## Preface

This thesis describes the conversion of a drum assay measurement computer system (Digital Computer System PDP-11/05), at EG&G Mound Applied Technologies, with an IBM PC. The conversion of the computer system was primarily a team effort. For this, I am indebted to Mr. Allen Campbell and Steve Rowe of the Safeguards Applications Development and Nuclear Material Control Group at Mound, and to Ernie Tyra of the Electrical Engineering Group. Also, many thanks to Major Beller, my thesis advisor at the Engineering Physics Department, who made this all possible.

Claude A. Irvine

## Abstract

This paper describes the conversion of a DEC PDP-11/05 computer system, previously used in Canberra's Model 2220B segmented gamma scanner, with an IBM PC. Two tasks necessary for completion of the project involved reestablishing communications with a Canberra Series 35+ multi-channel analyzer and a scan table controller. An additional serial/parallel card was installed in the PC to reinstate communications with the multi-channel analyzer. For computer control of scan table controller operations a digital input/output card was used along with an external electromechanical relay board; when implemented together this hardware setup replaces functions that were normally processed through a motion control interface card housed within the DEC. Software consisted of Canberra's PC Toolkit while newer programs were written in Microsoft's QuickBASIC 4.5 and Macro Assembler 5.1. Five codes were written--two of these are device drivers written in assembly language and the other three are menu and control programs written in QuickBASIC. The modification enables simplified programmer enhancements.

## HARDWARE UPGRADE OF A SEGMENTED DRUM ASSAY SYSTEM

### I. Introduction

During the past several years EG&G Mound Applied Technologies has been using a Canberra Model 2220B segmented gamma scanner for measuring the amount of  $^{238}\text{Pu}$  in waste drums. This system has worked well, however the computer, a DEC PDP-11/05, was difficult to program and implementing additional enhancements proved even more formidable. Thus a decision was made to replace the outmoded DEC with a small personal computer, an IBM PC.

However, the up-to-date computer system would still have to manage control over the existing equipment. Especially important was initiating operation of a Canberra Series 35+ multi-channel analyzer (MCA) and a scan table controller (STC). In the DEC system, a motion control interface (MCI) card controlled the STC by acting as a switch closure device; so as a substitute in the PC, a digital input/output card was used in conjunction with an external electromechanical relay board. For reconnection of bi-directional communication circuits between the PC and the MCA a serial/parallel card was installed. Finally software was developed to run the modified drum assay system.

Next, the development of the DEC to PC conversion is explained by subdividing the following report into two parts. For the reader unfamiliar with drum assay measurements, the first part is a short discussion of the equipment used and how a drum assay procedure is performed. The second part (Chapter 3) is a detailed discussion of the DEC to PC conversion. Most of the drum assay equipment is shown in Figures 1.1 and 1.2, with Figure 1.2 showing the present system at Mound as a result of the computer upgrade.

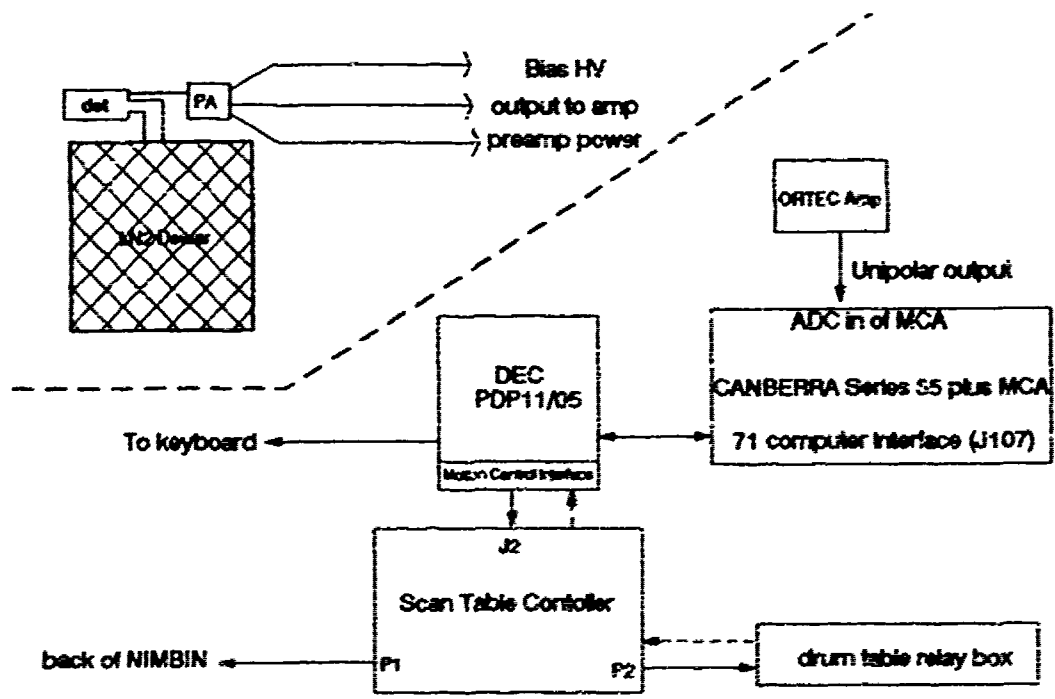

Fig. 1.1 Original Drum Assay System Configuration

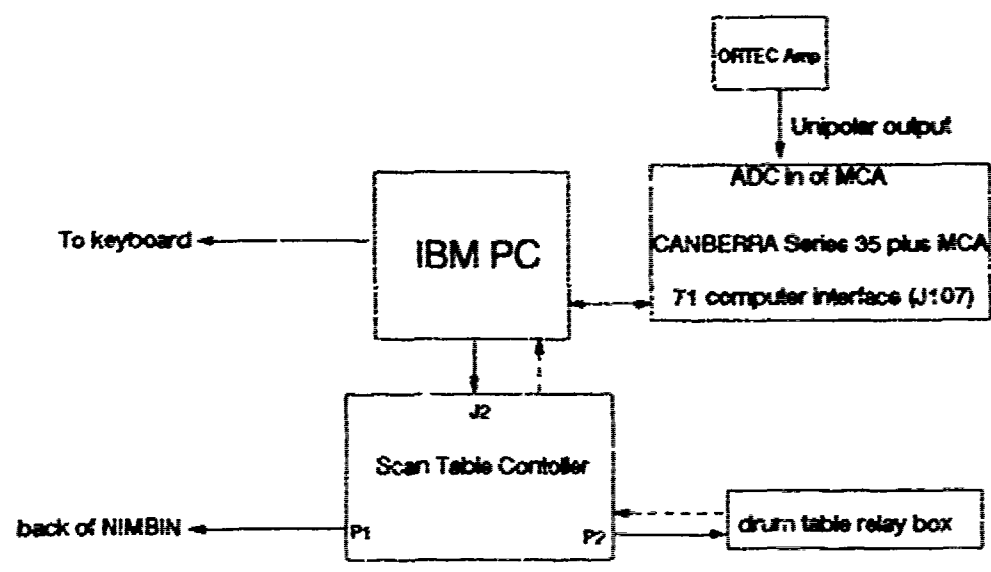

Fig. 1.2 Present Drum Assay System Configuration

## II. Principal Method of Drum Examination

The simplest, non-invasive method for assaying radionuclides in sealed drums is by spectroscopy of gamma rays that are sufficiently energetic and intense to penetrate the walls of the drums. In most instances, spectra obtained by a high-resolution detector, such as an intrinsic germanium, coaxial detector used at Mound, will be characteristic of specific radionuclides. However, the success of an assay depends on the activity of the source, the mode of decay of the radionuclides and whether they emit gamma rays of sufficient energy to penetrate the walls of the drum. Complications are further introduced by the shielding factor of the drums and drum contents. Yet in most cases the determination of the radionuclide identities are readily obtained by examination of the gamma peaks in a spectrum.

### Drum Assay Measuring Equipment

A complete drum assay system usually consists of a number of distinct, separately-bought nuclear instrumentation modules, or instead, a complete system can be purchased. There are several companies that build integrated drum assay measurement systems, only one in particular is discussed in this report, the system used by Mound which is manufactured by Canberra Industries, Inc.

The following is a list of equipment of the drum assay measurement system:

1. A gamma-ray detector, to determine the energy of the absorbed gamma rays.
2. Pre-amplifier and spectroscopy amplifier, for amplifying and shaping the signal.
3. Multi-channel analyzer, for determining the gamma-ray peaks.
4. Computer, for analyzing the data.
5. A drum table platform, for manipulating waste barrels.

The above listing does not include ancillary items such as power supplies, drivers, cables, etc., nor does it account for software that is critical for controlling an entire system.

#### *Drum Assay Procedure*

To begin the procedure a sealed drum of known radioactive waste, called the calibration standard, is placed on a rotating platform and elevated to expose its lower side to a collimated, gamma-ray detector. Next, the drum is scanned by the detector for a preset duration. Then the drum is lowered to another position and another scan is completed. Note: each successive step of the moving stage is controlled through the use of computer software. Finally, once the entire length of the drum has been scanned, the computer generates a report of the contents based on the radionuclides identified from the gamma-ray spectra observed (see Appendix A for a sample print-out).

One purpose of the calibration standard is to determine the absolute efficiency of the detection system. This information is then used as input data for future drum assay measurements. In addition, the data serves as a benchmark for subsequent measurement control runs. For this purpose the *Mound Technical Manual*<sup>1</sup> specifies that calibration data be taken both before and after each session of drum assays to confirm that the detection efficiency of the system hasn't changed. After completing a calibration run, successive assays following the same routine can be repeated for one or more drums.

### III. Hardware Upgrade at Mound

The scanning system modified at Mound Nuclear Safeguards and Development Group was a Canberra Model 2220B. Since the purpose of replacing the DEC with a PC was to attain a more efficient and reliable scanning system, a spin-off would be simplification of code enhancements. However, modernizing the hardware necessitated installation of three boards--a serial/parallel card, a parallel input/output card and an electromechanical relay board--to replace functions formerly controlled by the DEC. This chapter discusses installation of those items and of software developed to enable PC-to-STC hardware handshaking and to link Canberra-supplied communication programs to the MCA.

Microsoft QuickBASIC was the primary language for software development. Hence all software programs would run inside, or in conjunction with, the QuickBASIC Interpreter. Hardware drivers were written in Microsoft MACRO and then compiled and linked as a QuickBASIC library. As a consequence, the library module has to be loaded when QuickBASIC is started.

