MONOVALENT LIGANDS OF COMPLEMENT RECEPTOR 2 INHIBIT WHEREAS POLYVALENT LIGANDS ENHANCE ANTI-Ig-INDUCED HUMAN B CELL INTRACYTOPLASMIC FREE CALCIUM CONCENTRATION¹

GEORGE C. TSOKOS,2+* JOHN D. LAMBRIS,* FRED D. FINKELMAN,* EVANGELOS D. ANASTASSIOU, AND CARL H. JUNE⁸

From the *Department of Medicine, Uniformed Services University of the Health Sciences, Bethesda, MD 20814; 'Kidney Diseases Section, National Institute of Diabetes, Digestive and Kidney Diseases, National Institutes of Health. -1 -1 -12

We have performed experiments to investigate the CR2, including the murine mAb HB5, have been produced role of ligands for complement receptor 2 (CR2) in human B cell activation. Flow microfluorimetry was used to assess changes in free intracytoplasmic calcium concentration [Ca²⁺] in indo-loaded B cells, immediately after exposure to anti-µ antibody and to monovalent or polyvalent CR2 ligands. As monovalent ligands we used the C3d fragment and synthetic C3 peptides (peptides P14, residues 1201-1214, and P28, residues 1187-1214). As polyvalent ligands we used i) an intact monoclonal mouse anti-CR2 antibody (HB5) and its F(ab')₂ fragment, ii) tetravalent P13 ((residues 1202-1214) 4-template), and iii) P28 conjugated to BSA (molar ratio 5/1) Anti-CR2 antibody HB5, tetravalent P13, and P28 conjugated to BSA, enhanced the ability of $F(ab')_2$ fragments of the IgG fraction of goat anti-human μ antibody to increase human B cell [Ca²⁺]i. In contrast, the monomeric CR2 ligands C3d and P28 inhibited the anti- μ -induced increase in human B cell [Ca²⁺]i. Multivalent P13, P28, and the HB5, by themselves, did not affect B cell [Ca²⁺]i. These experiments suggest that the valence of the CR2 ligands is crucial for the nature (synergistic vs antagonistic) of the message transmitted through the CR2. Ľ

CE CHU

CR2³ is a 140-kDa glycoprotein (1-3) that specifically binds iC3b, C3dg, and C3d fragments of C3 (4, 5) and the EBV envelope protein gp350/220 (6, 7). CR2 is expressed primarily by B cells, although it has been found on other cell types (5, 8).

CR2 binds a site on C3 that is composed of residues 1205-1214 of the C3 sequence (9). Synthetic C3 peptides P14 (residues 1201-1214) and P28 (residues 1187-1214) bind to CR2 (9, 10) and can be used as ligands in functional assays. A number of murine mAb that bind human

(4, 8).

CR2 has been considered to play a role in B cell differentiation and proliferation. Polyclonal and monoclonal antibodies to CR2 (11-13) as well as particle bound C3d (14) have been shown to enhance B cell responses in different systems. More recently, HB5 has been found to act synergistically with μ -chain-specific antibody to increase B cell intracytoplasmic free calcium ([Ca²⁺]i) (15). Monomeric fluid phase C3d, in contrast, has been found to inhibit murine B cell proliferation (14). P14 and P28 peptides inhibit the maturation of murine B cell progenitors (16) while they support the growth of CR2-binding EBV lymphoblastoid B cell lines (10).

Cross-linking of B cell surface Ig induces hydrolysis of phosphatidylinositol 4.5-bisphosphate by phospolipase C to inositol trisphosphate and diacylglycerol. Inositol trisphosphate causes the release of intracellular calcium from endoplasmic reticulum (17-21). [Ca2+]i can be accurately measured in isolated B cells using the Ca2+dependent indicator indo-1 (21, 22).

In this study we used the anti- μ -induced increase in $[Ca^{2+}]i$, an early event in B cell activation, to study the role of CR2 in B cell function. We found that CR2-mediated modulation of B cell activation is ligand-valencydependent, in that monomeric ligands inhibit the anti-uinduced increase in [Ca2+]i whereas polyvalent CR2 ligands enhance the ability of anti- μ to increase [Ca²⁺]i.

