONG 3000 ANNIHILATIONS.

(3) SEARCH FOR $\bar{P}$ FUSION CATALYSIS AND ITS PROPERTIES IS A GOOD COMPLIMENTARY RESEARCH TO μ^--CATALYSIS.

ANTIPROTON INDUCED FUSION REACTION

OPTIONS FOR A LABORATORY MICROFUSION FACILITY (LMF)

BRUNO AUGENSTEIN

THE RAND CORPORATION
SANTA MONICA, CA

PRESENTED AT THE ANTIPROTON TECHNOLOGY WORKSHOP
HELD AT BROOKHAVEN NATIONAL LABORATORY
10 MAY 1989

SPECIAL DOE LABORATORY?

BROOKHAVEN MEETING,
MAY 10, 1989

WORKSHOP ON ANTIPROTON TECHNOLOGY

RAND

Bruno Augenstein May 2, 1989—1

DOE LABORATORY MICROFUSION FACILITY (LMF) FOR TESTING

- Valid operational requirement
- Why have an LMF?
  - — Simulate underground explosions in laboratory setting
- Against what contingencies?
  - — Nuclear test ban: complete, or more restricted than current limitations
- No "assured design" yet for meeting LMF requirements

RAND

RAND Vugraphs PC May 2, 1989—2

WHAT CAN DO WE DO WITH AN LMF?

- Maintain nuclear design competence (complement, validate computations)— ideally, with many tests per year
  - — Equation of state; opacity; energy flows; design principles
  - — Exploratory research on new concepts
  - — Effects simulation
- "Laboratory" facility → maximum energy releases in ~1/10 - 1 ton HE range
- Keep core proficiency program going
  - — Prevent technological surprise, breakout

RAND

TWO OPTIONS FOR LMF

CONCEPTUAL STAGE (DOE)

- Very high energy laser, particle beam
  - — Ignite small TN pellet
- TN energy release
  - — 200-1000 MJoules
- Effects simulation
  - — Radiation, EMP, etc.
- Projected cost goals
  - — $700 to 1000 million
- Construction projections
  - — 5-6 years?
  - — Available late 90s?

ALTERNATIVE POSSIBILITY

- Use antiproton source
  - — Based on J. Solem paper ('87 Proceedings)
  - — Additional classified paper (Solem, Mayer, Augenstein)
  - — Other related aspects (Pennsylvania State Group - G. Smith, et al)

(Both options have two distinct regimes:
1. Ignite fuel, very local region;
2. Conditions for sustained propagation of ignition.
2. >> 1. in experimental preparations)

RAND

ANTIPROTON OPTION FOR LMF

- Initial experimentation
  - — Standard initial tools
    - Antiproton source (~10^{14} - 10^{16} antiprotons/year) – use a small fraction
    - Portable storage
  - — Significant Technical issues
    - Space/time compression of antiproton bunch; target configuration; precision diagnostics (much death by normal matter effects.)
    - Parameterized by Solem; Pennsylvania State group
- Broad-scale experimentation (comparable to laser, PB option plans)
  - — Source roughly equivalent to Large Hadron Facility capability
  - — Progress in storage, extraction, post-extraction compression

RAND

RAND Vugraphs PC May 2, 1989—5

LMF RECOMMENDATIONS

- DOE sponsor serious look at antiproton option
  - Comparable ground rules to laser, PB option
- Two cost bases
  - Piggy-back on Large Hadron Facility source, if firmed up; or,
  - Stand-alone source comparable to Large Hadron Facility source
- Evaluate range of simulation experimentation possible
  - Availability for other kinds of experimental uses

(fac. for LMF allows basic science expts. and expts. in other fields – e.g., propulsion, power generation)

- Criteria for antiproton option viability (initial screening)
  - Comparable range of uses
  - Highest cost option (stand-alone source) ≤ laser, PB projections

(reason for belief — highest cost much less than laser, PB costs)

RAND

RAND Vugraphs PC May 2, 1989—6

MODELING ANTIPROTON - PLASMA INTERACTIONS

(ANTIMATTER THRUSTER MODELING)

JOHN L. CALLAS

JET PROPULSION LABORATORY

INTRODUCTION TO CP VIOLATION STUDIES WITH Pbars

D. C. PEASLEE

DEPARTMENT OF PHYSICS AND ASTRONOMY
UNIVERSITY OF MARYLAND

PRESENTED AT THE ANTIPROTON TECHNOLOGY WORKSHOP
HELD AT BROOKHAVEN NATIONAL LABORATORY
10 MAY 1989

CP Violation

Kaon decay (Fitch + Cronin, 1964)

$K_s \to 2\pi, \quad K_L \to 3\pi, \quad \Gamma_L \sim .002\,\Gamma_s$

Limitations:

1) Two parameters only, ϵ and ϵ'.
No other $\not{CP}$ in (u, d, s) at present.

