#### ABSTRACT

Land mines are a continuing threat to the mobility required by the modern army. Efforts to develop solutions for the problems presented by mines are hampered by a lack of useful, realistic, high resolution models.

To assist in developing the needed modeling capabilities, several methodologies are proposed. Methodologies for modeling vehicle navigation error, mine encounters, plow displacement of mines, bypassing obstructions and the presence of overwatching direct fires are developed and explained. These methodologies are then implemented using SIMSCRIPT and SIMGRAPHICS into a minefield breaching model. The model can be run in a graphics mode, allowing a visual validation of the model algorithms.

The problem of plow width versus breaching force casualty rates is examined as an example of the potential utility of the model.

#### ACKNOWLEDGEMENT

I wish to thank Dr. John Farr of the Waterways Experimentation Station for his assistance in researching the history of the Engineer Model Improvement Program. Readers interested in obtaining a copy of the software code should contact Dr. Farr. His address is available in the initial distribution list. I also wish to thank Professor Sam Parry and LTC William Caldwell for their assistance in developing this thesis and for their guidance in its construction. Finally, I wish to thank my wife Susan for her support and understanding over the months of programming and writing that went into the model and this paper.

Alan A. Anderson

#### I. INTRODUCTION

Currently, the Army's countermine capability is inadequate. Efforts to address this shortfall have been ongoing since the early 1980s and have resulted in some successes. Assessment of Operation Desert Storm requirements indicate that the mobility enhancement capability of the Army's detection and breaching assets needs improvement. [Ref. 1: p 72]

Mobility and maneuver are essential elements of the U.S. Army's Airland Battle Doctrine. Anything which restricts or limits our ability to maneuver is a potential hazard to the implementation of this doctrine. Land mines are such a hazard.

Events in the Middle East have recently highlighted deficiencies in our capability to effectively and rapidly respond to the problem presented by mines. In part this problem is due to the fact that the state of the military art in regards to countermine warfare has progressed very little since World War II. During this same period, advances in electronics and integrated circuits have enormously increased the capabilities and lethality of modern mines. Modern land mines are a largely unquantified impediment to the maneuverability required for successful implementation of the Airland Battle doctrine.

The deficiencies in the capabilities of the U.S. Army to conduct countermine warfare operations have long been recognized. Numerous ideas and programs have been suggested to alleviate the problem. Unfortunately, there is a corresponding lack of capability to effectively model mine and countermine scenarios and the proposed equipment. Since actual field experience is limited, and testing is both expensive and dangerous, modeling is a cost effective way to gain insights into the dual problems of dealing with, and of using, land mines. A brief background of the program currently being under taken to remedy the modeling deficiencies is presented as a motivator for this thesis.

In 1979, the Review of Army Analysis [Ref. 2] found numerous deficiencies in the Army's computerized combat models. These deficiencies included poor documentation, poor response to study needs, inconsistent results, differing data assumptions, lack of interface structure, and limited (or no) functional area representation. As a result, a directive was published in April 1980, implementing an Army Model Improvement Program (AMIP). The tasks and responsibilities of AMIP are described in Army Regulation 5-11.

The Engineer Model Improvement Program (EMIP) is a part of the AMIP designed to ensure that the engineer functional area is properly represented in the Army's hierarchy of approved combat simulation models. The EMIP plan was published by the Engineer Studies Center [Ref. 3]. Major elements of the EMIP plan provide for changes to the Combined Arms and Support Task Force Evaluation Model (CASTFOREM), Vector-In-Command Model (VIC), the Force Evaluation Model (FORCEM), and for the development of an Engineer Functional Area Model (EFAM). Priority was placed on enhancements to VIC and the development of a VIC-based EFAM. This work was conducted by the US Army Corps of Engineer Laboratories and was completed in FY91.

Another goal of EMIP was to develop high resolution engineering specific simulation models. Deficiencies exist in analytical tools that can be used to perform studies of breaching operations of both linear (e.g., opposed river crossing operations) and area obstacles (e.g., obstacle complexes which might include tank ditches, concertina, minefields, etc.). The CASTFOREM can be used for these types of studies, however, scenarios can require several man years worth of development time. The JANUS(A) interactive simulation model can be used for quick turn around studies. However, since JANUS(A) is an interactive simulation model, parametric studies are difficult if not impossible to perform.

Since the breaching of minefields is currently the highest priority within the engineering community, a major requirement exists for an analytical tool to conduct future material studies on such systems as the Combat Mobility Vehicle (CMV) and the Wide Area Mine (WAM), in support of the combat engineers. In addition, a tool is needed to address force structure (number of plows and rollers needed in a typical armor company) and tactical problems (location of breaching assets during various tactical formations) that presently need additional analysis.

The lack of high resolution tools to investigate minefield interactions is the stimulus for this thesis, which is intended to provide a baseline tool for use in investigating the dynamics of minefield breaching. Several basic methodologies for high resolution discrete modeling of minefield and vehicle interactions are proposed and then implemented in a SIMSCRIPT program. The resulting model is currently limited in scope, dealing solely with the more conventional mines and with plowing as the only breaching technique. However, the routines, functions and structure of the model provided facilitate the modeling of additional attributes of the minefield problem.

Interested readers are also directed to the thesis written by Captain Malcolm Garland [Ref. 4]. The model written for that thesis uses some of the maneuver methodologies developed here to investigate the utility of using artillery fires to reduce mine density prior to the conduct of a minefield breach.

#### **II. PROBLEM DISCUSSION**

#### A. MINES

The military forces have been dealing with effective land mines since World War I. Since that time, human ingenuity and the motivation provided by numerous wars have resulted in continuously improved effectiveness for the military land mine. With the advances in the state of the art brought on by modern technology, land mines have become a very real threat to the success and even the survival of an attacking force.

Mines are unique among obstacles. Not only do mines fill the traditional role of an obstacle by delaying an attacking force, but land mines also have the capability to inflict other costs upon that attacker. Among them,

- lost time
- damage to equipment
- casualties
- lost ability to maneuver
- lost momentum
- logistical burden
- loss of morale.

Most of these costs are measurable to some extent, so a quantitative evaluation of the costs for a given minefield scenario can be made without the requirement to link these costs to a tactical result. Alternative ideas may be compared in terms of cost without consideration of what criteria are to be used for defining acceptable or unacceptable. A computer model can be used to develop an estimate of the costs involved.

Mines pose a psychological as well as physical obstacle. A soldier that is worried about setting off a land mine will not be as aggressive as the soldier who is confident that a reliable path exists through the minefield. Morale is likely to suffer if no reliable means of dealing with the threat produced by land mines exists.

Avoiding a minefield may be worse than going through it. One use of mines is to deny a force the ability to maneuver in the mined area. In this way, minefields are used to channelize the attackers into prepared killing zones, allowing a small force, protected by minefields, to deflect an attacker into an engagement area designed to destroy it. The best course of action may be to breach minefields rather than to predictably attempt to go around them.

There are several broad categories of military mines used on the modern battlefield. These categories include, but are not limited to, chemical, antipersonnel, and antivehicular mines. Antitank mines are a subset of the antivehicular mine family. Such mines are designed to immobilize or destroy armored vehicles and their crews.

#### 1. Mine Designs.

Antitank mines perform their function by either attacking the vehicles ability to move, resulting in what is called a mobility kill, or by the complete destruction of the vehicle, which is known as a catastrophic kill. A mobility kill is achieved by destroying one or more of the vehicles' vital drive components, usually breaking the track, thereby causing the vehicle to be immobilized. With a mobility kill, the weapon system may still continue to function. A catastrophic kill will result in the entire vehicle and/or crew being destroyed.

Current production antitank mines may weigh up to 25 pounds, be contained in either plastic or metallic cases, and come in a variety of colors. Some mines are designed to be mechanically emplaced, while others are intended to be emplaced by hand. Antitank mines may be buried beneath the surface by either manual or mechanical means, or they may be surface scattered. Many countries have developed or are developing the ability to remotely deliver surface mines. Different types of mines are often mixed together.

Mines may be used in a variety of circumstances. Nuisance minefields are placed in order to hinder and disrupt an enemy. Hasty protective minefields are laid out to provide quick protection for a defending force. Deliberate minefields are obstacles integrated into the defensive plan and are usually of high density and emplaced in specific patterns.

#### 2. Distinguishing Characteristics.

Conventional antitank mines can be distinguished by the type of engagement mechanism used and the method of fuzing that initiates the engagement. Engagement mechanisms include blast, self forging penetrators, and shaped charges. Methods of fuzing are numerous, but include single or multiple pressure pulses, command firing, magnetic influence, seismic vibrations, and motion detecting. Many mines also allow for the provision of antihandling devices to prevent removal. Blast mines attack their target through blast caused by the detonation of a quantity of high explosive. These mines usually produce a mobility kill but a catastrophic kill is possible.

Self-forging mines engage their victims with an explosively shaped metal penetrator designed to defeat the thinner underside of a vehicles' armor and spray shrapnel and plasma throughout the inside of the vehicle, with the designed intent of igniting fuel, detonating ammunition, and killing the crew. The usual result of a successful engagement of this type is a catastrophic kill.

Horizontal-effect mines use a shaped charge to penetrate the thinner sides or top of armored vehicles, possibly resulting in a catastrophic kill. Depending on the type of sensors and fuzing used these mines may be emplaced a considerable distance from the expected engagement areas. These types of mines are frequently placed on the sides of roads and other vehicular avenues of approach, or they may be used to overwatch conventional minefields to prevent the use of breaching equipment.

Antitank mines are further distinguishable by their fuzing. There are three broad categories of antitank mine fuzes; track-width fuzes, full-width fuzes, and widearea fuzes.

Track-width fuzes are usually pressure-actuated and require the wheels or tracks of the vehicle to pass directly over the mine. This type of fuze will normally produce a mobility kill since it will detonate directly under the tracks or wheels.

Full-width fuzes, such as tilt-rod, magnetic-influence or seismic fuzes, are designed to be effective across the entire width of the target. This type of fuze is usually employed in conjunction with a self forging or shaped charge warhead to produce a catastrophic kill when the mine is straddled by an approaching vehicle. When a full-width fuze is activated under the wheels or tracks of a target vehicle, a mobility kill usually results because most of the energy is absorbed by the vehicle suspension.

Wide-area fuzes are used to enable mines to attack vehicles which do not pass directly over the mines location. The fuze may be as simple as a trip wire activating a horizontal-effect off road mine, or as complex as seismic activated, infrared searching, homing munitions. Such fuzes are normally placed on mines designed to produce a catastrophic kill.

#### **B. BREACHERS**

The only currently available solution to the problem presented by any buried or surface laid mine, regardless of its fuzing, is to detect and identify it as a mine and then:

- destroy it in place with explosives
- mechanically extract it or push it aside
- pull it out with a long rope or wire from a protected position.

