ACKNOWLEDGEMENTS

This paper represents the product of extensive thought and many individuals have influenced its development.

I would like to thank Colonel William B. York, Jr. for his common sense approach to management information and Lieutenant Colonel Robert Moore for giving me the tools required to write this discussion. I would be remiss if I did not thank Mr. Richard Weckel for his invaluable assistance in collecting the data which forms the basis of this report.

The patience, guidance, and confidence of Colonel Johnny L. Conner were especially helpful as he served as my preceptor for the residency year.

Finally, I would like to acknowledge my wife Judith and my sons, Brian and David. Their exquisite patience and understanding of the seemingly endless hours made it all possible.

CHAPTER I

INTRODUCTION

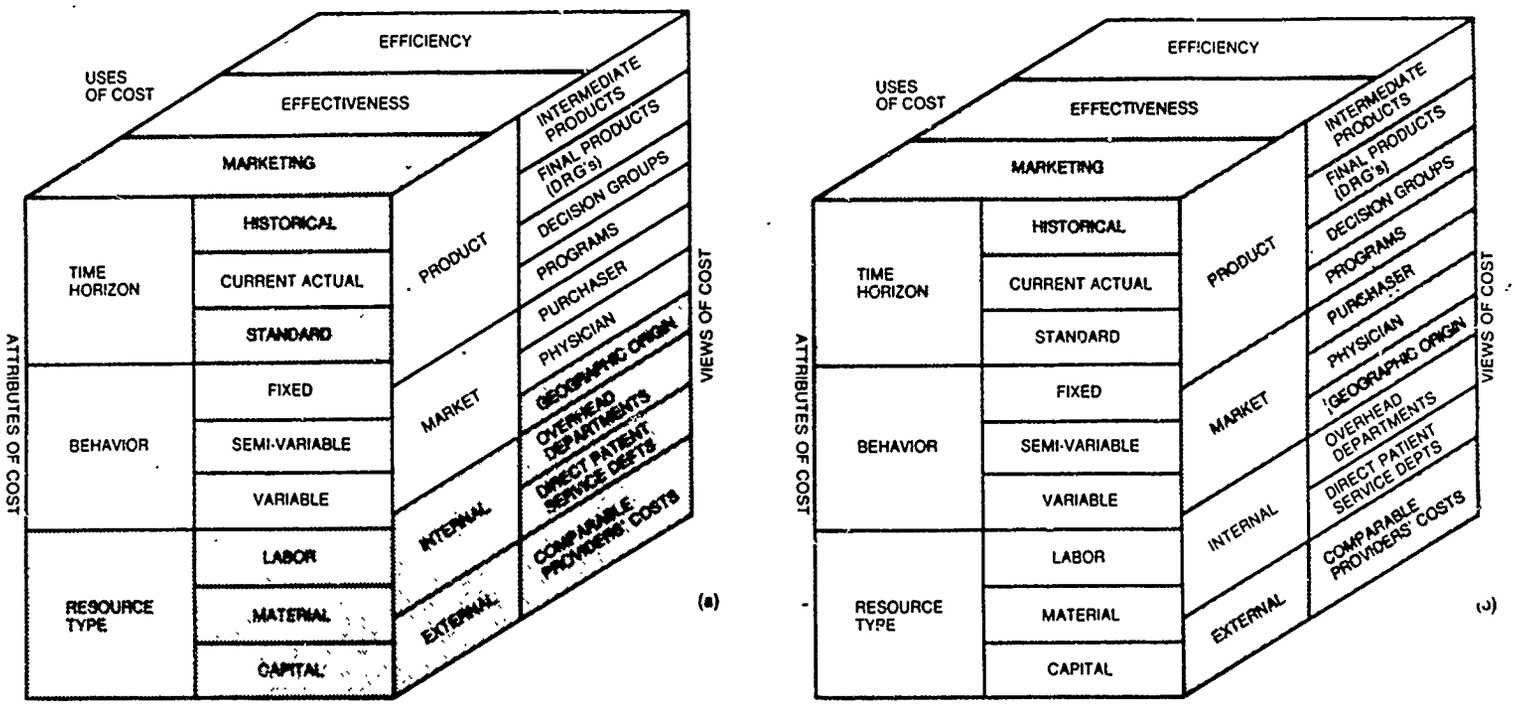
Conditions which prompted the study.

The hospital industry is furiously redefining itself. Competition within the industry has sent hospitals into home care and hotel management, into billboard writing and advertising. One of the strongest forces acting on our hospitals is the reimbursement mechanism. In addition to Medicare, other Prospective Payment Systems (PPS) are beginning to appear.[1] As more and more care is reimbursed at fixed rates, there is greater pressure to provide care within the boundaries of defined resource constraints. Cost-based reimbursement is on the wane.

This has resulted in the development of a new approach to the concept of cost analysis. The usefulness of simple aggregate compilation and percentage of cost by type of insurer is diminished in favor of segmented accounting along product lines. The determination of what constitutes the hospital product and its different product lines is part of the industry redefinition process. When a manager speaks of product costs, the financial analyst responds by asking what kind of product, type of cost, and planned uses for the information. Hospital financial managers must "avoid committing to a single-dimensional view of cost."[2] The diagram at figure 1 portrays the complex nature of approaching cost information.

If one accepts the organizational notion of the hospital as a matrix organization[3], it would follow that a matrix-based

