Geographic Resources Analysis Support System (GRASS) Version 4.0

by
James D. Westervelt
Michael Shapiro
William D. Goran
David P. Gerdes

The Geographic Resources Analysis Support System (GRASS) is a geographic information and image-processing system originally designed to serve land managers and environmental planners at Army installations. GRASS is an integrated set of programs that provide digitizing, image processing, map production, and geographic information system capabilities to its users. GRASS is written in "C" and is ported to computers running the UNIX operating system. Since its initial development, GRASS has been developed for many applications on a number of different hardware configurations.

GRASS Version 4.0 includes significant additions and modifications to system libraries and programming code. This manual contains a program-by-program description of each program's capabilities and uses; a summary of command-line options; and lists of associated or related programs.

Approved for public release; distribution is unlimited.
The contents of this report are not to be used for advertising, publication, or promotional purposes. Citation of trade names does not constitute an official endorsement or approval of the use of such commercial products. The findings of this report are not to be construed as an official Department of the Army position, unless so designated by other authorized documents.

FOREWORD

This document was developed for the U.S. Department of Agriculture Soil Conservation Service under reimbursable Project R-FED-SCS, "Office of GRASS Integration"; Work Unit VH1. The SCS technical monitor was Dr. Richard Liston, USDA SCS-CGIS.

This work was performed by the Environmental Division (EN) of the U.S. Army Construction Engineering Research Laboratory (USACERL). The USACERL principal investigator was Marjorie Larson. Dr. Edward Novak is Acting Chief, USACERL-EN. William D. Goran is team leader of the Spatial Analysis Systems (SAS) Team. The USACERL technical editor was William J. Wolfe. Information Management Office.

In addition to the authors cited on the cover, this manual was a product of the efforts of many contributing authors: Jacinda Barbehen, Deborah Brinegar, Kurt Buehler, Joo Joo Chia, Chuck Ehlschlaeger, Jean Ezell, David Gerdes, Andrew Heekin, Michael Higgins, Hewijin Jiau, Mark Johnson, Marjorie Larson, Mary Martin, Jean Messersmith, Jan Moorman, Christine Poulsen, Melissa Records, Marilyn Ruiz, Michael O'Shea, David Stigberg, Scott Tweddale, L. Van Warren, Scott Wade, and Hong Zhuang (USACERL); Michael Baba and David Johnson (DBA Systems, Inc., Fairfax, VA); Chris Rewerts and Raghavan Srinivasan (Agricultural Engineering Department, Purdue University); Antony Awaida and Kewan Q. Khawaja (Intelligent Engineering Systems Laboratory, Massachusetts Institute of Technology, Cambridge, MA); James Hinthome and David Satnik (Central Washington University); Dennis Finch, Tom Howard, and Bruce Powell (National Park Service); James Farley (Arkansas Archeological Survey); Donald Newcomb (U.S. Naval Oceanographic Office); Greg Koerper (USEPA Environmental Research Laboratory, Oregon State University); Chris Emmerich (Autometric, Inc.); Kenneth Shepardson (Spectrum Sciences and Software, Inc.); Ali R. Vali (Space Research Center, University of Texas, Austin); Dale White (Pennsylvania State University); Larry Band (University of Toronto); P.W. Carlso, Paul H. Fukuhara, R.L. Glenn, M.L. Holko, and Harold Kane (U.S. Department of Agriculture Soil Conservation Service [USDA SCS]). To all those who spent many hours testing this software prior to its release, special thanks are also given.

Special recognition is also given to: George W. Hageman (SOFTMAN Enterprises, Boulder, CO); Daniel S. Cox (In Touch, Atlanta, GA). Thanks are also due to Dr. A.V. Hershey (U.S. National Bureau of Standards) for the use of the public domain version of the Hershey Fonts in the program dfonts, and to Jeff Poskanzer for the use of the Portable Pix Map (PPM) utilities.

COL Daniel Waldo, Jr., is Commander and Director of USACERL, and Dr. L.R. Shaffer is Technical Director.

INDEX 533

DISTRIBUTION
1 INTRODUCTION

Background

This reference manual details use of each program distributed with version 4.0 of the Geographic Resources Analysis Support System (GRASS), a public domain image processing and geographic information system (GIS) originally developed by researchers in the Environmental Division of the U.S. Army Construction Engineering Research Laboratories in Champaign, IL. The GRASS system is used to input, manipulate, analyze, and output geographic data by users in both military and nonmilitary, public and private agencies, based in North America, Europe, and other parts of the world.

Although most GRASS development has been conducted at USACERL, system integration, development, testing, distribution, training, and support are performed by numerous publicly and privately operated sites throughout the world. GRASS version 4.0 implemented significant additions and modifications to system libraries and programming code. Mechanisms are needed to transfer current technology and information about GRASS to user and development sites.

This manual explains the capabilities, syntax, and use of current GRASS programs. Chapters are ordered alphabetically, by program name, one program to each section. Each section contains:

- the program name and a short description
- a synopsis of files associated with the program
- a full description of the program’s capabilities and uses
- a summary of the command-line options associated with the program
- a list of associated or related programs
- a list of program authors.

Each section may optionally include: a description of the program’s operation in “interactive mode,” and a discussion of “bugs,” program limitations, or special notes of potential interest to GRASS users.

Throughout this manual, program inputs to be explicitly entered by the user are printed in bold text. User-specified inputs (i.e., variables set by the user) are set in italic type. Boxed text shows information output to the user’s terminal screen.

Scope

This document details the use of GRASS version 4.0 programs released in July 1991. Figures and facts about GRASS relate to the 4.0 and previous releases. Some elements of this document will be dated and inaccurate for post-4.0 software releases.

Mode of Technology Transfer

GRASS is being transferred to the field through the following mechanisms: training programs, hands-on experience, a user support center, newsletters, extensive documentation, institutional structures at the Army and Interagency levels, communication networks, and other forums: GRASS source code can be obtained by anonymous ftp from moon.cecer.army.mil. Current information is available from the GRASS Information Center at USACERL, which can be contacted by Phone: 217-373-7220; Fax: 217-373-7222; or e-mail: grassbug@zorro.cecer.army.mil.
GRASS, a product of the U.S. Army Corps of Engineers Construction Engineering Research Laboratory (USACERL), in Champaign, IL, is an integrated set of programs designed to provide digitizing, image processing, map production, and geographic information system capabilities to its users. Although most GRASS system development continues to be conducted by the Environmental Division of USACERL, system integration, development, testing, distribution, training, and support are performed by numerous publicly- and privately-operated sites throughout the world. Other agencies have also written programs for distribution with GRASS.

