13. ABSTRACT (Maximum 200 words)

This report documents the development and demonstration test of an automated identification system for parachutes. This system features a bar code tag which replaces the paper logbook used to record parachute data. Pack, repair and issue data are collected on portable readers and transferred to a computer for storage and report generation.

The automated system was developed to prevent loss of data, eliminate duplication of effort, and provide a database to facilitate inventory forecasting and the determination of improved service life criteria.

PREFACE

The purpose of this effort was to demonstrate the feasibility of a prototype automated identification system for parachutes. The objectives in developing this automated system were to: reduce labor; prevent loss of data; eliminate duplicated efforts; and provide the database necessary to develop improved parachute service life criteria.

The author wishes to thank the following:

Jonathan Given, Plans and Systems Analysis Division (PSAD), Aero-Mechanical Engineering Directorate (AMED), for his assistance in testing the prototype automated identification system for parachutes.

SSG Wayne Lovely, CW2 Rafael Alvarez, and the riggers of the 10th Special Forces Group (A) at Fort Devens, Massachusetts, for participating in the test.

CW3 Bruce Riggins, Parachute Engineering Branch, AMED, for sharing his technical expertise during the development of the system.

Gretchen Lawniczak, PSAD, AMED, for her secretarial support.

PROTOTYPE AUTOMATED IDENTIFICATION SYSTEM FOR PARACHUTES

INTRODUCTION

Background

In 1988, the U.S. Army Natick Research, Development and Engineering Center (Natick) identified a need to develop methods to enhance the capabilities of Army parachute packing facilities. Natick tasked the Manufacturing and Engineering Applications Center at Worcester Polytechnic Institute (WPI), Worcester, MA to make recommendations for improvements. They investigated automated identification technologies in various areas including: 1) radio frequency; 2) magnetic stripe; 3) bar codes; 4) optical character recognition; 5) vision; and 6) voice recognition.

WPI focussed its efforts on bar coding, the most widely applied technology of those considered, due to its low cost, proven technical feasibility, ease of use, and standardization. The other technologies researched suffered from insufficient memory, lack of maturity, lack of standard software, and high cost. WPI recommended a bar code system including labels, printers, hardware and software.

Professor Stephen Kwan of Boston's Northeastern University continued the investigation and found that WPI's recommended system had become outmoded. Dr. Kwan studied the manual parachute data recording system used at Fort Bragg, North Carolina, where there are several distant facilities dealing with over 36,000 parachutes. He proposed a local area network (LAN) bar code system to automatically track and manage parachutes. Further investigation revealed that parachute facilities at other military installations handle approximately 1000 parachutes in one building and would not require a LAN. We therefore developed a simplified version of Dr. Kwan's system to test the feasibility and benefits of the concept.

Objective

Our objective was to develop a prototype system (hardware and software) to automatically collect and store parachute data. We hoped the system would:

1. reduce labor;
2. prevent loss of data;
3. eliminate duplicated efforts; and
4. provide the data necessary to formulate improved service life criteria.

CURRENT MANUAL SYSTEM

The current methods of collecting and storing parachute pack and repair data are totally manual. The data is recorded in DA Form 3912, a 3-inch-square log book containing 20 pages (see Appendix A). The parachute serial number, type, part number, date of manufacture, canopy contract number, date placed in service, station and unit are recorded on the inside cover. The log book is folded in thirds and stored in a riser pocket.

The T-10 and MC1 family of troop-type personnel parachutes have a maximum age life of 16.5 years and a maximum service life of 12 years. A chute's age life is the amount of time that has passed since it was manufactured. The service life is the amount of time that has elapsed since the day it was removed from its carton and "placed in service." If a parachute is manufactured 6.5 years before it is placed in service, its service life will be reduced to 10 years because of the age life limitation. Numbers of times used and conditions of use are not considered in determining a parachute's service life limit.

Before packing a personnel parachute, the packer must check the manufacture date and the date placed in service to verify that the chute has not exceeded its age or service life. Once a chute is packed it can remain on the shelf for up to 120 days before it has to be repacked. Therefore, if less than 120 days of service life remain when the dates are checked, the parachute will be retired. When the parachute is packed, the packer must record the pack date, deployment bag (d-bag) number, and his signature in the log book. An in-process inspection is then performed, and the in-process inspector (IP) also must sign the log book, as seen in Figure 1.

