XNUSIM - Graphical Interface for a Multiprocessor Simulator

Pang, Swee-Chee

Computer Science Division Department of Electrical Engineering and Computer Science University of California, Berkeley, California 94720

Abstract

Xnusim is an X11 Window Interface for the Multi-Processor simulator Nusim. It is a display oriented interface between the simulator and the user via *UNIX¹sockets* with graphical objects such as menus, buttons etc. It is designed in such a way that would allow it to be used with other simulators of the same class. This paper intends to describe the functionality of the objects, structures and program modules of XNUSIM in detail.

Section 1

Introduction

Xnusim was built with the intention of giving Nusim a more visual interface. Nusim[NC89] is a simulator for the PPP (Parallel Prolog Processor) [Fag87] which is part of the Aquarius Project, at the University of California at Berkeley[DS88]. However, aside from knowing the input-output semantics and the kinds of commands nusim accepts (refer Section 5), Xnusim does not require knowledge of what level simulation is performed and what kinds of details are involved in the simulator, so long as it adhere to some fixed set of criteria which will be presented at the concluding section (Section 6).

Due to this method of interface, xnusim should not be difficult to be converted to interface with other simulators, especially if care is taken in writing a simulator with similar debugging capabilities. Section 5 will describe methods of interfacing with xnusim, changes that can be easily made, and will also outline the criteria for writing a compatible simulator.

Xnusim is an interface built on top of the X Toolkit Library [MAS89] under X Protocol Version 11 Revision 3¹[GSN89, SG86]. A brief introduction into the X11R3 Windowing system and the XToolkit along with some of the other software used will be presented in Section 2. In this same section, the 4.3BSD Communication Protocol [LMKQ89] will also be discussed; to be specific, the use of sockets which is what xnusim uses to communicate with nusim.

¹The X Window System is a trademark of MIT. Copyright ©1985, 1986, 1987, 1988 Massachusetts Institute of Technology, Cambridge, Massachusetts, and Digital Equipment Corporation, Maynard, Massachusetts.

Section 3 will present an overview of xnusim, while Section 4 will explain the technical details that makes up the complete xnusim program set. The concluding section will discuss improvements possible or desirable. Attached as appendixes are the man page, a list of xnusim's procedures and files where they may be found and after that, a list of the entire xnusim program in C.

Section 2

General System Requirements and Overview

2.1 X Window System

The X Window System[SG86] was designed by MIT as a windowing system which runs under 4.3BSD UNIX and several other variants and has since become available for the VAX/VMS, MS-DOS and other operating systems as well. The display server is a network-transparent interface that accepts output requests from various client programs and handles user input which could be of the form of keyboard or mouse events. The client programs need not necessarily be located on the same machine. The version of X used is the X Protocol Version 11 Revision 3 System (X11R3) [GSN89]. Xnusim cannot be used with X of a lower protocol system since it makes use of certain features which had become available only in the X11R3 system. It is conceivable that it will run on later releases with minor or no changes at all.

In order to more easily implement the system, the X Toolkit[MAS89] was used. It is also believed that although much of the X11 system might be changed with latter releases, updates and bug fixes, the X Toolkit is a relatively stable application package and utilizing it instead of direct interface to the X11 system calls would render the software more lasting and less reliant on the system and the update versions.

The X Toolkit Intrinsics, redesigned for the X11R3 windowing system, is intended

to provide some basic mechanism to build sets of *widgets* for any application environment. A widget is the fundamental abstraction and data type of the X Toolkit and can be visualized as a blackbox state machine with associated input/output semantics. Some widgets display information like text or graphics while others may serve as a container for other widgets The Intrinsics is built on top of Xlib and serves as an abstract, object based extension to the X Window System. X Toolkit provides an interface which is consistent throughout, and a small set of intrinsics easily used to write applications and at the same time provides those same set of Intrinsics suitable for building other widgets. Because of the way the Intrinsics is designed, constructing other widgets is almost trivial.

In writing xnusim, extra widgets such as the "Scroll" and "MenuBox" widgets were constructed and used along with the basic X Toolkit Intrinsics. Documentation for these two widgets are available as part of the distribution for these new widgets, or may be found, respectively, in the subdirectories "Scroll" and "MenuBox" under the "xnusim" directory.

