Hartstone Benchmark User's Guide, Version 1.0

Abstract: The Hartstone benchmark is a set of timing requirements for testing a system's ability to handle hard real-time applications. It is specified as a set of processes with well-defined workloads and timing constraints. The name *Hartstone* derives from *HARd Real Time* and the fact that the workloads are presently based on the well-known Whetstone benchmark. This report describes the structure and behavior of an implementation in the Ada programming language of one category of Hartstone requirements, the Periodic Harmonic (PH) Test Series. The Ada implementation of the PH series is aimed primarily at real-time embedded processors where the only executing code is benchmark and the Ada runtime system. Guidelines for performing various Hartstone experiments and interpreting the results are provided. Also included are the source code listings of the benchmark, information on how to obtain the source code in machine-readable form, and some sample results for Version 1.0 of the Systems Designers XD Ada VAX/VMS - MC68020 cross-compiler.

1. Introduction

The Hartstone benchmark comprises a series of requirements to be used for testing the ability of a system to handle hard real-time applications. Its name derives from Hard Real Time and the fact that the computational workload of the benchmark is provided by a variant of the Whetstone benchmark [Curnow 76], [Harbaugh 84], [Wichmann 88]. "Hard" real-time applications *must* meet their deadlines to satisfy system requirements; this contrasts with "soft" real-time applications where a statistical distribution of response times is acceptable [Liu 73]. The rationale and operational concept of the Hartstone benchmark are described in [Weiderman 89]; in particular, five test series of increasing complexity are defined and one of these, the Periodic Harmonic (PH) Test Series, is described in detail.¹

This user's guide describes the design and implementation of the PH series in the Ada programming language [LRM 83]. The overall structure and behavior of the benchmark programs are described, implementation-dependent aspects of the design are noted, and guidelines for performing the experiments described in [Weiderman 89] and interpreting their results are provided. Source code for the benchmark and sample results for the Systems Designers XD Ada VAX/VMS to Motorola MC68020 cross-compiler, Version 1.0, are included as appendices, as well as information on how to obtain machine-readable copies of the Hartstone source code and supporting documentation.

This Ada implementation of the Hartstone PH test series is aimed primarily at real-time embedded or "bare-board" target systems. It is assumed that on such systems the only executing code is the Hartstone code and the Ada runtime system. Hartstone can be used to gauge the performance of the Ada runtime system and its ability to handle multiple real-time tasks efficiently. As this guide explains, Hartstone is not a simple benchmark that produces just one number

¹This document is recommended reading for people wishing to gain a broader understanding of the issues that motivated the concept of the Hartstone benchmark.

representing the "score" of the runtime system. The output from all Hartstone experiments must be considered, as well as the characteristics of the target processor, when drawing conclusions based on Hartstone results.

2. Periodic Harmonic Test Series

2.1. Periodic Tasks

The Periodic Harmonic (PH) Test Series is the simplest of the five test series defined in [Weiderman 89] for the Hartstone benchmark. The Ada implementation (the "Delay/ND" design discussed in [Weiderman 89]) consists of a set of five periodic Ada tasks that are independent in the sense that their execution need not be synchronized; they do not communicate with each other. Each periodic task has a *frequency*, a *workload*, and a *priority*. Task frequencies are harmonic: the frequency of a task is an integral multiple of the frequency of any lower-frequency task. Frequencies are expressed in Hertz; the reciprocal of the frequency is a task's period, in seconds.

A task workload is a fixed amount of work, which must be completed within a task's period. The workload of a Hartstone periodic task is provided by a variant of the well-known composite synthetic Whetstone benchmark [Curnow 76] called Small_Whetstone [Wichmann 88]. Small_Whetstone has a main loop which executes one thousand Whetstone instructions, or one *Kilo-Whetstone*. A Hartstone task is required to execute a specific number of Kilo-Whetstones within its period. The rate at which it does this amount of work is measured in Kilo-Whetstone instructions per second, or *KWIPS*. This *workload rate*, or speed, of a task is equal to its per-period workload multiplied by the task's frequency. The *deadline* for completion of the workload is the next scheduled activation time of the task. Successful completion on time is defined as a *met deadline*. Failure to complete the workload on time results in a *missed deadline* for the task. Missing a deadline in a hard real-time application is normally considered a system failure. In the Hartstone benchmark, however, processing continues in order to gather additional information about the nature of the failure and the behavior of the benchmark after deadlines have begun to be missed. Therefore, in the Ada implementation of the PH series, if a task misses a deadline it attempts to compensate by not doing any more work until the start of a new period. This process, called *load-shedding*, means that if a deadline is missed by a large amount (more than one period, say) several work assignments may be cancelled. Deadlines ignored during load-shedding are known as *skipped deadlines*. The reason for load-shedding is that "resetting" offending tasks and letting the test series continue allows more useful information to be gathered about the failure pattern of the task set. The conditions under which the test series eventually completes are discussed in Section 2.2.

Task priorities are assigned to tasks according to a *rate-monotonic* scheduling discipline [Liu 73], [Sha 89]. This means that higher-frequency tasks are assigned a higher priority than lower-frequency tasks. The priorities are fixed and distinct. The rate-monotonic priority assignment is optimal in the sense that no other fixed-priority assignment scheme can schedule a task set that cannot be scheduled by the rate-monotonic scheme [Liu 73]. In the Hartstone task set, priorities are statically assigned at compile time via the Priority pragma. Task 1 has the lowest priority and task 5 has the highest. The main program which starts these tasks is assigned a priority higher than any task so that it can activate all tasks via an Ada rendezvous.

A task implements periodicity by successively adding its period to a predetermined starting time to compute its next activation time. Within a period, it does its workload and then suspends itself until its next activation time. This paradigm, based on the one shown in Section 9.6 of the *Ada Language Reference Manual* [LRM 83], was adopted because of its portability, portability being one of the major objectives of the Hartstone benchmark. The implications of using this paradigm are discussed in Section 5.4.

2.2. Hartstone Experiments

Four *experiments* have been defined for the PH series, each consisting of a number of *tests*. A test will either *succeed* by meeting all its deadlines, or *fail* by not meeting at least one deadline. The Hartstone main program initiates a test by activating the set of Hartstone tasks; these perform the actual test by executing their assigned workloads, periodically, for the duration of the test. A test will always run for its predefined test duration. When a test finishes, the results are collected by the main program and a check is made to see if the test results satisfy a user-defined *completion criterion* for the entire experiment. If they do, the experiment is over and a summary of the entire experiment is generated; if not, a new test is initiated and the experiment continues. Experiment completion criteria are defined later in this section.

Each new test in an experiment is derived from the characteristics of the preceding test. The first test, called the *baseline test*, is the same for all experiments: activate the initial set of Hartstone tasks (called the *baseline task set*) and collect the results from them. As an example, the baseline test below has a total workload rate of 320 Kilo-Whetstone instructions per second (KWIPS)² allocated as follows:

Task No.	Frequency (Hertz)	Kilo-Whets per period	Kilo-Whets per second
1	2.00	32	64.00
2	4.00	16	64.00
3	8.00	8	64.00
4	16.00	4	64.00
5	32.00	2	64.00

			320.00

²This baseline test is different from that of [Weideman 89]; the frequencies and workloads have been doubled. This doubling was done initially to cause deadlines to be missed after fewer iterations, so that experiments would complete in a shorter time. The original task set proved to be too low a starting point for the cross-compiler and target used in Hartstone prototype testing, the Systems Designers XD Ada compiler, and a 12.5 MHz Motorola MC68020 target processor. During subsequent testing on a number of different cross-compilers, stronger reasons for increasing or decreasing the frequencies and workloads of the baseline task set emerged. A more detailed discussion of desirable properties of the baseline task set appears in Section 5.2.

The four experiments are:

Experiment 1: Starting with the baseline task set, the frequency of the highest frequency task (task 5) is increased for each new test until a task misses a deadline. The frequencies of the other tasks and the per-period workloads of all tasks do not change. The amount by which the frequency increases must preserve the harmonic nature of the task set frequencies: this means a minimum increase by an amount equal to the frequency of task 4. For the previous example, this sequence increases the task set's total workload rate by 32 KWIPS (16 Hertz, the frequency increment, times task 5's per-period workload) at a time and tests the system's ability to handle a fine granularity of time (the decreasing period of the highest-frequency task) and to switch rapidly between processes.