2) Fundamental question unresolved:

i) $|\Delta S| = 2$ only (superweak)

ii) $\begin{cases} |\Delta S| = 1 & \text{(milliweak)} \\ \text{and } |\Delta S| = 2 & \text{by second-order} \end{cases}$

(2)

<u>Hadron decay</u> (T.D. Lee, 1966; Overseth + Pakvasa, 1969)

Non-leptonic,

$$\Xi^- \to \pi^- + \Lambda$$
$$\quad \llcorner\!\!\to \pi^- + p$$

<u>vs.</u>

$$\Xi^+ \to \pi^+ + \bar{\Lambda}$$
$$\quad \llcorner\!\!\to \pi^+ + \bar{p}$$

Compare: decay rate, $\Gamma - \bar{\Gamma}$

$\alpha(\vec{\sigma}\cdot\vec{p})$, $\alpha + \bar{\alpha}$

$\beta(\vec{\sigma}\times\vec{\sigma}'\cdot\vec{p})$, $\beta + \bar{\beta}$

In principle, 3 new measures of ~~CP~~

$\Longrightarrow$ All are $|\Delta S| = 1$

Enabling procedure (Donoghue, 1986)

$$\bar{p}p \to \bar{\Xi}\,\Xi$$
$$\to \bar{\Lambda}\,\Lambda$$

Production: strong interaction, preserves CP

∴ Perfect anticorrelation of initial states,

$$\underset{\sim}{\sigma} = -\underset{\sim}{\bar{\sigma}}, \quad \underset{\sim}{p} = -\underset{\sim}{p}$$

Eliminates major uncertainties.

Estimates for K-M, Higgs, Left-right:

$\Xi \to \pi\Lambda$

$$|\beta+\bar{\beta}| \sim 10^{-4} \text{ to } 10^{-3} \sim 3|\alpha+\bar{\alpha}|$$

$\Lambda \to \pi p$

$$|\beta+\bar{\beta}| \sim 10^{-4} \text{ to } 10^{-3} \sim 7|\alpha+\bar{\alpha}|$$

Implementation

(4)

1) Don't attempt $(\Gamma-\bar{\Gamma})/(\Gamma+\bar{\Gamma}) \sim 10^{-6}$ to 10^{-5}

2) $|\alpha+\bar{\alpha}|_{\Lambda} < |\alpha+\bar{\alpha}|_{\Xi}$ (estimate)

3) $|\beta+\bar{\beta}|_{\Xi}$ only feasible. Λ decay analyzes $\underset{\sim}{\sigma}'$

Conflicting aims:

i) $\sigma_{\Lambda\bar{\Lambda}} \sim 10\, \sigma_{\Xi\bar{\Xi}}$, but CP parameters largest (estimated) for $\Xi\bar{\Xi}$.

ii) For $\Xi\bar{\Xi}$, $|\beta+\bar{\beta}| > |\alpha+\bar{\alpha}|$; but $|\alpha+\bar{\alpha}|$ simpler, perhaps higher acceptance.

LOOKING AT CP INVARIANCE AND QUANTUM MECHANICS IN $J/\psi \to \Lambda\bar{\Lambda}$ DECAY

M.H. TIXIER ET. AL. PHYS. LETT. 212B, 523 (1988)

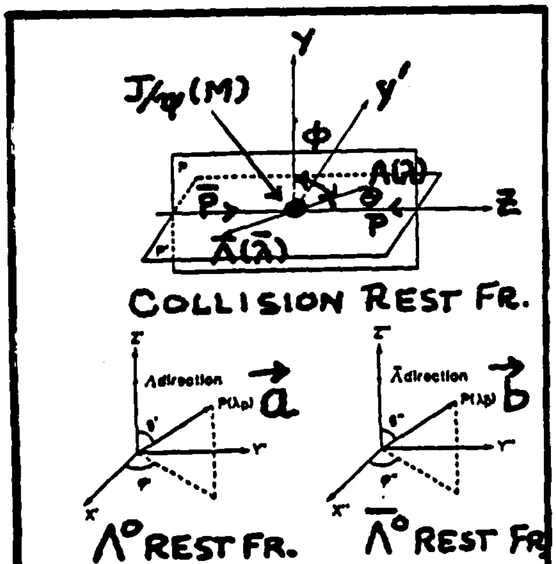

Fig. 1. Λ, Λ̄, p, p̄, π⁺ and π⁻ angles.