2.2 UNIX 4.3BSD Communication Protocol

One of the many features in UNIX 4.3BSD is that of interprocess communciation (IPC)[LFJ+86, LMKQ89]. It provides capabilities from network level to process level communications via relatively simple and transparent means. The 4.3BSD IPC allows different processes to communicate via many different ways and levels.

For the purpose of xnusim, communication was needed between that of xnusim and the nusim simulator. Nusim was designed primarily without considerations of whether a higher level interface was available and used, and takes it's input and output from the terminal. Since one of the goals of xnusim was to provide an interface that was invisible to the simulator as well, the most appropriate means of communication was thought to be that of *pseudo terminals*. The pseudo terminal model has two parts: a master and a slave terminal part.

The main process, for example, xnusim, may send data, in our example, this could be a command to nusim, through the master side which will be passed to the slave

SECTION 2. GENERAL SYSTEM REQUIREMENTS AND OVERVIEW

"terminal" as stdin. Any process (nusim) which exist at the slave end will then be able to pick this data up as normal standard input. Similarly, the process at the slave end may output to either standard error or standard output (stderr and stdout respectively) and these will be picked up at the master end as data from the slave and may then be processed accordingly (like output into the main window etc).

Using this method of communication, nusim is completely oblivious to the existence of a process image of xnusim executing above and controlling it.

Section 3

Overview of Xnusim and User Reference

3.1 Design Considerations

Xnusim was designed as an interface to nusim, but it was also desired that xnusim be sufficiently flexible to be easily adapted to other simulators. Therefore, an interface that was loosely coupled to the simulator was decided upon. Loosely coupled in the sense that the simulator has no knowledge of the existence of xnusim, and xnusim has little knowledge of the workings of the simulator. And what little xnusim needs to know about nusim in order to function was localized into specific parts, so as to minimize the modifications necessary to allow it to further with other simulators.

Figure 3.1 is a simple construction of the visualization of the design consideration for xnusim. In the figure, xnusim communicates with the user via the X11R3 window system, through the use of menus, command buttons, and keyboard entries. All these are processed by the window system before passing down to xnusim. Xnusim communicates with the simulator (through IPC) in such a fashion that the simulator thinks it is in direct communcation with the user.

This method of communication gives the most flexibility to xnusim and also frees the programmer of the actual simulator (nusim) from needing to put the interface into consideration when designing the simulator.

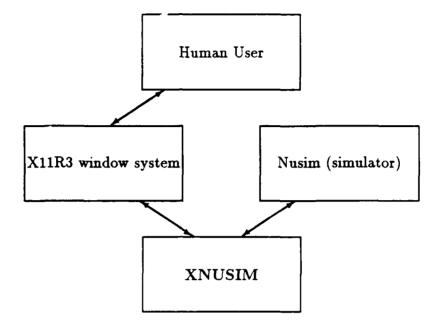

Figure 3.1: XNUSIM's communication virtual view

The main objective of xnusim is to provide a graphical interface which is capable of supporting a parallel processor simulator and give the user a visual and easy to understand mouse-menu oriented system. The behavior of the simulated programs can be studied by observing the processors/tasks displayed by xnusim. Therefore, the capability of displaying information for multiple processor and tasks was necessary. But the user must be given an option to choose the number and which of the processor/task(s) to display at will since the use of single screen display limits the amount of information possible (xnusim can be easily reconfigured to display on multiple screens).

3.2 Windows

Xnusim is a window oriented display, and manages several windows, which are, technically speaking, actually widgets. And for the purpose of this section they will be used interchangeably unless specifically mentioned otherwise, due to subtle technical differences. Upon startup, a large window appears which contains several subwindows, menu-windows