For armor operations, the fastest and safest mine removal technique is to either detonate it from a distance, or mechanically extract or push aside any mine which happens to be in the path of the vehicle so that if the mine were to detonate it would do so with minimum danger to personnel and little or no damage to the vehicle. A number of techniques and devices for accomplishing this action have been devised over the years. The most common and proven of these follow.

<u>Full Width Plow.</u> Full width plows are blade and tine assemblies designed to remove mines for the full width of the blade and spill the mines, as well as a significant amount of soil to either side of the breach lane. They are usually a permanent part of a specially designed engineering vehicle. Such vehicles are specifically designed with the horsepower required to push the blade through a variety of soil types.

Current plows may make single pass lanes up to five meters wide, and depending on soil type up to 40 centimeters deep. The tines are typically designed to remove mines 20 centimeters in size or larger. Plows may be particularly effective at removing surface laid mines, since the depth of cut need be only a few centimeters.

Full width plow vehicles tend to be slow. Their designs are optimized to provide the tractive forces necessary to move large amounts of soil. Being slow, they are particularly easy targets for the enemy forces typically overwatching minefields. Being breachers, they are given a high engagement priority by the defenders.

The designers of mines are also not without recourse when confronted with plows. Although the plow itself is usually quite sturdy, some of the mechanisms used to control the depth of cut are more vulnerable. Mines equipped with an antihandling device will go off when disturbed by the blade. The resulting blast, depending on the size and type of mine, may be sufficient to damage the blade or the more delicate control mechanisms, thereby rendering the blade less effective and more vulnerable to the remaining mines in its path. Area effect mines are not dependent on the close proximity of the target for activation, and these types of mines, when added to the minefield, would be particularly useful in destroying the breachers.

<u>Tank Mounted, Track-Width Plow.</u> Track width plows consist of plow assemblies which mount directly onto tanks. A major advantage of using track width plows is that they may be made organic to the unit, and therefore be constantly available for use. These devices plow the area immediately in front of the vehicle tracks, uprooting and/or displacing mines to the outside of the vehicle's path. The plows are capable of removing land mines or booby traps which are surface laid or buried up to 15 centimeters below the surface.

A weighted chain assembly, sometimes called a "dog bone" is strung between the two plows, in order to activate (harmlessly in front of the tank) any tilt rod type mines encountered.

Track width plows have several limitations. The "dog bone" only clears tilt rod type mines from beneath the vehicles. Influence type mines which happen to lay between the track plows would not be removed by either the plows or the "dog bone". Tanks, while capable of using the plows, are not designed for this type of activity, so there are consequences with regard to the depth of plowing possible and the maximum speed at which the vehicle can plow. Damaged plows may cause the vehicle to be at least temporarily disabled until the damaged equipment can be jettisoned.

As mentioned before, a counter to the use of plows is the attachment of antihandling devices onto the mines. Plows are vulnerable to mine explosions, and one or two may destroy the plow's effectiveness.

Flail. A flail is a rotating cylinder, mounted in front of the vehicle, with chains, sometimes tipped with weights, attached to the cylinder. As the cylinder rotates, the

chains or weights pound the ground in front of the vehicle. This action is intended to detonate or physically destroy any mines in the path of the flail. Exploding mines, unless very powerful, will at most destroy a single chain and weight. This type of equipment tends to be quite complicated mechanically and is generally not organic to maneuver elements.

<u>Tank Mounted Roller.</u> Rollers are heavy cylinders which are either rolled in front of the breaching vehicle, or towed behind it. A roller clears mines by detonating them with direct pressure. The roller is made of a material tough enough to absorb several detonations.

One counter to this breaching technique is a delay fuze timed to detonate a short period of time after activation, hopefully (from the mines owner's viewpoint) under the breaching vehicle. Another counter-counter measure would be a multiple pressure pulse fuze, which must be activated several times before it detonates its explosive charge, thereby allowing several vehicles to pass before detonating and blocking the lane. Rollers are usually used to 'proof' minefield lanes.

Line Charge. Line charges are used to detonate mines in the projected path of the breaching force. A rocket is used to tow a explosive filled hose across the minefield. The explosive in the hose is then detonated. The overpressure created by the explosion detonates pressure fuzed mines that are in the vicinity. Pressure mines equipped with a fuze which requires a long pressure pulse will not be affected. Influence mines are also not likely to be affected unless they are so close to the charge as to be physically destroyed by the blast.

<u>Fuel Air Explosive.</u> Fuel Air Explosives (FAE) use a similar technique as the line charge. An explosive vapor is created and then ignited. The resulting explosion is very intense and intended to clear pressure fuzed mines in the area of the blast by creating a pressure pulse.

#### C. DOCTRINE

#### **1. Countermine Operations**

The taskforce commander, when in combat, can expect to be confronted by a variety of obstacles. These obstacles must be overcome to maintain the initiative and the momentum of the attack. The taskforce commander must quickly decide whether to bypass, breach, or force through the obstacle.

The obstacle should be scouted to determine if it is part of an occupied defensive position, and if so, the enemy strength and locations.

"Forcing through" is a term used to describe the tactic of ignoring a minefield and attempting to simply drive across it, using only the equipment on hand and with a minimum of preparation. Vehicles may travel in single file in an effort to reduce risk, however, casualties are an expected result of this technique. Forcing through a minefield obstacle is used only as a last resort. Forcing minefields can cause substantial losses of personnel and equipment. The urgency of the taskforce mission will be the deciding factor.

When an obstacle is encountered, it must be rapidly reconnoitered to determine if bypass routes exist and if such routes are covered by enemy fires. When possible, current doctrine calls for enemy minefields to be bypassed rather than breached since bypassing maintains the momentum and conserves critical countermine assets. However, any decision to bypass must consider the possibility of the friendly units being channelized into kill zones.

If the decision to breach is made, then the type of breaching operation to be conducted must be decided. If time is important, then the unit may attempt a hasty breach. If time is less critical, or if the likelihood of a successful hasty breach is very poor, then the taskforce may conduct a deliberate breach of the obstacle.

The hasty breach is a tactical assault breach used when the momentum of the attack must be kept up. If engineer assets are currently attached or reasonably available, they may be used. Any organic breaching equipment will be prepared and utilized. The breach will usually be conducted while under enemy fire and because of mission critical time constraints, speed of execution is important. When the time available to begin the conduct of the breach of a minefield is not critical, a deliberate breach may be conducted using engineers and specialized breaching equipment.

Maneuver forces assigned the mission of breaching the obstacle will normally be organized into specific elements as part of the assault breaching plan. These elements are known as the breaching force, the assault force and the support force.

The breaching force has the mission of actually creating the lanes through an enemy obstacle system for the assault force to pass through. These forces are normally composed of engineers, scouts, and armor. If available and time permits, specialized breaching equipment is obtained and utilized. After the breach is completed, the breaching force is normally reorganized to assist the assault force.

The assault force has the mission to attack through the breach, penetrate the defense, and destroy the enemy. An assault force is normally built around a combined

arms tank unit. The assault force will attempt to stay within the boundaries of the lane created by the breaching force.

The support force includes all units providing close, continuous, overwatching fires to support first the breaching force and then the assault force. The support force normally consists of tanks; wire-guided missile systems; organic indirect fire elements; field artillery in close support; and chemical company (smoke) elements if available. The support force may be required to widen initial lanes created by the breaching force, or support another unit in that task with suppressive fires.

The assault force and then the support force provide suppressive fires as the obstacle is reconnoitered and the breaching force prepares to breach. If the decision is made to breach the obstacle, flank security must be provided.

The actions taken by the various elements in the conduct of a breaching operation follow:

- <u>Support Force</u>. The support force occupies overwatch positions in order to protect those elements moving through the obstacle. The support force will provide direct and indirect suppressive fires on the enemy. The support force will use smoke (pots, mortars, artillery, grenades) as appropriate to degrade enemy observation of the obstacle.
- <u>Breaching Force</u>. As an obstacle is encountered, the breaching force immediately occupies covered and concealed fighting positions; hastily coordinates specific tasks; and prepares equipment, demolitions, and routes to the obstacle. Once enemy fires are suppressed, the breaching force rapidly breaches the obstacle. The force then secures fighting positions near the far side of the obstacle as quickly as possible.
- <u>Assault Force</u>. As the breaching force is breaching the obstacle, the assault force prepares to attack through the obstacle. Once the breaching force secures initial positions on the far side, the assault force attacks through the obstacle and destroys enemy elements that may be able to place direct fires on the obstacle. Then it either continues the advance as the lead element for the attacking unit, or occupies hasty defensive positions as the support force passes through and takes the lead in the attack.

When a unit is attacking across open terrain, the minimum distance between lanes should be 250 to 300 meters. This keeps the enemy from blocking more than one lane with a single artillery concentration. The distance between lanes may be greater than 300 meters, depending on the commander's ability to maintain control of his force.

#### 2. Mine Operations

Planning for the effective use of minefields as obstacles requires the consideration of numerous factors. Foremost must be the commander's plan of operations. For most mines to be effective as an obstacle considerable planning must go into the logistics of transporting the mines to the desired location and then installing them. Some mine types are quite bulky and require extensive logistical support as well as individual installation. Others are small and can be rapidly emplaced with mechanical devices, or be delivered from missiles, aircraft or artillery.

For the purposes of this paper, the only minefield parameter used will be the density of the minefield. Minefield density is used as a means of expressing the relationship between the number of mines emplaced and the size of the minefield. It provides an indication of the "effectiveness" or "difficulty" of the minefield as an obstacle. There are two ways of expressing minefield density: linear density and area density.

The linear density of a minefield is the average number of mines by type per meter of minefield front, regardless of the depth of the minefield.

Area density is a measure usually associated with scatterable mines. The measurement specifies the number of mines per square meter of minefield area.

#### D. DISCUSSION

This model currently only represents the use of plows to displace mines from the vehicle path. The only mines currently modeled are pressure, influence, and an antihandling fuzed mine which will be called a "contact mine". The model is designed for the easy addition of other mine types and breaching techniques.

One of the problems relating to the breaching of minefields involves tradeoff analysis between the survival of the breacher and the effectiveness of the lane the breaching vehicle creates.

The survivability of the breacher is a function of the time required to complete the breach lane and the effectiveness of the breaching technique. The time aspect of this function is dependent upon the type and amount of enemy overwatching fire assigned to the minefield. Assuming at least a token amount of overwatching fires, then the more time it takes for the breacher to make the lane, the longer it is exposed to the overwatching fires and the greater the likelihood of the breacher being disabled by those fires. Another consideration is that the longer it takes to complete the breach, the longer the defender has to react by moving in reinforcements and calling for supporting fires.