#### *Problem Definition*

To complete the changeover, the PC needed to interface with existing equipment by performing three main functions:

1. Communicate bi-directional data transfers with an external MCA, via serial interface for command/control functions and parallel interface for data transfers.

2. Function as the control panel by supplying driver signals and sensing feedback signals to and from the STC (the STC drives trolley motors and lifts the drum turntable up and down, and performs other various functions).
3. Analyze spectral data taken by the MCA.

Furthermore, development of new software would be needed to replace existing codes. Originally the DEC PDP-11/05 controlled input and output functions by using BASIC/RT-11 language programs provided by Canberra. This software consisted of 3 main modules:

1. A BASIC language interpreter, with callable machine language functions for system control and data acquisition.
2. A calibration program.
3. A general purpose program that included several BASIC subroutines for allowing the computer to control MCA functions, like setting up a region-of-interest (ROI), doing a spectral peak search, or presetting counting time, etc. (a more universal set of subroutines that parcels control and data transfers between the DEC and MCA is given by Larry V. East<sup>2</sup>).

Because all of the other drum assay equipment was retained, newly written programs for the PC would have to execute identical tasks to the above BASIC/RT-11 language programs. Thus the modified drum assay system would still operate similarly to that of the original DEC system.

#### *Electrical Mapping of Hardware*

This section discusses installation of new hardware necessary to connect the PC with the MCA and STC. MCA communication hardware consisted of a parallel driver card

(commonly called the Fast IBM Interface or 3576) and a serial communication card (just referred to as the PC Interface or 3575). PC to MCA electrical connections were established by installing a serial/parallel (S/P) adapter board in slot #2 of the PC, and coupling both serial ports by way of a 9-pin null modem cable, 9-pin to 25-pin adapter, and 25-pin ribbon cable. Similarly, the parallel ports were connected with a shielded 25-pin cable. Figure 3.1 shows the wiring diagram and cable connections.

Additionally, since there was a limited number of serial ports on the PC, a Clear Signal T-Switch Box was spliced into the serial line so other applications could utilize the same serial port. Serial hardware handshaking is enabled when the switch on the box is in the "A" position.

The baud rate for the logic board in the MCA was set to 1200bps. Higher transmission speeds are also possible, however, the *CANBERRA PC Toolkit Software Manual*<sup>3</sup> advises if Microsoft Windows is to be used the baud rate of the serial port should be less than or equal to 1200bps, thus assuring no characters are lost in the transfer process. It was decided to limit data transmission to 1200bps for now, thinking that in the future windowing capability might be applied.

Because a common setting of 1200bps on both PC-to-MCA communication boards was used, installing both serial and parallel communications were a necessity because of the huge

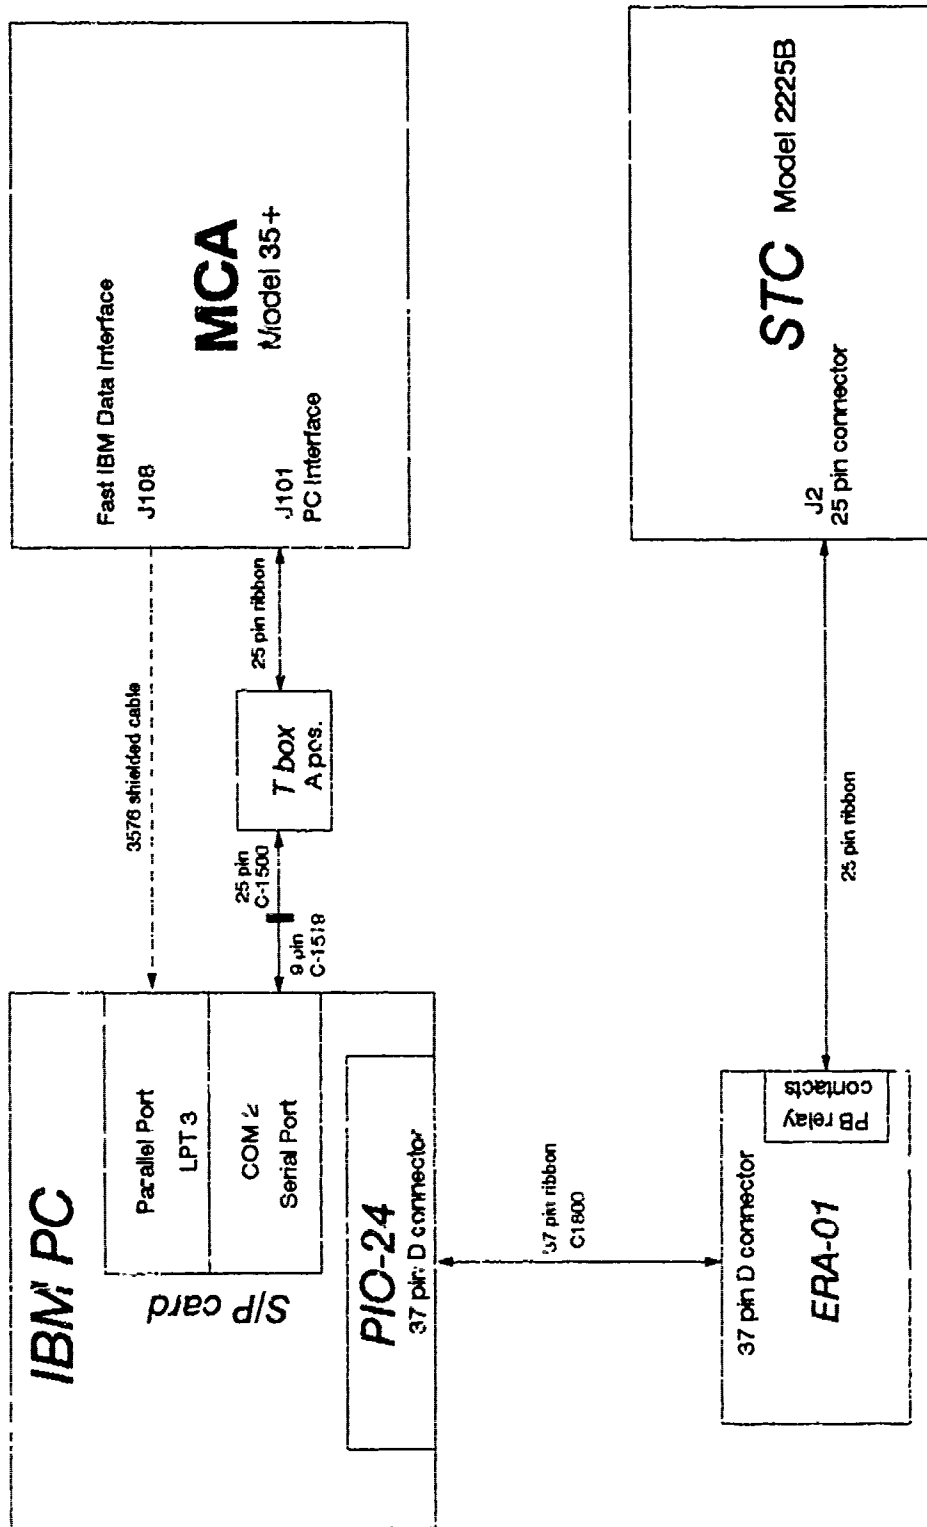

Figure 3.1 PC to MCA/STC Wiring Diagram

amount of data sent over the lines (the MCA could send up to 8192 channels of information). Transferring that amount of data through a serial line would take up too much time, so to minimize the transmission interval, command and control functions were routed over a serial line while data transfer used parallel exchange. Note however, parallel data transfer was not critical since all MCA functions could be handled through serial communications.

For PC-to-STC communications, a high-output current, parallel digital interface (PIO-24) was installed in PC slot #5 (base address 304 hex), along with an external electromechanical 8 channel SPDT relay board (ERA-01), to route PC to STC communications. All digital input/output lines from the PIO-24 are connected to the ERA-01 via a MetraByte C1800 ribbon cable. Cabling from the ERA-01 to STC is by way of a 25-pin ribbon cable. Again, Figure 3.1 shows the wiring diagram for cable and equipment connections, and Figure 3.2 shows a schematic of the electrical connections.

The PIO-24 and ERA-01 devices are the functional equivalent of the MCI card (recall Figure 1.1). Originally, the MCI served 7 control lines by sinking 300 ma to common ground of an EG&G ORTEC NIM power supply. But the PIO-24 could only sink 64 ma to ground, so it was used to drive the ERA-01. Sink current is maintained for 7 control lines through a set of relay contacts on the ERA-01 board. In addition, 5 sense lines from the STC enter the ERA-01.