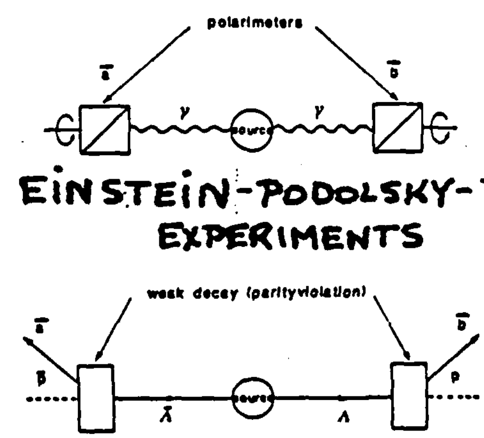

Fig. 2. Analogy between $\Lambda\bar{\Lambda}$ decays and traditional EPR experiments.

N.A. TÖRNQUIST PHYS. LETT. 117B, 1 (1986

$$\frac{\partial\sigma}{\partial\cos\theta\,\partial\Omega'\partial\Omega''} \propto 2\left[1-(P_\Lambda^2/E_\Lambda^2)\sin^2\theta\right](1-\alpha_\Lambda a_n b_n) + (P_\Lambda^2/E_\Lambda^2)\sin^2\theta\left[1-\alpha_\Lambda^2(\vec{a}\cdot\vec{b}-2a_x b_x)\right]$$

1) CP INVARIANT
2) NO ASSUMPTION ON REL. $\Lambda,\bar{\Lambda}$ POLARIZATION

a) $P_\Lambda^2/E_\Lambda^2 = 0.48\,(J/\psi)$, $\alpha_\Lambda^2 = 0.412$

b) $\hat{n}$ orthogonal to $\vec{N}y'$ (J/ψ polarization) and $\hat{x}$

1847 $J/\psi \to \Lambda\bar{\Lambda}$ EVENTS
(8.6×10^6 J/ψ DECAYS

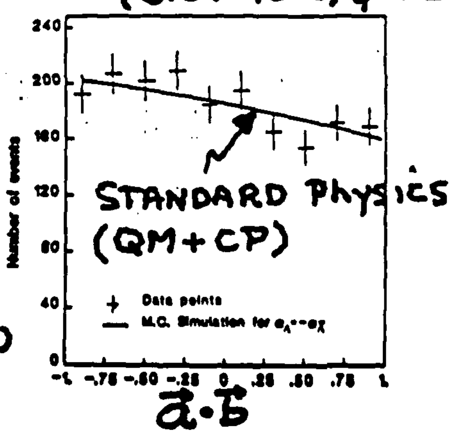

Fig. 7. The a·b distribution. MC simulation and data

TO TEST CP, SET $\alpha_\Lambda^2 = -\alpha_\Lambda\alpha_{\bar{\Lambda}}$. ASSUMING VALIDITY OF Q.M., $\alpha_{\bar{\Lambda}}$ IS EXTRACTED FROM $\vec{a}\cdot\vec{b}$ DISTRIBUTION ⇒
$\alpha = (\alpha + \bar{\alpha})/(\alpha - \bar{\alpha}) = 0.01 \pm 0.10$ (−0.07 ± 0.09, P. BARNES ET. AL. PHYS. ...

FURTHER TESTS OF CP INVARIANCE IN $J/\psi \to \Lambda^0 \bar{\Lambda}^0$

1) GOAL: 10^{-4} ERROR IN A

2) PRESENT LIMITS: $\sim 10^{-1}$

3) FIRST STEP $\Rightarrow 10^{-2}$

1) J. DONOGHUE ET AL, PR D34, 833 (1986)

2) L. WOLFENSTEIN, ANN. REV. NUCL. PART. SCI 36, 137 (1986)

E-760: $\text{RATE} \simeq (5 \times 10^{31}\, cm^{-2} s^{-1})(10^{-30}\, cm^2)(0.13 \times 10^{-2})$ [BR $J/\psi \to \Lambda\bar{\Lambda}$]

$* (0.64)(0.64) = 0.027\ SEC^{-1}$ [BR $\Lambda \to p\pi^-$, $\bar{\Lambda}^0 \to \bar{p}\pi^+$]

EXTRAPOLATE DM2 RESULTS (2×10^3 EVTS.) TO 10^{-2} LEVEL (2×10^5 EVENTS)

$$\frac{2 \times 10^5\ EVTS}{0.027\ SEC^{-1}} \Rightarrow 7.4 \times 10^6\ SEC\ (2.8\ \text{months})$$

WILL PROBABLY GET DONE FOR FREE (SYSTEMATIC ERRORS ??)