JUMP, INSPECTION AND REPACK DATA

DATE			BAG NUMBER	ROUT INSP	R E P K	PACKER NAME	INSPECTOR NAME	U N I T
DAY	MO	YR						
1	7	91	D136353			<i>Wester</i>	<i>James</i>	10 th

FIGURE 1. RECORD OF PACK DATA IN LOG BOOK

A final inspector also inspects the chute and transfers the information recorded in the log book to the daily pack report (see Appendix B). When a chute requires repair, it is sent unpacked to the maintenance area where the type of repair, repairer, inspector and repair date must be written in the log book. The same information is duplicated on DA Form 2404, Equipment Inspection and Maintenance Worksheet (see Appendix C).

The log book sometimes gets separated from its parachute. When this happens, a new log book is started. The pack and repair history of the parachute is lost. Entries in the log book are often difficult to read due to indecipherable hand writing or exposure to water or sand.

When parachutes are issued for a mission, a Malfunction Officer/NCO Checklist is completed to record the following: mission date; drop zone name, location, and elevation; aircraft type, serial number, altitude, and speed; departure airfield; unit being airlifted; surface winds; visibility; type operation; and type parachutes used. Total quantities of parachutes issued are denoted on DD Form 1150, Request for Issue or Turn-in. Individual serial numbers are not listed on the form.

The current manual system of parachute data collection makes it impossible to determine the conditions of use for each parachute in a unit's inventory. It is quite likely that the log book will be lost during a parachute's 12 year service life, making it impossible to keep a record of all packs and repairs. In addition, there is no way to forecast inventory needs because no master list of pertinent parachute information is kept.

PROTOTYPE AUTOMATED SYSTEM

An automated system to collect and store the parachute data could prevent loss of data, eliminate duplication of effort, and provide a database to facilitate inventory forecasting and the determination of improved service life criteria.

Our prototype automated identification system for parachutes replaces the paper log book with a laminated bar code tag. Pack, repair and issue data are collected on portable readers and transferred to a computer for storage and report generation. A complete list of items purchased for the prototype system can be found in Appendix D.

Bar Coding

A bar code is a group of parallel bars (usually black) of varying widths separated by light spaces (usually white) of varying widths. Each bar and space stores a piece of information. A scanning device reads the bar code by moving a beam across the symbol and uses software to interpret its meaning.

An advantage of bar codes is that they were developed to be used by people with little or no technical knowledge. Other basic benefits include speed, accuracy and reliability.

Over 100 different bar code symbologies or "languages" have been created. But standardization in the bar code industry has reduced the number of symbologies that are used on a regular basis. The automotive, grocery, and health industries have chosen standard symbologies. The Department of Defense chartered the Logistics Applications of Automated Marking and Reading Systems (LOGMARS), which selected Code 39 as its standard symbology. Code 39 requires five bars and four spaces (three are wide and six are narrow) to represent a single character.

Code 39 has the following advantages:

DISCRETE - This means that it has gaps between characters, unlike continuous symbologies where the information is treated as one unit and must be printed as one unit, limiting the types of printers that can be used.

SELF-CHECKING - The ability to guard against undetected errors. A "read" is registered only if the entire code is scanned and if it has not been damaged by some physical means. Some codes need to add a check character, which increases the length of the bar code.

ALPHANUMERIC

FULL ASCII CAPABILITY

EASY TO PRINT

HIGH IMMUNITY TO SUBSTITUTION ERROR - Substitution error rate is the ratio of the number of incorrect characters to the total number of entered characters.

VARIABLE LENGTH - Code 39 can encode as many characters as needed for the application. Fixed-length codes use a set number of characters in any bar code label created using that code. If the fixed length is eight characters, all bar coded items must have an eight character identification number. If they are currently twelve characters long, four characters must be taken off. If they are currently five characters long, three must be added.

The bar code tags created for the parachutes display the information found on the inside cover of the log book in human readable form. The bar code encodes a P to identify personnel chutes or a C to identify cargo chutes, followed by the parachute serial number and the two-digit month and two-digit year that the parachute should be taken out of service (for personnel chutes only). That information is displayed in human readable form in the interpretive line printed below the bar code. The bar code labels are then laminated and cut to size using a custom die cutter (see Figure 2 below).

