*Abstracts* (if necessary, and identify of page number)

The important issue of how the superconducting transition temperature  $T_c$  in disordered systems changes near the M-I transition where strong localization ( $k_F l \sim 1$ ) is expected has been studied in the  $\text{Nb-Ge}$  system. In the high  $\text{Nb}$  concentration, which is in the weakly localized regime,  $T_c$  decreases linearly with decreasing  $\text{Nb}$  concentration from 7.5 K (7.5 at. %  $\text{Nb}$ ) at a rate of 0.18 K/at. %  $\text{Nb}$ . In this region the ratio of electron-phonon coupling constant  $\lambda$  to the bare density of states  $N_c(0)$  is constant, which is consistent with the Varma-Dynes tight-binding model. An extrapolation of the linear behavior of  $T_c$  in this regime yields the disappearance of  $T_c$  near 35 at. %  $\text{Nb}$ . However, measurements show that  $T_c$  exists down to 13.5 at. %  $\text{Nb}$ . A non-superconducting metallic phase is found to exist between 13.5 at. %  $\text{Nb}$  at which concentration the insulating phase occurs. (FAS) ←

10 Abstract (Cont.)

Superconductivity in very thin films of niobium has been investigated. By use of the ion gun which has been installed in the evaporator it has been possible to identify 3 separate mechanisms which contribute to the reduction in  $T_c$  as the film thickness is decreased, namely lifetime broadening, proximity effect and localization. Then upon elimination of the first two, the effect of localization in the weakly localized limit is found to agree quantitatively with theory except for  $\leq 15 \text{ \AA}$  where the fall off of  $T_c$  is less than expected.

A small single grid ion source has been constructed in order to promote the growth of metastable films at low temperatures. A high flux of  $N_2^+$  at energies as low as 20 eV has been achieved. Studies indicate that the ion beam promotes the growth of single crystal AlN compounds at lower temperatures. Preliminary studies on the growth of transistor metal nitrides have been initiated.

Progress has been made on a new ultra high vacuum M.B.E. evaporator being constructed at Stanford with funds from the DOD Instrumentation Program. A vendor has been selected and a purchase order made for the design-study of the load-lock/transfer arm and substrate configuration. This is the most sensitive and critical part of our unique concept of load-locking and transferring the complete substrate configuration into and out of the evaporation chamber. Sputtering of molybdenum disulfide onto the disassembled parts - balls, races, and retainers has been chosen as the first step in improving the reliability of the ball bearings used in the present method of evaporation rate control.