Figure 1. Multiple uses, views and attributes of cost



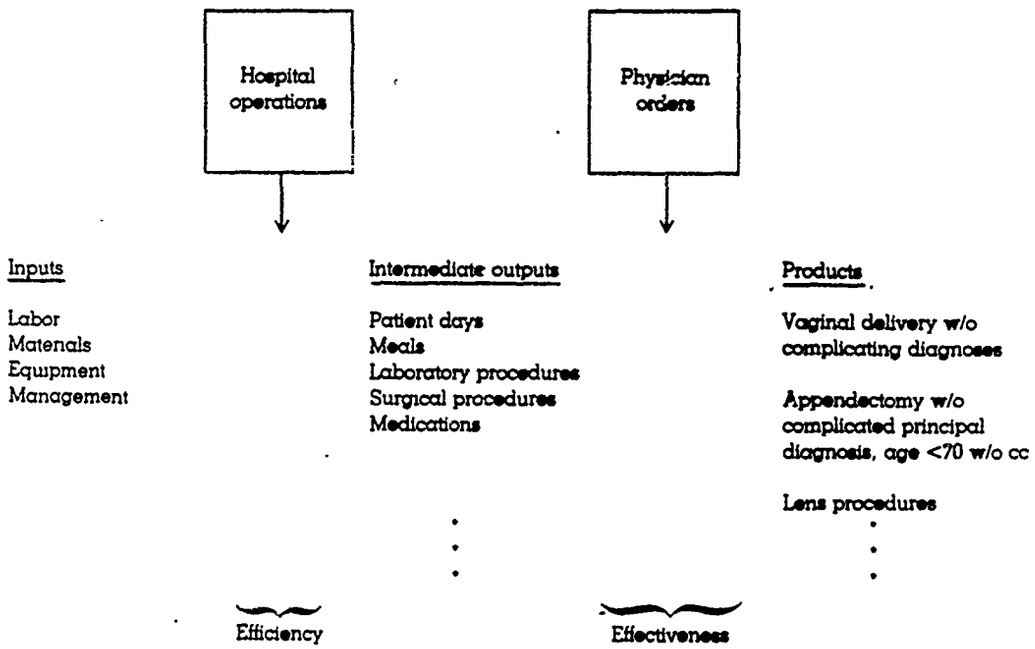
The Cost Cube: multiple uses require multiple views and attributes. (a) Analysis of contribution margin for Medicare cases, by product line/physician. Use: efficiency and effectiveness (to identify profitable or unprofitable DRGs and/or physicians); Views. product (down to units of service) and market (purchaser and physician); Attributes. current actual costs, recognizing variability. (b) Monitoring departmental performance. Use. efficiency, View: internal (by department); Attributes. current actual versus standard, recognizing variability, costs are by resource type.

control system which integrates the physicians into the formal management structure of the hospital would have the greatest likelihood of success.[4] Young and Saltzman describe a matrix-based control system with four principle features: a redesigned cost accounting system, a realignment of management responsibilities, a variance based reporting system, and a system of peer monitoring and sanctions. Under this system, providing the appropriate cost information to the responsible individual, who is answerable for cost behavior will promote systematic reductions in the expense base of the institution. In this scenario the responsible individual would not always be the Administrator. According to Vancil's fundamental management control criteria,[5] the measures used by top management to judge performance should be appropriate to the level of control exercised. And physicians have control over the effectiveness of hospitals, while the administrators have control over its efficiency. Figure 2 portrays this relationship of control to the nature of the hospital products.[6]

While there are other reasons to desire product cost information, such as competitive bidding, marketing, planning, and budgeting, the element of control in order to simultaneously maintain profitability and quality is foremost.

The military health care delivery system is not immune to the shifting financial sands. While not as abrupt as the private sector struggles with the Prospective Payment System, the Department of Defense is poised to shift to a specialty specific method of reimbursement for both inpatient and outpatient care. This new method, termed the Health Care Unit

Figure 2. Control of efficiency and effectiveness



(HCU), for the first time will permit the determination of differential earnings by various specialties.[7] This may be anticipated to create pressure to manage resources in entirely new ways. Many see the HCU as merely an interim step on the way to diagnosis specific reimbursement formats for both inpatient and outpatient services.

Hence, it follows that Department of Defense facilities will likewise not be immune to the changes in information requirements. One of the essential issues surrounding both capitation and Diagnostic Related Group (DRG) reimbursement is the question of modifying provider use of ancillary services in order to achieve quality health care at the lowest cost.

As the financial face of health care delivery in America is changing, health care information systems must keep pace. Health care planners on the one hand say they are most interested in receiving fixed and variable costs broken out by product lines, yet are the most disappointed because of the unavailability of this kind of data.[8] There is no single reason for this shift in information requirements, because it is tied to the multiple issues of reimbursement, pricing, marketing, planning, and investing. The only way to intelligently bid for contracts with Health Maintenance Organizations (HMO's) and other prepaid plans, or whether to expand, shrink, cut, or make or buy product lines is to have product cost and profitability data available. An administrator must know whether the medical staff is managing cases within budget using a mechanism to monitor expenditures against individual admissions.

Problem Statement.

This study will demonstrate a method to determine product costs for chemistry laboratroy tests. (Using the typology of products in Figure 2, chemistry tests may be considered intermediate products or final products, depending on whether the laboratory is marketing tests separately outside the hospital, e.g., under a Veterans Administration sharing agreement.) This method may be applied to other ancillary service areas in an effort to more accurately determine the laboratory component of the cost of individual patient care.

Objectives

Four objectives comprise the design of the study: to determine the comprehensive cost of performing chemistry tests in the central laboratory of the Darnall Army Community Hospital; to identify the direct and indirect components of the cost of performing chemistry tests; to develop a method to assign all indirect cost components to tests performed; and, to recommend changes in approach and methods used in the present accounting and record keeping systems.

Criteria

In order to be compatible with the present Medical Expense and Performance Reporting System (MEPR, formerly Uniform Chart of Accounts (UCA)), the chemistry test product cost will result in a single unit cost made up of the aggregate of direct and indirect costs. The general cost finding method of Krieg et al. [9] will serve as the model for the basic approach.

The chemistry test products will be defined as those

orderable test procedures which are recorded on the College of American Pathologists Workload Recording System.[10] Each can be ordered by health care practitioners. Recorded workload will therefore be regarded as either test procedures or non-test procedures, and all non-test procedures will be either incorporated into appropriate test procedures or considered as an indirect element of expense.

Assumptions.

For the purposes of this study, it is assumed that adequate records are on hand to formulate sufficient cost information, and that the available records accurately reflect actual work practices.

Limitations.

The hospital does not possess an automated laboratory information system to capture or report laboratory procedures, workload, or cost information. Cost information collected and computed will be gathered from multiple sources and computed on a personal computer using Lotus 1-2-3 (trademark). For this reason, the study is limited to only the chemistry laboratory. The methods discussed are applicable to other workcenters within the pathology laboratory, with the exception of microbiology. The problem of product definition is much more difficult in microbiology, because the workload recording system counts individual steps required to perform studies, rather than the studies themselves.