FIGURE 2. PARACHUTE BAR CODE LABEL DESIGN

Printer

The parachute data is added to the database on the computer and is then transferred to the INTERMEC 3000A thermal direct bar code printer for creation of the label. A thermal transfer adapter was installed on the printer because labels produced with thermal direct printers cannot be read by all readers and require the use of special heat sensitive paper which would not withstand the lamination process. Installation of the adapter alleviates these problems, resulting in labels resistant to darkening or fading from heat or light. Another advantage is the outstanding quality which makes it possible to print bar codes of high density, allowing more characters to fit on the label. The 3000A printer is compact (6.8" H x 9.3" W x 12.3" D, weighing 10 pounds), compatible with a variety of operating systems, and includes LabelWorks bar code label design software.

Trakkers

The portable bar code reader selected for the prototype automated identification system for parachutes is the INTERMEC Trakker 9440. A bar code reader consists of a scanner and a decoder. The scanner produces the signal representing the bars and spaces of the bar code. The decoder converts the signal so that a computer will understand it. The trakker is compact, weighs only 16 ounces, and includes INTERMEC's Interactive Reader Language (IRL) software for the development of application programs. The trakker has 64K random access memory and self-contained battery packs which eliminate the need for bulky expansion units. A lithium battery pack provides backup for the application program and data collected, should the battery pack become discharged. The four line liquid crystal display provides the space to indicate prompts for the user.

The trakker supports a variety of input devices and its RS-232 interface allows for communication to computers. The input device purchased for the prototype system is the INTERMEC 1260 visible light wand capable of scanning high density bar codes. The wand is a contact bar code reading device which requires the user to actually touch the label with the tip of the wand while scanning. Hand-held wands (also called light pens) are the most commonly used bar code readers due to their low cost and variety of models. They are reliable and economic for scanning labels on a hard, flat surface such as that of our prototype parachute tag.

Trakker programs

The trakker is autodiscriminate, meaning that it is able to read up to eleven different symbologies and automatically decode the label being scanned. But because we are using only Code 39, the trakkers were configured to read just that one symbology. Programs to collect pack, repair and issue data were developed using the IRL software.

Issue program

The issue program collects the following data: mission number and parachute identification. The program was created to collect data to track the numbers and conditions of use for each individual parachute.

The issue program has four options: 1) record parachutes issued; 2) record parachutes returned undeployed; 3) transmit data; and 4) end.

Option 1 is used to scan each parachute before it is issued for a mission. The mission number must be input first. [The mission number is assigned when the data from the Malfunction Officer/NCO Checklist is first added to database on the computer using the "add mission" option.] Each parachute bar code label is then scanned. The program verifies that each bar code label is a valid parachute identification and that the parachute has not yet reached its out of service date.

Option 2 is used to record any parachutes that are returned undeployed so that the issue record can be deleted from the database.

Option 3 is used to transmit the data from the trakker to the parachute database on the computer. This is accomplished using the trakker's RS-232 interface and selecting the "upload issue data" option on the computer. The computer sends a signal to the trakker to indicate it is ready to receive the data, and waits for the trakker to return the signal before transferring the data. When a file is transmitted to the computer, it is only copied. The data remains in the trakker file until a command is issued to erase it. Therefore, when the transfer is complete, the program asks the user if the data should be deleted from the trakker. This prevents any loss of data should a problem occur during the transfer.

Pack program

The pack program collects the following data: packer, in-process inspector, final inspector, parachute identification, d-bag number, and date.

The pack program has four options: 1) record in-process inspection data; 2) record final inspection data; 3) transmit data; and 4) end.

The in-process inspector (IP) is responsible for collecting the in-process inspection data with option 1. The IP first scans his own identification bar code. The program verifies that the bar code label scanned is a valid IP identification. The IP then begins recording the data by scanning the parachute bar code. The program verifies that the bar code label scanned identifies a parachute and that the parachute has not yet reached its out of service date. The program also checks that the in-process inspection data has not yet been recorded for that parachute. The d-bag number is then entered using the keypad on the tracker. An error message results if the d-bag number entered has already been recorded for another parachute. The packer identification is then scanned and verified, completing the data collection for one parachute. The IP can continue collecting data for other parachutes without scanning his own identification bar code again.

The final inspector (FI) is responsible for recording the final inspection data with option 2. The FI first scans his own identification bar code. The program verifies that the bar code label scanned is a valid FI identification. He then scans the parachute bar codes and the program searches the file to match the final inspection data with the in-process inspection data. An error will result if an attempt is made to record the final inspection data before the in-process inspection data has been entered. The current date is appended to all transactions.

Option 3 is used to transmit the pack data to the computer in the same method discussed for the issue program.