Whatever their origin, all programs distributed with GRASS 4.0 undergo scrutiny and testing prior to their release. This chapter describes the syntax and use of GRASS 4.0 programs that have undergone (and survived) alpha-and beta-testing (i.e., initial testing by program developers, and subsequent testing by out-of-house users). These programs constitute the bulk of GRASS, and are respectively referred to in the documentation as "Alpha Programs" and "Main Programs." "Main Programs," which receive both alpha- and beta-testing prior to their release and are located in the src directory, are compiled automatically during general GRASS compilation. "Alpha Programs," which receive only alpha-testing prior to release and are located in the src.alpha directory, must be compiled separately by the user. The GRASS Installation Guide distributed with GRASS 4.0 software explains the compilation procedure.
NAME

d.3d - Displays three-dimensional images based on raster map layers.

d.3d [-40a] map=-ame elevation=-ame [from_coordinate=x,y,z]
               [to_coordinate=x,y,z] [exaggeration=value] [lines=value] [field=value]
               [color=name] [box=name]

DESCRIPTION

d.3d displays three-dimensional graphic images based on GRASS raster map layers. The user identifies
the viewing point, the line of sight, a vertical exaggeration factor, the viewing angle (field of view), the
frequency and color of vector grid lines to appear in the display, the map to be displayed in three
dimensions, and the map whose category values are to be used as elevation values in the three-
dimensional image.

The program will be run non-interactively if the user specifies all needed parameter values and flag
settings on the command line. Alternately, the user can simply type d.3d on the command line; in this
case, the program will prompt the user for parameter values and flag settings using the standard
interface described in the manual entry for parser.

Three-dimensional images can also be generated through the GRASS d.display program.

COMMAND LINE OPTIONS

Flags:

-1
   Display lines only, without displaying the raster base map.
-0
   Show zero elevations.
-a
   Each grid-cell is rendered using four elevation coordinates: one for each corner.
   By default, each corner takes the value of the grid-cell to the lower right. With
   the -a option each corner is calculated to be an average of the four bordering cell
elevation values.

Parameters:

map=name
   The raster map layer used to generate the color shown in the three-dimensional
   output (i.e., the map whose x and y values will be displayed, using the z values
   present in the elevation map layer.)

elevation=name
   The raster map used to generate the texture in the three-dimensional image (i.e.,
   the map whose category values will become the elevation values in the three-
dimensional map displayed). This need not be an elevation map layer, although
   elevation is commonly used.
   Default: elevation

from_coordinate=x,y,z
   Coordinates of the viewing point, given as: northing,easting,elevation. The
   default from_coordinate value is appropriate for the spearfish sample data set.
   Default: Calculated at run-time just south-west of the south-west corner.

to_coordinate=x,y,z
   Coordinates of center of view, given as: northing,easting,elevation. The
   default to_coordinate value is appropriate for the spearfish sample data set.
   Default: Calculated at run-time as the center of the image.
**exaggeration=value**

Vertical exaggeration factor. This value is multiplied by the "elevation" values (category values) in the elevation map layer. As the vertical coordinates are exaggerated, the elevation (z) value of the center of view (the to.coordinate) should be increased.
Default: 2.0

**lines=value**

North-south and east-west trending lines can be drawn on the three-dimensional image output, to enhance the three-dimensional effect. The lines value specifies the number of rows and columns to skip between lines. 0 means "display no lines." Lines will be drawn in the color stated. The user can elect to only display these lines, without displaying the map, by setting the -l flag.
Default: 1

**field=value**

The field of view (viewing angle) in the image, stated in degrees.
Default: 30

**color=name**

Color of vector lines drawn on the output.
Options: color, white, red, orange, yellow, green, blue, indigo, violet, gray, black
Default: gray

The resulting three-dimensional image is drawn in the active frame on the graphics monitor. The user should select and erase the full graphics monitor frame before running d.3d to prepare the screen for graphics. Refer to the GRASS program 3d.view.sh for a demonstration of the d.3d program.

**INTERACTIVE MODE**

The interactive mode prompts for the raster map to be rendered, the raster map to be queried for elevation information, and an optionally saved set of saved viewing parameters. The user is then presented with a form in which the options can be modified.

It is suggested that the following procedure be used to efficiently find the correct viewing parameters. Start with a gross grid (by default, a resolution is chosen that limits the total number of rows and columns), display lines only, set line colors to "color" (lines take their color from the map), set the box color to something other than "none", and use the default viewing coordinates. Experiment with the viewing coordinates until the map is positioned in a desirable configuration. When the map is lined up correctly, set the display resolution as low as you like for a final image.

**BUGS**

Several additions to this program have been suggested. These include the following:
1) Border the image with a visually appealing curtain.
2) Add x,y,z coordinates and scale information to the displayed three-dimensional image.
3) Provide a graphic-oriented user interface for identifying viewing parameters.
4) Display output more quickly by doing mathematics in integers.
5) Add the option of plotting vector map layers.

NAME

d.ask - Prompts the user to select a GRASS data base file from among files displayed in a menu on
the graphics monitor.

(GRASS File Management Program)

SYNOPSIS

d.ask help

d.ask element=name,description [prompt="message"]

DESCRIPTION

d.ask is designed for shell scripts that need to prompt the user for the name of a data base file in the
user's current GRASS mapset search path. After d.ask is invoked with needed parameters, the mouse
becomes active and a menu containing files of the specified element type is displayed on the user's
graphics monitor. The user is prompted by the prompt "message" to select one of the listed file names
with the mouse. Specifically, the query that appears to the user takes the form:

  Double click on the  prompt "message"
  Double click here to cancel

(A list of files of the specified element type from each of the mapsets
listed in the user's mapset search path is also displayed.)

After the user responds, the mouse is deactivated and the displayed menu is erased from the screen
(leaving any underlying materials on display intact). Three lines are written to standard output (the
user's terminal screen):

  name=file_name
  mapset=mapset_name
  fullname=file_name@mapset_name

Parameters:

element=name,description
  Name of a GRASS data base element, followed by a one word description of
  the element. GRASS data base elements are mapset subdirectories; these
  include: bdlg, cats, cell, cell_msc, cellhd, colr, colr2, dig, dig_ascii, dig_att,
  dig_cats, dig_plus, dlz, group, hist, icons, noise, paint, site_lists, and windows.
  The description will be used to display an error message to the screen if no
  files of the named element type exist in the user's mapset search path. The
  prompt "message" will appear in the pop-up menu displayed on the user's
  graphics monitor. The files listed in the menu will be of the specified element
  type, and exist in mapsets listed in the user's current mapset search path.

prompt="message"
  A brief message with which the user will be prompted. If this message
  contains more than one word, it should be enclosed within double quotes (""").
  It is a non-selectable message displayed in the menu bar of a pop-up menu.
  Selectable items in the displayed menu include a cancel option and any of the
  files in the mapset subdirectory name in the user's mapset search path.