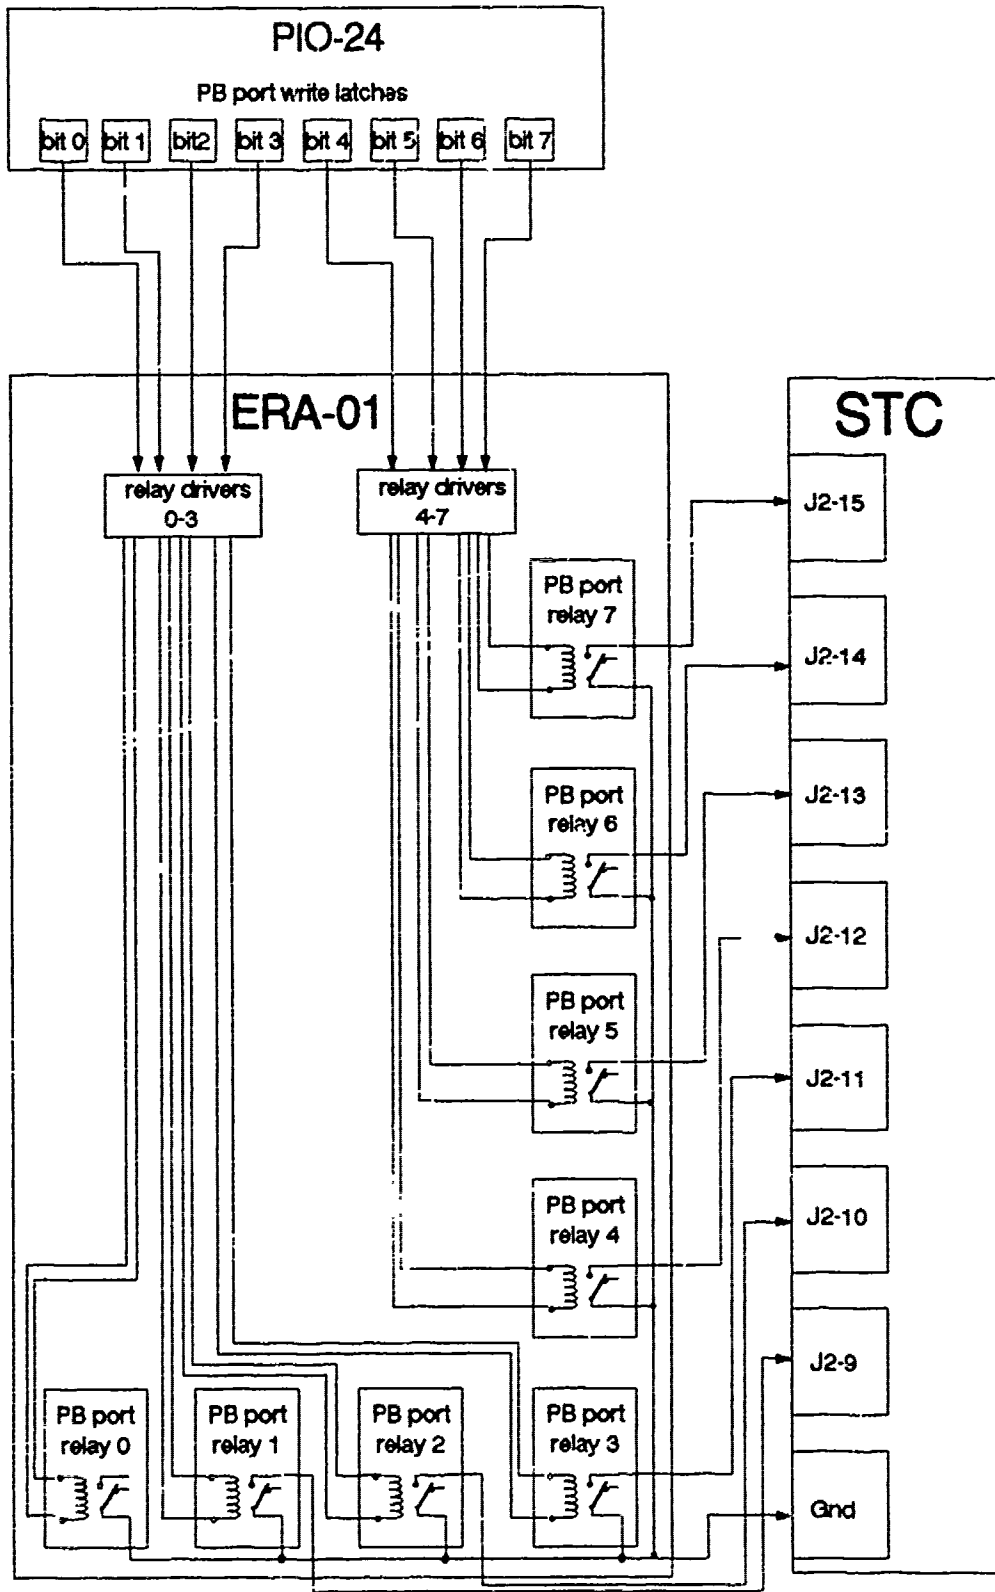

Figure 3.2 PIO-24 to STC Schematic

These lines are for sensing contact closure only and are presently disconnected. For more information on control and sense lines, see the next section, "Establishing PC to STC Communications."

Three of the 7 PIO-24 control lines drive 3 relays on the STC: K1, K2, and K3. Output from K1 and K2 set the "return" and "advance" contacts of 6 small relays on the drum turntable panel box. The panel box has 7 large contact relays (CR's 1-7) which drive the left and right trolley motors and drum rotation motor; the small relays (CR's 8-13) are the relay drivers for CR's 1-7. Output from K3 opens and closes a shutter used by the transmission source. The other 4 control lines (1-4) turn on display lamps on the STC panel.

Appendix J shows each control line connection on the PIO-24, ERA-01 and STC. For example, control line 5 is PB port bit 5 on the PIO-24, PB port relay normally open contacts on the ERA-01, and pin connection J2-13 on the STC. In actuality a port bit does not directly join end to end a port with its relay contacts, however, what is meant is the port bit can energize a corresponding relay on the ERA-01. Furthermore, the "common" contacts of all the relays are connected to J2-25, which is common ground of the NIM power supply. Since the contacts of the PB port relays are normally open, no connection is made to ground. However, setting a PB port bit high on the PIO-24 (through TableSYS.ASM)

will close the proper relay on the ERA-01 and short the normally open contacts to ground--in essence, activating a control line. In this way the PIO-24 and ERA-01 combination can replace functions formerly managed by the MCI.

#### *Establishing PC to MCA Software Communications*

The Canberra S370 PC Toolkit is a collection of driver and utility programs (17 total) useful for setting remote control communications between a Canberra MCA and an IBM compatible computer. The 3 most important programs are PCUTIL.BAS, MCAS.COM and SETMCA.COM (page 13 of the PC TOOLKIT SOFTWARE manual provides an in-depth explanation of each program). These programs establish serial communication. Both MCAS and SETMCA are executable device drivers while PCUTIL is a GWBASIC utility program. The essential codes for parallel communication are BINS.COM, BINSTUFF.OBJ and FASTRAN.EXE. Both FASTRAN and BINSTUFF are FORTRAN test programs, while BINS is the parallel device driver. Since all 6 programs were vital in governing MCA operations, each one was installed.

The first prerequisite was to check the settings of the S/P board port addresses. By default, initial factory settings activate software handshaking using serial port #2 and parallel port #3. Port allocation was verified by CHECKCOM.COM, a program that verifies port availability and determines whether or not the port is suitable for serial or

parallel communications. Then the device drivers, MCAS.COM and BINS.COM, were installed in CONFIG.SYS. Appendix B lists a print-out of CONFIG.SYS. Since the jumper in the S/P card was set to COM2 and LPT3, the device driver arguments in CONFIG.SYS (for MCAS.COM and BINS.COM) are COM2 and LPT3, respectively.

Finally, SETMCA was added to AUTOEXEC.BAT. Appendix C lists a printout of AUTOEXEC.BAT. SETMCA sets the software for serial communication to operate at 1200bps--the same as the baud rate setting on the MCA logic board. Note: when changing the baud rate, failure to set the logic board and SETMCA to the same value will disable serial handshaking.

Since Canberra specified serial communications could be accomplished in either BASIC or FORTRAN languages, and parallel data transfer by using FORTRAN only, a principal language needed to be selected. The Microsoft QuickBASIC Interpreter became the primary language for code development because of its outstanding debugging capabilities. However, this meant FASTROM had to be rewritten in QuickBASIC with BINSTUFF converted over to a QuickBASIC library, and lastly, PCUTIL needed to run inside the interpreter.

Proper operation of the serial communication line was checked by running PCUTIL under GWBASIC. Several commands were given, e.g., initialize the MCA and set regions of interest, in verifying serial hardware setup. No problems were encountered.

DrumSYS.ASM. The original BINSTUFF was a collection of 5 FORTRAN subroutines that passed data back and forth to the device driver, BINS. However, BINSTUFF didn't work, at least in the QuickBASIC environment. Replacing the object code meant BINSTUFF had to be rewritten in assembly language, and also had to be Microsoft compatible in order to be linked as a QuickBASIC library. Appendix D lists the assembly source code for DrumSYS.ASM--essentially the same 5 procedures as in BINSTUFF but condensed into one code and data segment and rewritten with Microsoft Macro Assembler<sup>4</sup> directives/instructions and BASIC calling/naming conventions.

Two of the five procedures are documented in-depth, while the other three share instructions similar to those observed in the first two procedures. And all of them foster DOS interrupt functions and standard File Control Blocks.

Because documentation on BINS and BINSTUFF was nonexistent, it made deciphering the original BINSTUFF difficult. Apparently DEVICE is used as a symbol for the ASCIIIZ string, 'BIN1.' This means BIN1 is a device (opened by BINS) for writing data to during a parallel data transfer. In the same fashion, FILEHANDLE is a symbol that contains the file handle.

DOS interrupts open and close the file BIN1. For example, the first interrupt (INT 21/3D) in the OPENBI procedure accesses the file private to the current process. On a successful return, BIN1 is opened with the read/write pointer at the beginning of the file. The file handle (a 2-byte number, or word) is used in later DOS interrupts to reference back to BIN1. Actually, file handle is the 2-byte offset address while DS (Data Segment register) points to the segment address, also 2 bytes.

After BIN1 is opened, the next procedure, INBIN, performs the actual data transfer. Now parameters are passed to the procedure along with the return address. A requirement of BASIC is to declare assembly-language procedures as FAR. Hence, the return address is 4 bytes long. This may not seem important at first, but when DrumSYS.BAS calls these procedures it makes a difference. The reason for this is the way BASIC calls an assembly-language program. By default, BASIC passes parameters to a procedure by reference as a 2-byte address<sup>5</sup>. But as will be seen later on in DrumSYS.BAS, the parameters are passed as LONG, i.e., a 2-byte segment address in both SS and DS registers plus another 2-byte offset address--4 bytes total. First, BP, which serves as a framepointer, is pushed onto the stack. Next BP is loaded with the last value SP (Stack Pointer) pointed to--the old value of BP. Since BP never changes in the procedure, all 4-byte parameters pushed onto the stack,

and the 4-byte return address, can be referenced relative to BP. Thus, if 2 parameters were pushed onto the stack, [BP+12] would point to the first parameter, [BP+8] would point to the second parameter, and finally, [BP+4] would point to the return address. Then it is a simple matter to access the data as required in the rest of the procedure's body.

In summary, the original procedures from BINSTUFF were rewritten, and the new assembly-language program is called DrumSYS.ASM. Next, DrumSYS.ASM was made into a QuickBASIC library. From the DOS prompt, DrumSYS.ASM is compiled into an object code using the command:

```
> MASM DrumSYS.ASM /zi
```

The option /zi is an assemble-time option that produces an object file in CodeView format. CodeView is a symbolic debugger from Microsoft and is useful for troubleshooting machine code. For now, the compiled code called DrumSYS.OBJ is linked as a QuickBASIC library using the command:

```
> Link /q DrumSYS.OBJ,DrumSYS.QLB,,BQLB45.LIB /co
```

Again, the /co option is used for CodeView only.

To call the procedures inside the QuickBASIC Interpreter, QuickBASIC has to be loaded with the command:

```
QB /l DrumSYS.QLB
```

Now the QuickBASIC Interpreter has all five procedures available for accomplishing parallel data transfers. In the

following section, the conversion of FASTRAN into the code DrumSYS.BAS is discussed along with how parameters have to be defined before they can be passed to DrumSYS.QLB.