MATERIALS AND METHODS

Cells. Peripheral blood MNC were obtained from heparinized, blood by Ficoll-Hypaque density centrifugation. Human spleen cells were obtained through the Tissue Procurement Service of the Clinical Center of the National Institutes of Health.

Reagents. Affinity-purified F(ab')2 fragments of the IgG fraction of goat anti-human μ (purchased from Jackson ImmunoResearch Laboratories, West Grove, PA) were used to stimulate B cells. PElabeled monoclonal mouse IgG1k anti-human CD20 antibody was purchased from Becton Dickinson (Mountain View, CA). PE-labeled Leu-4, Leu-M3, Leu-7, and Leu-11 (Becton Dickinson) were used in some experiments. HB5 mouse IgG2ak anti-CR2 was obtained from the American Type Culture Collection, Rockville, MD. F(ab')2 fragments of HB5 were prepared by pepsin digestion and separated from undigested IgG2ak molecules by absorption with protein A Sepharose (Pharmacia, Piscataway, NJ). Purity was demonstrated by SDS-PAGE analysis. F(ab')2 fragments of the IgG fraction of goat antimurine IgG antibody were purchased from Cappel-Cooper Biomedicals (Malvern. PA). F(ab')2 fragments of goat anti-human-µ and/or HB5 antibodies were bound onto cyanogen bromide-activated Sepharose (Pharmacia) according to the provided instructions.

C3 was prepared from human plasma and C3d was prepared by digestion as previously described (23). C3-derived CR2-binding pep-

tides (P14 and P28) were prepared as previously detailed (9, 10). Both baild to CR2 but P28 binds with a higher affinity than does P14 (9). The P13-template was synthesized according to the principle of Mutter et al. (24) as previously detailed (10). In brief, the amino acid template was synthesized first on a resin by using butyloxylcarbonyl-Lys(F-moc)-OH for four cycles. Four P13 peptides were synthesized on the template-resin after deprotection of the F-moc protected sites. The final product was cleaved from the resin and purfied by gel filtration. It was calculated that the majority (>90%) of the CR2 were occupied when P28 was used at concentrations greater than 60 μ g/ml in cell suspensions of 1 × 10⁶/ml (10). P28, to which a cysteine residue was added to the amino-terminus, was conjugated to BSA as described by Lerner et al. (25). The P28:BSA molar ratio was calculated to be 5:1.

Intracellular ionized calcium assay. [Ca2+]i in single cells was measured as described (26, 27). Briefly, cells were loaded with the acetoxymethyl ester of indo-1 (Molecular Probes, Eugene, OR). Initial concentrations of $3 \,\mu M$ of this compound, resulted in an intracellular indo-1 concentration of 20 to 50 µM. After the loading procedure the cells were washed, placed in fresh medium at 2.5×10^6 /ml and stored in the dark at room temperature until analysis. Immediately before each assay, indo-1-loaded cells were diluted to 1 × 106/ml with medium (HBSS, containing 1 mM CaCl₂, 1 mM MgCl₂, 20 mM HEPES, and 10% FCS), equilibrated at 37°C and analyzed by flow cytometry at 400 to 500 cells/s. For each cell analyzed the ratio of violet:blue fluorescence was digitally calculated in real time. The (Ca2+11 (nM) was calculated from the indo-1 violet to blue ratio after proper calibrations were performed as previously detailed (27). Before loading with indo-1 the cells were stained with PE-labeled anti-CD20 or with a mixture of PE-labeled anti-Leu-4, Leu-M3, Leu-7, and Leu-11 by incubating for 30 min at 4°C. This permitted the identification (gating) of B cells by positive or negative selection. respectively. Preliminary experiments demonstrated that prior staining of cells with anti-CD20 antibody had no effect on the anti- μ -induced increase in (Ca²⁺)i.