EXAMPLE

Given the following input,

  d.ask element=cell,raster  prompt="raster map layer to be used"

d.ask will prompt the user to select a raster (cell) file from among those listed in the "cell" directories
of the mapsets listed in his current mapset search path. A pop-up menu will be displayed on the user's
graphics monitor, containing the prompt:

  Double click on the  raster map layer to be used
  Double click here to cancel

GRASS 4.0 (Summer 1991) U.S. Army CERL 15
If the user selects a file name from the displayed menu, \texttt{d.ask} writes three lines to standard output:

\begin{verbatim}
name=file\_name
mapset=mapset\_name
fullname=file\_name@mapset\_name
\end{verbatim}

The output is in the form of /bin/sh commands to set the variable \texttt{name} to the file name specified by the user (of the \texttt{element} type requested by \texttt{d.ask}), \texttt{mapset} to the GRASS mapset in which this file resides, and \texttt{fullname} to the name of the file and its mapset.

If the user elects not to select a file but instead chooses the "Double click here to cancel" option, the mouse will be deactivated and no variable assignments will be returned to standard output.

If no files of the specified \texttt{element} type are found in the user's current mapset search path, the mouse is activated and the following message is displayed on the user's graphics monitor:

\begin{verbatim}
No element description files found
Click here to continue
\end{verbatim}

\textbf{NOTES}

Parameter values (the \texttt{element} name and description, and prompt message) cannot be supplied to \texttt{d.ask} interactively; they must be supplied on the command line or from a file.

\textbf{SEE ALSO}

\texttt{g.ask, g.filename, g.findfile, g.gisenv, g.mapsets}

\textbf{BUGS}

This program calls other GRASS programs that may generate confusing error messages. Example: an error message from the program \texttt{d.menu} will appear if a nonexistent map element is chosen.

\textbf{AUTHOR}

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME
d.colormode – Allows the user to establish whether a map will be displayed using its own color table or the fixed color table of the graphics monitor.

SYNOPSIS
d.colormode
d.colormode help
d.colormode mode=name

DESCRIPTION
d.colormode establishes what color table will be used to display maps to the graphics monitor.

Parameters:
mode=name Options: fixed or float

Each time a new raster map layer is drawn on the screen, a color table associated with that map is loaded into the graphics display monitor. The command d.colormode mode=fixed requests that the monitor’s color look-up table be fixed (i.e., static). The effect is that colors drawn on the screen by graphics calls will not change when subsequent maps are drawn to the screen. When the fixed option is used, the colors in the map’s color table are mapped to the nearest colors available in the monitor’s fixed color table. When the float option is used, the map’s color table is loaded directly into the monitor’s color look-up table.

There are advantages to using each color display mode. The d.display and d.colors programs allow the user to interactively modify the color tables of maps displayed to the graphics monitor. This is done by allowing the user to directly modify the monitor’s color look-up table. Hence, to accommodate this option in d.display and d.colors, the d.colormode mode=float option is chosen. However, this option has the sometimes undesirable effect of changing the colors in which other maps are subsequently displayed to the graphics monitor (although it does not actually change the color tables of these latter maps). The float colormode is therefore best used when the user wishes to interactively change a map’s color table, or when the user wishes to display one or more maps having the same color table. The fixed option allows any number of maps to be displayed to the screen, where each map uses different colors, but all use the same fixed color look-up table. You cannot toggle a map’s color table when running in fixed mode.

This program will be run non-interactively if the user specifies the color mode on the command line (e.g., by typing d.colormode mode=fixed or d.colormode mode=float). Alternately, if the user simply types d.colormode on the command line, the program will prompt the user for the color mode using the standard GRASS parser interface described in the manual entry for parser.

NOTES
Some devices support only a fixed color look-up; e.g., ink-jet printers, plotters, and the AT&T 6300 (running a DEB board). The number of color categories capable of being displayed is also device-dependent; if your colors fall outside this range when in float mode, they may not be displayed in the colors indicated in the map’s color table file. However, the color table files themselves will accurately represent the user’s changes.

Color table files associated with raster map layers are stored in the user’s current mapset under the colr and colr2 directories.

BUGS
It is strongly recommended that the user erase the graphics monitor screen (e.g., by running d.erase) immediately after changing the mode between fixed and float.

NAME

d.colors – Allows the user to interactively change the color table of a raster map layer displayed on the graphics monitor.
(GRASS Display Program)

SYNOPSIS

d.colors
d.colors help
d.colors map=name

DESCRIPTION

A color table file associates specific colors with the categories of a raster map layer. The user can change these map category color assignments (i.e., change the map's color table) interactively, by first displaying the raster map to the graphics monitor and then running the program d.colors. If you have first set d.colormode to "float" before displaying the map to the graphics monitor, any color changes that you subsequently make while in d.colors will immediately (and interactively) appear on the graphics display. Otherwise, if d.colormode is "fixed," any color changes made using d.colors will not immediately be shown on the graphics display; however, any color changes saved will still alter the map's color table and will appear next time the raster map layer is redisplayed (see d.colormode and d.colorable). Note that some graphics display monitors or drivers cannot support interactive color change.

The user must first display the relevant raster map layer to the active frame on the graphics monitor (e.g., using d.rast or d.display) before running d.colors. The user can then either enter the name of the raster map layer whose color table is to be changed on the command line (e.g., by typing: d.colors map=sails), or type d.colors without program arguments. If the user simply types d.colors without program arguments on the command line, d.colors will ask the user to enter the name of an existing raster map layer using the standard GRASS interface described in the manual entry for parser.

In either case, the user is then presented with the d.colors command menu, shown below. This menu is the same as the category and color changing portion of the d.display menu. The d.colors commands are listed beneath the Category Pointer Movement, Color Modification, Replotting Screen, and Quitting sections below. Commands are invoked by typing in the single-key response shown to the left below. (Longer descriptions of these commands appear to the right.) Results from invoking these commands will be reflected in the Category and Category Number sections of the d.colors screen. On the d.colors screen menu, commands appear in the right half of the screen, and the current status of categories appears in the left half of the screen.