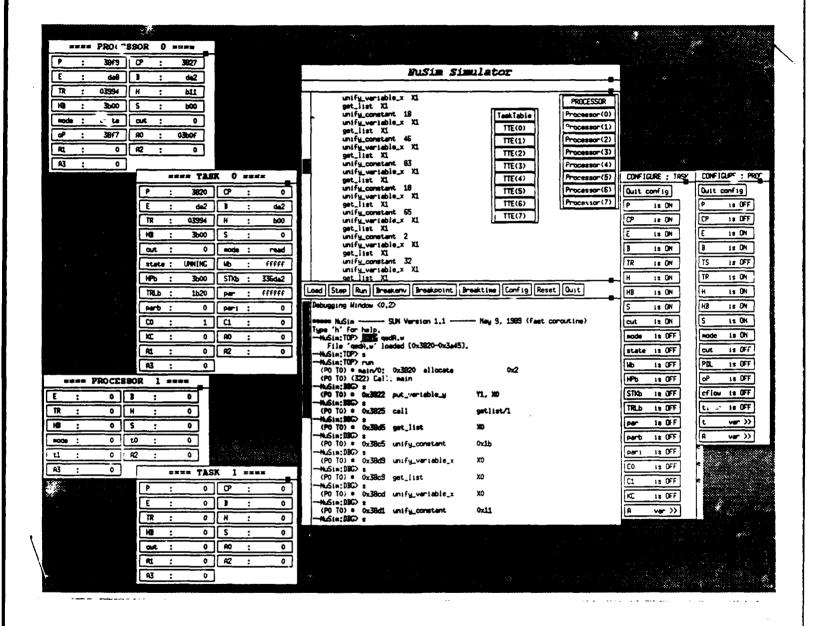

Figure 3.2: XNUSIM's screendump of all stable windows

SECTION 3. OVERVIEW OF XNUSIM

may appear on request and also windows for configuration and a window each for individual task/process that the user chooses to display. The following subsections will discuss each of the type of windows. Figure 3.2 shows a diagram of most of XNUSIM's windows, and it is suggested that this be used for cross-referencing the description to follow. In this figure xnusim's "stable" windows are displayed. Ey stable windows, it is meant that the windows will not disappear the moment the mouse leaves that window. The step sized has been set to 2 in the figure as can be noted by comparing the step display in the main debugging window and the listing window.

3.2.1 Main Window I: Titlebar

The titlebar widget shows the title currently assigned to nusim (easily changed in "defaults.h" as "SimulatorName"), but also serve as the sensitive point for starting up of the main menu which allows the display of processors and tasks.

3.2.2 Main Window II: Helpbar

The help widget simply display any error message or messages explaining the use or name of the window that the mouse is in.

3.2.3 Main Window III: Listing Window

This window is where the program(s) being simulated is loaded into. There is a cursor in the window which will always be updated to point to the current instruction being executed after each "step" or "run" instruction. The user may reposition the cursor anywhere and then set breakpoints at the position where the cursor is (refer 3.2.4). Nested (or include) files are listed one after the other in the window, in the order by which the simulator returns them.

3.2.4 Main Window IV: Command Window

The command window consists of several command buttons, and all these commands may be activated by pressing the left mouse button (unless otherwise reconfigured)

on that command button. Below is a short description and explanation of the command buttons as they appear in xnusim.

- Load Pressing this button will create a dialog widget where you may enter the filename of the byte compiled program which you wish to simulate.
- Step Pressing this button makes xnusim step the simulator n times where n may be configured under the config option (see below).
- Run Pressing this button for the first time sends the "run" command and subsequently it will send the "c" command (for continue) which will cause the simulator to run itself until the end, an error or a stop point. Pressing reset (see below) will cause it to send the "run" command the first time this button is activated after that.
- Breakenv A dialog window with two inputs, one for process environment, and the other for task environment, will pop up and the user may change them. A return key at either input line ends this function.
- **Breakpoint** A menu listing whether the user wishes to select setting trace/break points at the current cursor position or wishes to input his own trace/break points and a list of all deletion options currently available will be displayed. Of the list of options offered, if no breakpoints were set, the list of deletion options is empty; if only one break/trace point was set, the list has only that member; and if more than one were set, the list has the "delete all" option as well.

Breaktime A dialog window will be available to set the breaktime (or delete it).

All three are updated at the point of pressing the button, so the user may set/change these on the main debugging window (refer Subsection refdebugwin) and the updates will be available here as well.

Config This button activates the config window which currently contains 3 parts:

- Step Where a dialog window will pop up for the selection of the number of steps which the step button will perform.