Experiment 2: Starting with the baseline task set, all the frequencies are scaled by 1.1, then 1.2, then 1.3, and so on for each new test until a deadline is missed. The per-period workloads of all tasks do not change. The scaling preserves the harmonic frequencies; it is equivalent to multiplying the frequencies of the current test by 0.1 to derive those of the next test. As with experiment 1, this sequence increases the total workload rate in the above example by 32 KWIPS. By contrast with experiment 1, the increasing rates of doing work affect all tasks, not just one.

Experiment 3: Starting with the baseline task set, the workload of each task is increased by 1 Kilo-Whetstone per period for each new test, continuing until a deadline is missed. The frequencies of all tasks do not change. This sequence increases the total workload rate in the example by 62 KWIPS at a time, without increasing the system overhead in the same way as in the preceding experiments.

Experiment 4: Starting with the baseline task set, new tasks with the same frequency and workload as the "middle" task, task 3, of the baseline set are added until a deadline is missed. The frequencies and workloads of the baseline task set do not change. This sequence increases the total workload rate in the example by 64 KWIPS at a time and tests the system's ability to handle a large number of tasks.

When the computational load, plus the overhead, required of the periodic tasks eventually exceeds the capability of the target system, they will start to miss their deadlines. An experiment is essentially over when a test misses at least one deadline. For the purpose of analysis, it may be useful to continue beyond that point; therefore, tests attempt to compensate for missed deadlines by shedding load, as described previously. A Hartstone user has the choice of stopping the experiment at the point where deadlines are first missed or at some later point. The *completion criteria* for an experiment are largely defined in terms of missed and skipped deadlines. An experiment completes when a test satisfies one of the following user-selected criteria:

- Any task in the task set misses at least one deadline in the current test.
- The cumulative number of missed and skipped deadlines for the task set, in the current test, reaches a pre-set limit.
- The cumulative number of missed and skipped deadlines for the task set, in the current test, reaches a pre-set percentage of the total number of deadlines. This criterion is an alternative to specifying an absolute number of missed and skipped deadlines.

- The workload required of the task set is greater than the workload achievable by the benchmark in the absence of tasking. This is a default completion criterion for all experiments.
- The default maximum number of extra tasks has been added to the task set and deadlines still have not been missed or skipped. This is a default completion criterion for experiment 4. If this happens, the user must increase the value of the parameter representing the maximum number of tasks to be added.

2.3. Overall Benchmark Structure and Behavior

The Ada implementation of the PH series consists of three Ada packages and a main program. A Booch-style diagram illustrating dependencies between these Hartstone units is shown in Figure 2-1. The arrows represent with clauses. The Workload package contains the Small_Whetstone procedure that provides the synthetic workload for Hartstone periodic tasks. The Periodic_Tasks package defines the baseline set of tasks, and a task type to be used in the experiment where new tasks are added to the baseline set. The Experiment package provides procedures to initialize experiments, get the characteristics of a new test, check for experiment completion, and store and output results. It also defines the frequencies and workloads to be assigned to the baseline task set, as well as the experiment completion criteria. Initialization of an experiment includes a "calibration" call to Small_Whetstone to measure the procedure's raw speed; this is why the dependency diagram shows a dependency of package Experiment on package Workload. The main Hartstone program controls the starting and stopping of tasks, and uses procedures provided by the Experiment package to output results of individual tests and a summary of the entire experiment.

The compilation order of the packages and main program is as follows:

```

package Workload
package Periodic_Tasks
package Experiment
procedure Hartstone

```

Tasks obtain the starting time, duration, frequency, and workloads of the test from a rendezvous with the main Hartstone program and then proceed independently. On completion of a test, the results are collected by the main program in a second rendezvous, and may optionally be written at that point. The main program then starts the next test in the experiment and the experiment continues until it satisfies the user-defined completion criterion. On completion of the experiment, a summary of the entire experiment is generated. Details of the output produced by Hartstone tests are given in Section 5.1.

Figure 2-1: Hartstone Dependency Diagram

3. Hartstone Portability

The Ada version of the Hartstone benchmark for the PH series is written entirely in Ada and is intended to be portable over a wide range of Ada compilation systems. However, it does have certain implementation-dependent features which can be classified in two broad categories: features affecting the portability of the source code and features affecting the runtime performance of Hartstone executable code. The principal portability issues are Hartstone's use of mathematical library functions and predefined types. These also influence the performance, of course, but a discussion of performance factors will be deferred until Section 5.4.

Mathematical Libraries. The Small_Whetstone benchmark (and the full Whetstone benchmark, from which it is derived) performs computations involving transcendental functions; these functions are typically provided by a mathematical library package supplied with the Ada compilation system. The names used by vendors for mathematical libraries vary greatly, so a user will need to ensure that the correct library name for the system is being used in the `with` and `use` clauses in the body of package `Workload` wherein `Small_Whetstone` is encapsulated. Also, the names of some of the functions in these libraries may vary: for example, in some libraries, the natural logarithm function is named "Log," while for others it is named "Ln." An additional problem is caused by the fact that "Log" is used, in some libraries, to designate the base 10 logarithm function. The `Small_Whetstone` procedure requires the natural logarithm function for its calculations to be correct, so inadvertent use of a base 10 function will cause a runtime exception. This exception is typically either a `Constraint_Error` or an exception defined within `Small_Whetstone` that is raised when `Small_Whetstone`'s internal self-check fails. The Hartstone package `Workload` is commented with guidelines for dealing with several vendors' mathematical library names and function names. By default, it renames the natural logarithm function as "Log," the name proposed by the WG9 Numerics Rapporteur Group [WG9 89].³

Pre-Defined Types. The predefined types `Integer` and `Float` are used within Hartstone on the assumption that most implementations of these types provide sufficient range and accuracy for Hartstone needs. The counts of met and missed deadlines computed by Hartstone, for example, are expected to be much less than the maximum integer value of a 16-bit machine, and a floating-point type with 6 digits of accuracy provides one-microsecond accuracy for Hartstone timing calculations performed in floating-point. However, before running the Hartstone, the user should check the `Digits` attribute of the integer and floating-point types to ensure that they meet these range and accuracy assumptions.

³The WG9 (Working Group 9) proposal defines the specification of a generic package of elementary functions and a package of related exceptions. Its content derives from a joint proposal of the association for Computing Machinery (ACM) SIGAda Numerics Working Group and the Ada-Europe Numerics Working Group. Draft 1.1 (October 1989) of the proposal has been submitted for consideration as an international standard.

4. Running Hartstone Experiments

The Hartstone benchmark is primarily for embedded real-time target processors that are connected to a host system from which the executable Hartstone code is downloaded. Because of this, and for portability, it is assumed that the only code executing on the target system is the Hartstone code and the Ada runtime system. The Hartstone benchmark makes no explicit calls to Ada runtime system functions or to any kernel operating system layer interposed between it and the Ada runtime system. Additionally, and in particular, no assumptions are made about the Ada runtime system support of host-target file I/O or interactive screen I/O. Therefore, all experiment characteristics (e.g., test duration, task set characteristics, experiment number, experiment completion criterion, etc.) must be known at compile time: in this implementation they cannot be entered interactively or read from a host file. Similarly, the benchmark does not attempt to open any file on the host for output of results. At a minimum, it is expected that the output procedures of the Text_IO package will be capable of writing output to a terminal connected to the target processor. In the SEI host-target environment, the serial ports of the various targets are connected to corresponding serial ports on the VMS host. Output from the targets is displayed in a window on the host console as it arrives at the host serial port. Some cross-compilers provide the capability to capture such host input automatically in a file; for those that do not, the /LOG qualifier of the VMS DCL command SET HOST/DTE/LOG <port_ID> will create a log file of all input arriving at the host serial port.

A user of Hartstone performs one experiment per download. The benchmark is not set up to do multiple experiments per download; the idea is that each separately downloaded experiment begins with the runtime system in the same initial state. To choose an experiment to perform, a user modifies one line in the body of the Experiment package. The criterion for stopping the experiment (for example, stop after a total of 50 deadlines have been missed) may also be set in the next line. By default, the experiment outputs the results of each test in an experiment as the test completes. This is useful for monitoring the progress of an experiment. The user may disable this "full output" option in favor of simply producing a summary of the entire experiment when the experiment completes. Instructions for making these changes are provided as comments in the body of the Experiment package in a section clearly marked as the user-modifiable section. This section also defines two string variables that should be initialized by a user to provide a brief description (e.g., name, version number, target CPU type) of the compiler and target processor. Following these modifications, the package body must then be re-compiled, and the Hartstone benchmark re-linked to produce a new executable module for the chosen experiment.