Repair program

The repair program collects the following data: repairer, inspector, parachute identification, types of repair, and date.

The repair program has 3 options: 1) record repair and inspection data; 2) transmit data; and 3) end.

The repair inspector is responsible for recording the repair data using option 1. The inspector first scans his own identification bar code. The program verifies that the bar code scanned is a valid inspector identification. He then scans the identification of the person who made the parachute repairs, followed by the parachute bar code label. The program verifies that the bar code scanned identifies a parachute. An 8.5" by 11" laminated card, with a bar code representing each type of repair, was created for use in conjunction with the repair

program (see Appendix E). The inspector scans the appropriate repair bar code on the card. If necessary, the program will prompt the inspector to enter the gore, section, or line number by scanning the appropriate bar codes at the bottom of the laminated card. The inspector can continue recording repairs for one parachute until the F4 function key is pressed to scan a different parachute bar code.

Option 3 is used to transmit the repair data to the computer in the same method discussed for the issue program.

R:BASE Programs

The database and customized menu driven, user-friendly programs for the prototype automated identification system for parachutes were created using R:BASE relational database management software. A description of the database structure can be found in Appendix F. Figure 3 shows the prototype system menu tree.

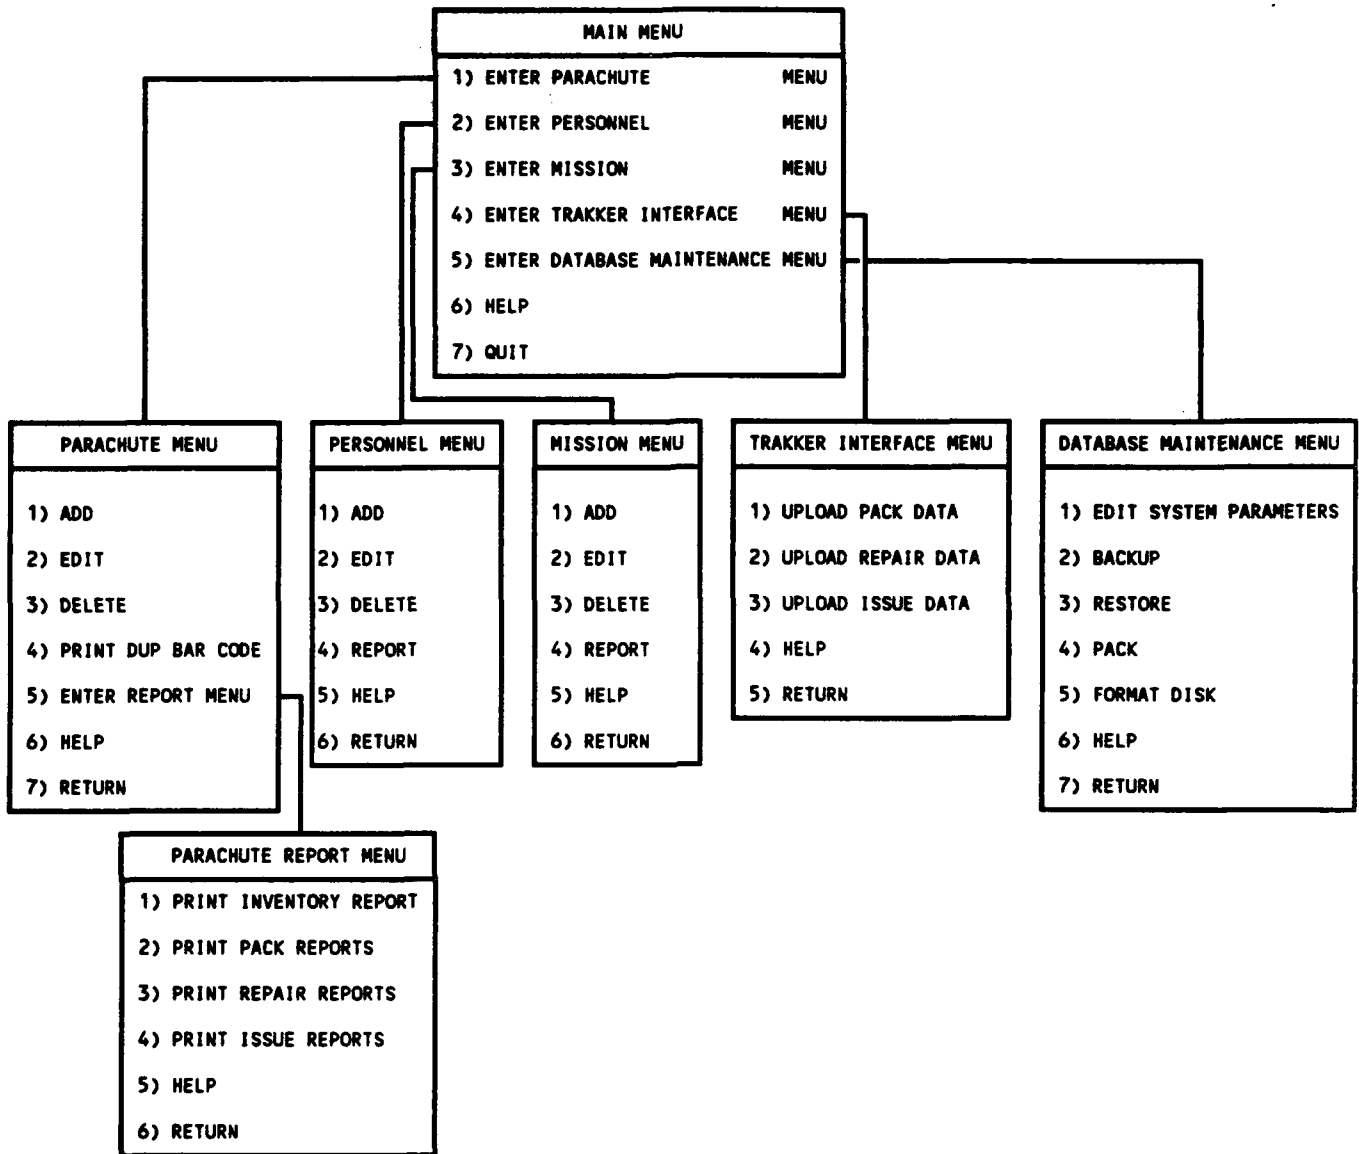

FIGURE 3. PROTOTYPE SYSTEM MENU TREE

The Parachute Menu is used to add the parachute data to the database for storage and creation of the bar code label. From the parachute menu, the user can enter the Parachute Report Menu which generates reports based on the data collected and transferred to the computer using the Trakker Interface Menu. Samples of parachute inventory, pack, repair and issue reports can be found in Appendix G. Mission data is entered using the Mission Menu. Sample mission reports also can be found in Appendix G.

PROTOTYPE SYSTEM DEMONSTRATION TEST