CATEGORIES

0  No Data
1  (Category 1 description)
2  (Category 2 description)
   ....
   ....

CATEGORY NUMBER:

RED  0  0%
GREEN 0  0%
BLUE  0  0%

Shift Incr: 10 3%

CATEGORY POINTER MOVEMENT

D/d down (cats)  Move pointer to next category
U/a up (cats)  Move pointer to previous category

COLOR MODIFICATIONS

R/r RED  Increase/decrease RED intensity
G/g GREEN  Increase/decrease GREEN intensity
B/b BLUE  Increase/decrease BLUE intensity
Changing categories - The keys d, D, u, and U are used to move to a different category. The lower case letters move up, u, and down, d, the category list one category at a time. The upper case letters move 10 categories at a time for fast movement. The cursor does wrap between the first and last categories. The current category is noted on the text screen with an arrow, and is indicated on the graphics screen by a box around the current color.

Changing colors - The color associated with the current category can be changed with the R, r, G, g, B, and b keys. The upper case letters increase the intensities of red R, green G, and blue B for the current category; the lower case letters decrease the intensities of these same colors for the current category. Video devices make all the colors of the spectrum by mixing red, green, and blue. For those accustomed to red, yellow, and blue being the primary colors, this can be confusing. For starters, yellow is made by mixing red and green. The intensities are listed on the text screen as percentages.

Keys I and i increase and decrease the percentage change that each keystroke of one of the color keys (R, r, G, g, B, b) causes in its respective color. The increase increment is initially set to 10%. Thus, pressing the R key will increase the red component of the current category by 10%.

Highlight - The h key toggles between the current category color and the current highlight color. This color is initially black but can be modified as above while in highlight mode. Blinking can be accomplished by repeatedly striking the h key. When changing to different categories using the movement keys as described above, while in highlight mode the category colors will be always left showing their actual colors. Only one category is highlighted at any one time.

Saving the current color table - Pressing the c key will save the current color table as you have modified it. This table will then be used next time you display or paint this raster map layer.

Color table toggle - Different types of color tables are suitable for different raster map layers. The key t flips between the following color tables: red, green, blue color ramp; gray scale; smooth changing color wave; random colors; and the saved color table.

Color table shift - The entire table is shifted up and down using the + and - keys.

Quitting the d.colors program - Pressing the Q key will cause you to quit the d.colors program. If colors have been modified but not saved, d.colors will ask:

Colors changed
Save the changes? (y/n)

The user should type in y to save changes, or n to not save changes, before quitting the program. If the user types n, the program will ask:

Quit anyway? (y/n)

NOTES

To see map color changes reflected on the display monitor as you make them, you must put the monitor in float color mode before running d.colors. It is also wise to erase the display screen after changing the color mode.
The map whose color table is to be altered with \texttt{d.colors} must already be on display in the active display frame on the graphics monitor before \texttt{d.colors} is run. This can be done using the command \texttt{d.rast map=\textit{name}} (where \textit{name} is a raster map layer whose color table the user wishes to alter).

The user might type the following sequence of commands to interactively change the colors of a raster \textit{soils} map:

\begin{verbatim}
d.colormode mode=float
derase
d.rast map=soils
d.colors
\end{verbatim}

After the user has saved any color changes made with \texttt{d.colors} and exited the program, the user could then redisplay the \textit{soils} map with the new colors by typing:

\begin{verbatim}
d.colormode mode=fixed
derase
d.rast map=soils
\end{verbatim}

Some color monitors may not support the full range of colors required to display all of the map's categories listed in the map's color table. However, regardless of whether the user can see the color changes the user is effecting to a map's color table, any changes to a map's color table made with \texttt{d.colors} that are saved will appear in the map's color table.

Some monitors may not support an interactive color change capability.

NAME
d.colortable – To display the color table associated with a raster map layer.
(Grass Display Program)

SYNOPSIS
d.colortable
d.colortable help
d.colortable map=name [color=name] [lines=value] [cols=value]

DESCRIPTION
The GRASS program d.colortable is used to display the color table associated with a raster map layer
in the active frame on the graphics monitor. The map name should be an available raster map layer in
the user's current mapset search path and location.

Parameters:
map=name Name of a raster map layer in the user's current mapset search path whose color
table is to be displayed.
color=name Color of the lines separating the colors of the color table.
Options: red, orange, yellow, green, blue, indigo, violet, gray, white, and black.
Default: white
lines=value Number of lines to appear in the color table.
Options: 1 - 1000
cols=value Number of columns to appear in the color table.
Options: 1 - 1000

If the values of both lines and cols are not specified by the user, d.colortable
divides the active frame equally among the number of categories present in the
named raster map layer. If one option is specified, the other is automatically set
to accommodate all categories. If both are specified, as many categories as
possible are displayed.

The user can specify all needed parameters on the command line using the form:

d.colortable map=name [color=name] [lines=value] [cols=value]

If the user specifies the name of a map on the command line but does not specify the values of other
parameters, parameter default values will be used. Alternately, if the user types simply d.colortable
on the command line without any program arguments, the program will prompt the user for parameter
settings using the standard GRASS parser interface described in the manual entry for parser.

EXAMPLE
The user running the command:

d.colortable map=soils color=red lines=1 cols=3

would see the active graphics frame divided into three columns extending the full frame height. The
lines dividing the color table associated with the soils map would be displayed in red. The user would
see, at most, only three of the colors from the soils color table displayed in the active frame (because
the user requested that this frame be divided into three sections).

NOTES
If the user wishes to display the entire color table associated with a map, the user should either stipulate
a number of lines (rows) and columns (cols) sufficient to accommodate the number of categories in the
map's color table, or fail to assign values to one or both of lines and/or cols. If the user runs d.colortable
using the default number of lines and columns (the full graphics frame), all categories
from the map's color table will be displayed. However, if the user requests that the color table
associated with a map that has ten data categories be displayed in a graphics frame with only three
lines (rows) and two columns (a total of six cells), only six of the ten map categories will be displayed.
The user should run the command `d.colormode mode=float` before running `d.colorable`, for accurate display of the map's color table.

The user should run the GRASS program `d.erase` between runs of `d.colorable` to avoid confusion.