The default duration of a Hartstone test is 10 seconds, with a 5-second lag before the first test of an experiment begins. If full output is enabled (i.e., if complete test results are to be output as soon as the test completes) and nothing has happened 20 seconds, say, after the start of an experiment, then either Hartstone is broken or there is a host-target communication problem. Of course, if full output is disabled (i.e., no output is produced until the experiment finishes), a user should be prepared to wait a relatively long time to see the summary results.

5. Understanding Hartstone Results

5.1. Format of Results

By default, the Hartstone benchmark outputs the results of every test of an experiment as each test completes. It then prints a summary of the results of the entire experiment. The two-part output from a single test, including the characteristics of a test and its results, is shown below.

Experiment: EXPERIMENT_1
Completion on: Miss/skip 50 deadlines

Raw speed in Kilo-Whetstone Instructions Per Second (KWIPS): 1122.19

Test 21 characteristics:

Task No.	Frequency (Hertz)	Kilo-Whets per period	Kilo-Whets per second	Requested Workload Utilization
1	2.00	32	64.00	5.70 %
2	4.00	16	64.00	5.70 %
3	8.00	8	64.00	5.70 %
4	16.00	4	64.00	5.70 %
5	352.00	2	704.00	62.73 %
			----- 960.00	----- 85.55 %

Experiment step size: 2.85 %

Test 21 results:

Test duration (seconds): 10.0

Task No.	Period in msecs	Met Deadlines	Missed Deadlines	Skipped Deadlines	Average Late (msec)
1	500.000	0	7	13	626.683
2	250.000	40	0	0	0.000
3	125.000	80	0	0	0.000
4	62.500	160	0	0	0.000
5	2.841	3520	0	0	0.000

The *raw speed* of the benchmark is the number of Kilo-Whetstone instructions per second (KWIPS) achieved by the Small_Whetstone procedure. This calibration test is performed by the Experiment package when an experiment is initialized. The resultant non-tasking workload rate will always be better than that achievable by splitting the same workload among the five Hartstone tasks; it provides a metric against which the performance of the Hartstone task set can be measured. Both the raw speed calibration test and a Hartstone task include the overhead of calling the Small_Whetstone procedure. The performance requested of Hartstone tasks is expressed as a percentage workload *utilization*, which is computed as the ratio of the requested

task speed (in KWIPS) and the raw benchmark speed. The raw speed is assumed to represent 100% utilization. The utilization required of the entire task set is the sum of the individual task utilizations. Successive tests in an experiment increase the requested utilization to the point where deadlines are not met.

The *step size* of an experiment is an indication of the extra work required of the task set when the next test in an experiment is derived from the current test. Like the workload utilization, it is expressed as a percentage of the raw speed. As an example, for experiment 1 the extra work for the task set comes from increasing the frequency of the highest-frequency task, task 5. The additional work required of task 5 is its workload multiplied by the frequency increment defined for task 5 in experiment 1 (in the above example, it is 2 Kilo-Whetstones times 16 Hertz, giving 32 KWIPS). This KWIPS figure, expressed as a percentage of the raw speed KWIPS figure, is the step size for the experiment. It varies from experiment to experiment but remains constant for a specific experiment. The sum of the total requested utilization and the step size for the current test is equal to the next test's total requested utilization. The step size is the granularity, or resolution, of an experiment.

The sum of the met, missed, and skipped deadlines for a task should, in general, be equal to the task's frequency multiplied by the test duration (i.e., the expected number of activations for that task). The case where they do not add up will be discussed later. The average late figure for a task is the average amount by which the task missed its deadlines during the test. It is the sum of the amounts by which individual deadlines were missed, divided by the number of missed deadlines. For lower-priority tasks, it is an indication of the amount of preemption by higher-priority tasks. Skipped deadlines do not influence this figure; they are simply part of the process of "resetting" a task whose lateness is already known.

The summary output produced at the end of an experiment consists of four test results similar to those shown above. The four tests are: the first test in the experiment (the baseline test), the test with the highest utilization and no missed/skipped deadlines (the "best" test), the test which first experienced missed/skipped deadlines, and the final test performed. Example summary results for all four experiments are given in Appendix A.

5.2. The Baseline Test

To get meaningful results from the Hartstone benchmark it is important to define an appropriate starting point for Hartstone experiments. This starting point is the baseline task set and it must first be "tuned" for a user's cross-compiler and target before Hartstone can be used effectively. At a very basic level, "tuning" ensures that the baseline workloads and frequencies are such that an experiment neither runs hundreds of tests before completing, nor completes after running just a few tests. More importantly, a badly-chosen baseline test can lead to unexpected results (discussed later) that undermine the usefulness of the benchmark. This section will provide some guidelines for choosing an appropriate baseline test.

To determine if the characteristics of the baseline task set need to be modified, a user must run a Hartstone experiment "as is" and examine the output of the baseline test. The numbers to check

are the total workload utilization and the experiment step size. Every experiment first runs the baseline test, so the total utilization of the baseline test is the same for all experiments. The total utilization should be in the range of 10 percent to 30 percent, so that an experiment commences with a workload rate that is neither too low nor too high (a 50% utilization for the task set in the very first test, for example, would be considered too high). In the example shown in Section 5.1, the total workload utilization of the baseline task set is 28.50 percent (5 times 5.70%). If utilization falls outside the recommended range, the user must edit the task frequencies and/or workloads in the body of package Experiment to bring them into line. If total utilization falls below the range, the task set frequencies and/or workloads must be increased; if it falls above, they must be reduced.

The experiment step size, which represents the resolution of the total utilization, should also be within a range that ensures that the transition from one test to another does not cause either a very large or a very tiny increase in the total resolution. A step size of around 2 or 3 percent seems to be adequate. Step size depends on the parameters controlling the transition from one test to the next. It remains constant for a specific experiment, but varies among different experiments. For experiment 1, it depends on the frequency increment for the highest-frequency task; for experiment 2, it depends on the scale factor applied to all frequencies; for experiment 3, on the workload increment; and for experiment 4, on the frequency and workload of the extra task added for each new test. In the example, the step size is 2.85 percent (task 5's frequency increment times task 5's workload is 16 times 2, which is 32 KWIPS; this is divided by the raw speed, 1122.19 KWIPS, and multiplied by 100 to give 2.85). In general, adjusting the total utilization of the task set will also yield a reasonable step size, so the user should not need to modify the step size parameters.

When making adjustments to the baseline test, the user must be careful to keep the task frequencies harmonic, and must ensure, for example, that the frequency increment of experiment 1 also preserves the harmonic nature of the task set. Workloads must be integral values (the Small_Whetstone benchmark does not permit fractional workloads), so a task cannot be assigned a workload lower than one Kilo-Whetstone per period. By convention, workloads are such that the workload rate (in Kilo-Whetstones per second) of each task in the baseline set is the same.

It is possible for a baseline task set to be within the guidelines just described and yet still fail to run the baseline test successfully. Sections 5.4 and 5.5 provide some answers to this problem.

5.3. What the Results Mean

For any experiment there is no single number which best represents the result of the experiment. The nature of the experiment and the performance of the various Hartstone tasks must be taken into account when formulating a conclusion about the outcome of an experiment. Additionally, the results from all four experiments must be considered when the benchmark is used to evaluate the performance of an Ada runtime system.

The test result of most interest to a user of the Hartstone benchmark is the one representing the highest achieved utilization for an experiment, with no missed or skipped deadlines. In the cases

where the experiment is allowed to continue until a predefined number of deadlines have been missed or skipped, the result of the final test run is also of interest because it will show whether or not tasks missed their deadlines in the expected manner for harmonic tasks: the lowest-priority (lowest-frequency) task missing deadlines first, then the next-lowest-priority task, and so on up to the highest-priority (highest-frequency) task.

In each experiment, the step size for that experiment is very significant. The maximum achievable total utilization is represented with a granularity equal to the the experiment step size. Experiments 2 and 3, which affect all 5 tasks, tend to have larger step sizes than experiments 1 and 4, which affect only 1 task.