Once the prototype automated identification system for parachutes was developed, it was tested under actual conditions at Fort Devens, Massachusetts. Personnel from the 10th Special Forces Group (SFG) (A) participated in the test. The facility at Fort Devens includes a packing area with five packing tables and one final inspection table, a maintenance area, a storage area, and a shakeout tower.

On average, 120 parachutes are issued for a mission at Fort Devens. We therefore decided to bar code 150 parachutes so that all parachutes issued for a mission would be bar coded. The parachute serial number, type, date of manufacture, manufacturer, canopy contract number, and date placed in service were added to the parachute database. Laminated bar code tags for each of the 150 parachutes were created at Natick and delivered to Fort Devens in March 1991 where they were attached to the parachutes using black waxed string, called "super-tack", for storage in the riser pockets (same storage location used for the log books). Collection of parachute data using the manual system continued during the test. We intended to compare the automated system to the manual system by timing and observing the steps in each process and reviewing the paperwork generated.

Training of the 10th SFG (A) only required an explanation of our objective in developing the prototype automated identification system, a brief description of bar codes, and instructions on the use of the portable trakkers and wands.

Due to Operation Desert Storm and Operation Provide Comfort, the aircraft available for training missions at Fort Devens was severely limited. Personnel shortages also were a problem during this time. Under normal circumstances, 7 to 10 missions take place each month. During our test period, 1 April to 31 July 1991, only 7 missions took place. Because some of the parachutes that were not bar coded had to be issued at various times so that they would not exceed their 120 day packed shelf life, an average of only 39 bar coded parachutes were issued for each mission.

Test Results

The riggers had no problems using the trakkers to collect the parachute issue, pack, and repair data.

We recorded the time taken to collect issue data with the trakker. The average time required to scan each parachute was 7.34 seconds. Removing the parachute bar code tag from the riser pocket and replacing it after scanning accounts for the majority of the 7.34 seconds. Transferring the data to the computer took an average of .87 seconds per chute, and printing the issue report took an average of 1.25 seconds per chute.