Some of the distinct tests which are performed on a single instrument in the chemistry laboratory are not accumulated on the workload reports as separate tests. Instead, they are combined

as a single type of test performed on that machine. This has the effect of decreasing the distinction between tests that are significantly different in product cost. This is a severe limitation, because most chemistry laboratories can produce an analyte result using several different instruments, each of which may have a different unit cost. The ability to differentiate between a glucose determination done for $0.50 and one for $5.00 is lost because of this type of workload recording.

Because existing supply records are used in this study for purposes for which they were not originally designed, it is recognized that the method for determining the customer workcenter for consumable supply purchases will not be error free.

Review of the Literature

The various methods by which the concept of cost can be allocated against an intermediate to achieve the information to insert in the Detailed Cost per Unit of Service shown in figure 3 are as variable as the number of hospitals. Consultants are recommending that the level of detail incorporated be appropriate to the user needs, with the caveat that the simpler the method, the less accurate the result.[12] Some hospitals include replacement cost in their capital expenses, while others do not.

There is evidence that furnishing cost information is useful in modifying physician ordering habits, in which case the marginal test cost, reflecting savings by reducing test volume would be the most accurate way to portray cost information.[13] The inherent difficulty with determining marginal cost is the

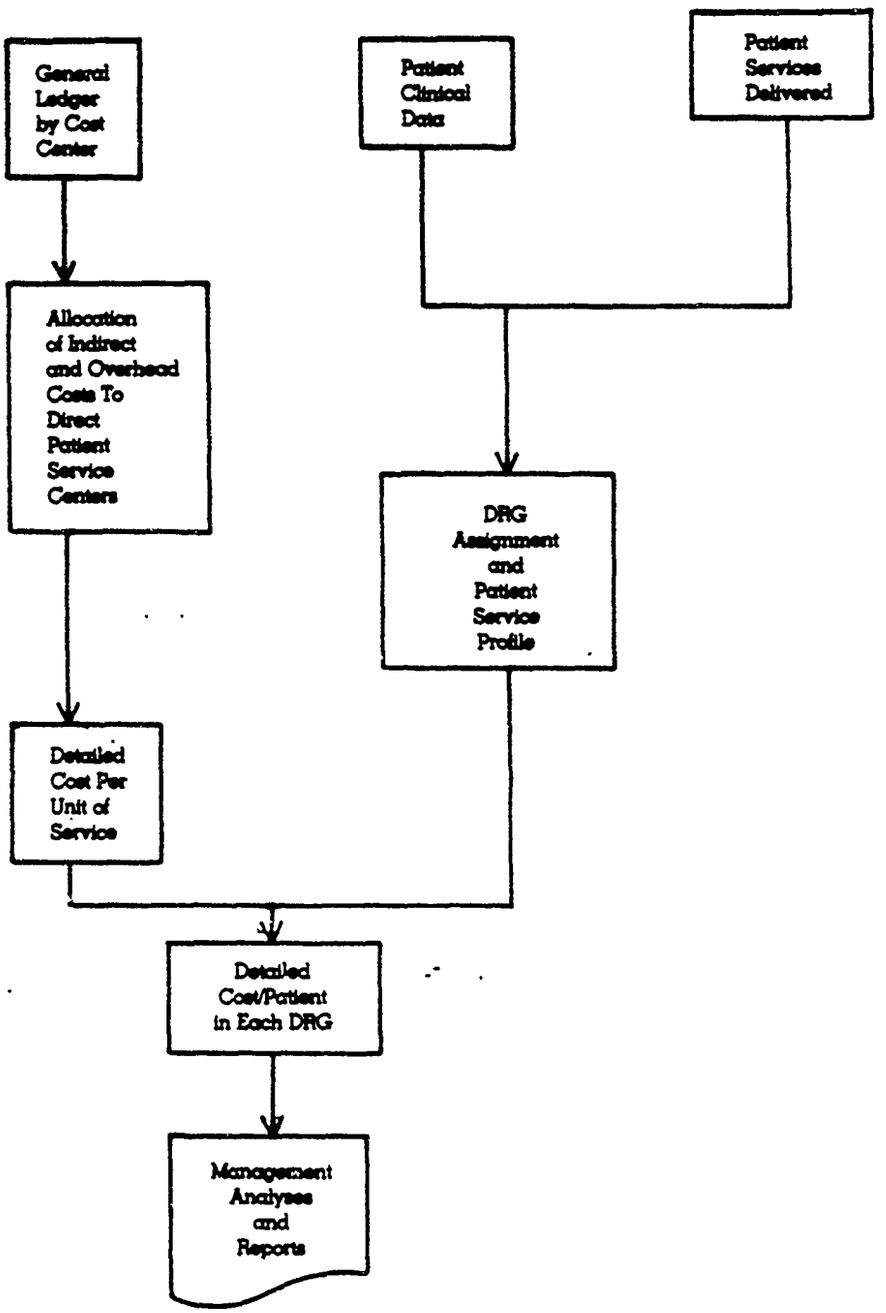


Figure 3 Overview of case mix cost accounting process.

problem of separating fixed, variable, and semi-variable costs. Because of the complex nature of laboratories, the semi-variable nature of personnel costs can be difficult to predict based on changes in workload and test mix. Finkelstein has approached this problem by targeting different levels of test utilization and predicting corresponding costs.[14]

Under cost-based reimbursement mechanisms, the usual practice is to allocate all departmental costs to specific tests based on a formula, relative value units or CAP work units.[15] None of these generally bears a close relationship to actual costs of performing procedures. Relative value units, depending upon their origin, are most closely related to fee schedules[16] or are the result of a composite expert opinion of relative resource utilization. The Medicare Cost Report and the Department of Defense Uniform Chart of Accounts use these allocation methods. The UCA technique of using CAP weighted workunit values to allocate pathology costs to patient care areas is approximate at best. Since the target accuracy of the method is only 25%, the system has little difficulty meeting its internal standard.[17]

The British standard method requires detailed time studies and questionnaires on consumption of materials in order to determine direct costs.[18] It does not incorporate overhead expenses, and features a seven year replacement time frame for equipment. Subsequent British authors[19] have suggested including overhead and lengthening the equipment life expectancy.

Broughton and Woodford have proposed an excellent two part cost determination method which is particularly useful for fee

setting.[20] They describe a method of identifying direct costs per test, those which can be described as required to perform the actual tests, and indirect costs per request, those other costs which are related to the overhead of providing the laboratory service. This results in an additive computation for each patient service composed of the direct cost of the test, plus the indirect cost of the request, which may include more than one test. This method has the inherent limitation that it requires much more complicated workload accounting methods than are currently employed by most laboratories, since most do not record numbers of requests.