- Processor A configuration list of all known registers for the processor module will be listed with their current display status (ON : display; OFF : not dislayed) or, if they're variable (eg A[0-7]), the arrow in place of the ON/OFF display will indicate that going there will make another window pop up showing which of the variable number (MAXNUM set in "processor.h") register is being displayed. The user may press on these button to update the display status of that register. Update is instantaneous and the user may leave this window active while selecting a new processor to display. As a policy decision, processors already being displayed will not have these update affect them. In reference to figure reffull-window1 Processor 0 and Task 0 in the figure were activated with the default registers selection and Processor 1 and Task 1 were activated after the set up change (compare with the "Configure" windows on right side of the figure which displays the register setup for the new processor and task and not the default).
- Task Similar to the processor module.
- **Reset** Terminates nusim and restarts it. This allows the user to be able to start with a clean copy of nusim without the need to quit xnusim and then re-setup the task/processor and other display features.
- Quit Simple enough: quits xnusim.

3.2.5 Main Window V: Main Debugging Window

This window is where the user will see the bulk of the activity occur. The communication between xnusim and nusim will be displayed here, and the user may edit and type in line commands to nusim directly from here too.

Section 4

Technical Details: Layout of Xnusim

4.1 Introduction

Xnusim is made up of and 2 widget library files and 14 files, 7 of which are "header" (".h") files, The library files have their own description and references, so this section will be mainly describing the 14 files. The names of procedures used in xnusim are shown in *Appendix A*. The manual page for xnusim is found in *Appendix B*. The actual listings of the 14 files are in *Appendix C*. Of these 14 files, 2 of them, *general.c* and *general.h*, are files which are useful for any program since commonly needed routines are placed there.

4.2 Descriptions of Individual Files

• general.c and general.h

The two files define the general routines that may be used for almost any application. Routines there maybe found in any good C book. Included are definitions for CALLOC, MALLOC, LARGE and forever which speak for themselves, min and max which return the larger/smaller of two, error which prints an error message and may quit if desired, inchr and instr which checks if a certain charactor/substring is in another string, and hextoi and itohex which converts between hexadecimal numbers and decimal numbers.

SECTION 4. TECHNICAL DESCRIPTION

• defaults.h

In this file is all the default names and sizes used by xnusim, and would probably be changed by the user when porting and re-adapting xnusim for other purposes. This file is needed by all the other files to get their default sizes, fonts and name used.

• interface.h

The file which is definitely sensitive to the kind of simulator used. Defined in here are the types of commands recognized, what is a PROMPT, and the functions available for general use by other files.

• mainmenu.h

Defines the window information and callback functions for the main menu (refer Section 3.2.1).

• manager.h

Basic definitions for Xtoolkit functions.

• menucmd.h

This is the Window counterpart to *interface.h.* It defines the commands which appear in the command window (refer Section 3.2.4) and the functions to call (in *handler.c*) when that command button is activated¹.

For both menu windows (main menu and command window), there is a help information which is displayed whenever the mouse enters that button. This help information is displayed in the help window (refer Section 3.2.2).

• processor.h

¹A button is termed "activated" when the mouse is placed at that button widget and the activation button, normally the left mouse button, is pressed.

SECTION 4. TECHNICAL DESCRIPTION

This should be more appropriately called $processor_and_task.h$, but this name was chosen as it is sufficiently long without being awkward. This file defines the maximum processors and tasks registers and what they are, and also defines the number of variable number register². It also defines the default registers of the entire set which is activated.

• handler.c

A common module for any Xtoolkit application program. All the functions that are called when the commands and menu buttons on xnusim are activated are described here. This probably needs to be modified whenever the commands are changed, but modifications could be simply cut and paste since most forms of buttons are available, and any programmer sufficiently versed in C and X11 will immediately recognize the order of changes. Most of these makes calls to the *interface.c* module (most probably via the *sendMsg* procedure) which does most of simulator dependent work. Most likely to change are the "Break" series of buttons since these were made specifically for nusim. But it was deemed necessary. This module has to be changed when it becomes desirable to interface xnusim with other simulators.

• interface.c

All of the simulator dependent functions are found here (except for those related to processors and tasks some of which may be found in the *misc.c* file). A more detailed discussion of some of the functions in this module is in order and the user is referred to *Section 5* for that. This file is the crux of the interface between nusim and xnusim. All of xnusim's calls from the user eventually ends up to some routine in this file. There is a routine (*MainDo*) which will recognize nusim's output and calls the appropriate routine (most probably also in this file) to update it's values, like the listing window (on load and step/run) and the processor/task windows (*misc.c* involved). It is possible to drop *misc.c* and attach these functions here, but it was decided to localize all processor/task related function to a file.