Once the effect of the step size on the experiment results is understood, the three most important numbers for a test are the total number of task activations, the raw speed, and the total utilization. The total number of activations (equal to the sum of the met plus missed plus skipped deadlines for the task set) is an indication of the amount of task switching overhead required of the runtime system. The total utilization is a measure of the useful work performed, while the raw speed is an upper bound on the amount of useful work capable of being performed.

For experiment 1, the utilization achieved by the highest-frequency task is important since it dominates the overall result (the utilization of the other tasks remains constant throughout the experiment). The maximum frequency achieved by task 5 is of considerable interest since it is the primary indication of the amount of overhead required of the runtime system. As task 5's period decreases, runtime overhead consumes an increasing percentage of the task's period. It is expected that the total utilization for experiment 1 will be lower than that of experiments 2 and 3 because task switching is the predominant factor.

For experiment 2, the utilization of each task is the same for a given test and increases uniformly from one test to the next as all the task frequencies are scaled up. The scaling has the effect of also increasing all task workload rates (as measured in Kilo-Whetstones per second).

For experiment 3, the highest-frequency task's utilization is again of interest because increasing the actual workload, while keeping the frequency constant, means that the workload consumes an increasingly large percentage of this task's period. This, of course, is true for all tasks in this experiment, but the effect is greatest for the highest-frequency task. Experiment 3 should, in general, have better total utilization than the other experiments, since only the workloads increase while the tasks' switching overhead remains the same. A large step size, however, may cause experiment 3's best test result to occur at a lower utilization level: the increase in requested utilization, in the transition from success to missed deadlines, may hide the fact that a smaller increase could have resulted in success at a higher level.

For experiment 4, the utilization of each task remains constant throughout the experiment, but the number of tasks, and hence the total utilization, increases. Of primary interest is the count of extra tasks added to the baseline set. This provides an indication of the runtime system's ability to handle a large number of tasks efficiently.

5.4. Factors Affecting Hartstone Performance

The principal factors affecting the performance of Hartstone PH tests are

- The implementation of task periodicity
- The resolution of the **delay** statement
- The resolution of `Calendar.Clock`
- The accuracy of the fixed-point type `Duration`
- The implementation of mathematical library functions
- Floating-point precision
- Miscellaneous overhead factors

Task Periodicity. The implementation of task periodicity in the Hartstone benchmark is based on the paradigm exhibited in Section 9.6 of the Ada Language Reference Manual [LRM 83], a version of which is shown below.

```
declare
  use Calendar;
  -- Period is a global constant of type Duration
  Next_Start : Time := Clock + Period;
begin
  loop
    Next_Delay := Next_Start - Clock;
    delay Next_Delay;
    -- do some work
    Next_Start := Next_Start + Period;
  end loop;
end;
```

This is a highly portable method of implementing periodic tasks in Ada. It is, of course, very dependent on how well the Ada runtime system implements `Calendar.Clock` and the **delay** statement. At a basic level, the performance of the Hartstone benchmark is a reflection of the performance of these two features of the Ada language. The issues arising from the implementation of these two features are discussed separately below. The other major issue associated with the above paradigm is the possibility of preemption of the task between the reading of the `Clock` and the start of the **delay** statement, resulting in an actual delay that is longer than the requested delay. It can be shown that this is not a problem for the periodic harmonic task sets used in the Hartstone benchmark.

Delay Statement Resolution. The resolution of the **delay** statement is how closely an actual delay matches a requested delay. A requested delay of one millisecond that is actually implemented as a ten or twenty millisecond delay will cause periodic tasks to start missing deadlines earlier than expected. It has also been implicitly assumed that the expiry of the **delay** statement is preemptive, i.e., that a lower-priority task currently executing will be preempted by a higher-priority task whose delay has expired. A non-preemptive **delay** statement will likely cause results that are at least as poor as, and probably worse than, those for a coarse **delay** statement resolution. Implementations using non-preemptive delays are technically non-conforming, but the current Ada Compiler Validation Capability (ACVC, Version 1.10) does not adequately test this.

Calendar.Clock Resolution. The resolution of Calendar.Clock is the time period between successive ticks of the clock. A Hartstone task performs arithmetic involving Calendar.Clock to determine the time remaining in its period upon completion of its workload. It then suspends itself by delaying until its computed "wakeup" time—the next scheduled activation time. A coarse Calendar.Clock resolution means that a coarse value will be used as the expression in the delay statement, thereby resulting in a flawed implementation of task periodicity. Also, a coarse clock resolution may cause variations in the calibrated raw speed of the Small_Whetstone procedure. There are large differences in the resolution of Calendar.Clock in current Ada cross-compilers, ranging, in those tested at the SEI, from 61 microseconds to 100 milliseconds. The ACM SIGAda Performance Issues Working Group (PIWG)⁴ benchmark suite contains tests to measure the resolution of Calendar.Clock and the delay statement. These resolutions should always be checked by users of Hartstone. (Note that, in general, the value of System.Tick is not the same as the resolution of Calendar.Clock; a test should always be performed to determine the actual resolution.) Sample results of these two tests, for the XD Ada MC68020 cross-compiler, are included in Appendix B.

Type Duration. The accuracy of type Duration can be determined by examining the value of Duration.Small. For many implementations, this value is 2^{-14} seconds, or approximately 61 microseconds. For some implementations, however, the value is 1 millisecond. In an attempt to minimize the cumulative errors possible in fixed-point Duration arithmetic, a Hartstone periodic task actually performs all arithmetic involving the types Time and Duration in floating-point. This is done by using floating-point variables to compute Next_Start and Next_Delay and converting Next_Delay to type Duration in the actual delay statement. The value returned by Calendar.Clock is of the private type Time and so cannot be converted directly. Instead the Calendar.Seconds function is used to extract the seconds portion of the Time value; this value is of the non-private type Day_Duration and so is amenable to direct conversion.⁵

Mathematical Library. The raw non-tasking speed measurement of the Small_Whetstone procedure is another important factor since it is the basis for the utilization figures and the experiment step size. The raw speed will depend on how efficiently the Small_Whetstone computations are performed. For example, the computations involve trigonometric, logarithmic, and exponential functions whose efficiency depends on whether they are implemented wholly in software on the main processor, or by special instructions on a co-processor, if one is present on the target board. Testing at SEI has shown that most mathematical libraries do take advantage of an on-board co-processor, but that even when they do, the differences in the performance of Hartstone's Small_Whetstone (and the PIWG full Whetstone benchmark) on the same target board are striking.

⁴The name, address, and telephone number of the current PIWG chairperson and other officers may be found in Ada Letters, a bimonthly publication of the ACM Special Interest Group on Ada (SIGAda)

⁵Because the seconds portion of the time value becomes zero after twenty-four hours, you should not run Hartstone through a midnight boundary. Depending on how Calendar.Clock is initialized, "midnight" for the target system may bear no relation to midnight as measured by a wall clock (which in turn may be different from time as measured by the host system).

Floating-Point Precision. The current implementation of Hartstone uses the type `Float` for all floating-point computations. Of the 8 Ada cross-compilers at the SEI, 7 implement type `Float` with 6 decimal digits of precision (`Float'Digits = 6`) while 1 implements it with 15. Rather than defining a machine-dependent package that simply contains a type `Hart_Float`, say, Hartstone uses the type `Float` on the assumption that it will always provide at least 6 digits of precision. Doing the computational workload of Hartstone (the `Small_Whetstone` procedure) in a higher-precision floating-point type may, of course, take longer. The user must be aware of this when comparing Hartstone results from different Ada implementations. For consistency, a floating-point type with 6 digits of precision should be used; this will usually be the predefined type `Float`, but, for some cross-compilers, may be `Short_Float`.

Miscellaneous Overhead Factors. Calling the `Small_Whetstone` procedure from within a Hartstone task is another factor affecting performance; the overhead of the call may be zero if in-lining is used and non-zero otherwise. Again, the PIWG suite provides tests to measure this overhead. Hartstone contains an inline `pragma` for `Small_Whetstone`; the user should check the compilation listings to see if the compiler is accepting or rejecting it. Even when the `pragma` is accepted there may still be a performance factor attributable to the location and the even/odd word alignment of the copies of the code in different areas of memory.