If the breacher is not effective at removing or disabling the mines in its path, the breacher may be destroyed by the minefield itself.

The usability of the resulting lane by trailing vehicles is also a function of the effectiveness of the breacher in eliminating the threat posed by the mines as well as the navigation accuracy of the vehicles. Trailing vehicle speed is also a factor, again depending upon the type and amount of overwatching fires present.

The issue comes down to the time required by the breacher to accomplish the breach versus the width of the breach lane. The time to accomplish the breach is an important factor because it directly impacts on the survivability of the breaching vehicle. Of course other factors also impact on the breaching vehicle's life expectancy. These include the amount and type of overwatching fires, vehicle armor placement and thickness, minefield characteristics, mine clearing effectiveness, etc. Intuitively, since the more dirt we are pushing, the slower we push it, we would want to plow a lane as narrow and as shallow as feasible.

The flip side of the problem is that the breach lane must be wide enough for trailing vehicles to "safely" negotiate the path. Realize that a single mine encounter may result in the lane being blocked. We cannot simply choose a width to accommodate the widest vehicle (probably a tank) but we must also allow for the fact that combat vehicles are not known for their precision handling, just as most military drivers are not known for their precision driving. A certain amount of "navigation error" is to be expected, and the lane must be wide enough to allow for this error.

Speed through a minefield, as it impacts on survivability, is important only when the minefield is covered by direct or indirect fire. When a minefield is covered by fire, the longer a vehicle is in the field, the greater the chance of immobilization. The movement speed through the minefield is initially a problem relating to how long it takes the breacher to make a lane. Non-breacher vehicles would stay out of the minefield until a lane has been made, or all breachers have been disabled. Upon completion of the lane, other vehicles would attempt to pass through. If they are immobilized, then the lane may be blocked.

#### **III. METHODOLOGY**

This thesis presents several methodologies, along with their corresponding SIMSCRIPT coded algorithms, which are designed to provide a basic framework for future minefield modeling efforts. The algorithms are intended to serve as a foundation for more ambitious efforts directed toward high resolution modeling of mobility and countermobility scenarios. The model currently has only one category (plows) of breaching equipment represented. The methodologies presented are designed to model basic minefield related activities to include:

- navigation by an assaulting force
- discrete mine-vehicle encounters
- mine displacement by plows
- overwatching fires by the defenders.

The methodologies and algorithms presented are flexible enough to apply to many different scenarios with only minor modifications. The model itself is designed for easy expansion and modification to include the addition of other types of breaching equipment, vehicles, mines, and obstacles.

The approach taken in presenting these methodologies is to first discuss the real life mechanics of the situation and the significance of the attributes which are to be modeled, and then to give a description of how the attribute is to be captured in the program code. Chapter IV will go into more detail as to how the program actual implements the algorithms and in Chapter V an example of how they can be used will be presented.

#### A. VEHICLE NAVIGATION

As a vehicle moves over an area, it casts a shadow or a "footprint" on the ground. In this paper, the actual area which passes under the tracks or wheels of a vehicle will be called the "pressure footprint" and that area which passes under any portion of the vehicle will be labeled the "influence footprint". Note that the pressure footprint is a subset of the influence footprint.

The individual footprints for multiple vehicles moving over a piece of terrain will vary as a result of several factors. If the taskforce consists of a variety of vehicle types, the physical dimensions of the different type vehicles will result in different footprints. The size of these footprints can be determined by examination of the vehicle specifications. Another less predictable cause of variation is what this paper will call "navigation error".

It is essentially impossible for any two vehicles to have precisely the same footprints, even if they have the same physical dimensions. This is because of inaccuracies inherent in the steering mechanisms of the vehicles and because of the human element introduced by the drivers of each vehicle. The human element may be particularly apparent at night. The resulting differences in footprints due to the mechanical and human inaccuracies is the "navigation error".

The situation may arise where a vehicle is unsuccessful in passing through a minefield even though it is attempting to follow the same path as a successful vehicle. Although there are multiple reasons why this might happen, one possible explanation is the difference in the respective vehicle footprints. Specifically, the trailing vehicle did not have exactly the same footprint in its traversal of the lane. Even small deviations from the lane may be hazardous. Figure 3-1 shows the resulting mine densities after a lane has been made by a full width plow and by a track width plow. Note that the only area that might be considered safe is that portion of the lane that makes up the pressure footprint of the breaching vehicle. The areas to either side of the lane are now more dangerous than they were originally, since they hold not only their original complement of mines, but also those mines displaced by the plows. It

is possible that the displaced mines will have a decreased lethality, however the worst case assumption is that any displaced mine is still capable of functioning as designed. At any rate, at least some of the displaced mines would still be viable, so the actual mine density of the lane shoulders has increased. Note also that the lane itself may still contain mines which were either buried deeper than the plow was set to dig, or slipped through the tines on the plow, or rolled back into the lane from the side spill.

This model makes provision for "navigation error" in the traversal of the minefield by multiple vehicles. The amount of navigation error used is a function of certain values input by the user. The methodology used is as follows.

The intent is for each taskforce vehicle to have a unique movement plan consisting of a user specified number of navigation checkpoints. Each vehicle will move from checkpoint to checkpoint, in a straight line between the adjacent checkpoints, following it's own unique (in the x dimension) movement plan. Each movement plan will have the same number of navigation checkpoints. Vehicles are assumed to have the desire to follow in the footprint of the lead vehicle, therefore, all deviation is measured from the actual centerline of the path made by the lead vehicle.

The y axis is arbitrarily designated as the center of the breach lane through the minefield. Since the first vehicle is not attempting to follow a lane, but is in fact making the lane, it is assumed to have no navigation error. It's movement plan consists of a series of navigation checkpoints located on the y axis.

The total distance, from start point to finish point, to be traveled by the taskforce is divided into a user specified number of equal intervals. The y-coordinates of the endpoints of these intervals become the y-coordinates of the movement plan

checkpoints for all taskforce vehicles. That is, the y-coordinates of respective checkpoints will be the same for all members of the taskforce.

For each checkpoint an x-coordinate is determined through use of a normally distributed random draw. Figure 3-2 depicts this procedure.

Figure 3-2 Determining the X-coordinate

The mean of the distribution is assumed to be zero, meaning that a vehicle is assumed to be as likely to deviate to the left as to the right. Should the user wish to modify this assumption, it is an easy matter to change the distribution parameters or even the distribution itself. The standard deviation used is a user input. The default value used for standard deviation is one meter. A normal distribution is used, because it is assumed (and would certainly be the desire of the vehicle crews) that the vehicles will tend to follow the center of the lane. Small deviations are not only likely, they are unavoidable. Large unintentional deviations are unlikely. Deviations are equally likely to occur on either side of the breach lane and there is no reason to believe that the magnitude of the deviations will differ as a result of on which side they occur, so the resulting distribution should be symmetric.

<u>a serie and the state series of the series </u>

The process of generating x-coordinates is continued until each vehicle in the taskforce has a series of checkpoints, unique in the x-dimension. An example of a resulting movement plan for one vehicle can be seen in Figure 3-3.

Figure 3-3 Vehicle Movement Path Example

Once the x and y coordinates of all of the navigation checkpoints for a vehicle have been determined, the equations for the lines which connect adjacent checkpoints are determined. This is done by first determining the slope, m, using the equation;

$$m = \frac{y_2 - y_1}{x_2 - x_1} , \ x_2 \neq x_1.$$

The y-intercept, b, is then determined by using one of the checkpoints at either end of the line, the previously determined slope, and the equation,

Each vehicle now has a unique movement plan governing its movement which also allows for navigation error. The vehicle will be moved along the line that connects its checkpoints at the rate indicated by the vehicle's speed. A pointer to the currently used line equation indicates to the program routines the appropriate slope and intercept values to be used for calculating the vehicle's location at any given time. When a checkpoint is reached, the pointer is moved to indicate the next line equation to be used. This process continues until the vehicle completes its movement or is immobilized. Note also that the actual use of straight line segments to describe the movement of tracked vehicles closely approximates the reality. Of course, in reality, tracked vehicle do not move in straight line segments of uniform length.
## **B. MINE ENCOUNTERS**

As described above, each vehicle has a unique movement plan for traversing the minefield, described by checkpoints and the equations for the lines which connect those checkpoints.

Each mine in the minefield has a type, a radius and an x and a y coordinate, which describes the unique location of that mine in the minefield. Type is used to identify the fuzing method used. Currently the model plays either pressure, influence, or contact (antihandling) mines.

Pressure fuzes require the tracks of the vehicle to actually pass directly over a portion of the mine before the mine will detonate. Influence fuzes only require that a portion of the vehicle pass over the mine, making them effective for the entire area of the vehicle as it moves over the field. Contact fuzes are similar to pressure fuzes in that they require some actual form of contact, either directly with a portion of the vehicle or by earth compressed by the weight of the vehicle, in order to function. They are distinguished however, by the amount of pressure required. Contact mines require only to be disturbed in order to activate. They are intended to destroy breaching equipment, detonating when a plow (or anything or anybody) attempts to move them. While this characteristic makes them a threat to most breaching techniques, such mines are generally quite vulnerable to breaching techniques that rely on explosively generating shock waves and overpressure to clear pressure mines from the minefield.

Encounters are calculated by first screening the entire list of mines to determine which ones are within a reasonable distance from the vehicle. By doing this we eliminate unnecessary calculations and speed up the simulation. Then, for each candidate mine, the equation of the line that passes through the center of the mine and is perpendicular to the vehicle path equation is calculated. First, the slope of the perpendicular line is determined through use of the theorem that two lines are perpendicular if and only if,

$$m_1 + m_2 = -1$$

where  $m_1$  is the slope of the vehicle path and  $m_2$  is the slope required for a line perpendicular to the vehicle path.

The equation for the perpendicular line is found using the point slope formula,

$$y_1 - y_2 = m_2(x_1 - x_2)$$
.

The intersection of the perpendicular line and the vehicle path is then determined by solving the two line equations simultaneously. This point is where the vehicle has a potential contact with the mine. Figure 3-4 illustrates the geometry of this procedure.

To determine if contact actually takes place, the distance between the center of the mine and the intersection point is calculated. Adjustments are made to account for mine radius and the fuzing mechanism used by the mine in question to determine if a contact will actually take place. If a contact will take place then the distance between the current location of the vehicle and the intersection point is calculated.

If an actual contact is possible, the mine identification and distance from the vehicle are recorded and compared with the current closest mine. If this mine is closer, its identification and distance become the current closest. The next candidate

Figure 3-4 Mine Encounters

mine is checked. This continues until all candidate mines are examined. The mine identification and the distance the vehicle must travel to the closest mine with which contact will occur are then returned to the calling routine.