²For the purpose of this paper, a "variable number register" is a register with suffixes from 0 to a maximum number defined in that file, like the "A" register which may have suffixes from 0 to 7 thus "A0"–"A7"

• main.c

Does the initial command line interpretation, performs the necessary "forking" of processes and executes each correctly. Trap for exit errors is also found in this file. The user is referred to the xnusim's manual page for the list of options available.

• manager.c

This is the main file for interfacing to Xtoolkit. It does the initial and main graphics set up for xnusim, defines each window, and their components and then display them. It also starts the infinite loop that executes xnusim's part of the Xtoolkit interface.

• misc.c

This file defines all of the modules needed for the processor and task subwindows. The processor and task windows are similar in nature, merely differing in names and actual register set. Thus, modifying one would imply modifying the other (refer to Section 5 for details on modification). The file contains the functions which pop up each processor/task window, the functions called when the values need to be updated, and the functions called when there is some configuration necessary for the register sets for the processor/task windows.

4.3 Interaction of Xnusim's Modules

To understand the interaction between these modules (files), the user should get familiar Appendix A that lists the functions, and which files contain these functions. To give a general view of the module's interaction, consider when the user types in a command . or presses a button. The eternal loop in manager.c captures that "event"³, then the related functions are called.

The key events are now described:

³events are any form of action related to the widgets, including exposure, kevboard input, mouse input, size change etc

- If the event is a keyboard input in main window, these functions are found in manager.c which is called and then returned to the eternal loop (forever line), unless the "return" key is hit, whereby the keyboard interpretation function in manager.c will call interface.c which will transmit that command to nusim, and then the eternal loop will be returned.
- If the event was that of a button pushed, then the functions in handler.c will be called which eventually (perhaps after some menu which are found in handler.c) will call *interface.c* which will again transmit that command to nusim, and then return to the eternal loop (in manager.c). If, however, this button was to perform some function with task/processor windows, the file misc.c will be called instead of the *interface.c*. Besides configuration, however, misc.c will eventually also call *interface.c*.

If there is any output from nusim, then as part of the eternal loop, the MainDo function in *interface.c* is called. Here, the function will detect the reply, does some simple interpretation and then pass it on to the appropriate functions in *interface.c*. When these functions return, it will then call the processor/task windows to update the appropriate table. Note that these will be done *iff* an output from nusim is expected.

A detail missing from the description is that whenever read and write is performed, the functions MessageRead/Write of main.c will be eventually called which does the raw block transfer between xnusim and nusim. These are NOT simulator dependent since they merely transfer the raw bytes from the master terminal to the slave terminal and vice versa.

Section 5

Interfacing Xnusim to Other Simulators

5.1 Introduction

As xnusim was designed, it was decided that a desirable feature would be to make xnusim sufficiently general that it would be easy to modify it to work with other simulators. Therefore xnusim was designed so that it made as little assumption on the way the simulator performs as possible. Also due to this, the simulator dependent functions have been localized to only a few modules. This section intends to outline these modules and methods of modifications that would allow xnusim to work with other simulators that adhere to the assumptions listed below.

- The simulator is assumed to have at most multiple processors and tasks of the same class, ie, all processors are homogeneous in terms of register sets, and similarly for tasks. In this class of simulator is included those simulators which have single task and single processor and those with either multiple tasks or processors which are homogeneous.
- Upon receiving any command, the simulator is assumed to output some feedback messages which always end with some predefined prompt. This feedback scheme is necessary only so that xnusim may perform updates correctly, while the predefined

prompt is used by xnusim to recognize that nusim has stopped sending output. For this reason, the simulator would need to have some fixed number of prompts to function properly.

- The simulator is assumed to need to load some source file which is in ascii format. Of this loaded format, it is assumed that the simulator will deal with the simulator at that level as well (It may or may not deal with other levels of coding). This is required to ensure that the listing window will perform some useful update with the source code that is loaded. Nested files and/or include files can be handled as well.
- It is also assumed that the simulator has command(s) that will enable xnusim to enquire about the status of the processor/tasks registers, current simulator position in source code, break points set.