DrumSYS.BAS. As pointed out earlier, BINSTUFF was to be called from a FORTRAN program called FASTRAN. FASTRAN was a test program that could transfer data files (MCA spectra) on disk to and from the MCA. It used a serial line for sending simple command functions while data were dispatched over a parallel line. The new FASTRAN, rewritten in QuickBASIC, is called DrumSYS.BAS. Appendix E lists the QuickBASIC source code for DrumSYS.BAS--practically the same lines as in FASTRAN but rewritten with Microsoft QuickBASIC subroutines and BASIC calling/naming conventions.

Another addition to DrumSYS.BAS was the ability to chain to Canberra's utility program PCUTIL.BAS. However, PCUTIL.BAS would not run in the QuickBASIC Interpreter, so it was modified. Because of the length of this program (approximately 800 lines of code), it is not listed here. The new program (PCUTILQB.BAS) is the same as Canberra's except with a few minor changes.

DrumSYS.BAS is adequately documented, so only a short discussion is included here. However, there are two important peculiarities. One has to do when DrumSYS.BAS is first started, and the other when parameters are passed to DrumSYS.ASM.

The serial device driver MCAS.COM opens two devices, denoted MCAIN and MCAOUT. These devices are used for MCA communication; note: they are not "ordinary" files. DrumSYS.BAS will write information to MCAOUT and read data from MCAIN in order to communicate with the MCA. If the MCA does not respond and an error condition occurs when DrumSYS.BAS opens MCAIN for input, press the INDEX and HOME keys (on the MCA front panel) simultaneously to clear the MCA and enable handshaking. In the event the above does not work, then press the YES key (on the MCA front panel) and retry. The previous steps should only be needed when the MCA is first turned on. The reason is because on the back of the MCA there is a switch that has three positions: Remote, Shared, and Local. When the switch is in the Shared position both the front panel keyboard and a remote computer can enable handshaking. However, during a cold start-up and when the switch is in the Shared position, the MCA electrically pulls one of the serial line pins low, thus disabling remote communications. The above procedure reinstates remote communications.

In DrumSYS.BAS parameters are passed to DrumSYS.ASM as LONG, i.e., a 2-byte segment address plus another 2-byte offset address. This implies numerical data must be declared LONG (4 bytes). In QuickBASIC an integer data type is only 2 bytes long, so failing to pass values as 4 bytes will eventually cause the computer to hang. The problem is

solved in DrumSYS.BAS with the "DIM SHARED IAR(8194) AS LONG" statement. Another concern is how the array IAR is passed. BASIC uses an "array descriptor" to pass arrays. The array descriptor lets BASIC access an array by pointing to the first element of the array's address. This is necessary because BASIC allocates computer memory dynamically; thus an array may shift in memory location when the program is run. Therefore QuickBASIC VARPTR and VARPSEG functions must be used when passing an array. However, one exception to this rule is if the array elements are passed by value. For more information on BASIC array descriptors see Microsoft's Mixed-Language Programming Guide.

#### *Establishing PC to STC Software Communications*

The STC (model #2225B) is the rack mounted control panel for the gamma scanner<sup>6</sup>. It is the main panel for starting an assay measurement sequence. The panel performs four central functions: SYSTEM POWER, SEGMENT SIZE CONTROL, TABLE ROTATION and PROGRAM CONTROL. These functions are summarized in the Segmented Gamma Scanner Operating Manual as follows:

1. SYSTEM POWER: Turns on the AC power to the drum rotator panel and contains the emergency stop button.
2. SEGMENT SIZE CONTROL: Limits the length of drum segments. Use of the RETURN button moves the drum table to the top position and using the ADVANCE button indexes timer to advance the drum table downwards. Note: RETURN and ADVANCE are computer controlled relays.

3. TABLE ROTATION: ON position the trolleys forward and starts drum table rotation. OFF position moves the trolleys backward and stops drum table rotation.
4. PROGRAM CONTROL: SHUTTER opens and closes the shutter. ABORT terminates the drum assay measurement. CALIB initiates the calibration procedure. INIT allows for manual calibration of drum. ASSAY starts the assay measurement procedure.

Two of the functions, SEGMENT SIZE CONTROL and PROGRAM CONTROL, deploy "digital" input/output lines to implement a drum assay procedure.

Presently there are 12 digital lines, 7 control lines and 5 sense lines. These are summarized in Table 3.1. The PC invokes operation of the control lines through TableSYS.ASM, the software driver for the STC. Right now all 5 sense lines are disconnected at the ERA-01 because of earlier troubles that were encountered when AC cross talk would feed back into the parallel digital interface and destroy integrated circuits; nonetheless, their functions have been replaced by using a time-delay procedure (in TableSYS.ASM) called Pause(x).

Most of the mechanics of the drum assay utilize control lines 5, 6 and 7. For example, invoking control line 6 (relay K2 energized) will activate a drum segment size timer; the timer is preset by rotating several thumb-wheel switches on its front face to a desired setting. Once the timer energizes it lowers the drum table platform until time has run out. Thus, the length of the segment drop is lim-

ited by the setting on the timer and remains constant throughout the drum assay procedure. Program flow will then issue commands to the MCA through CALIB.BAS (see Appendix H) to start collecting data. Issuing another control 6 again lowers the drum, and this cycle repeats until all segments have been analyzed. Similarly, control 7 (relay K1 energized) moves the drum table platform upwards, and control 5 (relay K3 energized) opens and closes the transmission source shutter.

TABLE 3.1  
STC Control and Sense Lines

<u>Control Line</u>	<u>Purpose</u>
1	Turn ASCPT lamp on.
2	Turn CALIB lamp on.
3	Turn INIT lamp on.
4	Turn ASSAY lamp on.
5	Open transmission source shutter and turn SHUTTER lamp on.
6	Move drum table downwards.
7	Move drum table upwards.
<u>Sense Line</u>	
1	Signals ABORT button has been pressed.
2	Signals CALIB button has been pressed.
3	Signals INIT button has been pressed.
4	Signals ASSAY button has been pressed.
5	Signals drum table is advancing.

TableSYS.ASM. TableSYS.ASM is the software driver for the PIO-24. It consists of 4 public assembly-language procedures (public means the procedures are accessible from another high-level language). These are

- (1) SetCRconfig(): initializes PIO-24 mode, no parameters are passed;
- (2) Set(x): will energize relays 1-7, pass numbers 1-7;
- (3) Clr(x): will turn off relays 1-7, pass numbers 1-7;
- (4) and Pause(x): will suspend program execution for 1 to 59 seconds. Procedure uses DOS system time and is independent of processor speed, pass numbers 1-59.

Appendix F lists the TableSYS.ASM source code, and Figure 3.3 shows a flow chart of each procedure. More important, however, is every directive and instruction in the code has been commented should the PIO-24 port addresses need to be changed.

The "twenty-four" in PIO-24 stands for 24 digital input/output lines. These 24 lines are divided equally among 3 ports: PA, PB, and PC. All ports are configured input only when the computer is first turned on. However, when DrumTAB.BAS (see next section) is started it initializes the control register on the PIO-24 using the SetCRconfig() procedure. SetCRconfig() zeroes the contents of the write latches (all ports) and configures PB as a write only port. Currently the PA and PC ports are not used.

