AFOSR-88-0081

November 1, 1987 - October 30, 1990

Approved for public release; distribution unlimited.

11 136

It should be noted at the outset that the PI's research described in this section was supported by one three-year AFOSR grant which expired October 31, 1990. A preproposal for renewal was approved by the AFOSR June 12, 1990 and the full proposal based on the preproposal was mailed July 20, 1990. On July 30 the PI was informed by telephone by the AFOSR that although this new departure in our research program had been unusually productive, recent fiscal cutbacks and changes in programmatic priorities necessitated that the full proposal be declined without review.

The primary objectives of the AFOSR grant were:

A. Exploration of the chemistry of silatranes such as 1 and azasilatranes such as 2.

B. Synthesis of silatranes in which silicon is pentacoordinated by nitrogens as in 3.

C. Synthesis of oligomers/polymers containing azasilatrane repeating units.

All three of these objectives were achieved.

What follows is a summary of the work associated with the objectives A-C given $\overline{\Box}$ above.

A. Exploration of the chemistry of silatranes and azasilatranes

In order to construct polymers of types 4 and 5, it was necessary to gain some knowledge of the reactivities (nucleophilicities) of the exocyclic axial, the equatorial, and the endocyclic axial substituents on the silicon in 1 and 2. The chemistries of these reactivity sites are now addressed in turn.

1. Reactivity of the axial substituent in silatranes and azasilatranes

The equatorial and axial oxygens in alkoxy silatranes such as 6 and 7 might be

expected to display increased basicity owing to electron induction into silicon by the *trans* axial tertiary amino nitrogen. We recently reported the first isolation and structural characterization of silatrane adducts in which the exocyclic axial oxygen behaves as the Lewis basic site.¹ Thus silatranes 6 and 7 are fully covalently bonded and hydrogen bonded to their Lewis acid components in the structures of $8(BF_4)$ and 9, respectively. The SiN_{ax} bond length decreases considerably (~0.5 Å) from 7 to $8(BF_4)$ (1.965(5) Å) and the

latter is the shortest such bond distance reported for any silatrane. The O(H)O distance in **9** (2.489 Å) is the shortest reported for an unsymmetrical hydrogen bond. The SiO_{ax} distance increases by a total of 0.17 Å in the order $7 < 9 < 8(BF_4)$.

Interestingly, cation 8 is the first reported example of a silatrane having an ideal TBP symmetry. Thus all others that have been structured contain silicon atoms that are at least ~0.1 Å above the O_{eq} plane. In this connection we have shown¹ that a prediction² that an ideally TBP silatrane should possess an Si-N_{ax} distance of 1.83 Å is incorrect by more than 0.1 Å.

Measurement of phenol v(OH) shifts reveals the basicity order $(Me_3Si)_2O < Si(OR)_4 < alkoxy silatranes <math>\leq Me_3SiOMe < Et_2O$. While this trend places the electron inductive ability of the silatranyl group ahead of (RO)_3Si, it is below that of an Et group.

Until we began the work supported by the AFOSR grant, there were only four azasilatranes (2) reported and very little was known about them. Structural evidence is accumulating, however, that these compounds possess Si-N_{ax} bonds at least as robust as those in silatranes (1).^{3,4} This is somewhat unexpected in view of the greater electronegativity of the equatorial oxygen substituents in 1 than in 2. Thus the Si-N_{ax} bond lengths in 10,³ 11⁴ and 12⁴ are very comparable to that in 7.¹ That the ethoxy oxygen

in these azasilatranes also displays Lewis base character is evident in complexes 13 and 14 which can be converted to 15 and 16, respectively in the presence of CO.

We carried out several interesting substitution reactions at the axial position. In reaction 2 the synthesis of the novel silatranium cation 18 is realized under very mild

conditions.⁵ Compound 18 is, however, very resistant to nucleophilic attack by F⁻, H⁻ and ⁻OR.

We converted azasilatrane 19 to 20³ and 21,⁶ which we planned to use as precursors to amido azasilatranes. Unlike silanes,⁷ 19 is unreactive to Si-H proton substitution by

amide.³ Unfortunately the range of Z groups in 22 formed via reaction 5 seems to be restricted to Z = H, OR, OAr, R and Ar.³

Attempts to synthesize the novel structure 23, which because of its zero dipole dipole moment, may be a volatile MOCVD precursor for SiN, were unsuccessful.⁸

The above studies were being extended to azastannatranes such as 24-27, a class of compounds we synthesized for the first time.⁶ A most curious observation in the crystal structure determination of azastannatrane 26 is that the two independent molecules in the unit cell possess substantially different Sn-N_{ax} bond lengths of 2.380(2) and 2.453(2) Å.⁹ Two different ¹¹⁹Sn chemical shifts in the solid state have also been observed.⁹ The most reasonable rationale for this observation is differences in crystal packing forces. This rationale has also been advanced¹⁰ to account for the observation that silatranes in the solid state, such as those we have structured, frequently exhibit shorter Si-N_{ax} distances than are found calculationally or in the gas phase by electron diffraction.

2. Reactivity of the equatorial substituent in silatranes and azasilatranes

Discussed in this section are addition of H^+ and R^+ to an N_{eq} site, displacement of the N_{eq} -H hydrogen by R, and solvolytic cleavage of Si- N_{eq} bonds.