Two other general approaches are used to assess test costs. Some authors measure actual costs of labor and materials required to perform individual tests or batches of tests, and then add factors to compensate for non-productive labor, wasted material and overhead.[21] This method does not allow for workcenter efficiency differences, nor does it necessarily guarantee that the sum of all unit costs will equal operating expenses. It does have the advantage of speed of calculation.

The method selected for this study measures aggregate costs for labor, material, and equipment that are required to perform tests. Expenses that cannot be identified with individual tests are allocated between workcenters, when a service is shared, and within the workcenter, when there is no sharing of services.[22] Although the CAP workload recording system is based on time study values, man-minutes of technician time,[23] Krieg measures actual elapsed time required to perform procedures, using a worksheet

similar to that prescribed by the College of American Pathologists.

Research Methodology

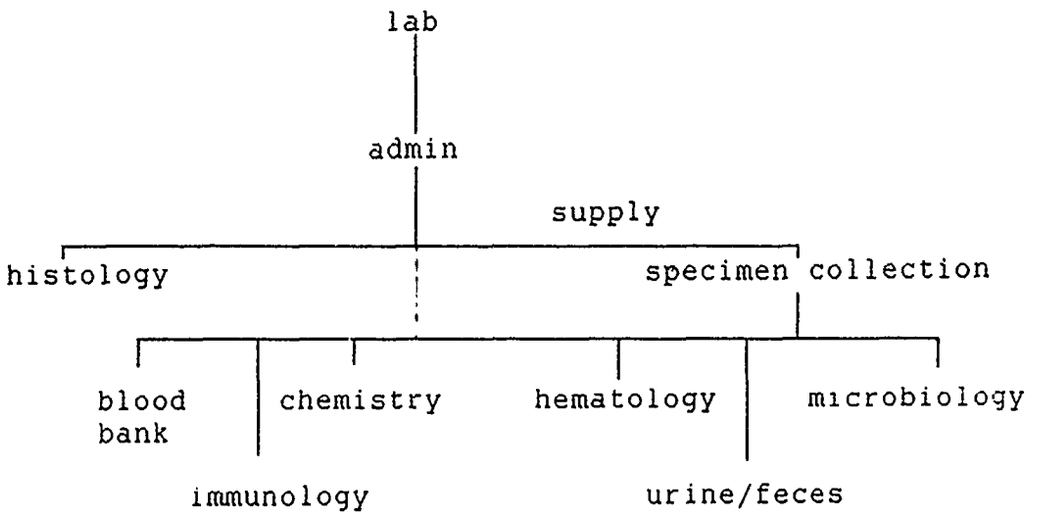
The general approach used here is modeled after Krieg et al. While his method describes costs for an entire department, this study will focus only on clinical chemistry. Rather than counting the individual items and products required to perform tests, this approach examines the aggregate resources used to produce output over a period of time. Six months is used as the time period for collecting workload, labor and material information. The last six months of FY 1985 were used for this purpose, since complete information for that period was available at the beginning of this project. Six requirements were necessary to complete the study: 1.) acquire data defining the tests and test counts; 2.) identify material costs, and allocate them to each test; 3.) identify overhead costs associated with the chemistry laboratory, and allocate those costs to each of the tests; 4.) identify and allocate equipment and maintenance costs; 5.) determine appropriate labor costs for each test; and, 6. calculate individual cost per test. The individual cost per test is calculated as the sum of the direct personnel, material, and equipment costs and the indirect personnel, material, equipment, and overhead costs.

You need beginning and ending inventory to accurately know materials costs.

Organization. Krieg uses a complicated "workstation tree" to show the inter-relationships of personnel and materials allocations. This approach was not considered necessary because of the size and scope of the laboratory. Figure 4 depicts the workcenters within the department. Indirect costs incurred by

workcenters are allocated to the activities beneath them on the diagram. Evening, night and weekend shifts are not shown on the workcenter organization, since they use the same equipment and supplies as the day shift personnel. The primary difference between shifts is in labor costs.

Figure 4. Workcenter organization



Product definition. Chase and Aquilano define a product as "the output from a productive system offered for sale or otherwise made available to some consumer."[24] The chemistry laboratory product is defined as the test procedures which are recorded on the College of American Pathologists Workload Recording System, used by the department. As noted earlier, this posed some problems. Because the system was used solely for staffing purposes, many test procedures whose time values were identical were grouped together, e.g. all of the Dupont (trademark) automated chemistry analyzer tests were listed under the single heading of albumin. Figure 5 shows a list of the actual procedures which are performed on this instrument. The materials for these different tests are not all priced the same. However, those differences will not be reflected in this study. A similar situation was encountered with the Abbott (trademark) therapeutic drug monitoring instrument, which is listed as only gentamycin and the Abbott (trademark) Astra instrument which is only shown as glucose.

Workload. Workload data was taken from the College of American Pathologists Workload Recording system for the months April through September 1985. Two sources of workload data are actually available, the CAP workload report and the hospital Uniform Chart of Accounts (Monthly Pathology Management Summary). The CAP report was used as a source document, since the UCA document is edited to produce the input for the CAP. In addition to the detailed workload by procedure for chemistry, workload was also collected for the other workcenters within the department for use in apportioning indirect expenses.

Figure 5. Dupont automated chemistry analyzer tests

calcium	bilirubin
magnesium	salicylic acid

glutamic-oxaloacetic transaminase	

Because the evening, night, and weekend shifts were not considered separate workcenters, it was necessary to incorporate that workload into the appropriate workcenters. This was done by counting a one month sample of the actual procedures done within each workcenter by the respective shifts. This information is then used in the apportioning of indirect costs.

As previously noted, the CAP workload reporting system also included non-test procedures. These could not be considered as products, rather, they are steps associated with doing actual tests. The 1978 Krieg study did not face this problem, because the counting of non-test procedures was not begun until 1981. To resolve this problem, information from the chief technologist was obtained in order to assign the time counted for doing these non-test procedures against the actual tests they were used to produce. This resulted in the calculation of a modified CAP weighted value for some of the tests. This was then used to assign labor costs more accurately.