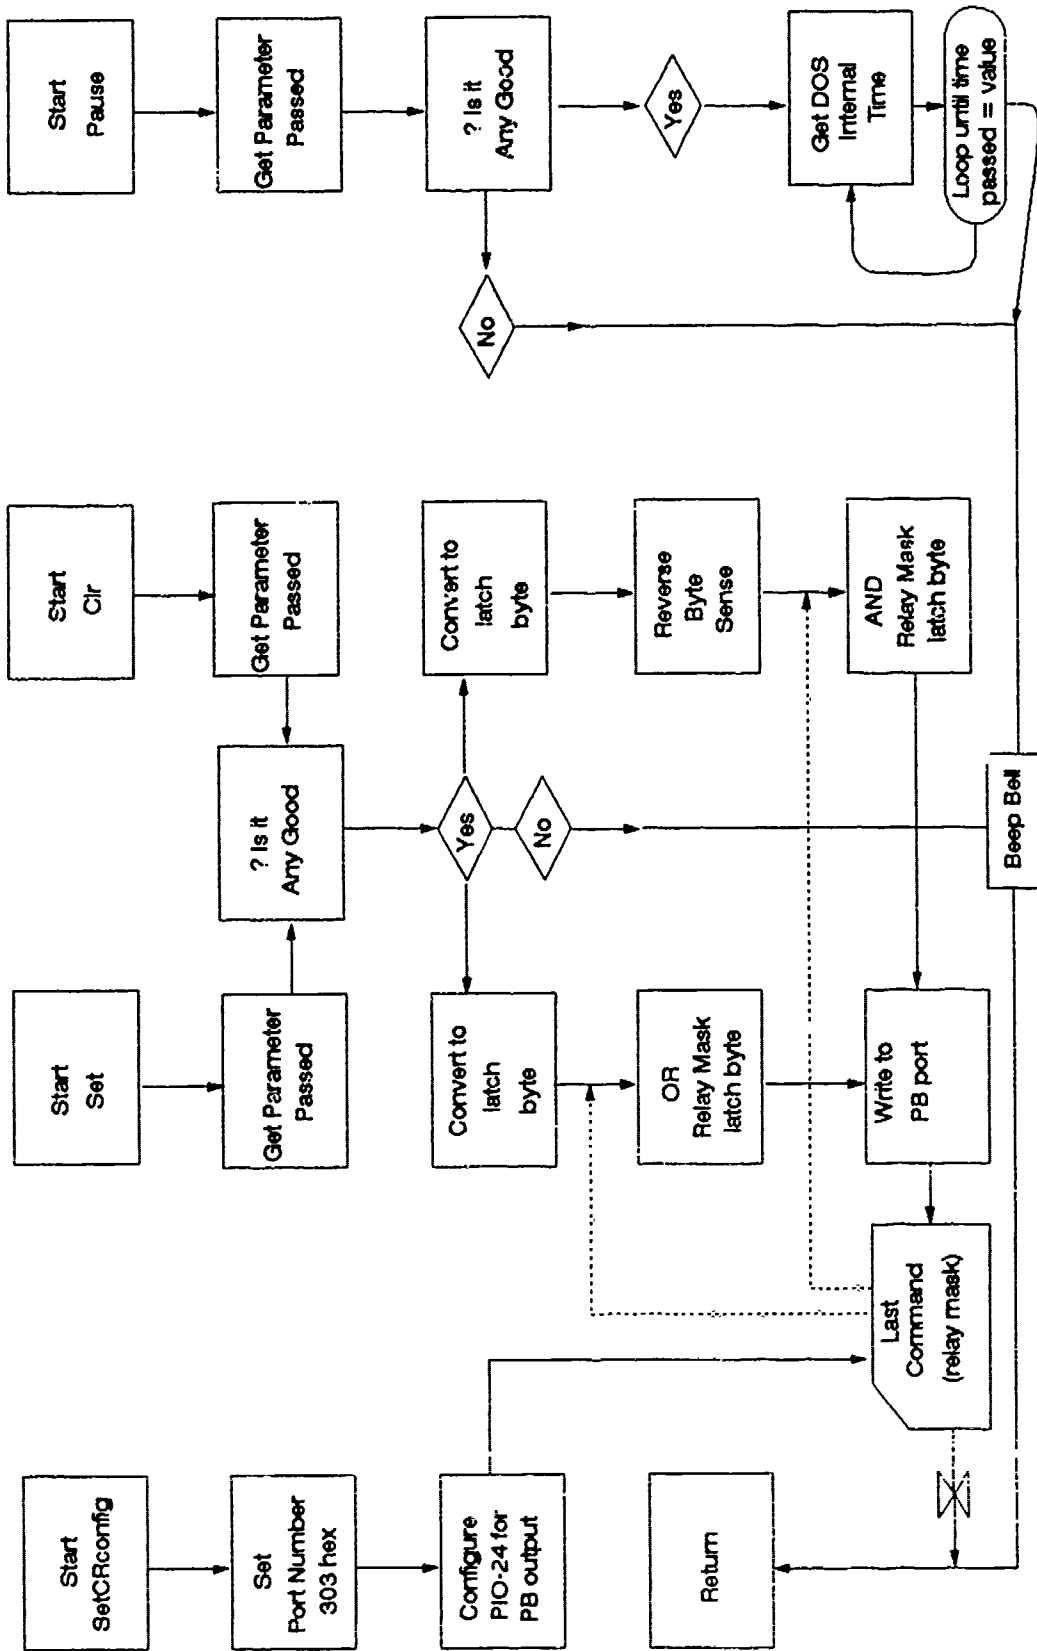

Figure 3.3 Flow Chart of TableSYS.ASM

⊗ : time delay

Functionally, procedures Set(x) or Clr(x) drive the PIO-24 by retrieving a 2-byte integer parameter placed onto the stack segment. The variable x is the parameter passed, and ranges from one to seven. Accessing the value is the same as described in the DrumSYS.ASM section. The parameter has a one-to-one correspondence with control lines 1 through 7. For instance, a value = 3 means control line 3. Next, the parameter is encoded to the relevant PB port relay. This is accomplished by raising the number 2 to the parameter power. For example, a parameter equal to 3 is changed to  $2^3 = 8$ . The new value is then converted to an 8-bit number that corresponds to the PB port relay on the ERA-01 (see Appendix J). Since there are 8 PB port relays (0-7) and only 7 control lines, each control line is mapped (again a one-to-one correspondence) to one relay. Hence a parameter = 3 means control line 3, PB port latch bit 3, and PB port relay 3, with the byte number sent to the ERA-01 equal to 00001000 (in binary).

That's the way the process should work, however, there's one slight problem. When examining a drum it's necessary to set more than one control line. Changing the sense of one bit would turnoff the other relays (bit sense = 0), so to solve the problem a copy of the last command sent to the PIO-24 is saved in the data segment. The symbol LAST is a direct memory operand that represents the address (segment and offset) of the last command byte, and is referred to as

a "relay mask". In general, the relay mask is formatted as two 4-bit nibbles. The low-order nibble (bits 0 through 3) corresponds to control lines 1-3. Likewise, the high-order nibble (bits 4 through 7) corresponds to control lines 4-7. In a Set(x) procedure a bitwise logical OR on the PB port latch register (BL register) and relay mask is performed. The new byte is placed in the AL register and sent out to the PB port. As a result, only the relay that needs to be activated is turned on, or in the case of a Clr(x) procedure, the relay is turned off. Clr(x) works similar to Set(x) except it uses a bitwise logical AND on the port latch register and the relay mask.

Finally, the procedure Pause(x) is just a time delay with x being the number of seconds (between 1 and 59) to delay by. Since Pause(x) uses DOS interrupts, timing is independent of processor type. Hence an AT style computer would have the same delay as a 386 type machine. Mainly Pause(x) serves as a substitute for the sense lines that were previously used in the old RT-11 BASIC codes. The purpose of the sense lines were to let the computer codes know the STC was busy running the drum table platform. As an alternative, the programmer counts the number of seconds for the STC to perform a specific task (for example, moving the drum down one segment might take 5 seconds) and inserts

the appropriate delay in his/her codes using `Pause(x)`. At first it might seem this appears like a cheap fix, however, it works well because of the constant RPM AC motors.

Like `DrumSYS.ASM`, compiling `TableSYS.ASM` into an object code is the same. In addition, the two object codes can be linked together to form one `QuickBASIC` library; then all of the procedures in both codes are available to `DrumTAB.BAS`, the menu program. Aside, an advantage of using assembly-language modules is that they can be interfaced from any high-level language without requiring modification should `DrumTAB.BAS` be written in another language.

#### *The Central Menu Program, DrumTAB.BAS*

`DrumTAB.BAS` is the main program that exploits all the features that have been talked about earlier. It can be started in the `QuickBASIC` Interpreter or compiled and linked separately into an executable code, `DrumTAB.EXE`, using `Make-Drum` (see next section).

Program flow starts, as seen in Figures 3.4 and 3.5, by setting the computer environment and initializing communications with the MCA and STC. Once successful, the code prints a menu on the display screen and then prompts the operator for his/her input. Depending upon which case was selected, the next step executes appropriate subroutines to perform the desired task. In the particular case of a drum assay procedure, `DrumTAB` executes `Set(x)` and/or `Clr(x)` pro-

cedures until it reaches the subroutine: Start Drum Assay Procedure. Then program management is transferred to an include file that controls MCA operations, like collecting ROI data, setting counting time, etc. Other than the exception of the include file, all operations are performed by DrumTAB--in conjunction with its library routines.