# C. MINE DISPLACEMENT

Mine plows are not designed to actually destroy the mines that they encounter. The mine plow performs its function by displacing any mines encountered, as well as a substantial amount of dirt, to either side of the breach lane. To perform adequately, the plow must actually remove the mines from the lane and place them far enough to either side that they are no longer a threat to vehicles navigating within the lane. Plows should be particularly effective against surface laid mines since they do not have to move much soil, thereby allowing the plow to maintain a reasonable speed while working on the lane.

As Figure 3-1 previously illustrated, while the area of the actual breaching lane becomes safer, the areas to either side of the lane actually become more dangerous. There is also a small but finite possibility of displaced mines rolling back into the lane after being moved by the plow.

Each plow type modeled has several parameters attached to it. Of particular importance is the effectiveness of the plow which is an attempt to capture the degree of thoroughness with which the plow removes mines in its path. An effectiveness of one indicates that the plow will remove every mine in its path, assuming that the mine is buried no deeper than the depth at which the plow is operating. An effectiveness of less than one indicates that a percentage of mines encountered will be missed by the plow, possibly to be encountered by the pressure or influence footprints of the plow itself or the trailing vehicles.

The methodology used to capture the consequences of plowing a lane requires that non-contact mines encountered by a plow be moved to the side of the lane. A new x and y coordinate is calculated for the mine based upon the location of the edge of the plow and a probability distribution. Should the mine be of the contact type, then further calculations must be made to determine the result of the encounter. That is, what degradation of effectiveness was inflicted upon the plow.

The distribution currently used is normal with a mean of 1.5 meters to the left or right of the plow edge and a standard deviation of 1 meter. The determination of which side of the plow the mine is displaced to is simply a matter of on which side of the centerline of the plow the mine falls. Since most plows are shaped somewhat like an inverted "V", mines located to the left of the centerline naturally are displaced to the left and those on the right to the right. The choice of the normal distribution and the parameters chosen are purely arbitrary and may be easily changed should the user desire. It should be noted though, that the choice of mean and standard deviation allow for a small possibility of the mine coming to rest within the lane.

### D. OBSTRUCTION AVOIDANCE

When a vehicle becomes disabled during the course of a minefield breach, either by overwatching fires or contact with a mine, it becomes part of the overall obstacle breaching problem. If the vehicle is negotiating the "cleared" lane when it becomes disabled, then the vehicles following it must take one of the following three actions in order to continue using the cleared lane.

First, the disabled vehicle may be extracted from the minefield by attaching cables or a tow bar to it and pulling it either the rest of the way through the minefield or back out over its entry path. This will result in considerable delay and increased exposure by all concerned to overwatching fires.

The trailing vehicles may attempt to push the disabled vehicle, either through the remainder of the minefield, or to one side of the cleared lane. Pushing a disabled tank through a minefield has sometimes been considered as a field expedient method of breaching minefields. There are numerous potential problems with this technique. If a track has been lost, the disabled vehicle will not move in a straight line. If the damage is extreme, then the disabled vehicle may not be moveable at all without special equipment. If the disabled vehicle is on fire, there is a danger of explosion and damage to vehicles in the proximity. A burning vehicle may also serve as a beacon and aiming point to enemy elements overwatching the minefield. The "pushing" vehicle may damage its own track and suspension components in the effort. The pushing vehicle may stray from the path in the attempt and also encounter a mine. If there are still crew aboard the disabled vehicle, either unable or unwilling to exit, pushing the vehicle into uncleared areas subjects them to further risk.

A final option is to go around the obstruction formed by the disabled vehicle, leaving the cleared lane and entering uncleared portions of the minefield for the

Figure 3-5

distance necessary to bypass the obstruction. The bypassing element would then reenter the cleared lane on the far side of the obstacle. Figure 3-5 depicts this action. Note the greater risk of mine encounter resulting from passing through the edges of the cleared lane and the uncleared portions of the minefield. If the bypass is successful, a new 'cleared', but unmarked, lane results. If unsuccessful, that is, if the bypassing vehicle is itself disabled, either by the minefield or by overwatching fires, then the lane obstruction becomes larger.

Bypassing vehicles will want to leave the cleared path for the shortest distance necessary in order to bypass the obstruction. This shortest path should include as little as possible of the higher mine density shoulders of the cleared lane.

Bypassing an obstruction in the lane may be a high risk technique, particularly if the mines have been laid out in belts and the obstructing vehicle has been disabled by a mine. In this case there would be a high probability of additional mines being to either side of the disabled vehicle. This situation may hold true for the entire width of the minefield.

The methodology presented in this model addresses only the tactic of bypassing a disabled vehicle. If the options of recovering or of pushing the disabled vehicle are desired those routines will have to be developed as an improvement or addition to the model.

Whenever a taskforce vehicle is disabled by either mines or overwatching fires, an obstacle is created. This obstacle entity will have the same physical dimensions and location as the disabled vehicle. The disabled vehicle will have its status changed to "inactive" and will be ignored for the remainder of that particular model run. The location and size of the newly created obstacle will be added to the obstacle list. Every time an active vehicle is changed to an inactive status due to a mine encounter or overwatching fires, the event calendar for the simulation must be purged of all pending encounter events. When this step is complete a new next encounter event for each active element is redetermined to prevent the occurrence of "invisible obstacles". An invisible obstacle is one which is ignored by the active vehicles in the simulation. They are ignored because they were created after the trailing vehicles had already determined their next encounter, which should now be an obstacle encounter, but since at the time of determination the obstacle did not exist, it was not considered.

All obstructions, and the vehicles that are attempting to bypass them, are approximated as circles by computing the two dimensional surface area of the obstacle or vehicle and then determining what radius a circle would have to have to encompass that area. This is done to allow an efficient algorithm which uses simple geometric constructs. The costs of using such an approximation are a relatively small loss of accuracy in the x and y coordinates of the vehicle's sides and rear. The geometry used for determining mine encounters does not use the circle approximation, but rather uses the appropriate vehicle dimensions.

When an active vehicle is determining what its next encounter is to be, the first step is to determine its current checkpoint interval and corresponding movement equation. The obstacle map is then referenced and obstacles which lie at least in part within that interval are examined as potential obstacle encounters. The next step taken is to determine the path a vehicle would have to take in order to bypass the obstruction. Logically the path should be as short as possible in order to minimize the vehicles exposure to the uncleared portions of the minefield and return to the cleared path as soon as possible. Given the circle approximation, the shortest possible distance would be a semi-circle in the direction of the shortest path around the obstacle. Since tracked vehicles typically move in straight line segments rather than semi-circles and since the calculations required to interface the quadratic circle equation with the linear equations used by the rest of the program would be extensive and run time expensive, a straight line approximation is used. The resulting path around the obstacle is played as an equilateral hexagon.

Figure 3-6 illustrates the hexagon bypass route as overlaid on an circular obstruction. The numbers 1 through 6 denote the corners of the hexagon and the letters A through F identify the six sides. Note that all six sides of the hexagon are tangent to the circle at their midpoints. The center of the circle has the same location as that of the obstruction and the radius of the circle is equal to the radius of the obstruction plus the radius of the bypassing vehicle.

The coordinates for each of the six corners of the hexagon are calculated as follows. Following along with Figure 3-6, the symbol  $\Omega$  is used to denote the x coordinate of the center of the obstacle. The symbol  $\delta$  is used to denote the y coordinate. The character r denotes the radius of the bypass circle. The value of r is determined by adding the radius of the obstacle to the radius of the bypassing vehicle. O denotes the center of the circle.

Construct vertical lines at + r and - r units from the center. Observe that side B of the hexagon is a segment of the vertical line located r units in the positive x direction from  $\Omega$  and that side E of the hexagon is a segment of the vertical line located r units in the negative x direction. With the top of the diagram representing 0°, construct vectors from the center of the circle directed outward at 60°, 120°, 180°,

240° and 300°. Corner 2 is located at the intersection of the 60° vector (labeled R on Figure 3-6) and the vertical line at + r. If a horizontal line is constructed through the center of the obstacle (labeled  $\delta$  on Figure 3-6) it can be seen that the triangle resulting from the intersections of the  $\delta$  line, + r vertical line, and R is a 30-60-90 degree triangle. From this observation we now know that the length of side B is

$$B = 2*\frac{1}{\sqrt{3}}*r$$

and that the length of the distance from the center to the intersection of the  $60^{\circ}$  vector and the +r horizontal line is

$$\frac{2}{\sqrt{3}}$$
\*r

Symmetry and similar calculations are now used to determine the coordinates of all of the remaining corners. The edge of the resulting hexagon will be used as the centerline of the path a vehicle must take in order to bypass the obstruction in the lane. The equations for the lines connecting the corner points are generated in the same manner as the lines connecting the navigation checkpoints. A slight modification must be made for the two vertical sides, **B** and **E**, since the slope of a vertical line is undefined. An approximation is made by making the slope of any vertical line equal to an extremely large number.

Variation (navigation error) can be added to vehicle footprints during a bypass by adding a small distance, randomly generated, to the value calculated for the obstruction radius.

The point at which a vehicle will exit from its original movement plan path and enter the bypass path is the point where the current movement path line and the line describing either side F or side A of the hexagon intersect. Actually, the movement plan equation will intersect both lines since none of the three lines is parallel to either of the others. The actual intersection of interest is the one which occurs on the hexagon itself.

The point where the vehicle regains the original movement path is called the "reentry point". The y location of corner 4 of the hexagon will be compared to the y locations of the navigation checkpoints to determine the boundary condition. That is, the interval where point 4 lies is the farthest interval the vehicle may reenter into from this bypass. The vehicle may possibly reenter in an earlier interval. All valid movement plan equations, the set of which consists of the line equations describing any movement plan segments between and including the movement plan equation used when the bypass path was initiated and the movement plan equation used within the boundary interval, will have their intersections with the lines describing sides D and C of the hexagon calculated.

The y coordinates of the intersections will be checked against the y coordinates of the checkpoints to which they correspond. If the y coordinate is valid, (i.e., if it falls within the appropriate interval) then the x coordinate will be checked against the xcoordinates of the intersections. The first valid intersection point will be used by the vehicle as the reentry point.

As mentioned earlier, vehicles are exposed to greater risk of mine contact when bypassing, which would indicate a good possibility of disabled vehicles being in close proximity to one another. Additionally, if numerous vehicles are disabled the calculations for bypassing become very complex. To reduce the complexity, obstructions are combined when they occur within a user specified distance from one another. This simplification is justified by the observation that there is unlikely to be sufficient distance between the disabled vehicles to allow a bypassing vehicle to pass between two vehicles, one of which was disabled as a result of an attempted bypass.