Proliferation assays. B cells (70 to 80% CD20⁺) were enriched from peripheral blood or spleen by depletion of monocytes through plastic adherence and T cells through sheep erythrocyte rosetting and were cultured in 96-well round-bottom microtiter plates at 50,000/well in medium RPMI 1640 containing 10% FCS. Cells were harvested 72 h after the initiation of the culture and were pulsed with 0.5 μ Ci/well of ³H-thymidine for 18 h before harvesting.

RESULTS

Cross-linking of IgM with $F(ab')_2$ fragments of goat anti-IgM antibody leads to a dose-dependent increase in $[Ca^{2+}]i$. In a typical experiment (Fig. 1) peripheral blood MNC were stained first with PE-labeled anti-CD20 and then loaded with indo-1. They were equilibrated at 37°C before use and exposed to graded doses of $F(ab')_2$ goat

Figure 1. Peripheral MNC were first stained with PE-anti-CD20, loaded with indo-1 and equilibrated to 37°C before analysis. $F(ab')_2$ -goatanti-human μ was added to cells at the indicated time (arrow) at different concentrations: $(---)_1 \exists \mu g/ml; (---)_1 \exists 0 \mu g/ml; (----)_1 \exists 0 \mu g/ml.$ The interval 0-100 on the abscissa is equivalent to 6 min. The concentration of Ca²⁺ was calculated as described in Materials and Methods and is expressed as nM.

anti-human μ . [Ca²⁺]i was observed to increase instantly and decline and plateau a few minutes later; similar responses were obtained from MNC from 14 different normal individuals and four different spleen B cell preparations that were studied during the course of these experiments. Peripheral cells were stained first with a mixture of PE-labeled anti-leu 4, leu-M3, leu-7 and leu-11, (negative selection) or with anti-CD20 (positive selection) before loading with indo-1 and analysis. Positively or negatively gated cells responded similarly to anti- μ .

To investigate the effect of monovalent CR2 ligands on the anti- μ -induced increase of $[Ca^{2+}]i$ we first exposed the cells to graded concentrations of C3d, the natural ligand of CR2, and then added anti- μ antibody. As shown in Figure 2, preincubation of cells with C3d for 5 min at 37°C inhibits the ability of 10 μ g/ml of anti- μ antibody to increase [Ca2+]i. In four more experiments, which were performed with either peripheral MNC (twice) or spleen cells (twice). C3d (60 μ g/ml) inhibited the anti- μ -induced [Ca2+]i response by 40 to 62%. C3d inhibition of the B cell $[Ca^{2+}]i$ response was greatest when the anti- μ antibody was used at 10 μ g/ml and less at higher and lower anti- μ concentrations (Table I). Preincubation of the cells with C3d for longer periods of time (up to 20 min), inhibited the anti- μ response to the same extent. Addition of C3d. simultaneously with the anti- μ antibody, had a less reproducible inhibitory effect. Addition of C3d alone at the time of the initiation of the analysis had no effect on B

Figure 2. Inhibition of the anti- μ -induced increase in B cell [Ca²⁺]i by C3d. Peripheral MNC were stained with PE-anti-CD20, loaded with indo-1 and equilibrated at 37°C before analysis. They were treated with 10 μ g/ ml (-----), 30 μ g/ml (-----) or 60 μ g/ml (------) of C3d, or were left untreated (----) before the addition of 10 μ g/ml of F(ab')₂-goat anti- μ .

cell (Ca2+)i (Fig. 3).

The above experiment was repeated, substituting for C3d the peptides P14 (residues 1201-1214 of C3) or P28 (residues 1187-1214 of C3). Preincubation of cells with P14 had little effect on the anti- μ -induced increase in [Ca²⁺]i (Fig. 4). Prolongation of this preincubation time up to 30 min still had little effect. Similarly, P14 failed to inhibit the anti- μ -induced human spleen B cell [Ca²⁺]i response (data not shown). In contrast, preincubation of cells for 5 min at 37°C with graded doses of P28, which is bound by CR2 with higher affinity than P14 (9), inhibited the anti- μ -induced increases of [Ca²⁺]i in a dosedependent manner (Fig. 5). P28 (100 μ g/ml) inhibited the anti- μ -induced [Ca²⁺]i response in six more experiments

Figure 3. Monovalent or polyvalent CR2 ligands have no effect on the B cell [Ca²⁺]i when present in the absence of anti- μ antibody. Peripheral MNC were stained with PE-anti-CD20, loaded with indo-1 and equilibrated at 37°C before analysis. At the position of the arrow we added: 30 μ g/ml anti- μ (-----), 100 μ g/ml P28 (-----), 60 μ g/ml C3d (------), 1 μ g/ml HBS (-----), or 50 μ g/ml of (P13)4-template (------).

