FINAL REPORT ON

"RADAR BACKSCATTER FROM THE SEA:
CONTROLLED EXPERIMENTS"

Richard K. Moore, Principal Investigator

This is the final report on ONR Grant N00014-89-J-3022. Since most of the work was in journal articles, conference proceedings, and reports, this report is brief.

Work continued, and was largely concluded, on analysis of the TOWARD, SAXON-CLT, and NILDEX data sets. Comparison between optical and radio measurements of ripple spectra at TOWARD showed favorable results. Although the wind direction was usually unfavorable for SAXON-CLT, we obtained useful data on modulation in the crosswind direction. We also demonstrated that a vector slope gauge can work, but for logistic reasons its deployment made its footprint close to the tower. Hence, the data are useful only for proof of concept, not for oceanographic application.

A new theory of SAR imaging of the ocean was developed. It incorporates elements of previous theories, but shows an improved way to find out the effects of signal modulations on the observed spectra. It confirms, by a different method, the results from several other theoretical and experimental studies on processor focus adjustment. These show optimum image contrast occurs for along-track wave motion when the processor is set to $(\text{phase velocity})/2$. The method of analysis used allowed closer examination of the basis for the two-scale (Bragg resonance with slope modulation) model for ocean backscatter. The results cast some doubt on the validity of the Bragg-scatter model for explaining many observed phenomena.

We built a 35-GHz radar to measure backscatter from the sea at mm wavelengths. It was successfully tested on a local lake and Lake Washington. This radar, with the addition (under grant N00014-89-J-3221) of a power amplifier, a 3-beam antenna, and a new control system, forms the basis for the high-performance vector slope gauge now in use at SAXON-FPN.

A list of publications and presentations resulting from this grant follows.