The combination of obstacles is accomplished by computing the centroid of the combined obstruction using the equations

$$x=\frac{(x_1+x_2)}{2}$$

where x is the x coordinate of the combined obstruction and

$$y = \frac{(y_1 + y_2)}{2}$$

where y is the y coordinate of the combined obstruction. The radius of the combined obstruction,  $r_c$ , is

$$r_{c} = \max(D_{c1}+r_{1}, D_{c2}+r_{2})$$

where  $D_{el}$  is the distance from the center of the combined obstacle to the center of obstacle 1,  $D_{el}$  is the distance from the center of the combined obstacle to the center of obstacle 2,  $r_i$  is the radius of obstacle 1, and  $r_j$  is the radius of obstacle 2. Figure 3-7 illustrates the geometry of these calculations.

Figure 3-7 Obstruction Consolidation

As the simulation progresses, multiple obstruction combinations may take place. For this reason, it is necessary to keep track of how many obstructions have been combined into a particular combined obstruction. When the centroid of a new obstruction being added to a combined obstruction is being calculated the x and ycoordinates of the combined obstruction must be weighted by the number of obstructions which make up the combined obstruction. The equation for the xcomponent is

$$x = \frac{(N * x_c) + x_2}{N + 1}$$

and the y component is

$$y = \frac{(N*y_c) + y_2}{N+1}$$

where N is the number of single obstructions making up the combined obstruction.

# E. OVERWATCHING FIRES

Unless being used as a nuisance, or as harassment, minefields are doctrinally covered by fire. Actual military experience has indicated that a minefield covered by fire is more dangerous to the attacking force than the combined effect of the mines and fires, each inflicted in isolation of the other. In other words, there appears to be a synergism between the mines and the overwatching fires. The whole is greater than the sum of the parts.

As a possible explanation for this effect consider that if given unlimited time, mines can be dealt with in reasonable safety. The risks from the mines goes up with the decrease in the time available to deal with them. Overwatching fires serve to make the environment of the minefield increasingly lethal over time, regardless if the vehicles are moving or not. Therefore the combination of the increased lethality of the minefield as a function of reducing the time available to traverse it, and the increased lethality of overwatching fires as a function of increasing the time exposed as a target, results in greater casualties to the attacker.

The techniques for dealing with incoming fire generally involve movement. In the case of indirect fires, the goal of an attacking force is to move out of the area where the fires are impacting. In the case of direct fires, an attacker will want to take cover and return fire, or use maneuver to close with and destroy the enemy. In either case, the attacking force is greatly hampered if it is attempting to deal with incoming fires while at the same time negotiating a minefield.

#### 1. Direct Fires.

The model allows the user to enter the number of red overwatching direct fire elements as well their rate of fire, and a separate factor which combines detection, acquisition, and engagement times. This factor is actually the  $\beta$  (mean) parameter of an exponentially distributed random draw for representing a time period to be added to the minimum time required to prepare the system for firing (rate of fire). A direct fire event is then scheduled to occur after this duration.

Upon the actual occurrence of the direct fire event, the target of the shot is determined. An algorithm based upon the number of target systems actually in the minefield is used to determine the allocation of shots. The user selects the proportion of fires to be allocated to the first of **n** vehicles in the minefield. The remaining proportion is equally divided among all the other vehicles currently in the minefield using the relationship:

Table 3-1 illustrates a possible series of proportions for a fire allocation scheme. The user can allow disabled vehicles to be included in the total count of vehicles in the minefield if so desired.

# of vehicles (n) in minefield	1	2	3	4	5	6	7	8	9
% of fires directed against Vehicle 1	100	80	70	60	50	50	50	50	50

**TABLE 3-1 FIRE ALLOCATION SCHEME** 

After the target is determined, a table lookup for the probability of kill,  $p_k$ , given a shot for this particular weapon/target combination is performed, a random draw conducted, and the appropriate result carried out. If the vehicle is disabled it becomes an obstruction to trailing vehicles. If the vehicle survives the engagement it will continue to move. The firer identification, the intended victim, the time and location of the event, and the result can be recorded as output data.

When the direct fire event for the red overwatching vehicle has been completed, another is scheduled to occur at a time (time to prepare round to fire) + (exponential delay) in the future.

## 2. Indirect Fires.

This version of the model currently does not support indirect fires.

## **IV. MODEL DESCRIPTION**

The methodologies described in Chapter III have been coded into an event driven minefield simulation model. This chapter contains a discussion of the assumptions under which the model was developed, a description of the model inputs and outputs, and a synopsis of how the model works. The descriptions of the model workings are of necessity fairly high level, as the model is quite large and the minute details are not the topic of this thesis. Documented source code listings can be found in Appendix C.

### A. ASSUMPTIONS AND MODEL LIMITATIONS

This model is intended as an implementation of the minefield interaction methodologies previously discussed. The purpose of the model (and the methodologies) is to duplicate some of the outcomes of real world interaction between vehicles, breachers, overwatching fires, and mines. Several assumptions and simplifications have been made which have obvious implications with regard to transferring the model results to real world applications.

## 1. Uniform terrain

A major assumption is that the terrain to be traversed is uniform in elevation and in all applicable soil characteristics. A modeled plow, once its movement velocity and plowing depth have been determined, moves at a constant speed unless a status change is imposed as the result of an event. In the real world, terrain and soils are rarely this predictable, and in the event that they were, vehicle operators and plow control mechanisms are unlikely to maintain either constant speed or constant plow depth. The impact of this assumption is that the variability in both breaching time and plow effectiveness may appear smaller than what would be expected.

## 2. Constant vehicle speed

Vehicles in the model move at constant speed throughout the simulation run. As a result there is none of the "accordion" effect between the vehicles that is nearly impossible to avoid in real world situations. Active model vehicles never get closer to each other than the interval input by the user during the model initialization. The one exception to this statement occurs when plowing vehicles are set to operate at a speed dictated by plow width and depth. In that case, the model user must either adjust the interval parameter which describes the initial interval between the plow(s) and the follow-on vehicles, or adjust the velocity of the trailing force to insure collisions do not occur as the result of the trailing force running over the plow(s). The model currently does not prevent nor react to active vehicles coming into physical contact.

The assumption of constant vehicle velocity greatly simplifies the movement calculations and is probably of little impact if the actual real world vehicle interval is anticipated as being relatively large and care is taken in the selection of the interval between plows and trailing vehicles.

#### 3. Obscuration

Obscurants are not explicitly modeled. Since any real world opposed breaching operation is likely to be intensely supported with smoke operations, this is a large simplification. Some of the effects of obscuration, in particular, vehicle navigation and target acquisition, can be captured by careful selection of the parameters used in the navigation and overwatching fire algorithms.

## 4. Breacher Types

The only breaching technique currently modeled is plowing. Since numerous different breaching systems exist, some of which were mentioned in Chapter II, this is a fairly large simplification of reality. Since the model is only intended to lay the groundwork for a high resolution minefield maneuver model, this shortcoming may be corrected at a latter date.

#### 5. Mine Types

Only three types of mines are modeled, and all three types are of a fairly standard, unsophisticated nature. Many of the more interesting mines under development and in some cases currently in use, are very sophisticated and use state of the art technologies and exotic engagement and fuzing mechanisms. The maneuver methodologies in this program will still be applicable, but the code for capturing the fuzing and mine engagement mechanisms for these weapons will be left as a future enhancement.

#### 6. Obstruction Types

Mobility obstructions, and the vehicles that must negotiate around them, are assumed to be of circular geometry. The reality is that obstructions come in a variety of shapes and sizes, and that vehicles are almost never circular. However, tracked vehicles do tend to move in straight line segments, and the assumption of a circular geometry allows the relatively simple calculation of a series of straight line segments as a bypass path. What is lost is some precision in the actual location of a bypassing vehicle relative to the obstruction as a function of the actual physical dimensions of the vehicles and obstructions being modeled. This loss of precision is not transferred to the mine encounter calculations as those are strictly a function of the actual vehicle specifications, mine types and mine locations.

The implementation of the model uses the circular assumption to generate a hexagon surrounding the obstruction (see Figure 3-6). The radius of the circle used is the sum of the radius of the obstruction and the radius of the vehicle. A hexagon computed to be tangent to the circular obstruction at the midpoint of each of its six sides is then calculated as the centerline of the vehicle bypass path.

### **B. PARAMETERS**

#### 1. Model Input Parameters

The model allows a wide range of scenarios to be examined easily by allowing most of the model parameters to be changed directly from the input screens. The use of SIMGRAPHICS has made possible an interactive graphic interface for data input. The input interface consists of a series of menus displaying default input values that can be modified, if desired, by the user. A useful byproduct of using SIMGRAPHICS for the input interface is that the allowable ranges of the input values are programmed into the menus. This prevents the entering of input values outside the range for which the model is designed. A list of the modifiable parameters, and their effect, follows.

## a. Mine parameters

- <u>Minefield depth.</u> The dimension of the minefield is collected as minefield depth. The depth is important as it impacts directly upon the amount of time required to breach and pass through the minefield. The actual width of the minefield is of lesser importance, since this model operates under the implicit assumption that a breach of a minefield has been decided on as the course of action. For display purposes, the minefield width is calculated to extend for a width equal to the scaled width of the display screen.
- <u>Mine radius.</u> The model treats individual mines as bodies having dimensions (specifically, radius) rather than simplifying the calculations by using a point mass assumption. The user is given the opportunity of entering a specific radius for each type of mine modeled. Each mine is assumed to be a cylinder with a known radius, measured in meters. The model is then able to consider the scenario where the vehicle track encounters only part of the mine.
- <u>Mine depth.</u> The average depth of a mine, measured in meters from the surface down to the top of the mine is an input. In the case of an unburied mine, the depth is zero. The depth of the mine will determine if a plow working at a specific depth actually encounters the mine.
- <u>Reliability of the mine</u>. The probability of a mine detonation given that the mine has been encountered by a vehicle is the reliability of the mine. In reality, this parameter is a complex function of (at least) the fuze type, the amount of time the mine has been in the ground, soil type, and mine design. If a value is not known for this input, the conservative (and default) value is 1.0.

## b. Plow parameters

- <u>Plow depth.</u> This value is used to determine if the plow will encounter the mines present in the field (when compared to mine depth). The plow depth will also impact upon the speed with which the plow is able to move through the minefield.
- <u>Plow width.</u> Plow width determines how wide the lane made through the minefield is. The width of the lane will impact on the ability of trailing vehicles to stay in the lane. Like plow depth, this factor impacts upon the speed with which the plow will be able to move through the minefield.
- <u>Plow effectiveness</u>. This is the probability that the plow will remove or neutralize a mine which it physically encounters. Depending upon the size of the mine and the spacing between the plow tines, it is possible for mines that are encountered by the plow to filter through the tines instead of being displaced to the side of the lane. A mine that is not removed or neutralized remains in its original location and with its original reliability.