During the pack process, we timed the following tasks required to manually record the pack data: verification of out of service date, entry of pack date, d-bag number and packer name, entry of IP signature, and completion of daily pack report. We also timed the following tasks required for the prototype automated system: scanning pack data (scan parachute bar code tag, enter d-bag number on keypad, scan packer identification badge), stamping pack date on back of parachute bar code tag, scanning parachutes at final inspection, uploading the data to the computer, and printing the parachute daily pack report. (The pack date had to be stamped on the back of the bar code tag because it is necessary to be able to determine the pack date at a glance. Chutes are arranged in the warehouse according to their pack date so that they can be issued before exceeding the 120 day limit.)

Table 1 shows the daily average times required for each of the tasks listed above, as well as average total time requirements for the manual and automated systems. Use of the prototype automated system saves approximately 11 seconds per parachute, which represents a 26% reduction. This time savings may have been slightly greater if turnover of those personnel operating the trakkers had not been so high. Additional time savings will most likely be realized by bar coding the d-bags, which was not done for the test phase but would be necessary for full implementation of an automated system.

More important benefits of the prototype automated identification system for parachutes include increased accuracy, elimination of duplicated efforts and the prevention of loss of data. Any data collected can be reported at any time in various formats. The automated system will also allow us to track the numbers and conditions of use for each parachute, which may provide criteria other than age for determining the service life of a parachute. It may also provide valuable information that can be put to use in the research and development of parachutes.

N = NUMBER OF OBSERVATIONS

We did not have the opportunity to collect much repair data using the trakker, since few of the bar coded parachutes required repair during the test period. The inspector just has to scan the appropriate repair bar code on the laminated card to record the repair. Certain types of repair also require entry of the gore number, section number or line number by scanning the numbers at the bottom of the card.

Questionnaire Results

Test participants were asked to fill out a questionnaire to provide feedback on the prototype automated identification system for parachutes.

The questionnaire solicited opinions on the ease or difficulty of handling the bar code tags and using the trakkers. The average rating on handling the bar code tags (inserting and removing from riser pocket, positioning and scanning at in-process and final inspections, etc.) falls between "neither easy nor difficult" to "moderately easy". The average rating on using the trakker and following the trakker program prompts falls between "somewhat easy" to "moderately easy".

The riggers were asked if they thought the prototype automated system was better than the paper log book system. In general, they agree that the automated system is an improvement over the current system. They feel that the automated system saves time and is easier to manage than the manual system. One commented that the automated system gives the in-process inspector the chance to take some of the workload off the packer, which is helpful on busy days. They also feel that the automated system will keep better records on the parachutes and prevent loss of data.

The riggers also were asked to list any features of the automated system they especially liked or disliked. In general, they think that the system is very easy to use. One commented that the system is great for issues and is helpful in identifying parachutes that should be taken out of service (expired service life). One in-process inspector noted that he dislikes having to share the trakker with the final inspector. (This is necessary in order to match the final inspection data with the in-process inspection data.)

Those personnel who deal with reporting parachute data on a regular basis were asked to review various reports and indicate their preferences. The reports differed in the format, but not in content. The reports included in Appendix G are shown in the preferred formats.

Other Test Observations

1. Stitching had to be ripped so the bar code tags could fit into some of the riser pockets. As the bar code tags are cut to the same exact size with a custom die cutter, this can only mean that there is some irregularity in the size of the riser pockets.

2. Under the manual system, the FI must flip through the pages of the log book to find the d-bag number for the latest pack entry. The d-bag number is then recorded on the daily parachute pack report. He next turns to the inside cover of the log book to find the serial number so that it, too, can be recorded on the daily pack report. Flipping through the log book seems to be a nuisance, especially since it is folded in thirds.

3. None of the bar code tags were lost during the test period. The "super tack" used to tie the tags to the riser is stronger than the string used to tie the log books.

4. During the packing process, the trakker must be shared by the in-process inspector and the final inspector so the program can match the in-process and final inspection transactions for each parachute. The inspectors decided that instead of passing the trakker back and forth for each parachute, the IP would use the trakker to record all of the in-process inspections and the FI would wait until the end of the day to record the final inspections.

5. Because various personnel were deployed at times, different inspectors operated the trakkers on different days. Therefore, inspectors who had never used the trakkers took a little longer at first to collect the data than those who had used the trakkers before. But after only four or five transactions, they overcame the learning curve.

