Paper presented at the 30th Annual Conference of the Military Testing Association, 27 November - 2 December 1988.

#### SUMMARY

The Automated Test Outline (ATO) research and development effort was designed to explore and resolve both technical and logistical problems associated with using occupational survey data to derive weighted subject matter areas for Specialty Knowledge Test (SKT) outlines. This paper discusses some of the issues that were addressed and resolved by research accomplished between October 1987 and December 1988. Issues discussed include: (a) the process for selecting appropriate subsets of tasks from a full task inventory for mailout to subject-matter experts in order to obtain task-level testing importance ratings; (b) interrater and test-retest reliability indices for testing importance ratings in 28 Air Force specialties; (c) the validity of the ATO procedure, as measured by the SKT teams' adherence to the computed testing importance weights for each duty-level outline area and each task; and (d) the relationship between field-validated testing importance and a variety of routinely available task factors, such as field-recommended training emphasis, task learning difficulty, average grade of members performing, and percent members performing and average percent time spent by members performing at the E-5 and E-6/7 paygrade levels.

i

#### PREFACE

This work was completed under Work Unit 77192014, Research in Manpower and Personnel Technologies, Advanced and Exploratory Development of Occupational Measurement Technology. This paper was presented at the 30th Annual Conference of the Military Testing Association and published in the proceedings of that event.

#### AUTOMATED TEST OUTLINE DEVELOPMENT: RESEARCH FINDINGS

#### I. INTRODUCTION

This paper reports research findings related to the production and use of automated test outlines (ATOs) for Air Force Specialty Knowledge Test (SKT) construction. Following a short review of the process used to develop ATOs, the major focus will be on the reliability and validity of obtained results.

#### **II. DEVELOPMENT PROCESS**

Briefly, task-level Predicted Testing Importance (PTI) values derived from off-the-shelf task factor components of Field Recommended Training Emphasis (TE); Task Learning Difficulty (TD); and Percent Members Performing (PMP), Percent Time Spent (PTS), and Average Grade Performing (AG) at the E-5 and E-6/7 paygrade levels are used to delimit Air Force specialty (AFS) knowledge domains in terms of restricted subsets of tasks from full task inventories. These subsets of tasks are then administered by mailout approximately 3 to 4 months prior to the start of SKT construction projects to random samples of 50 to 70 senior noncommissioned officers (NCOs) who currently work in the AFSs. These NCOs rate each task within the subset on a 7-point scale of specialty knowledge testing importance. The resulting field inputs are then processed, analyzed, and subsequently used to determine testing importance (TI) weights for each task in the mailout and to calculate test outline weights (numbers of test items to be written) for each major duty area of the specialty. These task-level testing importance ratings by field NCOs are key components within the ATO development process.

#### **III. RELIABILITY AND VALIDITY ESTIMATES**

SKTs are normally developed 6 to 18 months before their scheduled administration to Air Force enlisted personnel. Consequently, direct reliability and validity estimates for those SKTs constructed from ATOs will not be available until after the test administration cycle is completed (early 1989). However, the "goodness" of the process used to generate ATOs can be evaluated by examining reliability and validity indices associated with a primary component of the process: Field Validated Testing Importance (FVTI).

To date, ATOs have been developed for 28 AFSs. Table 1 lists interrater reliability estimates of FVTI for each of these specialties.

The Table 1 data show reasonably good interrater reliability estimates (all  $R_{11} = 0$  probabilities were less than .01).<sup>1</sup> Over 75% of the  $R_{11}$ 's exceeded .20 and no  $R_{kk}$  estimate was below .75. Although these levels of reliability are in accordance with expectations (as judged by the Air Force's ongoing experiences with the reliability of field NCO ratings of task learning difficulty), future research efforts will be directed toward increasing interrater reliabilities, primarily through clearer and more simplified rating booklet (task subset) instructions and the identification and segregation of more relevant rater subgroups. The low number of raters in some AFSs was attributable to a variety of causes: small rater populations; testing importance survey booklets

<sup>&</sup>lt;sup>1</sup>Deviant raters i.e., those whose correlations with the composite of all raters were not significantly better than zero at  $\propto$  = .05) were eliminated from the calculation of R<sub>11</sub> and R<sub>kk</sub> (usually less than 10% of sample).

returned too late for inclusion in ATO projects; high percentage of senior NCOs on travel, leave, or permanent change of station; and higher-than-average percentage of deviant raters.

#### Table 1. FVTI Interrater Reliability

Because the subject-matter experts (SMEs) who develop SKTs are from the same population as those selected to complete testing importance field rating booklets, we were able, in a limited number of cases, to readminister the rating booklets to assess the stability of FVTI ratings over time. mesults of this test-retest effort are contained in Table 2.

In approximately 75% of the cases, test-retest correlations were .5 or higher. Although there was a 3- to 4-month period between first (X) and second (Y) administrations and totally different administration environments (X was self-administered at the rater's home station, and Y was administered at the USAF Occupational Measurement Center (USAFOMC) by the contractor as part of the initial SKT construction in-briefing), these correlations in most instances tend to support rating stability. They are 1.5 to 3 times higher than the interrater agreement coefficients (R<sub>11</sub>'s) in Table 1, except for Air Force Specialty Codes (AFSCs) 321X1E and 427X3. There was no discernible trend with respect to mean ratings between first and second administrations. Rater variance tended to be smaller for the second administration (p < .02, Sign-Rank Test of Differences), indicating a conservative rating policy, which may be the result of the more structured second administration environment.