In a recent communication¹¹ we reported the synthesis of **28**, the first stable representative of incipient proton-assisted equatorial bond cleavage of a five-coordinate intermediate to be isolated.¹¹ Reaction 8 actually constituted an attempt to substitute the

axial proton of 19 by azide. Instead, Me_3Si^+ attacks N_{eq} sites, liberating the protonating agent HN₃. Interestingly compound 28 co-crystallized with 19 in the unit cell of 29. The molecular structure of 29¹¹ as well as its analogue 33,¹² determined by X-ray means, revealed that in each case the Si- $\dot{N}_{eq}H_2$ length is ca. 10% longer than the two Si- $N_{eq}H$ bonds in this cation. By analogous reactions of azasilatranes with MeOTf and Me₃SiOTf, the new salts 34-39 were synthesized.¹³

We carried out a variety of substitution reactions at the N_{eq} -H function in azasilatranes as exemplified by reaction 9 and Scheme I.^{3,14} Though the sterically elongated Si-N_{ax} distance in 51 (2.775(7) Å) is the longest ever recorded in an azasilatrane,

it is 24% shorter than the sum of the van der Waals radii, suggesting some degree of silicon interaction with the nearly planar N_{ax} .¹⁴

Solvolysis experiments on azasilatranes with MeOH revealed that the $Si-N_{eq}$ bond is more sensitive than the axial Si-H, Si-OEt or Si-CH₃ bond.¹⁵ In Schemes II-V it is seen that a) solvolysis of the substituent on N_{eq} may or may not precede Si- N_{eq} bond cleavage and b) monocyclic solvolysis intermediates are sometimes detected.

The rate and pathway of methanolysis appear to be strongly dependent on the strength of the N_{eq} -substituent bond and on the steric crowding these groups experience with the exocyclic axial group.¹⁵

3. Reactivity of the endocyclic axial substituent in azasilatranes

Although substantial Si- N_{ax} bond strength in azasilatranes is afforded by the presence of the three chelating five-membered rings, weakening of this bond has been seen to occur in the previous section by steric crowding (e.g., 51) and cleavage can take

Scheme Π

Scheme III

Scheme IV

59

place by solvolytic cleavage of one of the Si-N_{eq} bonds (e.g., 54). The weakened Si-N_{ax} interaction in 51 allowed us to synthesize 60^{14} in which the Si-N_{ax} distance $(3.561 \text{ Å})^{15}$ has increased from 2.775 Å in 51 to being close to the van der Waals radius (3.65 Å). The BH₃ adduct of 51 (61) is currently being structured.¹⁶

The reaction in which equatorially silvlated 38 is formed also affords the axially silvlated isomer 62 in an equilibrium which depends upon solvent polarity and temperature.¹² Arguments substantiating the possibility of a hypercoordinate nitrogen in 62 have been brought forward.¹³

B. Synthesis of silatranes pentacoordinated by nitrogen ligands

Although rational efforts to synthesize compounds of this type have thus far not been successful (See Section II. A. 1.; note however, 27) compound 29 upon heating under vacuum yields 63.¹² A similar reaction (also involving disproportionation, however)

produces 64 from 33.12 These are the first reported examples of silatrane-type systems

containing five nitrogens coordinated to the silicon. We also have preliminary evidence that 65 is formed in reaction 12.⁸

C. Synthesis of oligomers/polymers containing azasilatrane units

Two azasilatrane-based oligomers/polymers were partially characterized. The second step in Scheme VI gives rise to a small amount of a sublimate which may be 66. Further heating of the residue gives a solid 67 which has appreciable solubility only in DMSO.

The alternate routes in Scheme VII give a solid 68 which, encouragingly, is chloroform soluble. The ²⁹Si NMR spectrum of 68 displays two broad peaks indicative of four-coordinate (-25 ppm) and five-coordinate (-77 ppm) silicon. The ¹H NMR spectrum exhibits $N(CH_3)_2$ peaks but no detectable NH resonance, suggesting that all three N_{eq} -H

protons in 19 react with (Me₂N)₃SiH possibly giving rise to "star" polymer in which the equatorial nitrogens in the triangular SiN₃ moieties of the azasilatrane units are bridged by HSiNMe₂ groups.

Polymers 69-71 shown in reactions 13-15, respectively, formed under similar

19 + 2.5 HSi(NMe₂)₃
$$\xrightarrow{\Delta}$$
 69 (13)
(NH₄)₂SO₄

$$19 + 0.35 \text{ HSiCl}_3 + \text{HSi}(\text{NMe}_2)_3 \xrightarrow{\Delta, \text{ Et}_3\text{N}} 70 \qquad (14)$$

47 + 2.25 HSi(NMe₂)₃
$$\xrightarrow{\Delta}$$
 71 (15)
(NH₄)₂SO₄

conditions and were studied by NMR spectroscopy in both solution and the solid state. ²⁹Si NMR studies confirm the presence of both four and five-coordinate Si in all cases. The absence of NMe₂ and NH functions in 69 was inferred from DEPT-¹³C and DEPT-¹H spectra, respectively. While NH groups are not apparent in 70, NMe₂ groups do appear in both the ¹H and ¹³C NMR spectra. Using ¹H - ²⁹Si polarization transfer techniques, all the H-Si groups in 71 appear in the four-coordinate ²⁹Si region, while the MeSi moieties (originating from the starting atrane 47) resonate in the five-coordinate ²⁹Si region. In

contrast to 69 and 70, 71 possesses NH groups as judged from the ¹H NMR and IR spectra. The spectroscopic data are consistent with a linear polymer wherein one of the three NH functions on the silatrane 47 does not react.