## c. Vehicle parameters

- <u>Track width.</u> The actual width of vehicle tracks. This parameter will usually have different values for different types of vehicles. The model will currently handle up to five different vehicle types. The track width is used to determine the pressure footprint of the vehicle.
- <u>Vehicle width.</u> This is the actual width of the vehicle. Again, this parameter will usually differ from vehicle type to vehicle type. This value is used to determine the influence footprint.
- <u>Vehicle length.</u> The actual length of the vehicle. This value is used as part of the calculations for computing the vehicle radius which is used in the circle approximation of the vehicle area.
- <u>Vehicle radius</u>. This is currently not a direct user input value. For the purposes of bypassing obstructions, the model approximates both obstructions and bypassing vehicles as a circle. Since the only types of obstructions currently implemented in the model are disabled vehicles, this value is also used to determine the size of the obstructions. The radius of vehicles and obstructions are used to determine the distance bypassing vehicles must travel in order to get around them. Currently, the radius of a vehicle is a calculated value, found by multiplying the vehicle length by the vehicle width, and then solving for the radius of a circle which has that same area.
- <u>Vehicle speed.</u> This is the value used to determine how fast a vehicle will move through the minefield. The model currently treats vehicle speed as a constant. The plow vehicle's speed is a function of the width of the plow and the depth of the cut it makes in the ground.
- <u>Vehicle navigation accuracy</u>. This parameter is an attempt to determine how closely a trailing vehicle follows in the footprints of previous vehicles, particularly the first (plow) vehicle. Ideally, a trailing vehicle would follow exactly in the footprints of the lead vehicle. However, as was explained in Chapter II, this is rarely the case. When a trailing vehicle deviates from the footprints of the leader, it leaves an area of near zero mine density and enters an area of reduced, full, or increased mine density. This decreases the probability of survival for each trailing vehicle and for the formation as a whole. This parameter is entered as the value of the standard deviation of the x coordinate at each checkpoint in the movement path.

# d. Overwatch parameters

• <u>Number of overwatchers.</u> The number of red direct fire overwatching systems for the scenario being run. When the model is being run in graphics mode these elements are depicted at the top of the screen, but this location does not

represent their tactical placement. It is only an arbitrary placement for display purposes.

- <u>Type of overwatchers.</u> The model currently plays only one type of overwatching system.
- <u>Rate of fire</u>. This parameter represents the actual rate of fire of the red system as a function of reload and system cycle times. It is input by the user and treated as a constant by the program.
- <u>Acquisition rate</u>. This parameter is actually intended as a combination of detection, acquisition and engagement times for the overwatching systems. The value entered is the mean,  $\beta$ , of a random sample from an exponential distribution.

### e. Taskforce parameters

- <u>Number of full width plows</u>. The number of full width plows which will be used to make the breach. The first plow or vehicle has no navigation error, as navigation error is defined as deviation from the pressure or influence footprints of the lead vehicle. Any subsequent plows and vehicles implement the navigation error methodology. Subsequent plows are offset approximately one third vehicle width to either side of the lead plow in order to widen the effective lane through the minefield.
- <u>Number of track width plows</u>. This parameter is the number of track width plows used to make the breach.
- <u>Number of type 1 tracks</u>. This is the number of tracked vehicles of specific type 1. The model will accept values ranging from 1 to 15 for this parameter, but the larger the number the slower the graphics version will run. An additional consideration is that, depending upon the lethality of the scenario and the size of the minefield, the number of disabled vehicles (if excessive) may cause "gridlock" where the size of the resulting obstruction is larger than the boundaries of the minefield. Actually, it is unlikely that any unit commander would willingly put more than a dozen vehicles or so down a single lane of an assault breach. Test cases have shown no difficulty in handling breaching forces of up to 10 vehicles, but no predictions are made for more extreme cases.
- <u>Number of type 2 tracks.</u> The number of tracked vehicles of specific type 2. Just as for the type 1 tracks, the model will accept and attempt to run with up to 15 type 2 tracks. The same cautions apply.
- <u>Number of type 3 tracks</u>. The number of tracked vehicles of a specific type. The same cautions apply.

- <u>Interval between plows and tracks.</u> This parameter allows the user to specify a distance between the breaching vehicles and the trailing assault force. It differs from the interval between vehicles in that it allows separation of the breaching vehicle(s) from the vehicles that are merely trying to get through the minefield. This parameter was implemented, under the assumption that the tactical commander, during a breaching operation, would not want to place combat vehicles in the minefield until a lane had been completed, or at least until all other efforts to provide a lane had been exhausted. If this parameter is set to zero, then the model uses the interval between vehicles for all elements.
- <u>Interval between vehicles.</u> This parameter is used to determine the distance between vehicles moving single file through the minefield. Once set, it remains constant throughout a simulation run.
  - f. Tables
- <u>Vehicle versus Mine  $p_k$  Table</u>. The model allows the vehicle type versus mine type probability of kill table to be edited during the initialization phase. Distinct  $p_k$ s may be entered for each vehicle type/mine type combination.
- <u>Red Overwatching Fire versus Vehicle  $p_{t}$  Table.</u> The table of probability of kill given shot table for red overwatching systems versus blue taskforce vehicles can be edited during the initialization portion of a model run.
- <u>Direct Fire Allocation Table</u>. This table allows the user to determine the proportion of direct fire shots that will be allocated to the lead vehicle attempting to negotiate the minefield. Fires not allocated to the lead vehicle are distributed equally to any other vehicles that happen to be in the minefield at the time of the shot.

## g. Administrative parameters

- <u>Interval between checkpoints</u>. The interval between navigation checkpoints can be set during the initialization portion of a model run. The value entered impacts on how taskforce vehicle navigation error is played, as the y coordinate of each navigation checkpoint is a direct function of the distance between checkpoints. The smaller the interval, the more navigation checkpoints the vehicle will negotiate in the course of moving a specific distance. For each checkpoint, a navigation error in the x dimension is calculated.
- <u>Graphics on or off.</u> The graphics option provides a valuable means of validating the model and of displaying the results of a scenario. However, the use of graphics precludes the timely collection of multiple iteration results. To avoid this problem a switch is provided on the input menu which allows the user to turn the graphics off. This action significantly reduces the model run time (by at least an order of magnitude).

• <u>Number of iterations.</u> The model may be set to run multiple iterations with the same input data. For multiple iterations a mean and variance are calculated for the output elements. The number of runs is set during the initialization portion of a model run. If this value is greater than one then the model graphics are automatically turned off.

## 2. Outputs

Several values are produced as outputs by the model. Additionally, routines exist to capture the values of various data arrays within the model for validation purposes. All input values are recorded as part of the output file, to include the initial seeds used in the random number generators. The output values currently produced are:

- <u>Mine density</u>. This value is expressed in terms of the number of mines present by type per meter of front (linear density) and by the number of mines by type per square meter of minefield area (area density). Linear density is the average number of mines contained in a meter wide strip through the mine field in the direction of formation movement. Area density is the average number of mines per square meter of mined area. Mine density is of critical importance in determining the effectiveness of the mine clearer.
- <u>Mines displaced by plow.</u> This output is expressed as the number of mines displaced by plows during a model run.
- <u>Mine kills by mine type</u>. This output is expressed as the number of mine kills by mine type and by vehicle status. Vehicle status is expressed as either in normal mode or bypass mode.
- <u>Red overwatch shots fired.</u> This value is the total number of shots fired by red direct fire overwatching systems during a scenario run.
- <u>Red overwatch kills</u>. This value is the total number of vehicle kills generated by the red direct fire overwatching systems.
- <u>Time of death</u>. The time of death of any taskforce element is recorded and available as an output.
- <u>Time of completion</u>. For each vehicle surviving the breaching effort, the time it completed the traversing the lane is recorded and available as an output.

## C. THE MODEL

Figure 4-1 is a flow diagram of the encounter event logic used in the model.

#### 1. Events

Two types of events occur within the model. The first type, hereafter called "encounter" events, are composed of those events which take place as a result of vehicle movement. The second type of event, hereafter labeled "fire" events, are made up of those events which take place regardless of vehicle movement.

### a. Encounter events

There are three types of encounter events. They are navigation checkpoint encounters, henceforth called cp encounters, mine encounters, and obstruction encounters.

There are four varieties of cp encounters. These are initial checkpoint encounters, movement checkpoint encounters, bypass checkpoint encounters, and final checkpoint encounters. CP encounters are used to monitor and control the navigation of the taskforce through the minefield. All taskforce vehicles start at their respective initial checkpoints. The time of arrival at an initial checkpoint is determined by the vehicles place in the column, vehicle speed and the interval between vehicles. Movement checkpoints occur at user specified intervals and when connected by line equations, make up each vehicles movement path. At each movement checkpoint the path equation used to determine the exact location of the vehicle changes. Bypass checkpoints serve a similar function, however they are calculated as needed and then spliced onto the original movement path. Upon reaching the final checkpoint the vehicle has successfully negotiated the minefield.

۹

•

.

Figure 4-1

----- +----

Mine encounters occur when the movement or bypass path and the physical dimensions of a vehicle are combined with the location, size and fuzing mechanism of a mine resulting in an engagement.

Obstruction encounters can occur only after at least one vehicle has been disabled, with at least one vehicle trailing it (the disabled vehicle). An obstruction encounter initiates the generation of a bypass map consisting of the bypass checkpoints necessary for the trailing vehicle to bypass the obstruction.

Each vehicle has a maximum of one encounter event on the event calendar at any instant in time. Disabled vehicles no longer generate encounter events. When an encounter event is taken off of the calendar and completed, a new encounter event for that vehicle, if appropriate, is determined and scheduled.

This is done by a routine named NEXT.ENCOUNTER which performs a function call to each of three different routines, named DISTANCE.TO.CP, DISTANCE.TO.MINE, and DISTANCE.TO.OBS. Each of these routines determines the distance between the calling vehicle and its next encounter of each respective type. The routines then return the distance, and if appropriate, identification of the encountered entity (mine ID, or obstruction ID) to the NEXT.ENCOUNTER routine. NEXT.ENCOUNTER then compares the distances and determines which event is most eminent. A call is then made to the routine DELTA.TIME which computes and returns the time it will take that vehicle, moving at its constant speed, to move the appropriate distance. NEXT.ENCOUNTER then schedules the next event for that vehicle, either a NEW.CP, MINE.ENCOUNTER, or OBSTACLE.ENCOUNTER, at that time in the future. This process will continue until all taskforce members have been disabled or have reached their final navigation checkpoints. The only encounter event which can disable a vehicle is a mine encounter. If a vehicle is disabled during a mine encounter, a routine called CALENDAR.UPDATE is used to remove all encounter events from the event calendar. This is done to prevent events from occurring which may no longer be valid. After all encounter events have been removed the routine causes each active element to redetermine and reschedule its next event.