There are other sources of overhead which undoubtedly influence Hartstone but are difficult for users to measure. These include, but are not limited to, the tasks' switching time, time spent in the clock interrupt handler, time spent managing delay and ready queues upon expiry of a delay, cache hit/miss rates, time to switch between the processor and co-processor, and, possibly, periodic garbage collection. Highly-specific, fine-grained benchmark tests, or hardware timing capabilities such as those provided by a logic analyzer, are needed to detect and measure the effect of such items on Hartstone's performance.

5.5. Unexpected Results

In normal circumstances, a Hartstone experiment proceeds from the baseline test through a number of intermediate tests to a point where a test meets the predefined completion criterion for the experiment. The results of the experiment can then be examined to determine the overall utilization and the failure pattern when tasks began to miss their deadlines. Sometimes the results can be quite different from what the user expected. This section attempts to characterize a sample set of such results; it is based on actual results encountered during testing of Hartstone on various Ada cross-compilers and target processors.

Baseline Test Failure. As discussed earlier, one reason for this may be the fact that the baseline task set utilization is outside the recommended range. However, even when it is within range, other factors may cause missed deadlines in the baseline set. A non-preemptive `delay` statement, or one with poor resolution, means that the actual implemented frequency of a task is much less than the requested frequency. Since a task's period and activation times are computed as a function of the *requested* frequency, an implemented frequency that is lower will cause a task to delay needlessly and miss its scheduled activation times. Even a reasonable `delay` statement

resolution can still be overwhelmed when used in combination with a Calendar.Clock with poor resolution to implement task periodicity. The user's only recourse is to scale back the frequencies of the baseline task set (keeping them harmonic) and re-run the experiment. A rule of thumb: the benchmark is already in trouble if the period of the highest-frequency baseline task is less than the period between successive ticks of Calendar.Clock. For example, if the highest-frequency baseline task's frequency is 32 Hertz and the resolution of Calendar.Clock is 100 milliseconds, the task's requested 31.25-millisecond period will never be realized. The outcome may well be that Hartstone cannot manage a successful run of even the first test without scaling back the baseline task set. One possible, but highly machine-dependent solution to the problem is to use a high-resolution programmable timer (if one is available on the target system) as a source of periodic interrupts. A dispatcher program could field these interrupts and dispatch tasks at their assigned frequencies in the manner described in [Borger 89].

Excess Task Activations. When a periodic task runs at a fixed frequency, measured in task activations per unit time, in a test whose duration is a multiple of the unit time, then the number of times the task can be expected to activate is the product of the task frequency and the test duration. In the Hartstone benchmark, the outcome of any one run of a Hartstone periodic task will be a met, missed, or skipped deadline; therefore the sum of all such met, missed, and skipped deadlines reported by the task in a single test will equal the actual count of activations for that task. Testing has shown that, for the highest-frequency task of experiment 1, the actual activation count sometimes exceeds the expected activation count. The reason has to do with the way periodic tasks, in this implementation, keep track of time. A task starts at its assigned starting time, performs its assigned workload, and determines its next activation time by adding its period to the starting time. Each time around the task's main loop, the new activation time is compared with the test's finishing time (pre-computed by adding the test duration to the starting time) and the task executes for another cycle if the finishing time has not been reached. If the successive additions of the task's period to the starting time eventually yield a value exactly equal to the finishing time then the test finishes without extra activations. Because of rounding effects, however, the task may complete its "expected" number of activations and still manage one or more runs before the finishing time occurs. It is also possible that a coarse Calendar.Clock resolution will allow extra activations; since there is no external timing source in this version of Hartstone (e.g., periodic interrupts from a programmable interval timer, a highly implementation-dependent, non-portable solution), there is no way to cut tasks off at exactly the end of a test.

Inverted Task Set Breakdown Pattern. Because of the priority structure of the task set (highest-frequency task has highest priority, lowest-frequency task has lowest) one expects the lower-frequency tasks to be preempted by the higher-frequency tasks. Thus the expected breakdown pattern for the task set is that task 1 (lowest priority) will miss deadlines first, then task 2, and so on. Tests have shown that this is not always the case. In experiment 1, the frequency of the highest-frequency task is incremented for each new test, with the result that the task-switching overhead becomes an increasingly significant percentage of the task's period. Eventually, the rapid switching required of the task leaves no time for useful work, and the highest-frequency task starts missing deadlines before any of the other tasks start missing theirs. The effect of this breakdown pattern is that the total workload utilization for the task set may be poor, despite the fact that the highest-frequency task may have been driven to a very high frequency

before it started to miss deadlines. Tests have shown that the inverted breakdown pattern usually occurs if the total utilization of the baseline task set is less than 10 percent. The user should scale up the baseline characteristics (remembering to keep the task set frequencies harmonic) to overcome the problem.

Inverted Summary Results. During testing of Hartstone, the highest-frequency task of experiment 1 would sometimes miss a single deadline, but then meet all its deadlines in the next several tests. The experiment would continue normally until the task set began missing deadlines in the expected fashion, at which point the experiment would terminate. This situation can be detected by examining the summary reports produced at the end of an experiment. One of the summaries is the output of the "best" test—the one achieving the highest utilization with no missed deadlines. Another summary is the output of the test where deadlines were first missed. The test number of the "best" test normally precedes that of the "first missed" test; however, in the case where a test with missed deadlines is followed by one or more tests that do not miss deadlines, the test number of the "best" test is consequently higher than that of the "first missed" test. This phenomenon is still under investigation; preliminary testing with a logic analyzer indicates that the highest-frequency task may be blocked for varying amounts of time by runtime system activities such as delay queue management and Calendar.Clock updating. Depending on the amount of queue re-organization required, and whether or not the clock also needs servicing, the highest-frequency task may occasionally be blocked just long enough to miss a deadline.

Exceptions. The Small_Whetstone procedure raises an exception if it fails an internal check on the result of its computation. Two reasons for such a failure have been encountered during testing. The first was when the link-time memory layout parameters did not allow enough stack and heap space in the target board's memory for Hartstone. A simple readjustment of the parameters took care of the problem. The second reason was more subtle, involving different interpretations of the name "Log" as used in vendor mathematical libraries to denote a logarithm function. The logarithm function used within the Small_Whetstone procedure is intended to be the natural logarithm function (base e), not the base 10 function. Some vendors denote the former by "Ln" and the latter by "Log"; others use "Log" for natural logarithms and a name such as "Log10" for base 10 logarithms. If base 10 logs are used inadvertently (i.e., the user did not modify the Small_Whetstone procedure correctly for the mathematical library being used) the compilation will succeed but the computation performed by Small_Whetstone will produce a runtime exception.

Other exceptions, such as Storage_Error, can arise if not enough code space has been allocated for Hartstone (again, modifying the file that describes the target memory layout solves the problem), or if the runtime system provides support only for a default number of tasks (possibly defined by a user-modifiable link parameter) and this default is exceeded by the extra tasks created in experiment 4.

6. Future Work

It is expected that this report will be sufficient to enable a Hartstone user to run a series of experiments against a particular Ada compiler on a particular architecture. The sample outputs show what experiment results look like and some initial guidance on interpretation of results has been provided. However, in order to be a truly useful tool, it is necessary to be able to compare different implementations and provide a deeper analysis of results. Work is under way at the SEI to do just that. The Hartstone benchmark will be used to generate results for several different embedded systems cross-compilers. A subsequent report will describe these results and the analysis required to draw from them conclusions about the usability of the cross-compilers for hard real-time applications. The purpose of the report will not be to "rate" the various cross-compilers, but to show Hartstone users how to draw their own conclusions when evaluating the hard real-time characteristics of their own Ada compilers.

Appendix A: Sample Results for XD Ada VAX/VMS -> MC68020

A.1. Host-Target Configuration

The following is the host-target configuration used for generating the results reported here:

HOST: DEC MicroVAX II running VAX/VMS, Release 5.1-1
CROSS-COMPILER: Systems Designers XD Ada, Version 1.0, ACVC 1.10
TARGET: Motorola MVME133: 12.5 MHz MC68020 CPU with 12.5 MHz MC68881 Floating-Point Co-processor; one wait state; 1Mb RAM; 256-byte on-chip instruction cache

Full optimization (the default) was specified for all compilations. No checks were suppressed. The summary output for the four Hartstone experiments is shown in the next four sections.