CONCLUSIONS AND RECOMMENDATIONS

The prototype automated identification system for parachutes should be further developed and implemented. The test of the system demonstrated its feasibility and potential to reduce labor, eliminate duplicated effort and prevent loss of data. The data collected can be used to develop criteria other than age that can be helpful in determining the service life of a parachute. The data can also be useful in forecasting inventory needs.

INTERMEC equipment was judged the best suitable for the application at the time of our analysis and it performed well during the test. But the prototype automated identification system is not hardware dependent. If other hardware is considered for the fully-developed system, an economic analysis should be conducted before a final selection is made.

The prototype system is currently capable of collecting, storing, and reporting pack, issue and repair data and creating parachute bar code tags as described in the previous pages. The following paragraphs present issues that should be addressed, and recommended additions for an enhanced automated identification system for parachutes.

Ideally, the parachute manufacturers could create bar code labels for the chutes. The labels could be placed where the riser pocket is currently sewn on. They could either be laminated and stitched on, or they could slide into a pocket with a plastic front from which they could be scanned without being removed. If the tags do not have to be removed from the riser pockets more time can be saved during both the issue and pack processes. Another method of recording the pack date will have to be considered if the date stamp can no longer be used.

If the manufacturers do not create the bar code labels, they could be created at each parachute facility as they were for the test. We used a custom die cutter to cut the parachute bar code tags to size. This step could be eliminated by finding a vendor who would provide a laminate of the desired size.

If the bar code tags are created on site, keyboard data entry could be eliminated by using a wedge reader with a wand to scan laminated cards (similar to that created for types of repair) with bar codes identifying parachute manufacturers, type parachutes, dates and numbers. A wedge reader physically attaches to the side of the computer and converts a bar code signal into a keyboard signal which the computer is already able to read. Use of the wedge reader would reduce the time required to input the data and would also reduce errors made during keyboard entry.

Bar coding the reserve parachutes, deployment bags and cargo parachutes also needs to be addressed. Again, bar codes created by the manufacturers would be ideal, but they must be accessible after the chutes have been packed.

The issue of bar code tags for personnel identification requires further investigation. For the prototype test period, bar code tags which encoded the social security number and MOS were created for each person. Names were printed in human readable font below the bar codes. The packer badges were usually clipped to the end of the pack table where they could easily be scanned by the in-process inspector. Some of the packers expressed concern that a chute could be sabotaged and the wrong badge placed at the end of the table to be scanned. Other types of personnel identification badges will have to be considered. It may be necessary for the packers to wear their badges to ensure they are properly identified.

The parachutes should continue to be scanned at issue in order to collect the data necessary for developing additional criteria for determining parachute service life. This data could then be used to automatically generate DD Form 1150, Request for Issue or Turn-in. This form is currently filled out manually to record the total quantity of parachutes, reserve chutes and kit bags for a mission.

At most parachute facilities, the parachutes will be issued from the same building where they are packed, repaired and stored. At Fort Bragg, the parachutes are transferred from the pack facility to the marshalling area for issue. The tracker issue program may have to be modified to take this into account.

In addition to the data collected for personnel chutes, the data collected for cargo chutes should include the type of load and the number of additional parachutes used with that load.

When a parachute requires repair, a DD Form 1577-2, Unserviceable (Repairable) Tag-Materiel (Green) is filled out and attached to the chute before it is sent to repair. Instead of filling out this tag manually, the computer could be programmed to generate it. The user could enter the parachute serial number and scan the types of repairs required, and the computer could print the tag. The information could be stored to keep track of the pending repairs. Once the repairs are made, a repair status indicator could be changed from pending to completed.

There are other reports currently generated by hand by compiling pack and issue data collected over a period of a month or longer. The pack progress sheet tracks the number of parachutes packed by each person. It shows quantities brought forward as well as weekly, monthly and year-to-date totals of chutes packed. Another report tracks the number of missions and number of parachutes used for each mission. These reports could easily be computer generated by compiling the information collected on the trackers.

There should also be a method of transferring the parachute data if a parachute is permanently transferred from one unit to another.

A method of archiving pack, issue and repair data must be developed for parachutes that have been taken out of service (either because they have reached their out of service date or because they have been damaged beyond economic repair). This should be done once the data is no longer required for various reports. The archived data can be used for determining additional service life criteria and for research and development purposes. Archiving data over a year old is also suggested. Columns can be added to the tables in the database to indicate total numbers of packs, issues, and repairs that have been archived.