Figure 4. The CR2-binding peptide P14 fails to inhibit the anti- μ induced increase in [Ca²⁺]i. Peripherai MNC were treated as described in the legend to Figure 2. After equilibration at 37°C the cells were treated with (-----), 50 μ m/ml; or (-----), 100 μ g/ml of P14, or P14 (----) before exposure to 10 μ g/ml of F(ab')₂-goat anti- μ (arrow).

Figure 5. The CR2-binding peptide P28 inhibits the anti- μ -induced increase in [Ca²⁺]i. Peripheral MNC were treated as in the legend to Figure 2. After equilibration at 37°C they were treated with (----), 50 μ m/ml: or (-----), 100 μ g/ml of P28, or (----), no P28, for 5 min before the addition of 10 μ g/ml of F(ab')₂-goat anti- μ (arrow).

using peripheral MNC and 2 more using spleen cells; the percentage of inhibition ranged from 45 to 65%. As shown in Table I, P28 inhibited optimally the $[Ca^{2+}]i$ response, when the anti- μ antibody was used at 10 $\mu g/$ ml and to a lesser extent when higher or lower concentrations were used (Table I). Addition of either P14 or P28 at the initiation of the analysis, in the absence of anti- μ antibody, had no effect on $[Ca^{2+}]i$ (Fig. 3). These experiments show clearly that monovalent CR2 ligands inhibit an early, anti- μ -induced, B cell activation event, the increase of $[Ca^{2+}]i$.

Because polyvalent CR2 ligands have been reported to enhance B cell responses we next investigated the effect of exposure of human peripheral blood and spleen B cells to polyvalent CR2 ligands on their [Ca²⁺]i. As such we have used HB5 anti-CR2 antibody, F(ab')₂ fragments of the same antibody, a synthetic tetravalent CR2 ligand: the (P13)₄-template, and a pentavalent P28-BSA conjugate. Exposure of cells to intact HB5 for 5 min at 37°C (or for up to 20 min) before addition of 3 μ g/ml of the $F(ab')_2$ fragment of anti-human μ antibody clearly enhanced the increase of [Ca2+]i. The increase was dosedependent and the effect was reproduced in both positively and negatively selected peripheral blood (five experiments) and spleen B cells (two experiments). Optimal enhancement was observed when suboptimal concentrations (3 μ g/ml) of anti- μ antibody were used. Because cross-linking of B cell membrane Ig with the B cell FcR inhibits B cell activation (22), we repeated this experiment with the F(ab')₂ fragment of HB5. Similar results were obtained (Fig. 6). HB5 alone had no effect on [Ca2+]i (Fig. 3). To determine if a tetravalent ligand bound by CR2 would mimic the effect of the divalent HB5 antibody on the anti-µ-induced increase in [Ca2+]i, we studied the ability of the synthetic, tetravalent (P13),-template to affect the increase. Preincubation of cells with (P13). template before addition of F(ab')2 fragments of goat antihuman μ enhanced the anti- μ -induced [Ca²⁺]i increase (Fig. 7). As was observed with HB5, (P13),-template had

Figure 6. Effect of HB5 anti-CR2 antibody on the anti- μ induced increase in B cell [Ca²⁺]I. Peripheral MNC were treated as described in the legend to Figure 2, treated with 0.1 (.....). 0.5 (----), or 1.0 (-----) $\mu g/ml$ of F(ab')₂ fragment of HB5 or no HB5 (----) for 5 min, before exposure to 3 $\mu g/ml$ of F(ab')₂ goat anti- μ (arrow).