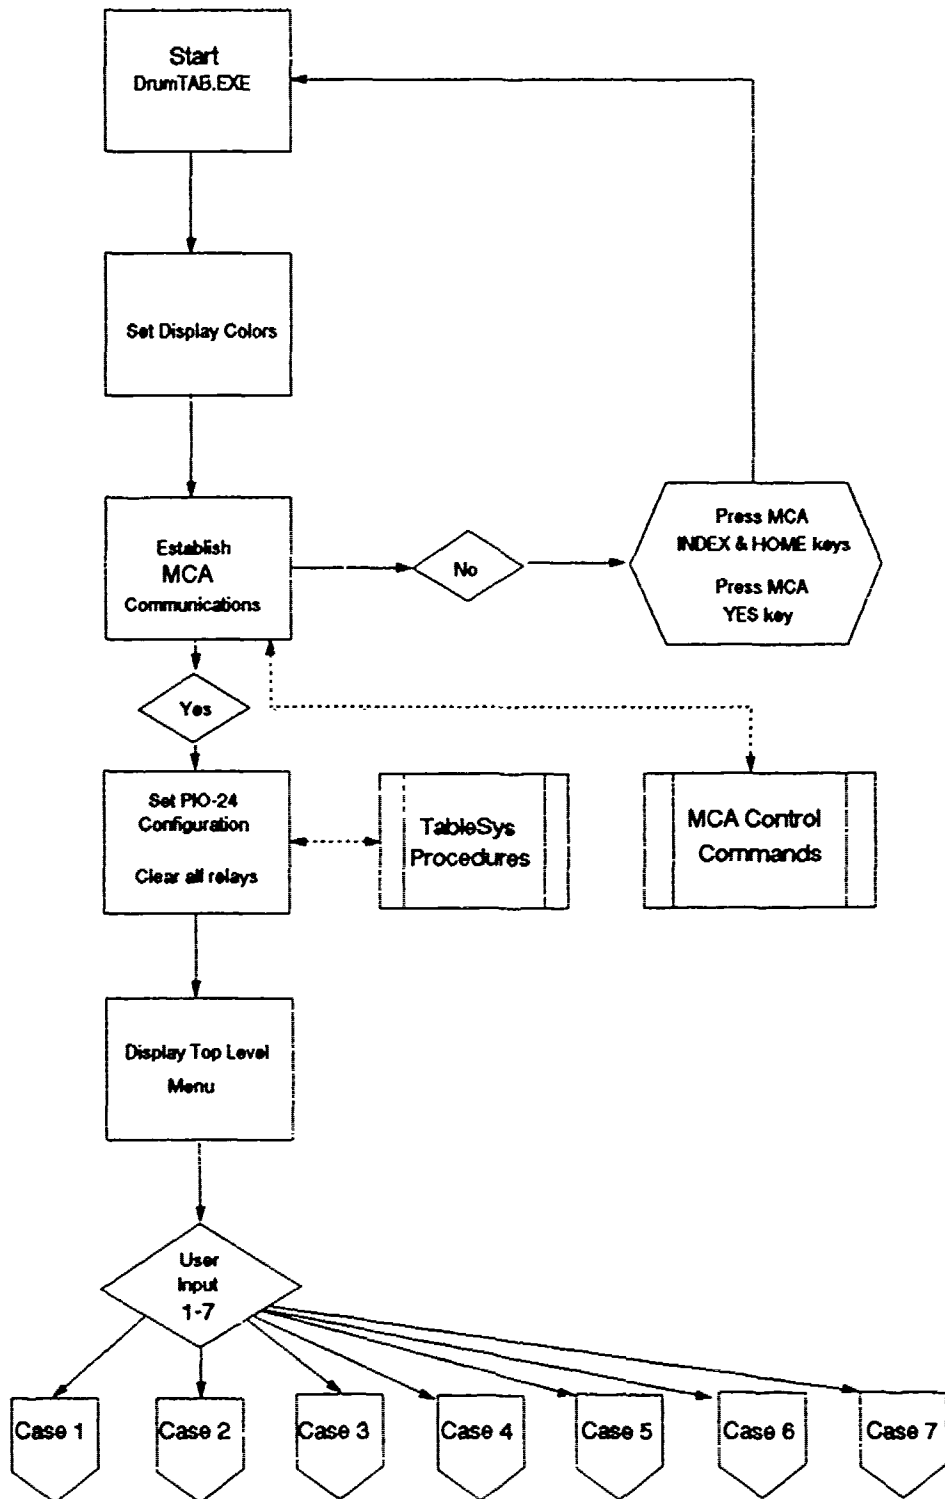

Figure 3.4 Flow Chart of DrumTAB.EXE

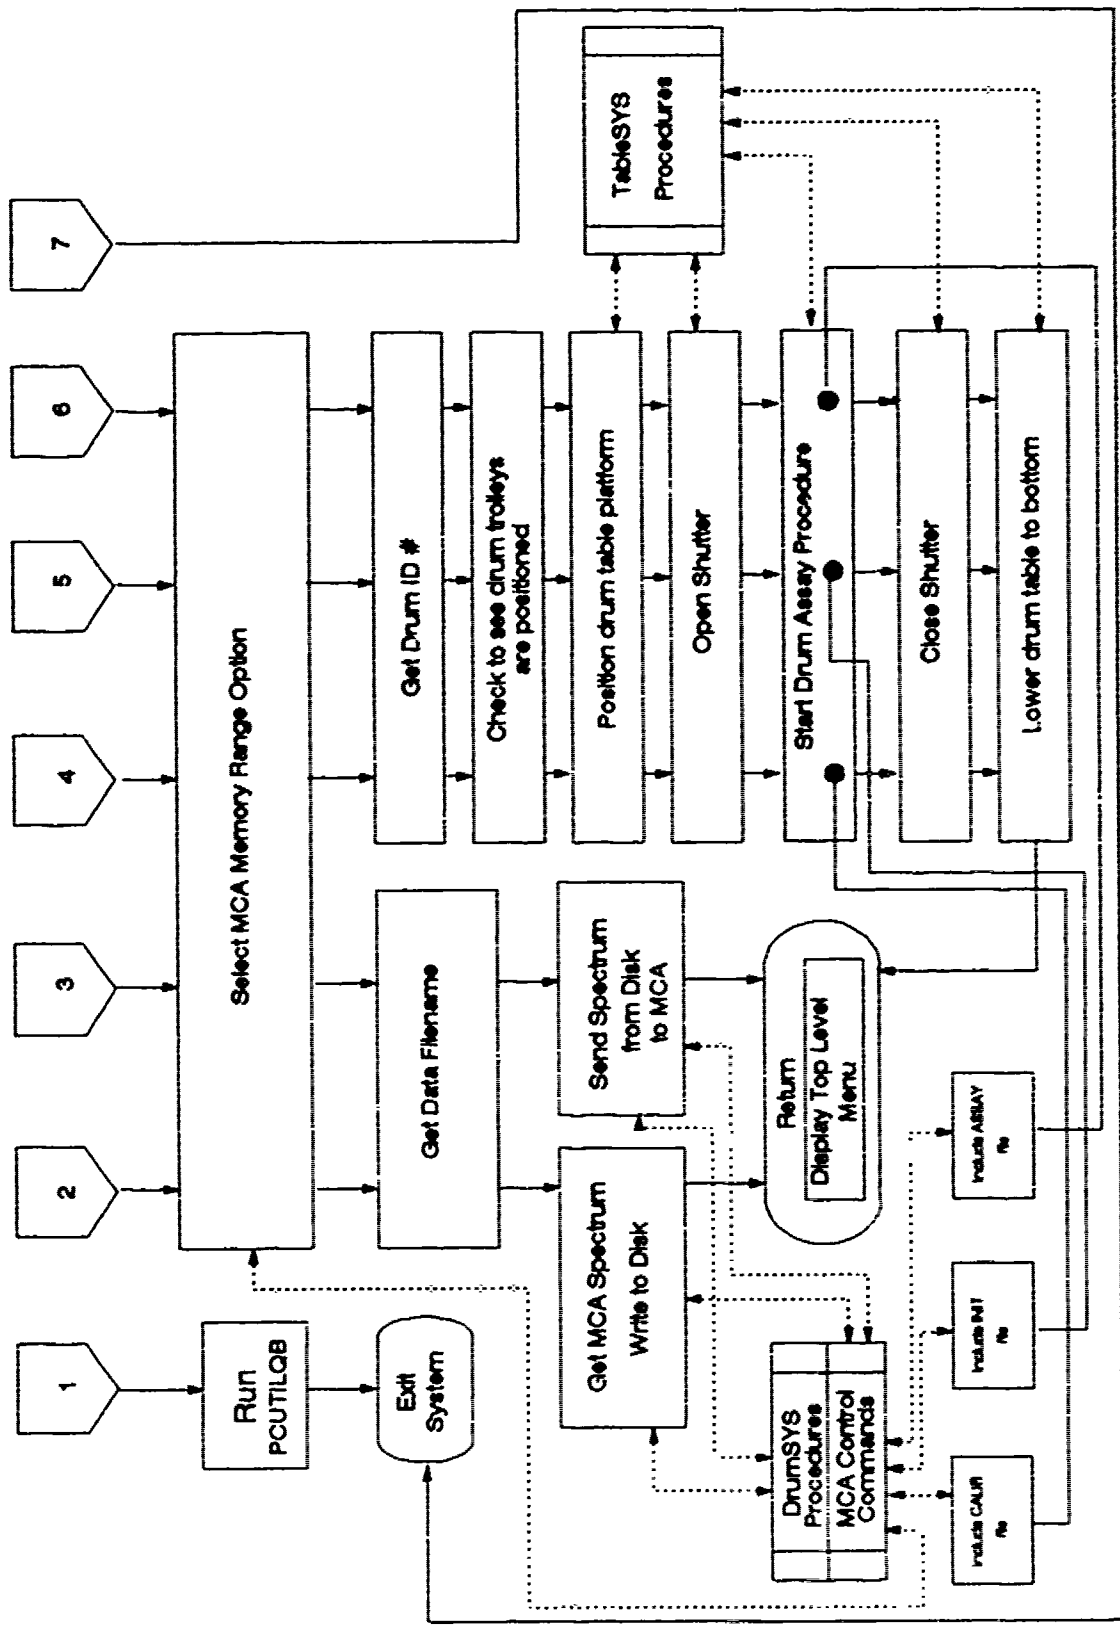

Figure 3.4 Continued

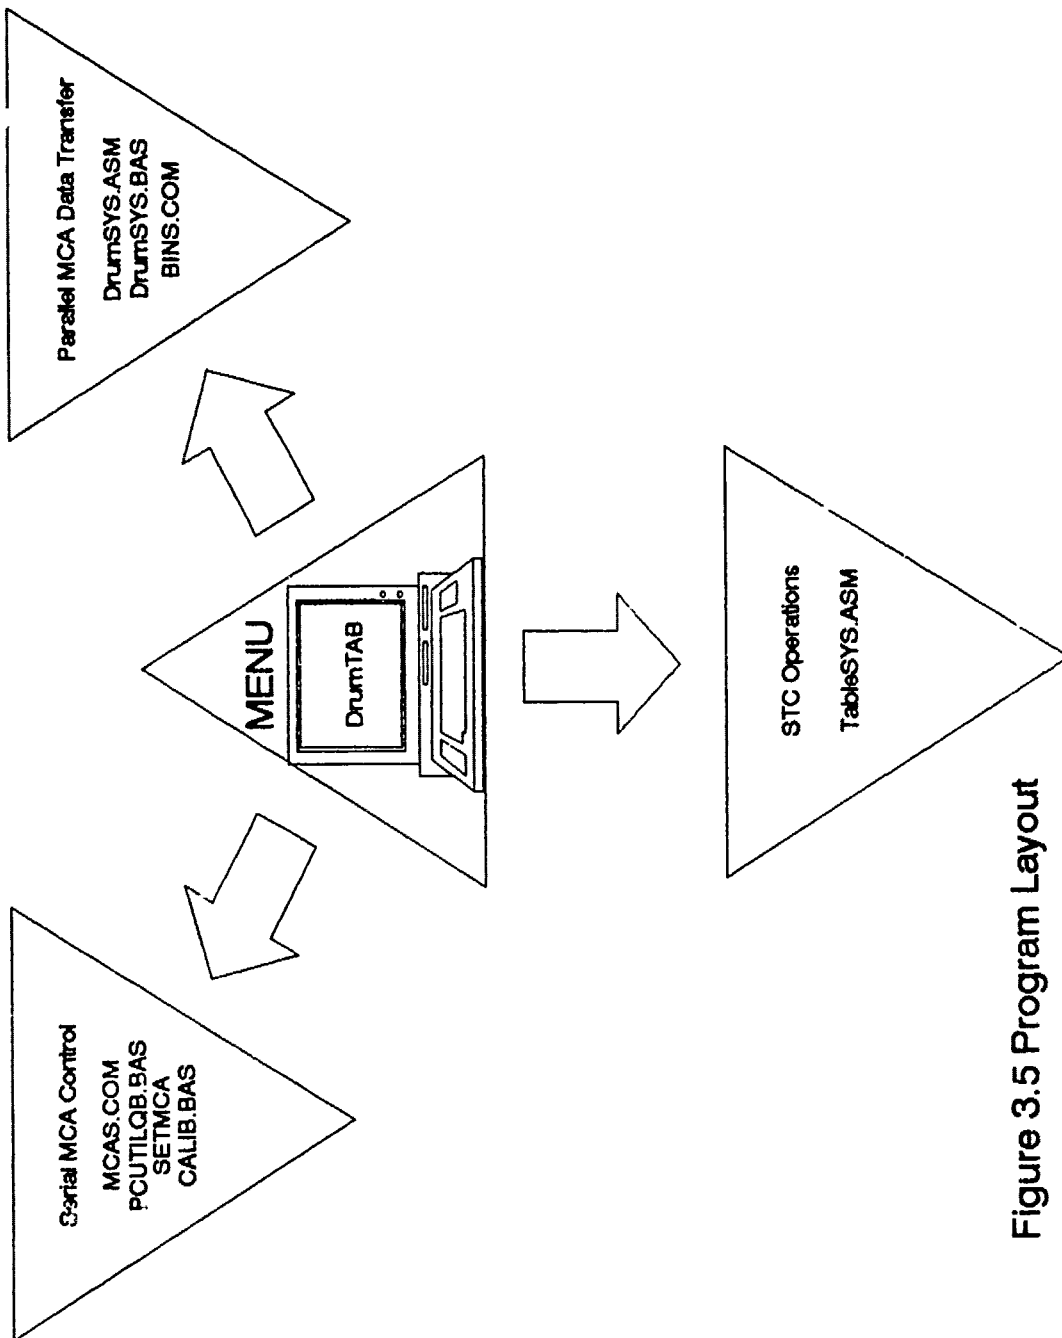

Figure 3.5 Program Layout

### Compiling and Linking Codes Using MakeDRUM

To simplify compiling and linking all codes necessary to run DrumTAB.BAS outside the QuickBASIC Interpreter, a short code called MakeDrum is used to construct DrumTAB.EXE.