Overhead. Annual overhead costs were obtained from the UCA stepdown of "BASOPS" functions. This figure includes building and construction costs as well as utility costs. The standard figures contain biomedical equipment repair costs. However, these were subtracted, since equipment specific repair figures were available. All overhead costs were apportioned using proportion of workload procedures.

Consumable supplies. Cost figures for consumable supplies were taken from two sources, the informal document register of local purchase requests, and the Customer Reorder List. Actual

prices from the hospital cost detail report (STANFINS) were compared against these informal records. All items were categorized by workcenter, and all chemistry items were associated with specific tests or equipment. Subtotals by test or equipment were calculated and assigned against the product list. Those which could not be associated with specific tests, e.g., controls and general supplies, were allocated on the basis of numbers of tests.

Equipment and maintenance. Data on capital equipment used in the department was obtained from the Army Medical Department Property Accounting System hand receipts and maintenance records. Annual capital costs were assessed based on the acquisition cost and a ten year life expectancy. Equipment costs were assessed for all accountable items regardless of dollar value. Information obtained from the chief technologist was used to assign individual equipment to test procedures. Workcenter equipment which could not be assigned to specific tests was allocated on the basis of tests performed.

Similarly, annual maintenance costs were taken from the actual expenditure records for labor and parts maintained by the medical maintenance branch of the logistics division. This was used instead of the medical maintenance cost which had been incorporated in the UCA step-down of BASOPS overhead. In this manner the costs were charged to the tests for which they were required. Annual costs were halved to obtain six month totals. These were incorporated into the summary of direct costs.

Labor. Staffing patterns for the chemistry workcenter were obtained from the chief technologist. Since the department employs a policy of rotating technical staff, average salaries taken from the UCA Expense Distribution report were used to compute labor costs. With the exception of half of the supervisor's time, all workcenter personnel time was counted to determine direct costs. Each test was categorized by the average pay of the personnel performing the test. This was done for all shifts, since the staffing is radically different depending upon the shift. A distinction was not made between the different grades of the staff of the routine day shift, since any of the technical staff, regardless of grade might be performing any test procedure. The labor cost for a given test was computed as:

$$\text{COST} = \text{6 MO AVG SALARY FOR SHIFT} \times \frac{\text{WEIGHTED UNITS}}{\text{TOTAL WEIGHTED UNITS}}$$

The six month total labor cost was incorporated into the direct cost summary as a component of the aggregate direct costs. No attempt was made to differentiate the labor cost of performing a given procedure during different shifts. Although, this could be done using the same data.

Indirect labor costs were calculated by spreading the remainder of the supervisor salary and the chemistry share of the administrative and pathologists time among the workcenter tests using proportion of weighted workload as an allocation factor. The UCA Expense Distribution report was useful for this purpose, because the report reflects the percentage of administrative and pathologist time attributable to the clinical pathology workcenters. The administrative portion represents the

department wide supervision, receptionist and clerical support, and the specimen procurement activity.

CHAPTER 2

DISCUSSION

General

The results of the detailed calculations following the methods detailed above are shown in Appendix D in the same general order as the methodology. This exercise was undertaken to demonstrate a method which could be applied to the entire department of pathology and other ancillary services. Broughton and Woodford[1] point out that isolated costing of one area of work is usually unsatisfactory, because the results cannot be cross-checked against the total expenditure.

This is certainly true in this instance, emphasizing the importance of costing all tests for the department. Before this is undertaken as a routine matter, a number of changes in accounting and general record keeping are necessary. These are addressed in the following chapter.

This aggregate approach has the advantage of taking into account the indirect costs that are not normally part of our thought process about costs.

Analysis of the Results.

There is a temptation to look at the costs shown on page D-64 from a relative rather than an absolute perspective. When

test A costs more than test B, that does not necessarily mean that the department spends more on test A than test B. Volume often reduces the per test cost, while driving the aggregate cost up. This is the inherent disadvantage of using unit costing for decision making. Broughton and Woodford make this point most strongly when they point out that the cheap tests generated on the multichannel analyzers, such as the Technicon (trademark) SMA II, actually stimulate demand to such an extent that "total expenditure rises until it consumes a major part of the budget,"[2] ($ 78,377.73, in this case). Conversely, the low volume tests tend to have a very high individual cost. There are several examples on page D-64 of tests which are offered, yet no procedures were performed. Hence, while the aggregate cost is relatively low, the test appears quite expensive. In some instances these reflect the availability of backup equipment to perform tests which are normally available as part of multi-channel equipment, e.g. bilirubin. It is, therefore, most important to examine both the per test cost and the aggregate cost when evaluating relative cost.

The method used to derive labor costs deserves some discussion. The figures obtained from the UCA Expense Distribution report reflect total compensation to both civilian and military employees. This includes paid fringe benefits and some arbitrary values of privelelges and discounts, and not solely salary expenses.

It is important to note that the method used to compute labor cost is not predictive. It does not take the number of

minutes required to do a test and multiply the salary rate per minute. This is possible using the CAP weighted workunits. However, because the time required to perform laboratory work is dependent on volume as well as the nature of the test, the resultant cost may exceed the actual expenditure. Broughton and Hogan could not identify a simple method for adjusting unit values for different workloads.[3] (This is one explanation for the observed economies of scale in laboratories.) Griffith maintains that trying to predict labor time using the CAP weighted values "probably leads to overstaffing the laboratory by a third to a half."[4] Therefore, the total weighted value for each test is only used to prorate the average salary expended against individual tests. There is no consideration of non-productive time in this determination for this reason.

One matter of interest was the question of the relationship of actual cost figures to the CAP weighted values. The DoD Medical Expense Reporting System (MEPR, formerly UCA) apportions pathology expenses to the various customer areas of the hospital on the basis of percent of weighted CAP workunits performed for respective customer areas.[5] This presumes that there is at least a relationship between cost and the relative CAP units, which are actually expressed in terms of man-minutes. The graph on page D-65 plots cost versus weighted units. At a .05 level of significance, there is no significant relationship between the two parameters (linear regression for the non-zero values, $t=2.04$, $p=.052$, $df = 25$). It would appear from this data that the CAP weighted value is not a very good estimate of relative cost. This is not unexpected, since it has been observed

elsewhere that military laboratories achieve significant economies of scale.[6]

Problems encountered. Apportionment is always inferior to direct association of costs with procedures. The essential management question becomes whether the expense required to obtain the information is worth the return on investment. Figure 6 illustrates some of the information systems which are available within the department. The organization and structure of these systems are not consistent with the objective of deriving product cost information. Figure 7 depicts the actual and desired levels of detailed information required for costing. The greatest difficulty was the time consuming nature of the data collection. This was due to the lack of detail and differing levels of accounting and coordination between the various information systems supporting the department.