Figure 7. Effect of (P13)4-template on the anti- μ antibody induced increase in B cell [Ca²]I. Peripheral MNC were treated as described in the legend to Figure 2. After equilibration at 37°C they were treated with 10 μ g/ml (---), 50 μ g/ml (---) for 5 min before adding 3 μ g/ml of F(ab')₂ goat anti- μ antibody.

no direct effect on B cell $[Ca^{2+}]i$ (Fig. 3). Preincubation of B cell-enriched human peripheral B cells with P28 bound to BSA (molar ratio 5:1), for 5 min before addition of anti- μ antibody. also enhanced (in three different experiments) the anti- μ -induced increase in $[Ca^{2+}]i$ (Table II). BSA alone had no effect on the anti- μ -induced increase in $[Ca^{2+}]i$.

Finally, we asked whether the observed effects of CR2 ligands on the anti- μ antibody-induced increase in B cell [Ca²⁺]i were associated with similar effects on anti- μ induced B cell proliferation. B cell-enriched peripheral blood cells (70 to 80% CD20⁺ cells) were cultured with Sepharose-bound F(ab')₂ fragments of anti-human μ in the presence or absence of HB5 antibody. The presence of HB5, either in soluble form or coupled to Sepharose, had no effect on the anti- μ -induced proliferative response. In contrast, culture of B cell-enriched PBMC with Sepharose beads, to which both anti- μ and HB5 antibod-

"Cultures were performed as described in Table II.

ies had been coupled, stimulated more DNA synthesis than did Sepharose beads that bore anti- μ , but not HB5 (Table III). Culture of B cell-enriched peripheral blood cells with soluble HB5 in the presence of 3 μ g/ml of soluble anti- μ failed to induce detectable DNA synthesis, and soluble HB5 had no effect on DNA synthesis induced by 10 μ g/ml of soluble F(ab')₂ of anti- μ . This was not surprising inasmuch as HB5 had little effect on the increase of [Ca²⁺] i that is stimulated by this concentration of anti- μ antibody.

Monovalent CR2 ligands had a clear inhibitory effect on the induction of B cell DNA synthesis by soluble $F(ab')_2$ fragments of anti- μ antibody. When B cell-enriched PBMC were cultured with soluble $F(ab')_2$ anti- μ antibody in the presence of graded doses of P28 or C3d, B cell proliferative responses were inhibited in a dose-dependent manner (Table IV). Thus, monovalent CR2 ligands inhibit both the induction of increased B cell [Ca²⁺]i and DNA synthesis by mitogenic concentrations of anti- μ antibody, whereas divalent or polyvalent CR2 ligands enhance the ability of submitogenic concentrations of anti- μ antibody to stimulate an increase in B cell [Ca²⁺]i but do not stimulate mitogenesis. Soluble divalent CR2 ligands have little effect on enhancement of B cell [Ca²⁺]i

1643

or DNA synthesis by mitogenic concentrations of anti- μ antibody and particulate, polyvalent CR2 ligands, whose effects on B cell [Ca²⁺]i are difficult to measure, only enhance the ability of anti- μ antibody to induce B cell DNA synthesis when they are associated with anti- μ in the same particle.

DISCUSSION

In the present study we have used flow microfluorimetry to study the effect of monovalent CR2 ligands or ligands capable of cross-linking CR2 on the ability of anti- μ antibody to activate B lymphocytes. Because of variability in earlier reports of the effects of CR2 ligands on B cell proliferation and differentiation (11–15, 28) we considered that the valency of the CR2 ligands might be important in determining the CR2-transduced signal. Hence, we used clearly defined monovalent, divalent, tetravalent, and pentavalent CR2 ligands. None of these ligands had any effect on [Ca²⁺]i if added alone at the initiation of the analysis.