#### b. Fire events

There are two types of fire events. Direct fire events and indirect fire events. Direct fire events are those events that take place in a simulated line of sight mode where the firer is assumed to be able to see the target being fired upon. Each red direct fire overwatch system will have only one fire event on the event list at any time. Direct fire events will not be directed at a specific vehicle until the event is removed from the event list. At that time the routine DIRECT.FIRE determines the actual target using the fire allocation algorithm previously discussed and resolves the engagement. There may be multiple direct fire events apportioned to the same target vehicle, but only one per firing vehicle at any one time.

Indirect fire events refer to the use of simulated artillery, where the firer is actually attempting to hit a spot on the ground. Having a line of sight to the target is not required or expected. Multiple indirect fire events may be on the event list, but they are directed at impact points and not specific vehicle entities. Should a vehicle be disabled by direct or indirect fire, CALENDAR.UPDATE is again called in order to clear the calendar of encounter events and reschedule encounter events for all active vehicles.

## **V. EXAMPLE PROBLEM**

This chapter documents a demonstration of the model through the use of an example problem. One of the issues that has arisen during the design of the new Combat Mobility Vehicle concerns the choice of an appropriate width for the blade attached to the front of the vehicle. The blade may be used for a variety of purposes, including as a plow for the breaching of minefields.

As discussed in Chapter II, the utility of a plow blade is dependent on tradeoffs made between the effectiveness of the lane created by its use and the survivability of the breaching vehicle. Intuitively, the wider the blade, the more dirt the vehicle must push, and the slower the vehicle will be able to move. If the lane is not wide enough to be safely negotiated by the trailing vehicles, then one or more of them may become disabled by a mine, thereby blocking the lane. Finally, the longer any vehicle remains exposed to overwatching fires while in the minefield, the more likely the event of its being disabled.

To demonstrate the potential utility of this model with regard to examining the effects of parameter changes on the scenario outcome, the following test case is presented.

# A. SCENARIO

The purpose of this scenario will be to evaluate the impact of mine plow width on the number of casualties inflicted upon a taskforce conducting the breach of a minefield. There are many variables which will impact on the results of a minefield breaching operation. The ones included in this scenario are:

- the density, depth and makeup of the minefield,
- the volume and accuracy of overwatching direct fires,
- the width of the cleared lane made,
- the speed of the breacher,
- and the navigation accuracy of the trailing taskforce.
  - 1. The Minefield

The scenario minefield is a surface laid, scattered minefield. Scattered refers to the fact that the mines are placed randomly, using a uniform distribution, within a minefield of 50 meters depth and 150 meters width. Three types of mines will be modeled in the makeup of the field. Table 5-1 shows the type, radius and probability of kill parameters used for the mines in this scenario.

Mine Type	Linear Mine Density	Radius of Mine	P <sub>k</sub> vs Full Plow	P <sub>k</sub> vs Track
Pressure	.2	.1 m	.05	.9
Influence	.1	.1 m	.05	.9
Contact	.025	.1 m	.5	.9

 TABLE 5-1
 MINE DATA

### 2. The Taskforce

The attacking force will consist of one full width blade breacher and five tracked vehicles for a total of six vehicles. A baseline case will also be run in which a taskforce consisting of six tracked vehicles with no plow will attempt to negotiate the minefield. Table 5-2 displays the model input parameter characteristics of the breaching force.

## TABLE 5-2 VEHICLE DATA

	Width	Length	Track Width	Track Width Nav. Error		
Plow	3.48m	9.03 m	.635 m	none	varied	
Track	3.48m	9.03 m	.635 m	.5 m	10 kph	

### 3. Plowing

The actual amount and type of force used by a prime mover to push a plow is a complex function of soil type, plow design, and plowing depth. The forces involved can be divided into two categories; the system tractive forces, and the plow draft forces. These forces are defined as follows.

System tractive force - The amount of force exerted by a prime mover against a given soil that can be used for maneuverability/mobility (turning, climbing, accelerating, etc.). This includes the amount of force the soil is able to generate as resistance versus the amount of force generated by the prime mover.

Plow draft force - The amount of force applied to plow tines, skids, and moldboards to conduct plowing operations in a given soil. [Ref 5. p IV-3]

Simplifying the problem of plow draft force considerably, we make the statement that under a given set of conditions, the faster the plow is pushed, the greater the draft force required. The relationship between plow draft force and prime mover velocity is roughly linear.

Continuing to simplify, we make the statement that with regard to tractive force, under a given set of conditions, the faster the plow is pushed the less tractive force is available. The relationship between tractive force and velocity is not linear.

The draft force required to move the plow is subtracted from the tractive force available to the prime mover. A positive net tractive force is necessary if the prime mover is to move forward. This means that no matter how much horsepower the prime mover has available, there is a point where the ambient conditions will not permit an increase in the forward velocity of the plow. The prime mover will be simply "spinning it's wheels".

Figure 5-1 illustrates the relationship between velocity and both draft and tractive forces. Figure 5-1 was derived from data extracted from a study done on the engineering development of a mine clearing plow system [Ref 8. p.IV-14]. The intersections between the tractive force and draft force lines are the points where further increases in velocity are not possible. The abbreviation TWMP stands for track width mine plow and FWMP stands for full width mine plow.

Figure 5-1

It is apparent that any specified prime mover will, under stipulated soil conditions, be able to move a designated plow at a certain maximum velocity. This point will be the intersection of the draft forces and the tractive forces generated under the aforementioned soil conditions. The calculations and computer programming required to calculate this point under any reasonable variety of soil conditions and vehicle configurations are of sufficient magnitude to be the subject of several volumes. For this example, we will simplify the situation by using the values in Table 5-3 for the maximum velocity of our plowing system under the given plow width.

System	1	2	3	4	5
Plow Width (m)	4.5	5.0	5.5	6.0	6.5
Velocity (kph)	8.0	6.0	4.6	3.8	2.8

TABLE 5-3 PLOW DATA

### 4. Red Overwatch

The red force overwatching the minefield will consist of a single red direct fire system which will have a rate of fire of one round every 30 seconds, and a mean acquisition rate of one target every 40 seconds. The overwatching system will not begin attempting to acquire a target until the system is prepared to fire. This means that rate of fire and time to acquire are treated as separate, non-overlapping periods of time. The time period between successive shots is the sum of these two periods of time. The p<sub>k</sub> given a shot will be .20 against both plows and tracks.
# B. TEST PLAN

The goal is to examine the number of taskforce casualties resulting from a breaching attempt as a function of plow width. The minefield model will address this goal by holding most parameters constant, varying only the plow width and the associated speed of the plowing vehicle. The interval between the plow and the trailing vehicles will be set for 300 meters, a value sufficient to prevent taskforce vehicle collisions under the described scenario.

The mean number of casualties for each plow configuration will be determined for 120 iterations of the model. A baseline scenario will be run with no plow system in order to determine the benefit derived from having a plowing system. V e h i c l e casualties will be subdivided into mean casualties caused by mines, mean casualties caused by direct fires, and mean casualties caused by mines while bypassing obstructions (a subset of mean casualties caused by mines). The mean values will then be examined to determine if differences are apparent and to see if the model results make sense.

The distribution of casualty counts will be determined over each group of 120 iterations. The number of casualties by vehicle position in the taskforce column will also be collected and presented. Finally, the survival rate of the different plow configurations will be determined and displayed.

#### C. PROBLEM RESULTS

Figure 5-2, presents the mean casualties inflicted during 120 iterations for each of the system configurations. The trend lines support the original reasoning with regard to the consequences of plow velocity and lane width. Note that the "no plow"

Figure 5-2

scenario results in the most mine inflicted casualties and the most total casualties. Casualties from direct fire go up with the decrease in breacher speed (increase in plow width). As plow width increases, the number of mine casualties initially goes down, but as direct fire casualties rise, so do the mine casualties, particularly those mine casualties inflicted during the conduct of obstruction bypassing. Another cause for the rise in mine casualties may be the destruction of the plow by direct fire prior to the completion of the breach.

The results indicate that under the given conditions, either Plow 2 (5.0 meters wide) or Plow 3 (5.5 meters wide) would result in the fewest overall taskforce casualties.

Figure 5-3 depicts the distribution of taskforce casualties results over the 120 iterations. The values generated do not contradict the expected results. The results also indicate that any plow system is better than attempting to negotiate the minefield with no plow.

	Мс	odel Ru	n <mark>Resu</mark> l	ts		
		120 iter	rations			
Run Casualty Counts						
	No Plow	Plow 1	Plow 2	Plow 3	Plow 4	Plow 5
No Casualties	10	53	76	•	80	51
1 Casualty	17	32	17	27	39	34
2 Casualties	22	•	11	12	14	•
3 Casualties	19	14	5	5	4	•
4 Casualties	18	7	2	5	2	7
5 Casualties	10	2	4	4	5	5
6 Casualties	12	3	5	1	•	7
Total Casualties	342	146	112	112	148	160

Figure 5-3

Figure 5-4 displays the number of iterations resulting in vehicle casualties at specific vehicle positions in the taskforce column. If present, the breacher will always be the first vehicle in the column. As expected, the slower the breacher moves, the greater the chance it will become a casualty.

		120	iterations				
Number of iterations where Specific Vehicle became Casualty							
	No Plow	Plow 1	Plow 2	Plow 3	Plow 4	Plow 5	
1st Vehicle	72	25	25	35	39	49	
2nd Vehicle	70	23	18	23	54	28	
3rd Vehicle	62	24	16	15	21	27	
4th Vehicle	50	<b>9</b> 0	22	12	19	27	
5th Vehicle	41	18	17	14	13	20	
6th Vehicle	38	22	18	13	22	18	

Figure 5-5 emphasizes this point by showing the actual survival rates for the five different plow configurations as a result of vehicle velocity, which equates to the amount of time spent exposed in the minefield.

Actual studies to determine the appropriate plow width would entail examination of a much greater selection of soil types, minefield configurations, and overwatching fire conditions. Also, this example uses fairly small sample sizes. Any study intended for actual design decisions should include a larger number of scenario iterations.

This example demonstrates the potential utility of the methodologies and the model for examining the problems associated with minefield breaching operations. The model may be particularly useful for examining complex problems that have no

-1

3

closed form solution and for which the costs and hazards of actual testing are prohibitive.

#### VI. CONCLUSIONS AND RECOMMENDATIONS

### A. RESULTS

The methodologies and algorithms presented in this model provide a good foundation for the effective high resolution, high fidelity, modeling of the dynamics involved in the traversal of minefields.