A.2. Experiment 1: Summary of Results

HARTSTONE BENCHMARK SUMMARY RESULTS

Baseline test:

Experiment: EXPERIMENT_1
Completion on: Miss/skip 50 deadlines

Raw speed in Kilo-Whetstone Instructions Per Second (KWIPS): 1122.19

Test 1 characteristics:

Task No.	Frequency (Hertz)	Kilo-Whets per period	Kilo-Whets per second	Requested Workload Utilization
1	2.00	32	64.00	5.70 %
2	4.00	16	64.00	5.70 %
3	8.00	8	64.00	5.70 %
4	16.00	4	64.00	5.70 %
5	32.00	2	64.00	5.70 %
			----- 320.00	----- 28.52 %

Experiment step size: 2.85 %

Test 1 results:

Test duration (seconds): 10.0

Task No.	Period in msecs	Met Deadlines	Missed Deadlines	Skipped Deadlines	Average Late (msec)
1	500.000	20	0	0	0.000
2	250.000	40	0	0	0.000
3	125.000	80	0	0	0.000
4	62.500	160	0	0	0.000
5	31.250	320	0	0	0.000

Last test with no missed/skipped deadlines:

Experiment: EXPERIMENT_1
Completion on: Miss/skip 50 deadlines

Raw speed in Kilo-Whetstone Instructions Per Second (KWIPS): 1122.19

Test 20 characteristics:

Task No.	Frequency (Hertz)	Kilo-Whets per period	Kilo-Whets per second	Requested Workload Utilization
1	2.00	32	64.00	5.70 %
2	4.00	16	64.00	5.70 %
3	8.00	8	64.00	5.70 %
4	16.00	4	64.00	5.70 %
5	336.00	2	672.00	59.88 %
			----- 928.00	----- 82.70 %

Experiment step size: 2.85 %

Test 20 results:

Test duration (seconds): 10.0

Task No.	Period in msec	Met Deadlines	Missed Deadlines	Skipped Deadlines	Average Late (msec)
1	500.000	20	0	0	0.000
2	250.000	40	0	0	0.000
3	125.000	80	0	0	0.000
4	62.500	160	0	0	0.000
5	2.976	3360	0	0	0.000

Test when deadlines first missed/skipped:

Experiment: EXPERIMENT 1
Completion on: Miss/skip 50 deadlines

Raw speed in Kilo-Whetstone Instructions Per Second (KWIPS): 1122.19

Test 21 characteristics:

Task No.	Frequency (Hertz)	Kilo-Whets per period	Kilo-Whets per second	Requested Workload Utilization
1	2.00	32	64.00	5.70 %
2	4.00	16	64.00	5.70 %
3	8.00	8	64.00	5.70 %
4	16.00	4	64.00	5.70 %
5	352.00	2	704.00	62.73 %
			----- 960.00	----- 85.55 %

Experiment step size: 2.85 %

Test 21 results:

Test duration (seconds): 10.0

Task No.	Period in msec	Met Deadlines	Missed Deadlines	Skipped Deadlines	Average Late (msec)
1	300.000	0	7	13	626.683
2	250.000	40	0	0	0.000
3	125.000	80	0	0	0.000
4	62.500	160	0	0	0.000
5	2.841	3520	0	0	0.000

Final test performed:

Experiment: **EXPERIMENT 1**
Completion on: **Miss/skip 50 deadlines**

Raw speed in Kilo-Whetstone Instructions Per Second (KWIPS): 1122.19

Test 22 characteristics:

Task No.	Frequency (Hertz)	Kilo-Whets per period	Kilo-Whets per second	Requested Workload Utilization
1	2.00	32	64.00	5.70 %
2	4.00	16	64.00	5.70 %
3	8.00	8	64.00	5.70 %
4	16.00	4	64.00	5.70 %
5	368.00	2	736.00	65.59 %
			-----	-----
			992.00	88.40 %

A.5. Experiment 4: Summary of Results

In the summaries that follow, the characteristics (frequencies, workloads, and utilizations) of the extra tasks added to the baseline set are all identical; therefore, some have been edited out for brevity. Similarly, some of the identical results produced by these extra tasks have also been omitted. Such omissions are indicated by ellipses.

Appendix B: Supporting PIWG Results

The following are the results of some ACM Performance Issues Working Group (PIWG) benchmarks for XD Ada 1.0 on the Motorola MVME133 board. The tests come from the December 12, 1987 release of the benchmarks. All compilations had full optimization in effect and no checks were suppressed.

B.1. Calendar.Clock Resolution

Test Name: A000090

Clock resolution measurement running

Test Description:

Determine clock resolution using second differences of values returned by the function CPU_Time_Clock.

Number of sample values is 12000
Clock Resolution = 0.000122070312500 seconds.
Clock Resolution (average) = 0.000122070312500 seconds.
Clock Resolution (variance) = 0.000000000000000 seconds.

B.2. Delay Statement Resolution

The delay values shown are in seconds.

Y000001 Measure actual delay vs commanded delay			
Commanded	Actual	CPU	Iterations
0.0010	0.0013	0.0013	4096
0.0020	0.0023	0.0023	2048
0.0039	0.0042	0.0042	1024
0.0078	0.0081	0.0081	512
0.0156	0.0159	0.0159	256
0.0313	0.0314	0.0314	128
0.0625	0.0626	0.0626	64
0.1250	0.1252	0.1252	32
0.2500	0.2501	0.2501	16
0.5000	0.5000	0.5001	8
1.0000	1.0001	1.0001	4
2.0000	2.0002	2.0002	2
4.0000	4.0001	4.0002	2
8.0000	8.0001	8.0002	2

B.3. Procedure Call Overhead

Test Name: P000005 Class Name: Procedure
CPU Time: 1.6 microseconds
Wall Time: 1.6 microseconds. Iteration Count: 1024

Test Description:

Procedure call and return time measurement
The procedure is in a separately compiled package
One parameter, in INTEGER

Test Name: P000006 Class Name: Procedure
CPU Time: 2.8 microseconds
Wall Time: 2.8 microseconds. Iteration Count: 1024

Test Description:

Procedure call and return time measurement
The procedure is in a separately compiled package
One parameter, out INTEGER

Test Name: P000007 Class Name: Procedure
CPU Time: 3.1 microseconds
Wall Time: 3.1 microseconds. Iteration Count: 1024

Test Description:

Procedure call and return time measurement
The procedure is in a separately compiled package
One parameter, in out INTEGER

Appendix C: Obtaining Hartstone Source Code and Information

Hartstone source code and supporting documentation can be obtained from the Real-Time Embedded Systems Testbed (REST) Project at the Software Engineering Institute in a number of different ways. Full details can be obtained by sending a request for information to the electronic mail or postal address listed below.

Electronic mail requests should be sent to the following Internet address:

HARTSTONE-INFO@SEI.CMU.EDU

Electronic mail received at this address will automatically return to the sender instructions on all available distribution mechanisms.

For people who do not have Internet access, the address to send information requests to is:

**REST Transition Services
Software Engineering Institute
Carnegie Mellon University
Pittsburgh, PA 15213-3890
Phone: (412) 268-7700**

Appendix D: Hartstone Ada Code for PH Series

The code in this appendix is listed in the order shown below.

Main procedure:	Hartstone
Package spec:	Experiment
Package body:	Experiment
Package spec:	Periodic_Tasks
Package body:	Periodic_Tasks
Package spec:	Workload
Package body:	Workload

The actual compilation order is

Package spec:	Workload
Package body:	Workload
Package spec:	Periodic_Tasks
Package body:	Periodic_Tasks
Package spec:	Experiment
Package body:	Experiment
Main procedure:	Hartstone

Hartstone Benchmark, Version 1.0

Unit Name: Hartstone

Unit Type: Main Procedure Body

Description:

Controls a single Hartstone experiment. A Hartstone experiment consists of a series of individual tests, with the tests being performed by a set of tasks. The tasks are required to perform varying computational loads within hard-real-time deadlines. (The name Hartstone comes from HARD Real-Time and the fact that the computational load is provided by a variant of the Whetstone benchmark.) This main program activates the set of tasks and collects results from it.

As each test completes, its results are stored and may optionally be output at that time. Also, a check is made to see if the entire experiment has completed. If not, the next test in the series is started. On completion of the experiment, a summary of the results is output.