Of course, these may or may not remain valid depending on the level of changes made to xnusim, but the simplest changes are necessary for those simulators adhering to the criteria given. The following section will discuss specifically how to modify xnusim to interface to simulators agreeing with those above.

5.2 Modifying The Interfacing Module

There are basically three things that need to be modified in xnusim to interface to the new simulator. The first is the way xnusim interpretes an output from the simulator, since it is expected that the simulators would definitely defer there. The modifications will be localized in the file *interface.c* in this case, and some changes to the file *misc.c*. The second is the names of registers for processors/tasks. This is only in *processor.h*. The third is the command buttons and the way they are handled. This is in the module *menucmd.h* and *handler.c*.

5.2.1 Simulator Communication

Most of the simulator interpretation is located in just one file, *interface.c.* The only other file is *misc.c* which has two procedures (one in *updateTask* and the other in

SECTION 5. INTERFACING TO XNUSIM

updateProc) that are dependent to simulators.

The two procedures in misc.c are images of each other, following the philosophy of treating tasks and processors similarly in this simulator, so description of only one is necessary. The procedure update Task first sends a command to the simulator to print out the current register condition for the specific task. The simulator's output is assumed to be of the form¹:

{({<SPC>*<REG>':'<SPC>*<VAL><SPC>*}*<rubbish>*)*'\n'}*

If the simulator output differs, then this procedure will have to be modified.

The file *interface.c* is where the major changes would be required. (Remember to change *interface.h* if necessary) Below is a quick discussion of most of the procedures, the rest would be self-evident after these.

needline: Probably would not need to be changed unless there is a change in which the interpreter is supposed to perceive an "end of output stream" from the simulator, which currently is when it reads a line ending with the PROMPT. It returns a line that is read each time.

doload: Needs to change only the part which sends the "load" command *iff* the simulator does not accept the command sequence of "load filename".

loadprocess: Parses through the buf variable passed (raw bytes read in). It assumes the buffer to be of the form:

```
{<rubbish>'\''<FILENAME'\''<rubbish>'['<SPC>*<ADR><SPC>*'-'<SPC>*<ADR>.SPC>*}*
```

where ADR is assumed to be a hex address (see procedure gethex) and the content is assumed to be the filename and the starting address and ending address of the file as it is loaded in memory. (This probably would need changing for another simulator) Once it gets the filename, it loads the file into the listing buffer, while updating the count of number of lines and where each line is in the charactor array that makes up the listing buffer. The loading part do not need to be changed. Next it tells the simulator to list it's version of the code, and then try matching it according to the file it loaded. It assumes the list to be of the format:

{<ADR><SPC>*':'<SPC>*<CODE><rubbish>'\n'}*

¹Expressed as a regular expression, where SPC is white space, REG is register name, and VAL is value of register

SECTION 5. INTERFACING TO XNUSIM

And will then match the lines according to this listing, line by line. It thus assumes the simulator will NOT modify the code as it is loaded. If the simulator does so, xnusim will run, but will not be able to update the listing window pointer accurately and may produce unpredictable results.

updateenv, updatebreaktm: These are also reliant on simulator and are quite similar, assuming the same command in the simulator will provide information for both, but on different lines. Code is simple enough to understand.

updatebreakpt: This assumes the first line would have a ':' if there had been any breakpoints set, otherwise it returns. Simulator should output breakpoints of the format:

{digit>+'.'[(<rubbish>':')U()]<ADR><SPC>*'('['b'U't']')'<rubbish>'\n'}*

Where address is the hexadecimal address of where the breakpoint is set, and the 'b' or 't' charactor indicates whether it is a break or trace point. This module probabley needs to be changed for other simulators.

sendMsg: The function which is most important in communicating to the simulator. Does multiple command communication to the simulator. For each command, it sends the command and then returns. For some commands it sends the command multiple number of times.

MainDo: This function is the loop that will read an output from the simulator if it is expected, and assumes there will be no more output for the time when it sees the PROMPT, and will also branch to the *loadprocess* and *updateProc/Task* procedures. It also respositions the listing window if it detects movement in the pointer in the simulator. Therefore, it is necessary to have the simulator output some address information if there is to be consistent update for the listing window with the actual stepping of the simulator.