Although the validity of SKTs constructed from ATOs cannot at this time be assessed directly in terms of increased job relevance of test content, it can to some extent be inferred by examining characteristics of FVTI ratings. As previously stated, FVTI ratings are used to establish

	First administration			Second a	······································

Table 2. Test-Retest Reliability (FVTI)

ATO weights (the recommended numbers of test items to write for each major duty area). For any given AFS, the number of these major duty areas can vary from as few as 8 to as many as 26. It seems reasonable to assume that the extent to which SKT construction teams adhere to these recommended duty area weights is an indication of the SME-judged goodness (validity) of the FVTI ratings and, to a lesser extent, the SME-judged appropriateness of the ATO development process. Table 3 shows the correlations between recommended and final (as adjusted by the test construction team) major duty area weights. An alternative explanation for the high degree of adherence to the ATO weights by the SMEs, in the opinion of several test psychologists, was the flexibility the SMEs had in selecting knowledge requirements when writing an item on a task.

The cc:relations listed in Table 3 range from .83 (AFSC 32151E) to 1.00. For the total set of AFSs, approximately 88% of the automated outlines had correlations (between recommended and actual weights) of .95 or higher. In approximately 44% of the cases, no weight change was necessary. These are positive indications and speak to the validity of the FVTI ratings.

In addition to being used to calculate recommended major duty area weights, FVTI ratings are also used to differentiate outline tasks into A (high testing importance) through D (low testing importance) categories, depending on the mean FVTI value computed for each task. If FVTI ratings are valid, one would expect a greater percentage of A tasks to be used to generate test items than B, C, or D tasks; to a lesser extent, one would expect that B tasks would be used to generate test items at a somewhat higher rate than C or D tasks, and that D tasks would have the lowest usage rate of all. Table 4 lists by task category (A, B, and C) the ratio of the proportion of test items written on tasks in that category to the proportion of tasks in that category appearing in the E-5 and E-6/7 outlines combined. The D category is not listed, because only one D task was used by one AFS. Even though tasks in the D category were not to be used without written justification, it is nevertheless significant that only one team felt

the need to justify the use of only one D task. On the other hand, although SMEs were required to write a minimum of one item on each A task, it is significant that the item/task ratio for A tasks substantially exceeds 1.0 in all AFSs, and there are no reversals in the expected decrease in item/task mitios from A to B to C.

Tables 5 and 6 examine the relationships between FVTI and five task-level factors: Predicted Testing Importance (PTI), Percent Time Spent by Members Performing (PTM), Training Emphasis (I'E), Task Learning Difficulty (TD), and Average Grade Performing (AG). Because of the large number of tasks used to compute these correlations, a coefficient of  $\pm$ .17 is significant at  $\propto$  = .05 (two-tailed), and  $\pm$ .22 at  $\propto$  = .01 (two-tailed).

						N (Tasks)
AFSC	PTI (E-5)	PTM (E-5)	TE	TD	AG	E-5/6/7
112X0	.55	.28	.72	.49	.00	127

As can be seen in Tables 5 and 6, FVTI correlations with PTI at both the E-5 and E-6/7 levels are relatively high, the single exception being AFSC 309X0. This AFS is probably the most diverse (heterogeneous) of all those for which outlines were developed. This diversity may also account to some extent for the relatively weak relationship between FVTI and PTI for this AFS. The FVTI correlations with TE and TD are in the expected direction and at the appropriate level for most of the sampled AFSs. At the E-5 level, we would expect TE to have a stronger impact on FVTI than at the E-6/7 level, as TE is essentially a measure of recommended training emphasis for first-term airmen. Conversely, we would expect TD to have a stronger relationship with FVTI at the E-6/7 level than at E-5 level, in that TD is an estimate of how difficult it is to learn to perform a task. Both of these expectations are confirmed by the correlations in Tables 5 and 6, which lend a degree of convergent validity to the testing

importance measure. However, the consistently strong, positive relationship between FVTI (E-5) and FVTI (E-6/7) could indicate the presence of an unwanted autocorrelation resulting from the dual-column "E-5/E-6/7" format employed in the rating booklets used to collect FVTI information.

It is evident from these findings that a single PTI equation for predicting F./TI will not be a feasible objective, and that more attention must be given to TD, which has been underweighted in the procedure for selecting tasks to be rated on testing importance.

#### IV. CONCLUSION

Although the statistical information gathered thus far is by no means overwhelming, it is very encouraging that it is uniformly in the right direction for almost all AFSs in which the occupational data-based, automated outline procedure has been applied. From a validity standpoint, the most telling evidence is yet to come. Final judgments must wait until the statistical characteristics of the end products (the administered SKTs) are analyzed and, most importantly, judgment must be withheld until comments from SMEs on subsequent revisions of ATO-developed SKTs and from supervisor and co-worker judgments of SKT examinees' job knowledge can be assessed. Examinee comments will possibly be available from two sources: a brief survey administered to the examinee before he/she leaves the testing room and complaint letters sent to the USAF Occupational Measurement Center (USAFOMC). The expectation is "hat there will be significantly fewer comments than in the past regarding lack of job relatedness of test items.