The model is highly portable. The program was written and tested on an IBM PC compatible computer, and has been run on both the 80286 and 80386 systems. The primary portability limitation is the availability of the SIMSCRIPT programming environment. Further details concerning system requirements are provided in Appendix A.

The model is entirely menu driven, allowing the user to change any of the input parameters without editing a file. The range of allowable input values is controlled by the SIMGRAPHICS input forms. The model outputs are automatically written to a data file for study and analysis.

The model is written in SIMSCRIPT and includes the icons and coding to run using SIMGRAPHICS. The graphics are a user option that is turned off should the user decide to run multiple iterations in a single session. The use of SIMGRAPHICS provides a visual validation of the model and of the model results. Users will have added confidence of being able to see how the model arrives at its results.

An unfortunate limitation of the SIMGRAPHICS feature is that it is specific to the machine environment in which it was developed. This means that the graphics in this model will only work on a DOS system based machine. A list of the icons as well as a figure depicting each one is provided in Appendix D to allow users, interested in transporting the model to a different system environment, a template for the icon construction.

The resulting model provides a basic high resolution modeling capability for the study of minefield dynamics with potential utility in either countermobility or mobility studies. The model can be used for both offensive and defensive scenarios and has a built in capability to examine a wide range of "what if" scenarios. The model also has potential as an optimization tool to examine such issues as optimum plow widths and optimum mine densities/mixes.

The use of the model as a low level, high resolution modeling tool, allows the user to collect a wide range of minefield breaching data, providing the military modeler with a capability to "validate" the minefield breaching portions of higher level, lower resolution military models. For example, as a high resolution model, the program can be used to determine expected unit delays and vehicle attrition as the result of an encounter with a specific type of minefield. These outcomes can then be used to evaluate the performance of higher level models to determine if the delays and casualty assessments they impose are reasonable, or the results can be used as data for the higher level models.

#### **B. FUTURE ENHANCEMENTS**

This model has been designed to allow easy modification of many of the model inputs. In addition, basic tools and functions are provided that allow for the easy addition of additional minefield objects. Possible improvements include adding additional breaching options such as mine rollers, line charges, and flails. Additional minefield features might include patterned minefields, multiple lanes, blue overwatching fires, antitank ditches, obscurants, and some of the more modern mine types. The addition of indirect fires to the overwatching fires as well as the ability to modify the rate of overwatching fires as a function of time should also be considered as a future enhancement.

### **APPENDIX A - SYSTEM REQUIREMENTS**

The model is written in SIMSCRIPT II.5<sup>®</sup>, a free-form, English-like, general purpose simulation programming language. SIMSCRIPT II.5 is a product of the CACI Products Company. The model also makes use of SIMGRAPHICS, a companion product which allows programs written in SIMSCRIPT II.5 to include animated interactive graphics.

Running the model requires SIMSCRIPT II.5 to be installed on the machine. Running the SIMSCRIPT compiler on a PC requires a math coprocessor and at least 640K of memory. The graphics have been run on both an EGA and a VGA monitor with no difficulty.

The model was developed on an IBM clone 286 machine, running at 16 MHZ, with a math coprocessor, and VGA graphics. The source code is claimed by CACI to be portable over a wide range of systems with only minor, system specific modifications required.

The graphics, unfortunately, will not transfer to a non-DOS environment. Should the user desire to operate the program on some other type of system which supports graphics, a SUN workstation for example, it will be necessary to recreate the graphic images (icons) and input displays (forms) stored as part of the program using the system specific SIMGRAPHICS software. A list of icons used and figure for each is included in Appendix D. Additionally, paper copies of the input forms are provided.

# **APPENDIX B - RUNNING THE MODEL**

This appendix contains instuctions for running the model and copies of the SIMGRAPHICS forms used to modify the model inputs. The input forms are included because although SIMSCRIPT code will run on a variety of computer systems, the SIMGRAPHICS portion of the code is unique to the type of computer system the graphics were generated on. To allow users the ability to recreate the forms on their specific platforms, they are reproduced in hard copy here. The character strings contained in brackets "< >" are the field identifications used by the SIMSCRIPT program to read the inputs.

Figure B-1 shows an overview of how the various model menus are interconnected. The first menu that will come up upon running the program is the master menu depicted in Figure B-2. From the master menu all other program menus can be accessed. Upon completion of input modifications, the user will return to the master menu and activate the start button.

#### SOURCE CODE LISTINGS

```
1 PREAMBLE
3 normally mode is real
 4
   EVENT NOTICES include GRAPHIC. UPDATE, STOP.SIM
 5
      every START has on ID
 6
      every MINE.ENCOUNTER has an ID, a MINE.ID
 7
      every NEW.CP has an ID
 8
      every OBSTACLE ENCOUNTER has an ID
9
10
      every DIRECT.FIRE has an ID
11
12 TEMPORARY ENTITIES
14
      every ELEMENT has a ELEMENT.X, an ELEMENT.Y,
15
        a STATUS, an ELEMENT. TYPE, a SPEED, a WIDTH,
        a LENGTH, a TRACK.WIDTH, an ELEM.RADIUS, a PLOW.EFFECT,
16
        a PLOW.WIDTH, a P.STATUS and an ELEMENT.NUM
17
18
19
        define ELEMENT.X and ELEMENT.Y as real variables ''element location
        define SPEED as a real variable
20
21
22
                              "status is 0 if inactive, 1 if normal movement
                             "2 if bypassing
23
24
        define STATUS as an integer variable
25
                              "type is 1 if full plow, 2 if track plow, 3,4,5
26
                              "if some other type tracked vehicle
27
28
        define ELEMENT. TYPE as an integer variable
29
                              "radius of element defined as the radius
30
                              "of the circle with same area as vehicle
31
        define ELEM.RADIUS as a real variable
32
        define WIDTH, and LENGTH as real variables
33
        define TRACK.WIDTH as a real variable
34
35
        define ELEMENT.NUM as an integer variable
36
37
                              "plow effectiveness, plow width and plow status
                             "has no effect unless vehicle is of type 1
38
                             "or type 2
39
40
        define PLOW. EFFECT and PLOW. WIDTH as real variables
41
        define P.STATUS as an integer variable
42
      every OBSTACLE has an OBSTACLE.X, an OBSTACLE.Y,
43
44
        a PT1.X, a PT1.Y, a PT2.X, a PT2.Y, a PT3.X, a PT3.Y,
        a PT4.X, a PT4.Y, a PT5.X, a PT5.Y, a PT6.X, a PT6.Y,
45
        a SLOPE.A, a SLOPE.F, a SLOPE.C, a SLOPE.D,
46
47
        a Y.INT.A, a Y.INT.F, a Y.INT.C, a Y.INT.D,
48
        and an OBS.RADIUS
49
50
        define OBSTACLE.X and OBSTACLE.Y as real variables "obstacle center
        define OBS.RADIUS as a real variable
                                                         obstacle radius
51
                                                       "hex point 1 coordinates
        define PT1.X and PT1.Y as real variables
52
                                                       "hex point 2 coordinates
53
        define PT2.X and PT2.Y as real variables
                                                       "hex point 3 coordinates
54
        define PT3.X and PT3.Y as real variables
                                                       "hex point 4 coordinates
55
        define PT4.X and PT4.Y as real variables
                                                       "hex point 5 coordinates
56
        define PTS.X and PTS.Y as real variables
                                                       "hex point 6 coordinates
57
        define PTS.X and PTS.Y as real variables
        define SLOPE.A and SLOPE.F as real variables 'slopes for hex sides A & F
define SLOPE.C and SLOPE.D as real variables 'slopes for hex sides C & D
58
58
        define Y.INT.C and Y.INT.F as real variables ''y intercepts sides A & F

## **APPENDIX D - GRAPHIC ICONS**

This appendix contains diagrams depicting the icons used in the graphics portion of the model. The icons are included because although the SIMSCRIPT code will run on a variety of computer systems, the SIMGRAPHICS portion of the code is unique to the type of computer system it was generated on. To allow interested users the ability to recreate the graphics on their specific platforms, the icons are reproduced here. The text strings ending in "icn" at the base of each diagram are the file names which the program looks for when using that particular icon. In the cases where multiple text strings appear beneath the icon (Figure D-2), multiple icons of this shape are used, each of a different color. Any of the icons may be of any color the user chooses. It is suggested that the bottom row of mine icons depicted in Figure D-6 be of the same color as these icons are used to depict inactive mines.

The "crosshairs" on each icon diagram identify the center of the icon which must be identified to the SIMGRAPHICS editor when constructing the icon. The measurement given at the bottom of each diagram provides the "scale" of the icon which must also be input to the editor before the icon is used.

ŧ

The simulation made 1 runs.

The full width plow used had a width of 4.50 and an effectiveness of 1.00

SUMMARY STATISTICS

MINES MOVED BY PLOW An average of 2.50 mines were displaced by the plow each run

MINE KILLS BY MINE TYPE

Mean	mine	kills	by	type	1	mines	Was	0.,	with	variance	0.
Mean	mine	kills	by	type	2	mines	Was	1.00,	with	variance	0.
Mean	mine	kills	by	type	3	mines	WES	0.,	with	variance	0.
Mean	mine	kills	by	type	4	mines	Was	0.,	with	variance	0
Mean	mine	kills	by	type	5	mines	Was	Ο.,	with	variance	0

Mean mine kills for all mine types 1.00, with variance 0.

DIRECT FIRE STATISTICS

RED OVE	RWATCH		
TYPE	STATUS	FIRE RATE	MEAN ACQ RATE
1	1	. 500	. 700

8

Red fired 3.0 direct fire shots. accomplishing 0. kills of blue taskforce vehicles.

Red direct fire overwatch killed a mean of 0. with a variance of 0. taskforce vehicles per run.

TOTAL TASKFORCE LOSSES The mean taskforce loss rate was .17 with a variance of .00

# **APPENDIX F - EXAMPLE MULTIPLE RUN RESULTS**

The model collects designated data throughout the course of a data run. Following is an example of one such run.

The raw data columns consist of the following data elements.

- A = Iteration number
- B = Mines Kills
- C = Direct Fire Kills
- D = Total Kills
- E = Mine Kills while bypassing Obstruction
- F = Time of Death for Vehicle 1 (0 if survives breach)
- G = Time of Death for Vehicle 2 (0 if survives breach)
- H = Time of Death for Vehicle 3 (0 if survives breach)
- I = Time of Death for Vehicle 4 (0 if survives breach)
- J = Time of Death for Vehicle 5 (0 if survives breach)
- K = Time of Death for Vehicle 6 (0 if survives breach)
- L = Time of Completion for Vehicle 1
- M = Time of Completion for last surviving vehicle