AUTHOR
James Westervelt, U.S. Army Construction Engineering Research Laboratory
NAME

d.display – A menu-driven, highly interactive display program for viewing maps and producing final map products

(Grass Display Program)

SYNOPSIS

d.display

DESCRIPTION

The GRASS program d.display is used to display maps on a graphics monitor and prepare final map products for printing. It is advisable to first run d.erase before each run of d.display to prepare the screen for graphics.

After invoking the command d.display, the DISPLAY MAIN MENU appears on the monitor. Options in this and subsequent d.display menus are selected through use of the pointing device (mouse). When the mouse cursor is over the desired menu selection, the user simply presses any button on the mouse.

D.display is a macro that allows the user to access a wide range of GRASS display functions in a menu-driven and highly interactive environment. Most of the functions accessible through d.display can also be run independently of one another by running the GRASS display (d.) commands listed in the SEE ALSO section, below. However, in many cases, these other d. commands give the user greater flexibility and make available more options than are available through the d.display menus. For example, the d.display label file option runs the d.label command using defaults. Users running d.label directly from the command line have the choice of stipulating specific label background and text colors, as well as text sizes and font types. Users running the label file option through d.display cannot specify these options; instead, default values are used (see d.label for default values used).

The d.display tool is best learned by playing with its options. Refer to the individual d. and other commands in the SEE ALSO section for a detailed examination of these functions.

NOTES

The user can also modify the current region settings from the DISPLAY MAIN MENU. Using the mouse, the user can choose to zoom in on a portion of the displayed raster map layer to create a smaller geographic region. Once the user has defined the corners of this area using the mouse, the smaller area is enlarged and replotted on the screen. The user can similarly choose to zoom out. In this case, the user uses the mouse to encompass that portion of the reduced map that the user wishes to make the current geographic region and display in the center of the screen. The larger map is then replotted and displayed. Finally, the user can enter geographic coordinates for the region's corners from the keyboard using the GRASS command g.region. This is done by selecting the type coordinates option.

The main menu also offers the user the option of hiding the main menu for ten seconds (hide menu for ten seconds).

The d.display command must be run in conjunction with a program which converts the GRASS graphics commands generated by d.display to the graphics commands that the current device understands. This device will almost always be a graphics monitor. On most systems the user is required to start up this other program separately from (and prior to) d.display. In such cases, a locally-defined program, usually "monitor", is used (see your GRASS manager). (For example, on MASSCOMP machines, the d.mom program must be running in the foreground on the graphics monitor. On SUN machines, the d.mom program can be started from any terminal and run in the background.)

d.display sends program output to the current graphics frame (set, by default, to the full graphics screen unless modified by the user). You can use d.frame to create and choose a smaller display frame on the graphics monitor for use by d.display.

See the GRASS macro 3d.view.sh stored under GISBASE/scripts for an example of how you can create a d.display-like macro using a shell script.
SEE ALSO

See 3d.view.sh or slide.show.sh under $GISBASE/scripts for examples of d.display-like macros.

NAME

d.font - Selects the font in which text will be displayed on the user's graphics monitor.

(GRASS Display Program)

SYNOPSIS

d.font

d.font help

d.font font = name

DESCRIPTION

d.font allows the user to select use of a specific text font for display of text on the graphics monitor. The GRASS program show.fonts.sh is a UNIX Bourne shell macro which names and displays the fonts that can be selected using d.font. If the user does not specify a font when using other GRASS programs that display text, the font type romans is used by default.

The user can run this program either non-interactively or interactively. If the user specifies a font type name on the command line the program will run non-interactively. Alternately, the user can simply type d.font on the command line; in this case, the program will prompt the user for a display text font type using the standard GRASS interface described in the manual entry for parser.

Parameter:

font = name

Name of a font type, from among the font types italicized below.

Default: romans

Options: (italicized)
cyrilc - Cyrillic
gohtgbt - Gothic Great Britain triplex
gohtgrt - Gothic German triplex
gohtitt - Gothic Italian triplex

greekc - Greek complex
greecss - Greek complex script
greekp - Greek plain

greeks - Greek simple
itallc - Italian complex

italiccs - Italiam complex small

italicxt - Italic triplex

romanc - Roman complex

romans - Roman complcx smdall

romand - Roman duplex

romansp - Roman plain

romans - Roman simplex

roants - Roman triplex

riptc - Script complex

scripts - Script simpley

NOTES

The font type romans is the fastest font type to display to the graphics monitor.

James Westervelt, U.S. Army Construction Engineering Research Laboratory

d.font uses the public domain version of the Hershey Fonts created by Dr. A.V. Hershey while working at the U.S. National Bureau of Standards.
NAME

d.frame - Manages display frames on the user's graphics monitor.

(GRASS Display Program)

SYNOPSIS

d.frame

d.frame help

d.frame [cepsD] [frame=name] [at=bottom,top,left,right]

DESCRIPTION

This program manages display frames on the user's graphics monitor. GRASS display programs at run-time connect with graphics rendering programs. While the display programs are identical on every hardware platform, the graphics rendering programs are (essentially the only GRASS programs) designed for individual hardware devices. These rendering programs are managed with the GRASS program d.mon. Graphics are displayed in rectangular frames on whatever graphics monitor the user is currently directing GRASS display output to. These frames are created and managed with this program, Note that GRASS frame contents are not retained when one frame covers another. You cannot shuffle frames from top to bottom and then back again. They simply define rectangular areas on the screen where subsequent drawing will occur. d.frame.

Flags:

c= Creates a new display frame on the graphics monitor.

e Remove all existing display frames and reinitializes the entire graphics screen (the full-screen display frame).

-p Prints the name of the active frame, in which GRASS display output will appear.

-s Selects a frame for the display of GRASS graphics. This frame is then known as the "active frame."

-D Prints the status of the user's graphics monitor and active display frame to standard output. Information includes the name and the dimensions of the current frame on the graphics monitor, given in the form bottom top left right. This function is useful for debugging output, and for determining display screen coordinates.

Parameters:

frame=name The name of the display frame to be created/selected.

at=bottom,top,left,right Where to place the frame (implies -c). Frame coordinates are stated in the form: bottom,top,left,right. The lower-left corner of the graphics monitor always is at location 0,0 while the monitor's upper-right corner is always at 100,100.

NOTES

If the user has created multiple display frames that overlap one another, whatever the user displays in the active frame will overwrite those portions of the underlying frame where these frames overlap.

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
**NAME**

d.geodesic - Displays a geodesic line, tracing the shortest distance between two geographic points along a great circle, in a longitude/latitude data set.