--|-----
--|
--| Unit Name: Experiment
--|

--| Unit Type: Package Body
--|

--| Description:

--| The characteristics of four experiments for the Hartstone Periodic
--| Harmonic (PH) test series are defined here. Also provided are the
--| procedures and functions to retrieve individual test characteristics,
--| store and display test results, check for completion of an experiment,
--| and output a summary of the entire experiment.
--|

--| An experiment consists of a series of tests. The tests are performed
--| by a set of tasks. The transition from one test to the next in the
--| series is achieved by increasing the computational load required of the
--| task set. The four experiments defined here are:

--| Experiment 1: Increase the frequency of the highest-frequency task

--| Experiment 2: Scale up the frequencies of all the tasks

--| Experiment 3: Increase the workloads of all tasks

--| Experiment 4: Add new tasks to the baseline task set

--| When the computational load required of the periodic tasks exceeds the
--| processor's capability they will start to miss their deadlines. They
--| will shed load by skipping workload assignments in an effort to reach
--| a point where a workload may again be attempted. Deadlines ignored
--| during load-shedding are known as skipped deadlines. The completion
--| conditions for an experiment are largely defined in terms of missed
--| and skipped deadlines. An experiment completes when a test satisfies
--| one of the following user-selected completion criteria:

- | (a) Any task in the task set has missed at least one deadline
--| in the current test
- | (b) The cumulative number of missed and skipped deadlines in the
--| task set, for the current test, reaches a pre-set limit
- | (c) The cumulative number of missed and skipped deadlines in the
--| task set, for the current test, reaches a pre-set percentage
--| of the total number of met + missed + skipped deadlines
- | (d) The workload required of the task set is more than it could
--| possibly achieve, i.e. when the requested workload is greater
--| than the workload achievable by the benchmark in the absence
--| of tasking. This is a default completion criterion for all
--| experiments.
- | (e) The maximum number of extra tasks has been added to the task
--| set and deadlines still have not been missed or skipped. This
--| is a default completion criterion for experiment 4. If this
--| happens, the user should increase the value of the parameter
--| representing the maximum number of tasks to be added.

--| Since this benchmark is primarily for embedded targets, no assumptions
--| are made about the availability of host-target file I/O, or the ability
--| to provide parameters to the executing benchmark interactively. It is
--| assumed that the only code executing on the target system is the
--| Hartstone benchmark and the Ada run-time system. Thus the experiment
--| to be performed, the conditions under which it stops, and the
--| characteristics of tests within the experiment are all defined here
--| and are changed by manual editing of this package body. The part of
--| the package that needs to be modified by users is small and explicitly
--| indicated by comments. For any given experiment, the changed package
--| body must be re-compiled, and the Hartstone benchmark re-linked and re-

```
--| loaded into the target.

--|
--| Unit Name: Compute_Raw_Speed
--|
--| Unit Type: Procedure Body
--|
--| Description:
--| This local procedure provides a "calibration" of the computational
--| load required of Hartstone tasks. A synthetic workload for each task
--| is provided by a variant of the Whetstone benchmark. This procedure
--| computes the raw speed of the Small_Whetstone benchmark, in the
--| absence of tasking, by determining how many thousands of Whetstone
--| instructions (Kilo-Whetstones) per second it can execute. Raw
--| speed is expressed in Kilo-Whetstone Instructions Per Second (KWIPS).
--| The performance of the Hartstone task set will be measured against
--| this non-tasking computation.
--|
--| The accuracy of this timing measurement will depend on the resolution
--| of Calendar.Clock.
--|

procedure Compute_Raw_Speed is

use Calendar; -- To achieve visibility of operations on Time values

```

Iterations : constant := 10_000; -- Thousands of Whetstone instructions
Start_Time : Calendar.Time;
Finish_Time : Calendar.Time;

```

```
begin
```

```

-- The number of loop iterations depends on the desired timing accuracy
-- and the accuracy of Calendar.Clock. For example, to achieve an
-- accuracy of one microsecond with a ten-millisecond Clock, the loop
-- should iterate 10000 times. Note that to achieve a constant overhead
-- the Small_Whetstone procedure is called repeatedly with a value of 1,
-- representing one Kilo_Whetstone. This is also how Hartstone tasks do
-- their workloads; the overhead of the procedure call is part of a
-- task's overall execution time.

```

```

--| Unit Name: Put_Results
--|
--| Unit Type: Procedure Body
--|
--| Description:
--| For the given test, outputs the name of the experiment, the
--| completion criterion, the characteristics of the task set (its
--| frequencies, workloads, and utilization) and the results

```

```

-| achieved by the task set (met, missed, and skipped deadlines).
-| Also outputs the raw (non-tasking) speed and the experiment
-| step size. Utilization is defined as the workload execution
-| rate expressed as a percentage of the raw speed. The step
-| size is the increase in utilization required of the task set
-| when performing the successor to the current test. It is
-| the "resolution" of the workload utilization.

-----
-|
-| Unit Name: Periodic_Tasks
-|
-| Unit Type: Package Specification
-|
-| Description:
-| This is the basic set of independent periodic tasks that performs a
-| test in a Hartstone test series. Each task has a specific frequency
-| and workload. The goal of each task is to complete its workload within
-| its period. The deadline for completion of the workload is the next
-| scheduled activation time of the task. For any given period, a task
-| will either meet or miss its deadline; at the end of the test each task
-| will report the total number of deadlines it met and missed, together
-| with the cumulative late amount by which deadlines were missed. To
-| enable a task to continue past the point at which deadlines are first
-| missed, tasks "reset" themselves by skipping one or more workload
-| assignments until they reach a point where a workload may again be
-| attempted. This process, called load-shedding, allows the failure
-| pattern of tasks to be studied when the task results are collected.
-|
-| Each task is assigned a priority according to the rate-monotonic
-| scheduling algorithm: higher-frequency tasks are given higher
-| priorities than lower-frequency tasks. Because Ada task priorities
-| are statically assigned, each task in the baseline Hartstone task
-| set with a unique priority is explicitly named.
-|
-| One of the Hartstone experiments requires the addition of new tasks.
-| These all have the same characteristics as a single specified task in
-| the basic task set. In particular, they will all have the same priority,
-| so a task type definition, provided below, can be used to define them.

--|
--| Unit Name: T1 .. T5
--|
--| Unit Type: Task Specification
--|
--| Description:
--|   Periodic task to perform an assigned workload at a specific frequency.
--|
--| Parameters:
--|   Entry Start: Provides the input test parameters.
--|
--|     Test_Start_Time: The time at which the task starts performing
--|       its requested workload.
--|
--|     Test_Duration: The length of the test, in seconds.
--|
--|     Task_Frequency: The number of times per second the task is
--|       required to perform its requested workload.
--|
--|     Task_Workload: The amount of work required of the task, expressed
--|       as a number of Kilo-Whetstone instructions. A variant of the
--|       Whetstone benchmark provides the computational load for the task.
--|
--|   Entry Stop: Allows the caller to retrieve test results from the task.
--|
--|     Task_Met_Deadlines: The number of times during the test that the
--|       task successfully completed its workload before its next scheduled
--|       activation time.
--|
--|     Task_Missed_Deadlines: The number of times during the test that the
--|       task failed to complete its workload before its next scheduled
--|       activation time.
--|
--|     Task_Skipped_Deadlines: The number of scheduled activation times
--|       which were not performed because of a previously missed deadline.
--|
--|     Task_Cumulative_Late: The sum of the amounts by which the task was
--|       late when it missed deadlines.
--|

--|-----
--|
--| Unit Name: Periodic_Tasks
--|
--| Unit Type: Package Body
--|
--| Description:
--| See the description in the package specification and the description
--| of the local procedure below.
--|
--| Because Ada priorities are assigned statically, the unique priorities
--| of the baseline task set are assigned to explicitly-named tasks via the
--| Priority pragma in the tasks' specifications. It is not possible, for
--| example, to define an array of baseline tasks whose elements are of a
--| single task type, and whose priorities can be assigned at run-time.
--| For similar reasons, a generic template is also not an option. Thus the
--| five tasks in the baseline set are task objects with distinct names and
--| priorities, hence the "duplication" of code below. The amount of text
--| duplicated is reduced somewhat by putting actions common to all tasks in
--| a procedure.
--|-----

```