Most importantly, personnel designated as potential users of the system should be involved in discussions of additional options or enhancements. As different versions of the software are developed, they should be demonstrated to the users who can provide comments and suggestions for improvement. The completed system must be designed to satisfy the user's needs.

APPENDIX F
Parachute Database

APPENDIX F

PARACHUTE DATABASE

Below is a list of some of the tables and fields included in the database for the prototype Automated Parachute Identification System. Other tables (not listed here) store system parameters, rules, reports and forms in the database.

The **PARACHUT** table stores all the pertinent parachute data.

FIELD NAME - DEFINITION

SERIALNO - parachute serial number
BARCODE - PCR from PARATAB table + serial number + OUTDATE
PARACODE - from PARATAB table to identify type of chute
MFGDATE - date parachute was manufactured
MFGCODE - from MFGTAB table to identify manufacturer
CONTRACT - number of manufacturer's contract
SVCDATE - date parachute was placed in service
OUTDATE - date parachute to be taken out of service (if personnel chute), calculated based on manufacture and service dates

The **PARATAB** table stores the parachute types and part numbers.

FIELD NAME - DEFINITION

PARACODE - one character parachute code
PARATYPE - type of parachute such as MC1-1B, T10-C, G-11A
PCR - P for personnel chute, C for cargo chute
PARTNO - part number

The **MFGTAB** table stores the parachute manufacturer data.

FIELD NAME - DEFINITION

MFGCODE - one character manufacturer code
MFG - manufacturer name

The **PACKHIST** table stores the parachute pack data.

FIELD NAME - DEFINITION

BARCODE - parachute identification from PARACHUT table
DBAG - deployment bag number
PACKER - packer identification, SSNMOS from PERSONNE table
IP - in-process inspector identification, SSNMOS from PERSONNE table
FI - final inspector identification, SSNMOS from PERSONNE table
TRANDATE - pack date

APPENDIX F (cont'd)

The **REPHIST** table stores the parachute repair data.

FIELD NAME - DEFINITION

BARCODE - parachute identification from PARACHUT table
REPCODE - repair code from REPTAB table to indicate type of repair
G/SLINE - gore, section or line number if necessary
REPAIRER - repairer identification, SSNMOS from PERSONNE table
INSPECTR - inspector identification, SSNMOS from PERSONNE table
REPCDATE - repair date

The **REPTAB** table stores the parachute repair type data.

FIELD NAME - DEFINITION

REPCODE - one character repair code
REPDESC - repair description

The **MISSINFO** table stores the mission data.

FIELD NAME - DEFINITION

MISSNUM - mission number
MISSDATE - mission date
DZNAME - drop zone name
DZLOCATE - drop zone location
DZELFEET - drop zone elevation
DZENVRMT - drop zone environment, such as salt water, fresh water, sand, gravel, grass
DEPARFLD - departure airfield
UNITLIFT - unit being airlifted
TYPEAC - type of aircraft
ACSERNO - aircraft serial number
ACALTFT - aircraft altitude
ACSPDKNT - aircraft speed
SURWKNKT - surface winds
VISMI - visibility
TYPEOP - type of operation
STATUS - mission status, such as planned, completed

The **ISSHIST** table stores the parachute issue data.

FIELD NAME - DEFINITION

BARCODE - parachute identification from PARACHUT table
MISSNUM - mission number from MISSINFO table

The **PERSONNE** table stores the personnel data.

FIELD NAME - DEFINITION

SSN - social security number
IDCARDNO - military identification card number
LNAME - last name
FNAME - first name
RANK - rank
MOS - military occupational specialty
UNIT - unit
SSNMOS - SSN+MOS for personnel bar code identification

APPENDIX G
Sample Reports

**APPENDIX G
SAMPLE REPORTS**

- G-1 Parachute Inventory Report sorted by Serial Number
- G-2 Parachute Inventory Report sorted by Type of Parachute
- G-3 Parachute Inventory Report sorted by Out of Service Date
- G-4 Parachute Pack Report for One Date
- G-5 Parachute Pack Report for Range of Dates
- G-6 Parachute Pack Report for One Parachute
- G-7 Parachute Repair Report for One Date
- G-8 Parachute Repair Report for Range of Dates
- G-9 Parachute Repair Report for One Parachute
- G-10 Parachute Issue Report for One Mission
- G-11 Parachute Issue Report for One Parachute
- G-12 Mission Report sorted by Mission Date
- G-13 Mission Report sorted by Drop Zone Location