Supply purchase official records are the cost detail reports generated by STANFINS (Standard Financial System, equivalent to a general ledger). For the purposes of this system, the department is divided into four accounts (account processing codes), clinical pathology, anatomic pathology, administration and blood bank. These documents reflect the initial commitment of funds and the final expenditures arranged by type of item (element of expense). It is not possible to determine the workcenter for which items are purchased using this document, although the figures are the most accurate listing of expenses. Manual informal departmental records, the document register and the customer reorder list, contained the workcenter information on

Figure 6. Financial Information Systems

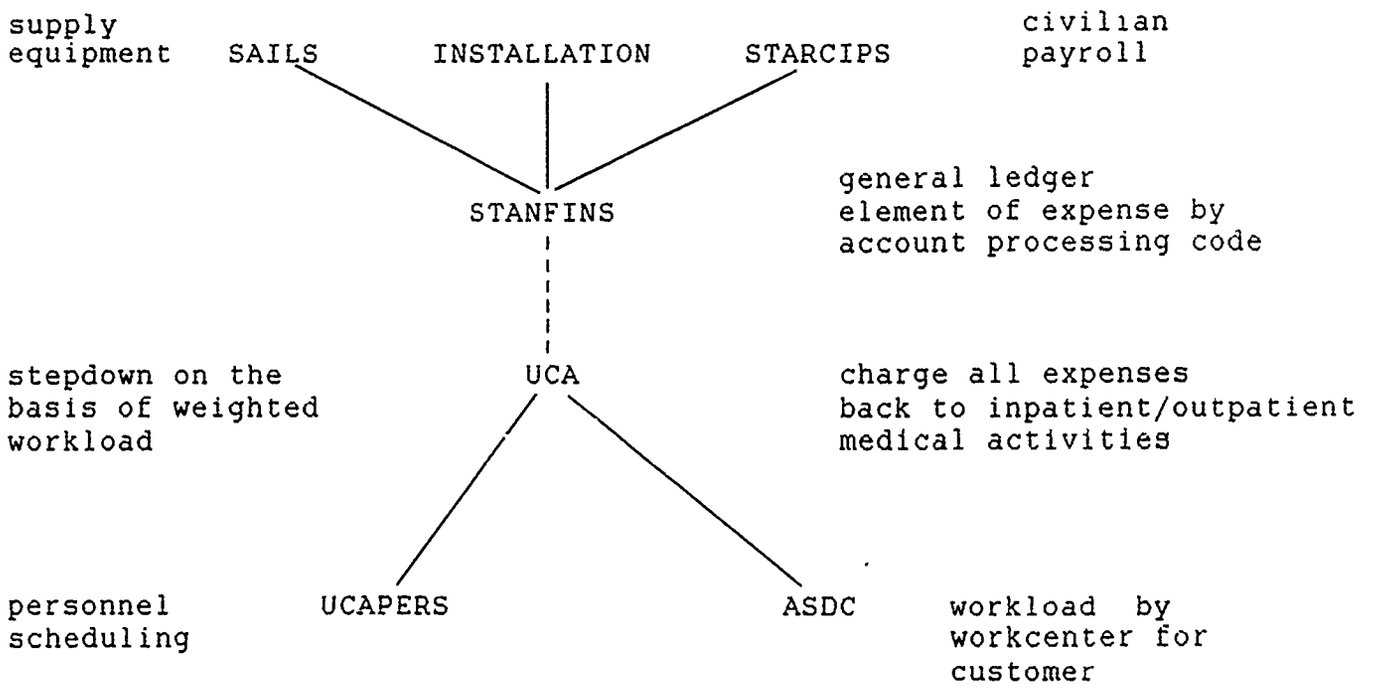

Figure 7. Accounting Structure

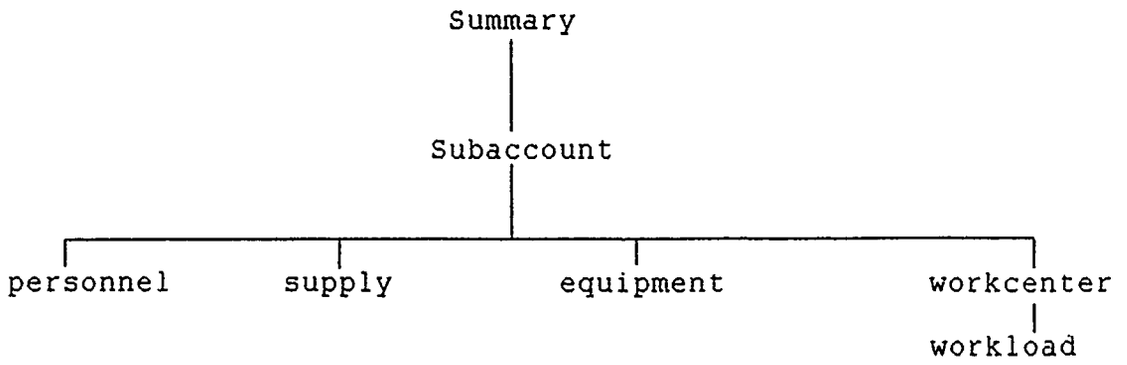
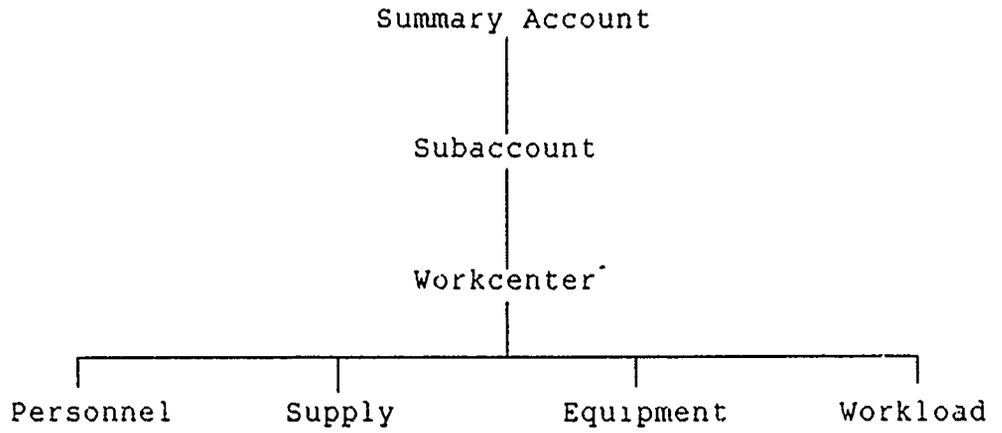
ACTUAL



DESIRED



each purchase. This data was entered into Lotus files, sorted, and subtotaled in order to obtain the data shown on pages D-12 to D-39.