*(GRASS Display Program)*

**SYNOPSIS**

d.geodesic

d.geodesic help

d.geodesic [coor=lon1,lat1,lon2,lat2] [tcolor=name] [lcolor=name]

**DESCRIPTION**

d.geodesic displays a geodesic line in the active frame on the user's graphics monitor. This line traces the shortest distance between two user-specified points on the curved surface of a longitude/latitude data set. The two coordinate locations named must fall within the boundaries of the user's current geographic region.

**COMMAND LINE OPTIONS**

This program can be run either interactively or non-interactively. If the user types d.geodesic on the command line without other program parameters, the mouse will be activated; the user is asked to use the mouse to indicate the starting and ending points of each geodesic line to be drawn. The default line color (white) and text color (red) will be used.

Alternately, the user can specify the starting and ending coordinates of the geodesic, line color, and text color on the command line, and run the program non-interactively.

Once the user indicates the starting and ending coordinates of the geodesic, the line and its length (in miles) are displayed to the user's graphics monitor.

**Parameters:**

- **coor=lon1,lat1,lon2,lat2**
  
  Starting and ending coordinates, in longitude and latitude values, of the geodesic line to be drawn.

- **lcolor=name**
  
  Line color in which geodesic will be displayed.
  
  Options: red, orange, yellow, green, blue, magenta, indigo, violet, gray, white, black
  
  Default: white

- **tcolor=name**
  
  Text color in which the length of the geodesic will be displayed.
  
  Options: red, orange, yellow, green, blue, magenta, indigo, violet, gray, white, black
  
  Default: red

**NOTES**

This program works only on GRASS data bases using a longitude/latitude coordinate system.

NAME

d.graph – Program for generating and displaying simple graphics to the graphics display monitor.

(GRASS Display Program)

SYNOPSIS

d.graph

d.graph help

d.graph [input=name] [color=name]

DESCRIPTION

d.graph draws graphics that are described either from standard input (default), or within a file (if an input file name is identified on the command line). If graphics commands are entered from standard input, a control-d is used to signal the end of input to d.graph.

The program can be run interactively or non-interactively. The user can run the program completely non-interactively by specifying the name of a graphics file containing d.graph graphics commands and the values of all needed parameters on the command line. The user can instead elect to run the program partially interactively, by specifying any/all of the parameters except the graphics file=name parameter on the command line. In this case, d.graph will expect the user to input d.graph graphics commands from standard input (i.e., the keyboard) and will (silently) prompt the user for these graphics commands.

Alternately, the user can simply type d.graph on the command line, and be prompted for the values of all parameters (the user can still input graphics commands from either an input file or standard input using this form). In this case, the user is presented with the standard GRASS parser interface described in the manual entry for parser.

Parameters:

file = name  Name of file containing graphics commands. This is a UNIX file name; the file must be located in the user’s current working directory or be specified by its full path name. If no filename is specified commands are taken from the standard input.

color = name  Starting color desired for graphics.

Options: red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, white, and black.

Default: white

The coordinate system used is 0-100 in x and 0-100 in y, regardless of the graphics monitor display frame size and aspect. The (0,0) location is the lower left corner of the active graphics monitor display frame. All values may be floating point.

The graphics language is simple, and uses the following commands:

# comment  A line of comment, which is ignored in the processing.

move xpos ypos  The current location is updated to xpos ypos. Values are stated as a percent of the active display frame’s horizontal (xpos) and vertical (ypos) size, and may be floating point values. Values are between 0-100. Note. A space must separate xpos and ypos.

draw xpos ypos  A line is drawn in the current color from the current location to the new location xpos ypos, which then becomes the current location. Values are stated as a percent of the active display frame’s horizontal (xpos) and vertical (ypos) size, and may be floating point values. Values are between 0-100. Note. A space must separate xpos and ypos.
color color
Sets the current color to that stated; subsequent graphics will be drawn in the stated color, until the current color is set to a different color. Options are red, orange, yellow, green, blue, indigo, violet, brown, magenta, gray, white, and black.

size xper yper
Subsequent text will be drawn such that the text is xper percent of the graphics monitor display frame wide and yper percent of the frame high. By default, the text size is set to 1 percent of the active frame’s width and 1 percent of the frame’s height if unspecified by the user (this may be too small to be seen by the user). Note. A space must separate xper and yper.

text line-of-text
The stated text is drawn at the current location using the current color, and the new current location is then positioned at the end of the text string.

icon type size x y
Draws an icon of types o, x, or + with specified size at location x,y. Note: type o designates a square.

polygon
xpos ypos
xpos ypos
....

The coordinates appearing beneath the word polygon, one pair per line, circumscribe a polygon that is to be filled with the current color.

EXAMPLE
For an example use of d.graph, examine the contents of the macro command $GISBASE/bin/grass.logo.sh, located in the GRASS command bin (which draws a GRASS logo by inputting d.graph graphics commands that are stored in a shell file). Note that the coordinates in the grass.logo.sh macro were taken directly off an image drawn by hand on graph paper.

NOTES
d.graph remembers the last screen location (xpos ypos) to which the user moved, even after the user erases the display frame. If the user runs d.graph repeatedly, and wishes to start anew with the default (xpos ypos) screen location, the user should clear the display frame between runs of d.graph.

LIMITATIONS
There are no automated ways of generating graphic images. It is anticipated that GRASS user sites will write programs to convert output from a resident graphics editor into GRASS d.graph format.

NAME

d.grid - Overlays a user-specified grid in the active display frame on the graphics monitor.

GRASS Display Program

SYNOPSIS

d.grid

Synopsis:

d.grid help

d.grid size=value [color=name] [origin=easting,northing]

DESCRIPTION

d.grid overlays a grid of user-defined size and color in the active display frame on the graphics monitor. The grid will overlay, not overwrite, the contents of the active display frame.

d.grid can be run non-interactively or interactively. If the user specifies the grid size and (optionally) the grid color on the command line the program will run non-interactively; if no grid color is given the default will be used. Alternately, the user may simply type d.grid on the command line; in this case, the program will prompt the user for parameter values using the standard GRASS user interface described in the manual entry for parser.

Parameters:

size=value Size of grid to be drawn in the active display frame, in current map coordinate system units. It should be noted that, depending on the scale of the map layer displayed in this frame, the grid may fall outside the user's viewing range.

Options: 0-100000

color=name Sets the current grid color to name.

origin=easting,northing Lines of the grid pass through this coordinate. The coordinate need not be within the current frame.

Options: red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, white, and black.