The changes in *misc.c* and *interface.c* will not affect the execution of other parts if the information returned and variables accepted are the same. It is believed that regularity and special keyword output from the simulator would make *interface.c* module relatively simple.

5.2.2 Register names

The file that needs to be changed is processor.h. For the purpose of xnusim, two kinds of registers are distinguished. The normal ones and those with variable number, like A[0-7] for nusim. The constants which control the number of registers and the number of variable registers are self-documented in that file. The names of each register for processor are in proc and those for task are in tte, both of which are charactor string arrays. Merely type in the names (remember to change MAXLEN if there are reasons to use registers name with more charactors than those defined there) in double quotes.

The variables process for processors and ttestat for tasks define the initial display information for xnusim's processor/task set. They define whether the corresponding register defined in proc or tte is, by default, being displayed, not being displayed or a variable register type. If it is the variable type, the number indicates the index (+1) into the corresponding procvar or ttevar arrays where the same displayed or not displayed information, as applied to variable registers, may be found.

5.2.3 Buttons

The last thing that probably needs to be changed is the handler.c module which handles the button responses. For each button that is changed, there is probably need to change the menucmd.h file which contains the names of the buttons and the functions they call. The comments in menucmd.h would be sufficient to modify that file. In order to modify the file handler.c, some knowledge of Xtoolkit is necessary. Since only basic functions like XtSetValues, XtPopup, XtAddEventHandler etc are used, basic knowledge of Xtoolkit and X11 system would be sufficient to understand and modify this module.

Section 6

Conclusion

6.1 Summary

This paper outlines the entire project for Xnusim, which started as a simple interface for a simulator under development at that time but developed into a general debugger interface. The paper covered the areas of what xnusim is, how xnusim is designed, what to modify when changes are needed, and what kind of support xnusim gives to and requires from the simulator.

Xnusim would definitely provide an environment that will ease the user from the need to keep track of several processors and tasks, and would make it easier for the user to debug the source code and understand how the parallelism functions because it displays most of the essential information via windows and allow the user to perform several tasks via simple button clicking.

Xnusim has been shown to be a powerful interface tool for simulators. Writing a simulator that is graphics in nature limits its used to that graphics environment. Writing a simulator without graphics capability makes studying parallelism and debugging source code a cumbersome process. Thus, xnusim serves as a solution to this seeming conflict. The simulator may still be used in non-graphics environment or any environment of a different nature, but when desired, xnusim will serve as the graphical link which will solve the second part of the problem.

6.2 Future Development

Many improvements are possible to xnusim. Some of them are outlined below.

- I Xnusim should become much more user friendly, for example, the "loading" (which could perform directory listing) command.
- II Xnusim's interface to the simulator could be improved, for example, listing of breakpoints in the listing window.
- III There is currently no summary information printed by xnusim. This is a definitely desirable feature to be included. But it has not been included since what kind of information and how these informations are to be arranged and gathered has not been well-defined.
- IV The module handler.c may be modified to be sufficiently general that it will become unnecessary to modify it for any modification to the simulator. This is possible if a protocol for defining what kind of menus, how these are to be manipulated and what functions they call is established. Then, the main function for interpreting this will be handler.c's heart, and possibly the procedure sendMsg of interface.c would become more sophisticated.
- V The next giant step would be to make *interface.c* a general file that does some form of regular expression interpretation and replies with some regular expression, all of which may be defined, again, by some protocol. If this is done, using a *configuration* file of some sort for the kind of simulator, xnusim would be able to handle different simulators without ever needing any recompilation, and would truely establish the ideal of being a general simulator interface. (Incidentally, this would include the modifications mentioned for the *handler.c* module, since it would not work otherwise)

With these modifications, xnusim would probably be a very useful package for people interested in designing parallel systems at different levels, debugging programs that are to be used in these systems, and studying the behaviour of different programs.

Manual Page for Xnusim

USER COMMANDS

NAME

xnusim – X window interface to a multiple processors/tasks simulator

SYNOPSIS

xnusim [-toolkitoption ...] [-m host:display] [-p host:display] [-t host:display] [-s simulatorname] [w-filename] [-e simulator options]

DESCRIPTION

Xnusim is a graphical interface to a multiple processor and task simulator, currently implemented for the simulator nusim, but could be modified to handle other simulators with similar needs. It provides visual feedback and mouse input for the user to interface into the simulator.