Appendix I lists MakeDrum. It implements Microsoft's Make Utility to re-compile and link programs that have been modified since the last time they were compiled. Hence MakeDrum shortens the amount of time a programmer spends at the keyboard writing assembler commands, and makes changes to any of the programs a cinch to do.

#### IV. Future Efforts

The test file, CALIB.BAS, was used as an include file in DrumTAB to check whether or not a drum assay procedure could be accomplished with the new hardware setup. A sample output from CALIB.BAS is seen in Appendix K. This is similar to the DEC print-out in Appendix A. However, extra work is needed to correct the number of counts under the full-energy peak for absorption/scattering losses; also, no error analysis was performed. Hence two undertakings, an error analysis and addition of correction factors, must be considered part of a drum assay measurement. Included in Appendix L are mathematical derivations for the correction factors. Also, enhancements in the way of mouse support, a split screen graphics menu, and modular code design should eventually be incorporated. Nevertheless, these, and the efforts mentioned above, are left as suggestions for yet another project.

## V. Summary

A DEC PDP-11/05 computer system, used in Canberra's Model 2220B segmented gamma scanner, was replaced with an IBM PC. Additional hardware for the computer upgrade included installation of a serial/parallel board, a digital input/output board (PIO-24) and an electromechanical relay board (ERA-01). Five computer codes were written: TableSYS.ASM, DrumSYS.ASM, DrumSYS.BAS, DrumTAB.EXE and CAL-IB.BAS. TableSYS.ASM is a software device driver for the PIO-24. DrumSYS.ASM and DrumSYS.BAS are used with Canberra-supplied software for parallel data transfers. DrumTAB.EXE is a main menu and control program, and CAL-IB.BAS is an include file that interfaces with a Canberra Series 35+ multi-channel analyzer. A drum assay measurement was accomplished using the above codes and the hardware setup as described in Chapter 3. A sample print-out is listed in Appendix K. The modification enables simplified programmer enhancements.

## Appendix F: Listing of TableSYS.ASM

```
; File called TableSYS.ASM, used to control PIO-24 card.
; Replaces CANBERRA/DEC ALR functions that controlled the
; motion control interface.
; Make into an object code (TableSYS.OBJ) by running MASM.
; Created by C. Irvine, Oct 90. Last edited Nov 90 for PIO-24 upgrade.
;
; Contains the following PUBLIC procedures:
;
;     SetCRconfig(): initializes PIO-24 mode, no parameters passed
;     Set(x):        will energize relays 1-7, pass numbers 1-7
;     Clr(x):        will turn off relays 1-7, pass numbers 1-7
;     Pause(x):     will suspend program execution for 1 to 59 seconds,
;                   procedure uses DOS system time and is independent of
;                   processor speed, pass numbers 1-59
;
;
;                   .286                ; 286 processor directives
;                   .SEQ                ; order segments as they appear
;
Data_Seg1      Segment Public 'DATA'
Last          DB ?                    ; 1 byte, last command
Data_Seg1     ends

,
' The following is a sample QuickBASIC program that performs data
' transfers using the serial PC interface for commands and the Fast I3M
' parallel interface for data transfer. Also, the program will execute
' drum assay measurements while controlling operation of the CANBERRA
' drum table and scan table controller.
,
' This program uses the MCAS.COM serial driver and BINS.COM parallel driver
' for communicating with the serial and parallel interfaces of the MCA.
' This program requires DrumSYS.QLB (a Quick Library containing several
' subroutines which will communicate with the parallel interface using
' the parallel driver BINS.COM) be loaded while in the QuickBASIC environment.
' In addition, this program uses assembly-language procedures to control the
' scan table controller. The procedures are located in the library called
' TableSYS.QLB.
,
' Both libraries, DrumSYS.QLB and TableSYS.QLB, have been merged into one
```

' Quick Library called DrumTAB.QLB. DrumTAB.QLB was created with the  
' command

' C:\QB45\LINK DrumSYS.OBJ+TableSYS.OBJ,DrumTAB,,C:\QB45\BQLB45.LIB /q /co

' The command to load the library from DOS is

' C:\QB45\QB.EXE /l C:\QB45\THESIS\DrumTAB.QLB

' To make DrumTAB.BAS into an executable file:

' 1. First save the file as a text file, i.e., ASCII.

' 2. Convert the file into an object code with the command

' C:\QB45\BC DrumTAB,DrumTAB,DrumTAB /zi

' 3. Convert PCUTILQB.BAS to an executable file

' C:\QB45\BC PCUTILQB.BAS /zi /v /x /w /o  
' LINK PCUTILQB.OBJ,PCUTILQB,,C:\QB45\BCOM45.LIB /co

' 4. Next make a library with the assembly-language procedures

' C:\QB45\LIB DrumTAB.LIB+DrumSYS.OBJ+TableSYS.OBJ /co

' 5. Link DrumTAB.OBJ with the command

' C:\QB45\LINK DrumTAB,,C:\QB45\BCOM45.LIB + DrumTAB.LIB /co

' the /zi let's one use Code\_View  
' the /co let's one use Code\_View  
' the /v /w /x options enables event trapping and indicates the  
' presence of ON ERROR with RESUME or RESUME NEXT  
' the /o creates a stand-alone .EXE program that doesn't need  
' BRUN45.LIB

' 6. Run the program by typing

' DrumTAB

' Note: To use Code\_View type CV DrumTab

' NOTE: The use of this program requires the following interfaces and  
' equipment be installed:

- ' Model 3575 PC Interface for serial communications
- ' Model 3576 Fast IBM Interface for parallel data transfers
- ' PIO-24 High Output Current Parallel Digital Interface
- ' ERA-01 Electromechanical 8 Channel SPDT Relay Board.
- ' Model 2225E Scan Table Controller

CANBERRA Series 35 Plus MCA

VERY IMPORTANT: This code includes a modified version of FASTRAN source  
code from CANBERRA Industries, Inc.

## Appendix L: Derivation of Correction Factors

Wall and matrix material correction factors are derived below for incorporation into CAL-IB.BAS at a later time.

### Activity

After selecting a signature gamma of interest, the activity,  $A(t)$ , of a sample can be calculated by

$$A(t) = \lambda N(t) \left( \frac{\text{dis}}{\text{sec}} \right) \quad (L.1)$$

where  $\lambda$  = decay constant and  $N(t)$  = number of atoms present at time  $t$ . Additionally, a specific decay rate,  $A_{sa}(t)$  or specific activity, can be defined by

$$N \left( \frac{\text{atoms}}{\text{gram}} \right) = Av / \text{Atomic Mass} \quad (L.2)$$

$$\lambda = \left[ \frac{\ln 2}{T_{1/2}} \right] \quad (L.3)$$

$$A_{sa}(t) = \frac{\ln 2}{T_{1/2}} \times \left[ \frac{Av}{\text{Atomic Mass}} \right] \left( \frac{\text{dis}}{\text{g-sec}} \right) \quad (L.4)$$

where

$Av$  = Avogadro's Number,  
 $T_{1/2}$  = half-life of the material.

Since the decay of most radioisotopes is not always followed by a sole gamma emission, the specific decay rate is more appropriately defined as

$$A_s(t) = f \lambda N \left( \frac{\gamma}{\text{g-sec}} \right) \quad (L.5)$$

where  $f$  ( $\gamma/\text{dis}$ ) is the fraction that decays by the signature gamma of interest.

To convert activity to count rate and vice versa, count rate,  $CR$ , is given by

$$CR = \epsilon_{abs} A_s m \left( \frac{\text{counts}}{\text{sec}} \right) \quad (L.6)$$

where  $m$  is the mass of unknown sample in grams, and  $\epsilon_{abs}$  is the absolute detector efficiency in counts/gamma ray.

Now one can measure the number of counts deposited in a detector and relate this to specific activity:

$$CR = \frac{C\lambda}{(1 - e^{-\lambda t_c})} \quad (L.7)$$

where  $t_c$  is the counting time, and  $C$  is the net number of counts under the signature gamma full-energy peak (excluding background). Furthermore,  $CR$  needs to be corrected for dead time losses, if appreciable.

In the particular case for  $^{238}\text{Pu}$ , where the half-life is fairly long, i.e., if  $\lambda t_c \ll 1$ ,  $e^{-\lambda t_c} \approx 1 - \lambda t_c$  by a Taylor expansion. Thus,

$$C \approx \frac{\epsilon_{\text{obs}} A_s m \lambda t_c}{\lambda} \quad (L.8)$$

or

$$A_s m \approx \frac{C}{\epsilon_{\text{obs}} t_c} \quad (\text{Bq}) \quad (L.9)$$

At first it appears the right-hand side of Equation (L.9) contains only one unknown; however,  $\epsilon_{\text{obs}}$  could easily be obtained by performing an assay with a calibration drum of known activity. Yet there is another factor that has been neglected, that is attenuation of the source in the drum itself. Using Equation (L.9) alone would not account for this, and it is derived next.

#### Transmission

A drum consists of a matrix material, unknown source or sources, and the outer walls. The parts of the matrix material and drum walls are of dissimilar substances so they attenuate the source signature gamma rays differently. This attenuation causes the observed count rate (Equation (L.7)) to differ from the ideal case in which neither the matrix material or drum walls are present, i.e., the count rate noticed in absence of attenuating materials. As a result data collected from the MCA will predict a wrong activity value, however, using an additional "transmission" source in conjunction with the unknown drum source will correct for most deviations.

First a distinction must be made between the different sources; hence the unknown source is designated the assay source. The assay source is not confined to a single area, and cannot be treated as a point source. Instead, it is uniformly distributed (almost always) throughout the entire drum among the matrix material. About the only complication present here, besides drum attenuation, is a single scan of one drum segment does not provide sufficient data to analyze the entire drum inventory. Scanning multiple segments (otherwise known as *m<sup>2</sup> ping*) and rotating the drum normally averages out any inhomogeneities caused by source geometry<sup>7</sup>.

Furthermore, the walls are usually considered separately, that is, not part of the matrix material. Thus drum attenuation is caused by two factors. One is wall attenuation, and the second is matrix material attenuation. Both add to the overall attenuation of the source radiation.