Occupancy of CR2 by monovalent ligands before stimulation of B cells with anti- μ antibody clearly inhibits B cell activation. In our study, monomeric C3d, a natural ligand of CR2, as well as the synthetic peptide P28, which represents the CR2 binding sequence (residues 1187-1214) of C3, inhibited the anti- μ induced [Ca²⁺]i increase. P14, another synthetic peptide (residues 1201-1214) that also binds to CR2 but with lesser affinity (9), failed to inhibit significantly the anti- μ -induced B cell [Ca²⁺]i response. In previous reports, monomeric CR2 ligands have been found to inhibit murine B cell progenitor (16) and lymphoblastoid B cell growth (10). Similarly, CR1 monomeric ligands inhibit B cell differentiation (29) and macrophage Ia antigen expression (30).

In contrast to the effects of monovalent CR2 ligands, polyclonal anti-CR2 $F(ab')_2$ (11). monoclonal anti-CR2 (12, 13) and glutaraldehyde bound C3d (14) enhance anti- μ antibody-induced B cell proliferation. Polymeric C3dg primes human B cells to proliferate more vigorously upon stimulation with anti- μ antibody (31). In this study we used $F(ab')_2$ fragments of HB5 to demonstrate that they enhance the ability of suboptimal concentrations of anti- μ antibody to induce an increase in $[Ca^{2+}]i$. This finding is in agreement with a recent report (15). We extended this observation by demonstrating that a synthetic tetravalent CR2 ligand ((P13)_4-template), and P28 conjugated to BSA (pentavalent) similarly enhance the anti- μ antibody-induced increase in B cell [Ca²⁺]i.

Our study thus demonstrates that the valence of the CR2 ligand determines whether it inhibits or enhances the early activation of B cells by anti- μ antibody. The mechanism by which CR2 ligands, depending on their valence, either inhibit or enhance anti-µ antibody-induced increases in $[Ca^{2*}]$ is not established. It is possible that the occupancy of CR2 by a univalent ligand directly generates a signal that inhibits anti-µ-induced phospholipase C activation (32, 33), whereas the cross-linking of CR2 directly generates a different signal that has the opposite effect. An alternative possibility is that CR2ligand interactions, rather than directly generating signals, affect anti- μ antibody induction of increased B cell [Ca²⁺]i by modifying the ability of a B cell membrane Igligand interaction to activate phospholipase C. Because such activation requires the cross-linking of membrane

Ig, and because membrane lg, when cross-linked, be comes associated with ligand-occupied CR2 (34), it i possible that cross-linking of CR2 by divalent or polyva lent ligands promotes the formation of domains of mem brane Ig that have the conformation required to activate phospholipase C. Such promotion of membrane Ig cross linking by an interaction between CR2 and a polyvalen ligand would be particularly marked when the ligands fo membrane Ig and CR2 were physically associated. Nota bly, we and others (15) have been best able to demon strate synergistic induction of B cell DNA synthesis by anti-Ig and anti-CR2 antibodies when these two antibod ies have been directly associated. In contrast to its promotion of membrane lg cross-linking when occupied by a multivalent ligand, CR2, when occupied by a univalent ligand, might act as a brake on the cross-linking of associated membrane Ig rather than contribute to its crosslinking. This could interfere with the establishment of cross-linked membrane Ig domains that are capable of activating phospholipase C, with the direct result that the increases in [Ca²⁺]i and protein kinase C activity are inhibited. This, in turn could limit the induction of a late event in B cell activation, such as DNA synthesis.

Regardless of the mechanism involved, the opposite effects of CR2 interactions with monovalent or multivalent ligands could have important physiologic effects on the development of humoral immune responses in vivo. Bacterial Ag that directly fix C by the alternative pathway would not only form Ag-C3 fragment complexes that could associate with multiple Ig and CR2 molecules on the surface of Ag-specific B cells, but would also release soluble, univalent C3 fragments. The multivalence of the C3 fragments on such a bacterium-C3 complex could contribute to activation of B cells specific for bacterial Ag, whereas univalent, circulating C3 fragments might inhibit the polyclonal activation of B cells that lack specificity for bacterial Ag. Thus, the opposite effects of monovalent and polyvalent CR2 ligands on B cell activation could provide a means by which the C system could simultaneously contribute to the generation of a specific antibody response and restrain the development of a polyclonal antibody response that would be drain on the immune system and could produce potentially harmful autoantibodies.