Equipment cost information, retrieved from the AMEDDPAS records, were all listed under a single account. In order to determine which workcenter used different items of equipment, handwritten annotations were consulted and summarized in Lotus files. A similar problem was encountered in evaluating labor costs. The lowest level of detail available in the UCA and UCAPERS reports were the subaccounts of clinical pathology, anatomic pathology, administration and blood bank. The personnel staffing and authorization document is organized into workcenters, yet, all of the accounting documents reflect a different level of detail. Staffing information was obtained from a master planning board in the office of the laboratory manager.

The only records which presented data by workcenters were the CAP workload records. Work performed by the second, third, and weekend shifts was readily identified and was easily associated with the appropriate workcenters. As previously noted, significant detail on individual tests performed on multi-channel and automated equipment was unavailable. Invoice data was available which would have matched the supply costs for these tests with actual workload figures. Without the workload figures for the specific tests, this was not possible.

Implications for Management

Matrix based control. "True cost savings result when reductions occur in fixed costs such as capital outlay for equipment, variable costs such as supplies necessary for repeated procedures, labor time required to provide a service ... or a combination of all three." [7] These are long term savings which can be achieved by administrative policy changes, decreases in utilization and strategic planning of services. Young and Saltzman describe four cost-influencing variables, case mix, resources per case, resource unit price, and resource efficiency (defined as services per diagnosis measured against some standard).[8] Each of these variables are under the control of different elements of the organization. Product cost information such as that produced by this study should be provided to enable each level to make decisions in the best interest of patient care and the financial health of the institution.

Resource unit price is under the control of the hosptial administration. Cost data heightens awarenes of the need for efficiency and enhanced productivity. Some short term savings can be gained by the discontinuation of a given test, avoiding the direct consumable costs, usually only a small proportion of total cost. However, combining cost data with workload and workload projections, demand for services can be predicted and scheduled, providing opportunities for improved labor productivity through variable staffing approaches. An example of a labor productivity problem in this case is the high indirect

departmental personnel expense (see page D-57). Griffith maintains that the only way "to control productivity in hospitals is to reduce employment."[9]

The most extensive use of product cost information involves the "potential of physicians and other primary care providers to become leaders in reducing hospital costs while maintaining quality care."[10] Physicians control the resources expended per case and the resource efficiency elements of the cost factors. An information system framework featuring cost data can provide feedback on individual case management and pattern analysis by individual providers. This allows for accountability for performance through peer review of variance. Accurate advance cost data is necessary for physicians to evaluate which of two medically acceptable treatment alternatives is more consistent with the hospital's cost containment efforts. This process can be facilitated by the publication of treatment guides and clinical treatment protocols which feature recommendations on tests, procedures, drugs, and ancillary procedures.

Finally, the Board controls the last cost factor of case mix through the designation of the scope of the hospital and the credentialing of the medical staff. Stanford University advocates making cost effective care a criterion for decision making for new services, medical staff appointments and reappointments, which would certainly get the attention of the medical staff.[11]

Medical Expense Performance Reporting. A mechanism is already in place in Department of Defense hospitals to track the utilization of laboratory tests by inpatient and outpatient

service areas (Automated System for Data Capture or ASDC), although not by the requesting physician or individual patient.[12] In addition to its redundancy with the CAP workload recording system, the data capture for this information is highly labor intensive and serves no other purpose within the department. Not unexpectedly, the data is not highly reliable. However, the data is used to apportion all of the department of pathology operational costs to the inpatient and outpatient service areas. This is done on the basis of percent of weighted workload. Using weighted workload in this manner presumes that there is a constant cost per weighted work unit. This is clearly not a valid assumption. Since the relationship is not linear, and it is not constant between facilities, (given the observed economies of scale), it would be highly preferred to use calculated product costs to determine a more correct method to allocate pathology costs to customer activities. Substituting calculated cost information for the CAP weighted value in the MEPR would result in a more accurate reflection of resources used.

Strategies to reduce costs. The purpose of collecting and analyzing product cost information is to influence behavior in order to keep total product costs less than reimbursement. In the federal sector the President has issued an Executive Order mandating productivity improvement within the Executive Branch of the Government of 20% by the year 1992.[13] It may be useful to examine the techniques used by the private sector hospital laboratories to cope with prospective payment and fixed reimbursement in order to develop a strategy to comply with such

an ambitious target. Hospital tactics include reducing the length of stay, favoring outpatient diagnosis, promoting structured care plans, assisting in home care and recovery, and a strong emphasis on restraint.[14]

At the internal level, the majority of hospital laboratories (59%) have reduced staff by an average of 12%. Nearly all of these reductions have bee. accomplished through attrition rather than firing. Many have expanded services, going into high volume business in an effort to reduce reference laboratory referrals. At the same time, they are expanding marketing efforts into the ambulatory care arena, and advocating the centers of excellence concept in order to market to other hospitals.[15]

At the external level, 53% of laboratories have begun monitoring test ordering per case. DRG matched criteria for specific test appropriateness have now been published by the College of American Pathologistss for a small number of DRG's, which may be useful for this purpose.[16] Computerized results are being used by 75% of large hospitals, and many have instituted automatic follow-up testing based on abnormal results, in an effort to reduce the length of stay of patients. Closer attention is being paid to the appropriateness of admission tests, routine and repetitive ordering, and the need for pathologist approval for certain high cost procedures.[17]

An excellent example of the kind of analysis that is possible with the availability of cost data for laboratory products is the study by Klatt, et al. on the effective cost of routine testing.[18] When Klatt compared the amount of routine testing for the creatine kinase (CK) enzyme against the number

that were actually clinically indicated for diagnostic purposes, he found that the effective cost was not the $0.64 reported by the laboratory, but $9.60. This kind of analysis makes a strong argument for pressing for more selective ordering and the manufacture of the selective laboratory technology to support it.