Default: gray

NOTES

d.grid will not erase grids already displayed in the active graphics display frame by previous invocations of d.grid; multiple invocations of d.grid will therefore result in the drawing of multiple grids inside the active graphics frame. (A command like d.erase, which erases the entire contents of the active display frame, must be run to erase previously drawn grids from the display frame.)

Currently, the grid size can only be drawn in the units of the map coordinate system used by the current GRASS location.

NAME  

d.his - Produces and displays a raster map layer combining hue, intensity, and saturation (his) values from user-specified input raster map layers.  

(Grass Display Program)

SYNOPSIS  
d.his  
d.his help  
d.his h_map=name [i_map=name] [s_map=name] [out=name]

DESCRIPTION  

his stands for hue, intensity, and saturation. This program produces a raster map layer providing a visually pleasing combination of hue, intensity, and saturation values from two or three user-specified raster map layers.

The human brain automatically interprets the vast amount of visual information available according to basic rules. Color, or hue, is used to categorize objects. Shading, or intensity, is interpreted as three-dimensional texturing. Finally, the degree of haziness, or saturation, is associated with distance or depth. This program allows data from up to three raster map layers to be combined into one new raster map layer that retains the original information in terms of hue, intensity, and saturation.

OPTIONS  

This program can be run non-interactively or interactively. It will run non-interactively if the user specifies on the command line the name of a map containing hue values (h_map), and the name(s) of map(s) containing intensity values (i_map) and/or saturation values (s_map). If the user also names an output map (out) on the command line, the combined hue, saturation, and intensity values will be saved as a raster map layer in the user's current mapset; otherwise, the resulting image will only be displayed in the active display frame on the graphics monitor. Alternatively, the user can run the program interactively by typing d.his without naming parameter values on the command line. In this case, the program will prompt the user for parameter values using the standard Grass parser interface described in the manual entry for parser.

Parameters:  

h_map=name Name of input raster map layer to be used for HUE values.  
i_map=name Name of input raster map layer to be used for INTENSITY values.  
s_map=name Name of input raster map layer to be used for SATURATION values.  
out=name Name of the output raster map layer combining hue, intensity, and saturation values from input layers.

While any raster map layer can be used to represent the hue information, map layers with a few very distinct colors work best. Only raster map layers representing continuously varying data like elevation, aspect, weights, intensities, or amounts can suitably be used to provide intensity and saturation information.

For example, a visually pleasing raster map layer can be made by using a watershed map for the hue factor, an aspect map for the intensity factor, and an elevation map for saturation. (The user may wish to leave out the elevation information for a first try.) Ideally, the resulting image should resemble the view from an aircraft looking at a terrain on a sunny day with a bit of haze in the valleys.

THE PROCESS  

Each map cell is processed individually. First, the working color is set to the color of the corresponding cell in the map layer chosen to represent HUE. Second, this color is multiplied by the red intensity of that cell in the INTENSITY map layer. This map layer should have an appropriate gray-scale color table associated with it. You can ensure this by using the color manipulation capabilities of d.display or d.colors. Finally, the color is made somewhat gray-based on the red...
intensity of that cell in the SATURATION map layer. Again, this map layer should have a gray-scale color table associated with it.

NOTES
This program produces an image and (optionally) a raster map layer with 1000 colors (10 intensities each of red, green, and blue). The resulting image and raster map layers will not display properly if the graphics display monitor does not have at least 1000 colors while the user is running in float colormode. Thus, unless the display device has 1000 colors, it is necessary to run the GRASS command

```
d.colormode mode=fixe;2
```

before running d.his. Otherwise, the colors will be incorrectly displayed on the graphics monitor.

Either (but not both) of the intensity or the saturation map layers may be omitted. This means that it is possible to produce output images that represent combinations of his, hi, or hs.

AUTHOR
James Westervelt, U.S. Army Construction Engineering Research Laboratory
**NAME**

**d.histogram** – Displays a histogram in the form of a pie or bar chart for a user-specified raster file.

(Grass Display Program)

**SYNOPSIS**

```
d.histogram
```

**DESCRIPTION**

**d.histogram** displays the category-value distribution for a user-specified raster map layer, in the form of a bar chart or a pie chart. The display will be displayed in the active display frame on the graphics monitor, using the colors in the raster map layer's color table. The program determines the raster file's category value distribution by counting cells.

**OPTIONS**

The user can run this program either non-interactively or interactively. The program will be run non-interactively if the user specifies the name of a raster map layer and (optionally) any other desired parameters and flags on the command line, using the form:

```
d.histogram [-zq] map=name [color=name] [style=name]
```

Options:

- **-z** Display zero-data information (cells with category value zero) in the histogram. If the -z flag is set, then cells with category value 0 in the named raster map layer will be included in the pie or bar chart. If this flag is not set, then cells with category value 0 will be excluded from the bar chart.

- **-q** Gather the histogram quietly, without printing messages on program progress to the user's terminal.

**Parameters:**

- **map=name** The name of an existing raster map layer in the user's current mapset search path for which a histogram is to be displayed.

- **color=name** The name of the color to be used for the axis, text-labels, and tic-marks on the pie or bar chart.

  Options: white, red, orange, yellow, green, blue, indigo, magenta, violet, brown, gray, and black.

  Default: **color=white**

- **style=name** The style of the histogram. If **style=bar**, then **d.histogram** will display the statistics in the form of a bar chart. If **style=pie**, then **d.histogram** will display the statistics in the form of a pie chart.

  Options: **bar** or **pie**

  Default: **style=bar**

**NOTES**

**d.histogram** uses the current geographic region settings and the current **mask** (if one exists).

**d.histogram** uses the colors in the map's color look-up table (i.e., the map's **colr** or **colr2** file). To view results correctly on the display monitor, make sure the color mode is correctly set before running **d.histogram** (i.e., set **d.colormode=float**).
\textit{d.histogram} does not erase the active frame before displaying output.

NAME
d.icons - Displays points, as icons, at user-defined locations in the active display frame on the graphics monitor.
(GRASS Display Program)

SYNOPSIS
d.icons
d.icons help
d.icons [-r] icon=name [color=name] [size=value] [points=name]

DESCRIPTION
d.icons graphically displays point (site) locations as icons in the active frame on the graphics monitor. Geographic coordinates are read either from standard input or from an input file whose name is stated by the user. At each site location, a user-defined icon is displayed.

OPTIONS
The user must enter at least the name of an icon file storing a graphic representation of the icon to be displayed, and the geographic coordinates of the points at which they will appear.