4) NEXT STEP $\Rightarrow 10^{-3}$

REQUIRES 2×10^7 $J/\psi \to \Lambda^0\bar{\Lambda}^0$, OR $\sim 10^{10}$ J/ψ's !!

J/ψ FACTORY @ $\mathcal{L} \simeq 10^{33}\, cm^{-2}\, sec^{-1}$

BEST BET IS PROBABLY e^-e^+ LINEAR COLLIDER?

PRODUCTION OF $J^{\pi C}$ EXOTICS IN $\bar{N}N \rightarrow$ mesons

PRODUCTION OF $J^{\pi C}$ EXOTICS IN $\bar{N}N \rightarrow$ mesons

What is a $J^{\pi C}$ exotic meson?

J = total angular momentum
π = parity $(\pm)$
C = charge conjugation parity $(\pm)$

$J^{\pi C}$ exotic quantum numbers cannot correspond to a quark-antiquark $(Q\bar{Q})$ system as for ordinary mesons $(\pi, \eta, \rho, \omega \cdots)$

Examples: $J^{\pi C} = 0^{--}, 0^{+-}, 1^{-+}$ are exotic

⇝ must have more complicated structure than $Q\bar{Q}$ ⇝ $Q^2\bar{Q}^2$, $Q\bar{Q}g$ ....

↑ excitation of the gluonic field

THEORETICAL PREDICTIONS FOR MASSES OF EXOTIC

consider $Q\bar{Q}g$ "hybrids" $(0^{-+} \text{ or } 1^{--})_{Q\bar{Q}} \otimes \begin{cases} TE\ (1^{+-}) \\ TM\ (1^{--}) \end{cases}$

$\uparrow\ {}^1S_0 \qquad \uparrow\ {}^3S_1$

lowest lying are ${}^3S_1 \otimes TE = \begin{cases} 1^{-+}\ (1^-) & \rho_g \\ 1^{-+}\ (0^+) & \omega_g \end{cases}$

Mass Estimates and Decays:

1) MIT Bag Model (Barnes, Close, deViron, NP B224, 241 (1983)

$M(\rho_g) \approx 1.4\ \text{GeV}$, $M(\omega_g) \approx 1.55\ \text{GeV}$

(Chanowitz, Sharpe NP B222, 211 (1983) give larger M's but ≈ same splitting)

2) Flux Tube Model (Isgur, Kokoski, Paton, PRL 54, 869 (1985))

$M(\rho_g) \approx M(\omega_g) \approx 1.9\ \text{GeV}$ [also $0^{+-}(0^-, 1^+)$, $2^{+-}(0^-, 1$

Selection Rules: $\rho_g \to \pi^{\pm} B^{\mp}, \pi^0 D$; $\rho_g \not\to \pi\eta, \pi\rho, \rho\omega, K^*$

3) QCD Sum Rules (Latorre et al, Z. Phys. C34, 347 ('87

$M(\rho_g) \approx 1.6 - 2.1\ \text{GeV}$

$\rho_g \to \pi\rho, K^*\bar{K}$ large, $\rho_g \to \pi\eta, \pi\eta'$ suppressed

Candidate for a J^{PC} exotic resonance:

D. Alde et al, Phys. Lett. B205, 397 (1988)

reaction $\pi^- p \to X^0 n$
$\quad\quad\quad\quad\hookrightarrow \pi^0 \eta \; (\ell = 1)$

X^0 seen as interference effect (asymmetry) with $\pi^- p \to A_2^0 n$
$\quad\quad\quad\quad\hookrightarrow \pi^0 \eta \; (\ell = 2)$

X^0 is $\boxed{J^{PC}(I^G) = 1^{-+}(1^-)}$ exotic

$M = 1406 \pm 20$ MeV, $\Gamma = 180 \pm 30$ MeV

Note: X should be accessible in $\bar{N}N \to \pi X$

$\hookrightarrow$ look for optimum channels

Experimental Searches for Exotics

1) LEAR at CERN

JETSET, CRYSTAL BARREL, OBELIX

2) Brookhaven AGS E818 Chung et al

$\pi^- p \to \rho_g^- p$ at 12 GeV/c

Decay chain: $\rho_g^- \to \pi^- f$, $f \to \delta^+ \pi^-$, $\delta^+ \to K^+ \bar{K}^0$, $\bar{K}^0 \to \pi^+ \pi^-$

overall reaction $\pi^- p \to K^+ \pi^- 3\pi^- p$

3) KEK (Japan)