CHAPTER III

CONCLUSION

FINDINGS AND CONCLUSIONS

General. The lead time to develop, procure, or modify functional automation in the federal medical sector is sufficiently long that a strategic plan should be developed now to accomodate a shift to diagnosis-based payment and the budget incentives that will accompany it within Department of Defense health facilities. As this study has demonstrated, the data can be obtained from available information systems to calculate product cost information. However, manual computation is an extremely time consuming task. The next logical step is the automation of the process, first by maximizing the existing data systems in order to facilitate manual computation and later through software development for automated data processing. At the University of California at San Diego, Kelliher has designed a Consolidated Operational Reporting system (CORE) which features product costing, labor productivity, inventory control, and capital productivity reporting.[1] And Ernst and Whinney is advertising the Standard Cost Manager (trademark) which develops standard cost profiles by individual procedure and product type.

Recommendations. Three major recommendations are presented as interim solutions until an off the shelf or totally tailor designed system can be obtained. The first group of recommendations deals with refining the existing information framework supporting the Defense hospital ancillary services to

offer the level of detail needed to facilitate the process (see figure 7). 1.) The duplication of the CAP workload recording and the MEPR workload data capture should be eliminated. The simplest solution is the discontinuation of the CAP workload recording system in favor of modifying the UCA workload reporting features to offer similar management reports. 2.)Workload recording should be modified to differentiate all orderable tests performed by distinct workcenters, where workcenters are redefined down to the lowest level of analytical equipment groupings. 3.) Account Processing Codes (APC's) for the purchasing and civilian pay processing systems (SAILS, STARCIPS, and Installation Accounts) should be realigned according to workcenters. Since a number of installations have plans to incorporate a six digit APC code in place of the current four digit codes, this should not be difficult. 4.) Corresponding realignment of the MEPR codes for use within the UCAPERS and MEPR should be made to insure that expenses recorded in the general ledger are passed appropriately to the cost accounting within the MEPR. 5.) Property records (AMEDDPAS) should be subdivided at least by section supervisors responsible for the various workcenters.

Secondly, a workload, staffing projection and productivity analysis system, similar to the Clinical Laboratory Management System developed by York[2], should be employed. It should offer a refinement of the CAP workload system which compensates for volume in the projection of staffing requirements. Ideally this system should be able to use UCAPERS and MEPR data which has already been collected. Recent inroads by the Datapoint

Corporation enabling the downloading of selected files from the MEPR data files may permit this kind of interaction to take place.[3]

Finally, operational data should be collected as a normal consequence of the production of the workcenter product, rather than a separate task. This would involve following the lead of the large hospital laboratories and automating result reporting and related functions. Workload, direct technician time, requesting activity or physician, and consumed resources could all be captured during the course of production mediated by a suitable automated laboratory information system.

Summary. While military medical facilities may not be actively involved with the marketing of hospital procucts, the analysis of intermediate and final product costs will become increasingly important because of the changing nature of reimbursement and cost containment in the federal medical sector. These costs will become an integral part of the measurement of efficiency and effectiveness of medical services as the Department of Defense plans to overhaul healthcare delivery to its authorized beneficiaries.[4] Military medical managers will need to become more astute in preparing and evaluating product costs at both the intermediate and final level in order to purchase contractual services intelligently and to manage existing military medical facilities in more efficient and effective manner.

APPENDICES

APPENDIX A

DEFINITIONS

DEFINITIONS

BASOPS. BASOPS is an acronym for base operations support, which describes services which are furnished to tenant military organizations by their host unit. Such support typically includes utilities, management operations, and maintenance.

Lotus 1-2-3. Lotus is a commercial software product with the capability to record and compute large tables of numbers termed "spreadsheets."

Medical Expense and Performance Reporting System. MEPR is the new designation for the Department of Defense expense recording system which prescribes standard workcenters, uniform performance indicators, and a cost assignment methodology. This program considers Inpatient care, Ambulatory care, Dental care and Special programs to be final operating expense accounts. Ancillary Services and Support Services are intermediate operating expense accounts whose expenses are reassigned to the final operating expense accounts.

UCAPERS. Uniform Chart of Accounts for Personnel is a distinct feature of the Uniform Chart of Accounts which permits scheduling and reporting of personnel time against designated workcenters. At the present, only the Department of the Army is using this feature.

Weighted workunits. The MEPR uses weighted procedures or weighted workunits as a measure of resource utilization in order to reassign expenses to final operating expense accounts. Weighted procedures are defined for dental, pharmacy, pathology, radiology, pulmonary function, cardiology, and nuclear medicine.

APPENDIX B

BASIS OF ALLOCATION

BASIS OF ALLOCATION

Direct Costs

Capital Equipment	The annual amortized cost of each item which can be readily matched with specific tests will be allocated based on relative proportion of tests supported.
Labor	Average salary for each workcenter shift will be allocated based on the CAP weighted values (man-minutes.) Only technician time will be considered. Working supervisor's time will be divided, 50% direct and 50% indirect.
Consumable Supplies	All purchases of items which can readily be identified as associated with specific tests will be considered as direct costs and will be allocated on the basis of patient tests performed.

Indirect Costs

Overhead	Clinical pathology overhead will be apportioned between workcenters on the basis of patient tests. Workcenter overhead will be allocated to tests on the basis of patient tests.

Capital Equipment	Annual amortized cost of equipment used by indirect centers (administration, etc.) will be apportioned between supported workcenters on the basis of numbers of patient procedures. Workcenter indirect equipment costs will be allocated to tests on the basis of patient tests.
Labor	Administrative, supervisory, clerical and specimen collection salary costs will be apportioned between supported workcenters on the basis of proportion of weighted workload. Indirect labor will be allocated to tests on the basis of weighted workload.
Consumable Supplies	The cost of all supplies used by indirect centers will be apportioned to supported workcenters on the basis of patient tests. Supply costs from materials which could not be matched with specific tests and those from the indirect centers will be allocated to tests on the basis of patient tests.