Xnusim provides windows for each processor (maximum configurable) and task which the user wish to see, and these are updated each time the simulator returns from it's tasks.

The *-mpt* options are used to describe the display where each of the main, processor and tasks windows will be displayed (respectively).

The simulatorname option allows the user to specify another simulator to run under *xnusim*. However, reprogramming is necessary to support other kinds of simulators. So, this feature, thus far, only allow for name changes.

The *w*-filename option allows the user to specify a default working file which may be passed to the simulator to load once the program is started up.

The -e option should be the last option. Xnusim treats all arguments following this option as argument to pass to the simulator Besides these, *xnusim* accepts all of the standard X Toolkit command line options (see X(1)), but is yet unable to understand the simulator's options.

Xnusim is made up of the following subwindows:

Title Bar Display the current simulator name. Also, when a mouse is place in this window, it triggers the *MainMenu*(see Below).

- Message Window Display any short Help message available and or messages from *xnusim* to the user.
- Listing Window Display the file that is currently being executed, and shows the last line that had been executed when stepping through.
- Command Window Provide a list of the commands which *xnusim* understands and is capable of executing. This is also modifiable.
- Main Window This window provides the actual simulator feedback and the user is allowed to type directly any command to the simulator through this window (Note: update MIGHT not be properly performed in that case).
- MainMenu Activated by the mouse entering the "Title Bar" region, it allows the user to choose to display/delete a processor or a task from the menu.

The relative sizes of any window in this set can be adjusted to suit the users needs. Although the default size is normally suggested. To select any command in a button-box, click the left mouse button.

Scrollbars can be found in both the Main and Listing windows. The left mouse button scrolls the text forward, the right scrolls backward and the middl mouse button selects the text at the current mouse position of the complete text relative to the scroll bar, changing the thumb position of the scrollbar. I ragging the middle mouse button moves the thumb along and changes the text displayed. The amount of scrolling depends on the distance of the pointer from the top of the scroll bar (or bottom). Top line scrolls one line, and bottom one screenful. Clicking the left button twice quickly on either the main or listing windows will select a word from the window which you may then echo back by clicking middle mouse. Typing a command into the debugging window will create the same effect as clicking the

mouse window.

COMMAND BUTTONS Main Menu Command	\$
Processor	Another window with a list of processor will popup, and choosing the processor from this new window will either delete it if it's already being displayed, or create a new window for this processor clicked.
Task	Same function as the Processor command but for tasks.
Summary	To be implemented: will display necessary statistics for the system.
Commands in Comman Load	ad Window Prompts for the filename and then loads the ".w" file. Can only be activated once because of simulator limitations.
Step	Steps throught the simulator "n" steps a time where n is defined at the Config button (see Below).
Run	Either starts or performs continuous execution (Note: the display will not be updated).
Breakenv	Prompts for new values for the processor and task break environment (see Nusim reference).
Breakpoint	Allows user to delete, and set breakpoints (could set at current cursor point in listing window, program will search for first "stoppable" code memory for inserting the stop.
Breaktime	Allows setting and resetting of the breaktime.
Config	Allows reconfiguration of a number of things. Pressing it pops up a new window where user can select the particular type to configure.
Reset	Resets the system so that you may re-run the simulator without need to exit the system. Since the simulator is actually re-runned, the whole system is completely refreshed. The only window which is not affected is the main (debugging display) window which merely reprints a start up line after the last line. This is so that you may click from the lines above to copy down.
Quit	Exits xnusim.

LIMITATIONS

Xnusim is still underdeveloped. Much needs to be done.

BUGS

Probably quite a lot. Still shaky because of inherent problems with socket communications and Xt11.

Xnusim is an XII Window Inte	rface for the Mu	1ti-Processo	r efmulator	Nucim					
Xnusim is an Xll Window Interface for the Multi-Processor simulator Nusim. It is a display oriented interface between the simulator and the user via									
UNIX ¹ sockets with graphical objects such as menus, buttons, etc. It is									
designed in such a way that would allow it to be used with other simulators									
of the same class. This paper intends to describe the functionality of the									
objects, structures and program modules of XNUSIM in detail.