$\pi^- p \to \rho_g^- p$ at 6 GeV/c

Decay chain: $\rho_g^- \to \pi^- \eta$, $\eta \to 2\gamma$

Search for $1^{-+}(1^-)$ exotic in $\bar{p}p \to \pi^0\pi^0\eta$

SIGNAL: $\bar{p}p\,(^1S_0) \to \pi^0 X^0\ (\ell_f = 1)$
$\quad\quad X^0 \hookrightarrow \pi^0\eta\ (\ell = 1)$

BACKGROUND: $\bar{p}p\,(^1S_0) \to \pi^0 A_2^0\ (\ell_f = 2)$
$\quad\quad A_2^0 \hookrightarrow \pi^0\eta\ (\ell = 2)$

$\bar{p}p\,(^1S_0) \to \pi^0 \delta^0\ (\ell_f = 0)$
$\quad\quad \delta^0 \hookrightarrow \pi^0\eta\ (\ell = 0)$

also $\sigma\eta\,(\ell_f = 0)$, $f\eta\,(\ell_f = 2)$ couple to $\pi^0\pi^0\eta$

Experimentally, look for $\pi^0\pi^0\eta \to \underline{6\gamma}$ (CRYSTAL BARREL)

Exotics in $\bar{p}p$ Annihilation:

A) All neutral modes

1) $\bar{p}p \to \pi^0 \omega_g \rightsquigarrow 2\pi^0 \, (\ell_f = 1)$ — $\pi^0 f$, $\pi^0 \sigma$ backgr.

2) $\bar{p}p \to \pi^0 \omega_g \rightsquigarrow \eta\eta \, (\ell_f = 1)$

3) $\bar{p}p \to \pi^0 \rho_g^0 \rightsquigarrow \pi^0 \eta \, (\ell_f = 1)$

4) $\bar{p}p \to \pi^0 \rho_g^0 \rightsquigarrow \pi^0 f \, (\ell_f = 2)$, $f \rightsquigarrow 2\pi^0$

B) Charged Modes:

1) $\bar{p}p \to \pi^\pm \rho_g^\mp \rightsquigarrow \pi^\mp B^0 \rightsquigarrow \pi^0 \omega \rightsquigarrow \pi^0 \gamma$ — CRYSTAL BARREL

2) $\bar{p}p \to \pi^\pm \rho_g^\mp \rightsquigarrow \pi^\mp D^0 \rightsquigarrow \pi^0 \pi^0 \eta$

3) $\bar{p}p \to \pi^\pm \rho_g^\mp \rightsquigarrow \pi^\mp \rho^0 \rightsquigarrow \pi^+ \pi^-$

Outlook: $N\bar{N}$ annihilation very promising as a means of producing exotic mesons X in reactions $N\bar{N} \to \pi X$

Difficulties:

1) Γ_X large ⇝ new states are broad resonance
⇝ detailed amplitude analysis need to extract interference effects

2) branching ratios for $N\bar{N} \to \pi X$ likely to be smal
⇝ no good theoretical estimate

Advantages:

1) $N\bar{N}$ annihilation potentially rich in gluonic excitations

2) $N\bar{N}$ at rest provides control of initial quantum numbers ($L=0$ or $L=1$)

3) $\bar{p}p \to \pi^0 X^0, \pi^{\pm} X^{\mp}$; $\bar{p}n \to \pi^- X^0$ gives quantum number filtration

Central Collision

Xf spectrum concentrated to low Xf region

Recent Cern Experiment of Ox-Pb Collision

Pion Production 240 at 200 Gev *Hydrodynamic*
107 Venus Calculation
300 Venus Central

Successive Collisions Increase P production

spectator Nucleus *~ 2 times of Proton collision*
Multiple collision *$\pi \to \bar{P}$.*

Modification of Venus Code

- Important Sampling Method
- Russian Roulett,

Careful Choice of Parameter is required

Two Calculations of Collision Events

- Creation of the string
- The fragmentation of Strings
- Convolution of two functions

More Sophisticated model

- Flux Tube model
- Quark Gluon Plasma Formation

Dynamics of Plasma expansion and Hadronization
Heinz et al Theory

- Fragmentation model using string model.

- *Baldin et al.* *C - Cu (3.8 GeV/A) $\bar{P}/\pi^-$ ratio 60 times of P. nucleus collision.*