```
with Workload;
```

```
with Calendar;
```

```
package body Periodic_Tasks is
```

```

--|
--| Unit Name: Do_Work
--|
--| Unit Type: Procedure Body
--|
--| Description:
--| Local procedure to do the work of a Hartstone task. Task periodicity
--| is implemented using the delay statement (expiry of a delay is assumed
--| to be pre-emptive) and Calendar.Clock. The Small_Whetstone procedure,
--| a variant of the composite synthetic benchmark, provides the task
--| computational workload. The workload is expressed in thousands of
--| Whetstone instructions (Kilo-Whetstones) and the rate of doing work
--| is measured in Kilo-Whetstone Instructions Per Second (KWIPS).
--| The deadline for completion of the workload during a task's period is
--| the next scheduled activation time of the task. Late completion of
--| the workload is defined as a missed deadline. Tasks continue to run
--| after deadlines are missed by skipping workload assignments until
--| they reach a point where a workload may again be attempted. This
--| process is called load-shedding and any deadlines ignored during it
--| are recorded as skipped deadlines.
--|
--| This procedure is based on the drift-free periodic procedure exhibited
--| in section 9.6 of the Ada Language Reference Manual. To avoid problems
--| of cumulative error with the fixed-point type Duration, computations
--| are performed in floating-point arithmetic and only converted to
--| Duration in the actual delay statement. Calculations involving the
--| type Time are also done in floating-point, by extracting the seconds
--| portion of the Time value (a private type) returned by Calendar.Clock
--| and converting it from Day_Duration to Float. Because only the seconds
--| portion is used, the test duration should not cross a midnight
--| boundary; the Day_Duration value returned by Calendar.Seconds becomes
--| zero after 24 hours.
--|
--| A number of implementation-dependent features are present in this
--| procedure: the accuracy of the Duration expression used in the delay

```

```

--| statement (depends on Duration/Small), the resolution of the delay
--| statement itself (the actual delay may be much larger than the
--| requested delay), and the resolution of Calendar.Clock (a coarse
--| resolution means that a coarse value will be used as the expression
--| in the delay statement, thereby resulting in a flawed implementation
--| of task periodicity).
--|

```

```

--|-----
--|
--| Unit Name: Workload
--|
--| Unit Type: Package Specification
--|
--| Description:
--| Encapsulates the synthetic computational workload of a Hartstone task.
--| The actual computation is performed by the Small_Whetstone procedure,
--| a variant of the Whetstone benchmark program. The amount of work
--| requested is expressed in thousands of Whetstone instructions, or
--| Kilo-Whetstones. An internal consistency check is performed on the
--| workload computation within Small_Whetstone; if it fails, an exception
--| is raised.
--|-----

```

package Workload is

Workload_Failure : exception; - Raised if Small_Whetstone self-check fails

```

--|
--| Unit Name: Small_Whetstone
--|
--| Unit Type: Procedure Specification
--|
--| Description:
--| Performs the computational workload of a Hartstone task. The
--| computation is a scaled-down version of the one performed by the
--| full Whetstone benchmark program. An exception is raised if the
--| computation fails to satisfy an internal consistency check. This
--| procedure does not return any "result" from its computation; its
--| sole function is to give a Hartstone task something to do.
--|
--| Parameters:
--| Kilo_Whets: The number of Kilo-Whetstone instructions to be performed
--| by the procedure. A value of 1 means one thousand Whetstone
--| instructions will be executed as the computational load.
--|

```

procedure Small_Whetstone(Kilo_Whets : in Positive);

- comments below
function Log(X : in Whet_Float) return Whet_Float
renames Float_Math_Lib.Log;

```

```

-----
-|
-| Unit Name: Small_Whetstone
-|
-| Unit Type: Procedure Body
-|
-| This version of the Whetstone benchmark is designed to have an inner
-| loop which executes only 1000 Whetstone instructions. This is so that
-| smaller units of CPU time can be requested for benchmarks, especially
-| real-time benchmarks. The parameter "Kilo_Whets" determines the number
-| of loop iterations; a value of 1 means the loop will execute 1000
-| Whetstone Instructions. A Whetstone Instruction corresponds to about
-| 1.5 machine instructions on a conventional machine with floating point.
-|
-| Small_Whetstone was developed by Brian Wichmann of the UK National
-| Physical Laboratory (NPL). The Ada version was translated at the
-| Carnegie Mellon University Software Engineering Institute from the
-| original standard Pascal language version (see references below).
-| This Hartstone version has been adapted from the Ada standard
-| version by making the Kilo_Whets variable a passed parameter, and
-| by raising an exception, rather than printing an error message, if
-| the benchmark's internal consistency check fails.
-|
-| Small_Whetstone uses the following mathematical functions, which are
-| listed here using the ISO/WG9 Numerics Rapporteur Group proposed
-| standard names for functions of a Generic_Elementary_Functions library
-| (Float_Type is a generic type definition):
-|
-| function Cos (X : Float_Type) return Float_Type;
-| function Exp (X : Float_Type) return Float_Type;
-| function Log (X : Float_Type) return Float_Type; -- Natural logs
-| function Sin (X : Float_Type) return Float_Type;

```

```

-| function Sqrt (X : Float_Type) return Float_Type;
-|
-| The name of the actual mathematical library and the functions it
-| provides are implementation-dependent. For Small_Whetstone, the
-| function name to be careful of is the natural logarithm function;
-| some vendors call it "Log" while others call it "Ln". A renaming
-| declaration has been provided to rename the function according to
-| the ISO/WG9 name.
-| Another implementation-dependent area is the accuracy of floating-
-| point types. One vendor's Float is another's Long_Float, or even
-| Short_Float. The subtype Whet_Float is provided so that the change
-| can be made in a single place; users should modify it as necessary
-| to ensure comparability of their test runs.
-|
-| Examples of some vendor mathematical library and log function names,
-| and the values of the 'Digits' attribute for the floating-point types
-| are provided in the comments below. The ONLY changes a user should
-| make to run Small_Whetstone are (a) the library name, (b) the log
-| function name, if necessary, and (c) the definition of the subtype
-| Whet_Float, if necessary. Any changes should be documented along
-| with reported results.
-|
-| References:
-| The first two apply only to the full version of Whetstone. The
-| first includes a listing of the original Algol version. The second
-| includes an Ada listing. The third reference also deals mostly with
-| the full Whetstone benchmark but in addition contains a brief
-| rationale for the Small_Whetstone benchmark and a listing of its
-| standard Pascal version.

    -- Module 9: Array references

    -- Note: In the Pascal version, the global variable I is used as both

```

- the control variable of the for loop and an array index
- within procedure P0. Because the for-loop control variable
- of Ada is strictly local, this translation uses a while loop.

```

I := 1;
while I <= N9 loop
  P0;
  I := I + 1;
end loop;

```

- Module 11: Standard mathematical functions

- Note: The actual name of the natural logarithm function used here
- is implementation-dependent. See the comments above.

```
Z := Sqrt( Exp( Log(E1(N9)) / T1 ) );
```

```
Sum := Sum + Z;
```

- Check the current value of the loop computation

```

if Abs(Z - Value) > Tolerance then
  Sum := 2.0 * Sum; - Forces error at end
  IJ := IJ + 1;    - Prevents optimization
end if;

```

```
end loop;
```

- Self-validation check

```

if Abs( Sum / Whet_Float(Kilo_Whets) - Value ) >
  Tolerance * Whet_Float(Kilo_Whets) then
  raise Workload_Failure;
end if;

```

```
end Small_Whetstone;
```

```
end Workload;
```

<p>The Hartstone benchmark is a set of timing requirements for testing a system's ability to handle hard real-time applications. It is specified as a set of processes with well-defined workloads and timing constraints. The name Hartstone derives from Hard Real Time and the fact that the workloads are presently based on the well-known Whetstone benchmark. This report describes the structure and behavior of an implementation in the Ada programming language of one category of Hartstone requirements, the Periodic Harmonic (PH) Test Series. The Ada implementation of the PH series is aimed primarily at real-time embedded processors where the only executing code is the benchmark and the Ada runtime system. Guidelines for performing various Hartstone experiments and interpreting the results are provided. Also included are the source code listings of the benchmark, information on how to obtain the source code in machine-readable form, and some sample results for Version 1.0 of the Systems Designers XD Ada VAX/VMS-MC68020 cross-compiler.</p>