The following derivation assumes wall and matrix material attenuation are the same, i.e., both are indistinguishable from each other and are lumped together under the general category of drum attenuation. Drum attenuation can be determined by using a transmission source with known activity emitting a gamma ray close in energy to that of the assay source signature gamma. Here, attenuation of the transmission source is defined by

$$T_t = \frac{T_{att}}{T_o} = e^{-\left(\frac{\mu}{\rho}\right)_t \rho_d x_t} \quad (L.1.1)$$

where

$T_t$  = transmission source attenuation,  
 $T_{att}$  = attenuated intensity of transmission source,  
 $T_o$  = unattenuated intensity of transmission source,  
 $\left(\frac{\mu}{\rho}\right)_t$  = mass attenuation coefficient of drum at transmission source gamma-ray energy,  
 $\rho_d$  = density of drum,  
 $x_t$  = transmission source pathlength (or distance through the drum).

Similarly, attenuation of the assay source is

$$T_a = e^{-\left(\frac{\mu}{\rho}\right)_a \rho_d x_a} \quad (L.1.2)$$

where

$T_a$  = assay source attenuation,  
 $\left(\frac{\mu}{\rho}\right)_a$  = mass attenuation coefficient of drum at assay source signature gamma energy,  
 $\rho_d$  = density of drum,  
 $x_a$  = assay source pathlength (or distance through the drum).

It also follows that

$$A_{meas} = A_{corr} \times T_a \quad (L.1.3)$$

such that  $A_{meas}$  is the measured assay source intensity from Equation (L.9), and  $A_{corr}$  is the intensity of the assay source, corrected for drum attenuation.

In a simple example where both transmission and assay sources experience the same attenuation and their difference in pathlengths is accounted for by some geometry factor,  $F_{geo}$ , for assay and transmission intensities close together\*

$$A_{corr} = \frac{A_{meas}}{T_a} = A_{meas} \frac{F_{geo}}{T_t} = A_{meas} \times \frac{T_o}{T_{att}} \times F_{geo} \quad (L.1.4)$$

Also, for assay and transmission sources far apart in energy

$$T_a = e^{-\left(\frac{\mu}{\rho}\right)_a \rho_a x_a} = T_i \left\{ \frac{\left(\frac{\mu}{\rho}\right)_a}{\left(\frac{\mu}{\rho}\right)_i \rho_{\text{ass}}} \right\} \quad (L.1.5)$$

Thus

$$A_{\text{corr}} = A_{\text{meas}} \times \left[ \frac{T_o}{T_{\text{att}}} \right]^{\frac{\left(\frac{\mu}{\rho}\right)_a}{\left(\frac{\mu}{\rho}\right)_i \rho_{\text{ass}}}} \quad (L.1.6)$$

As has been noted, wall and matrix material attenuation were considered inseparable. Next, individual corrections for wall and matrix material are addressed. Expanding Equation (L.1.3) for the two contributions yields

$$A_{\text{meas}} = A_{\text{corr}} \times e^{-\left(\frac{\mu}{\rho}\right)_{\text{wall}} \rho_{\text{wall}} x_{\text{wall}}} \times e^{-\left(\frac{\mu}{\rho}\right)_{\text{mm}} \rho_{\text{mm}} x_{\text{mm}}} \quad (L.1.7)$$

$$A_{\text{corr}} = A_{\text{meas}} \times F_{\text{wall}} \times F_{\text{mm}} \quad (L.1.8)$$

where  $F_{\text{wall}}$  is the correction factor for attenuation due to the drum walls, and  $F_{\text{mm}}$  is the correction factor for attenuation due to the matrix material inside the drum.

First the unattenuated activity/intensity of the assay source can be calculated by applying Equations (L.9) and (L.1.8). In addition, since mass or number density is proportional to activity, the assay source quantity inside the drum can be determined.

*Derivation of Wall Attenuation Factor,  $F_{\text{wall}}$ .* Drum wall attenuation is accounted for by

$$F_{\text{wall}} = \frac{1}{\sqrt{T_{\text{wall}}}} = \left( \frac{T_o}{T_{\text{empty}}} \right)^{\frac{k}{2}} \quad (L.1.1.1)$$

where

$$T_{\text{wall}} = \text{drum wall transmission} = \left( \frac{T_{\text{empty}}}{T_o} \right)^k,$$

and where  $T_{\text{empty}}$  is the transmission intensity thru an empty drum,  $T_o$  is the unattenuated transmission intensity, and  $k$  is the ratio of mass attenuation coefficients (of drum wall) at assay and transmission energies;  $k = 1$  if the energies are very close together.

The square root of  $T_{\text{wall}}$  is used since the transmission gamma rays pass through 2 walls of the drum whereas assay gamma rays pass through only 1 wall thickness. By neglecting air attenuation inside an empty drum, the transmission source attenuation is

$$T_t^{wall} = e^{-\left(\frac{\mu}{\rho}\right)_t^{wall} \rho_{wall} x_{wall}} \quad (L.1.1.2)$$

where:

$T_t^{wall}$  = transmission source attenuation in drum wall,  
 $\left(\frac{\mu}{\rho}\right)_t^{wall}$  = mass attenuation coefficient of drum wall at transmission source energy,  
 $\rho_{wall}$  = drum wall density,  
 $x_{wall}$  = thickness of one drum wall.

Then the assay source attenuation in the drum wall,  $T_a^{wall}$ , is given by

$$T_a^{wall} = e^{-\left(\frac{\mu}{\rho}\right)_a^{wall} \rho_{wall} x_{wall}} = T_t^{wall} \frac{\left(\frac{\mu}{\rho}\right)_a^{wall}}{\left(\frac{\mu}{\rho}\right)_t^{wall}} \quad (L.1.1.3)$$

where  $\left(\frac{\mu}{\rho}\right)_a^{wall}$  is the mass attenuation coefficient of the drum wall at the assay source energy. But from Equation (L.1.1)

$$T_t^{wall} = \frac{T_{att}}{T_o} \Rightarrow T_t^{wall} = \frac{T_{empty}}{T_o} \quad (L.1.1.4)$$

hence

$$T_a^{wall} = \frac{T_{empty}}{T_o} \left\{ \frac{\left(\frac{\mu}{\rho}\right)_a^{wall}}{\left(\frac{\mu}{\rho}\right)_t^{wall}} \right\} \quad (L.1.1.5)$$

And

$$k = \frac{\left(\frac{\mu}{\rho}\right)_a^{wall}}{\left(\frac{\mu}{\rho}\right)_t^{wall}},$$

$$\therefore T_a^{wall} = \left( \frac{T_{empty}}{T_o} \right)^{\frac{1}{2}} = \sqrt{T_{wall}} \quad (L.1.1.6)$$

Lastly, from Equation (L.1.3)

$$A_{corr} = \frac{A_{meas}}{T_a} = A_{meas} \times \frac{1}{\sqrt{T_{wall}}} \Rightarrow F_{wall} = \frac{1}{\sqrt{T_{wall}}} \quad (L.1.1.7)$$

Derivation of Matrix Material Attenuation Factor,  $F_{mm}$ . The transmission source attenuation (assuming a homogeneous matrix material) is

$$T_i^{tm} = e^{-\left(\frac{\mu}{\rho}\right)_i^{mm} \rho_{mm} x_{mm}} \quad (L.1.2.1)$$

where

$T_i^{tm}$  = transmission source attenuation in matrix material,  
 $\left(\frac{\mu}{\rho}\right)_i^{mm}$  = mass attenuation coefficient of matrix material at transmission source energy,  
 $\rho_{mm}$  = matrix material density,  
 $x_{mm}$  = thickness through matrix material.

Then the assay source attenuation in the matrix material,  $T_a^{mm}$ , is given by

$$T_a^{mm} = e^{-\left(\frac{\mu}{\rho}\right)_a^{mm} \rho_{mm} x_{mm} \beta} = \frac{e^{-\left(\frac{\mu}{\rho}\right)_i^{mm} \rho_{mm} x_{mm} \beta}}{\left(\frac{\mu}{\rho}\right)_i^{mm}} \left\{ \begin{matrix} \left(\frac{\mu}{\rho}\right)_a^{mm} \\ \left(\frac{\mu}{\rho}\right)_i^{mm} \end{matrix} \right\} = (T_i^{tm})^{k^{mm}\beta} \quad (L.1.2.2)$$

where

$\left(\frac{\mu}{\rho}\right)_a^{mm}$  = mass attenuation coefficient of matrix material at assay source energy,  
 $\beta$  = geometric correction factor<sup>9</sup> (.823 for cylinders),  
 $k^{mm}$  = ratio of mass attenuation coefficients in the matrix material at assay and transmission source energies.

But from Equation (L.1.1)

$$T_i = \frac{T_{att}}{T_o} = e^{-\left(\frac{\mu}{\rho}\right)_i^{wall} \rho_{wall} x_{wall}^2} e^{-\left(\frac{\mu}{\rho}\right)_i^{mm} \rho_{mm} x_{mm}} \Rightarrow T_i^{mm} = \frac{T_{non-empty}}{T_o T_i^{wall}} \quad (L.1.2.3)$$

where  $T_{non-empty}$  is the measured transmission intensity through a full or non-empty drum.

Thus from Equation (L.1.2.2)

$$T_a^{mm} = \left( \frac{T_{non-empty}}{T_o T_i^{wall}} \right)^{k^{mm}\beta} \quad (L.1.2.4)$$

And finally, from Equation (L.1.3)

$$A_{mm} = \frac{A_{meas}}{T_a} \Rightarrow A_{meas} \times \frac{1}{T_a^{mm}} \Rightarrow F_{mm} = \frac{1}{T_a^{mm}} \quad (L.1.2.5)$$

13. ABSTRACT (Maximum 200 words) This paper describes the conversion of a DEC PDP-11/05 computer system, previously used in Canberra's Model 2220B segmented gamma scanner, with an IBM PC. Two tasks necessary for completion of the project involved reestablishing communications with a Canberra Series 35+ multi-channel analyzer and a scan table controller. An additional serial/parallel card was installed in the PC to reinstate communications with the multi-channel analyzer. For computer control of scan table operations a digital input/output card was used along with an external electromechanical relay board; when implemented together this hardware setup replaces functions that were normally processed through a motion control interface card housed within the DEC. Software consisted of Canberra's PC Toolkit while newer programs were written in Microsoft's QuickBASIC 4.5 and Macro Assembler 5.1. Five codes were written--two of these are device drivers written in assembly language and the other three are menu and control programs written in QuickBASIC. The modification enables simplified programmer enhancements.