The user can run this program either non-interactively or interactively. The program will be run non-interactively if the user specifies the name of an icon file and (optionally) any other desired parameters on the command line, using the form:

d.icons [-r] icon=name [color=name] [size=value] [points=name]

If the user fails to specify the name of a points file on the command line, the program will prompt the user to enter geographic coordinates from standard input. If the user specifies at least the name of an icon file on the command line, any other parameter values left unspecified by the user will be set to their default values (see below).

Alternately, the user can simply type:

d.icons

on the command line, without program arguments. In this case, the user will be prompted for needed parameter values using the standard GRASS user interface described in the manual entry for parser. The geographic coordinates at which icons are to be displayed can still be input from an input file (points) in interactive use.

Flag:
-r Coordinates are input in reverse order (i.e., as northing easting).

Parameters:
icon=name The name of an existing file containing a graphic representation of the icon to be drawn. icon files can be created by the user using the p.icons command and are stored under the icons directory under the user's current mapset.

color=name Sets the current icon color to the name stated.
Options: red, orange, yellow, green, blue, indigo, violet, gray, white, and black
Default: color=white

size=value The icon scaling factor.
Options: 1-1000
Default: size=1

points=name The name of a UNIX file containing the geographic coordinates of sites at which icons are to be drawn. Since this is a UNIX file, the user should specify the name using standard UNIX file naming conventions. If this file is not in the user's current working directory, its pathname should be specified. The file contents
should consist of a series of geographic coordinates that fall within the boundaries of the current geographic region. Each site location should be stated on a separate line as an easting and northing (in that order) separated by a single blank space. If no points file is specified by the user, input is taken from standard input and should be given in the same form; to end standard input, type end (or press control-d).

EXAMPLE

An icons file contains a graphic representation of the icon to be displayed. Here, spaces represent areas of no color, and x's represent areas of color. For example, the user might construct an icon resembling a cross in the following way:

```
x
x
xxxxx
 x
 x
 x
 x
```

This icon might be stored in a file called cross (under the user's $LOCATION/icons directory). If the user specified that this be the icon file used while running d.icons, this cross would then appear in the color and size specified by the user, at each site location named in the points file.

Note: icons are created with the p.icons command.

The points file lists the geographic coordinates of site locations (at which icons will be displayed). This file should take the form:

```
easting northing
  
easting northing
  
easting northing
```

If the user sets the -r flag, the order of these coordinates should be reversed (i.e., coordinates should be given as northing easting).

If the points file is not specified, then the coordinates are read from the keyboard or across a pipe. This feature allows users to enter the coordinates by hand, or, more usefully, to get them from another program. For example, to display icons at locations specified in a sites list:

```
s.ott.asci name
```

```
d.icons icon=cross
```

where name is the name of a site list, and cross is the name of an icon.

NAME
d.label – Creates and displays text labels in the active display frame on the graphics monitor.
(GRASS Display Program)

SYNOPSIS
d.label
d.label help
d.label [size=value] [bgcolor=color] [textcolor=color] [font=font]

DESCRIPTION
d.label allows the user to create and display text labels in the active frame on the graphics monitor. It interactive requests that the user type in text and use the pointing device (mouse) to identify where this text is to be placed within the active graphics frame. The program will prompt the user for label size, background color, text color, and text font type, if the user fails to specify these values on the command line. Program prompts use the standard GRASS parser interface described in the manual entry for parser.

Parameters:
size=value Sets the label text size to the specified number. Values are stated as a percentage of the frame height; e.g., a size of 10 will make each line of text equal to one-tenth the height of the display frame.
Options: 0-1000
Default: 10
bgcolor=color Sets the color of the label background to the color stated.
Options: red, orange, yellow, green, blue, indigo, violet, gray, white, and black.
Default: black
textcolor=color Sets the color of the label text to the color stated.
Options: same as for bgcolor.
Default: white
font=font Sets the font type used for the label’s text to font.
Options: roman, romann, romanp, romans, scriptc, scripts, romansc, italicc, italics, gothic, gothgr, and gothgbt. The user can view these available fonts by running show.fonts.sh.
Default: romans (Roman simplex font type), or whatever font the user has set the font type to before entering d.label.

NOTES
This program will allow the user to display labels anywhere in the active display frame, even in areas lying outside of the current geographic region.
d.label will only allow the user to type in one line of text. The fully interactive program d.labels can be used to create text labels having as many as four lines.
d.label does not create paint labels files displayable by d.paint.labels -- d.labels does. These programs should be integrated in future GRASS releases.

BUGS
If the user is running GRASS under X Windows, and the user enters a text label longer than 80 characters (i.e., allows text to wrap onto a second line), X Windows will stop the user’s GRASS graphics monitor without throwing the user out of GRASS. If this happens, the user should simply restart a graphics monitor, using d.mon.

AUTHOR

James Westervelt, U.S. Army Construction Engineering Research Laboratory
NAME
d.labels – To create/edit GRASS paint label files for display on the graphics monitor.
(GRASS Display Program)

SYNOPSIS
d.labels

DESCRIPTION
The d.labels program allows the user to interactively create and modify paint-labels files for use with
the p.map and d.paint.labels programs. The paint labels files created will be stored in the user's
current mapset under the /paint/labels directory.
d.labels is fully interactive, and requires use of a graphics monitor. After the user has typed
d.labels
and has typed in the name of a new or existing paint-labels file, the user is asked to indicate label
positions on the display frame using the mouse-pointer, and to edit label parameters that define the
label's size, color, and other characteristics through use of a visual-ask (VASK) data entry screen. The
mouse can also be used to indicate the geographic coordinates of locations within the current
geographic region in the active frame. It is helpful to display a relevant data file in the active display
frame before running d.labels to provide visual clues for label placement.

USER PROMPTS
You will first be prompted to enter the name of either an old paint-labels file that you wish to modify,
or a new paint-labels file that you wish to create. The following is the file name prompt:

Enter the name of an existing labels file
Enter list for a list of existing labels files
Hit RETURN to cancel request
>

If you enter the name of a new (non-existent) paint-labels file, you are asked to indicate a location
falling within the current geographic region in the active display frame at which the label is to be
placed.

Mouse Buttons
Left: Place Label Here
Middle: Where Am I?
Right: Quit

Once you have indicated a position, you will be presented with a data-entry screen (also known as a
VASK screen) so that you can enter the paint-label parameters that define how the label will appear on
the display or on the color printer. Once you finish entering the label-parameters, and you hit the
<ESC> key to proceed, the label will be displayed on the screen. If you like the appearance of the
label, enter "y" to the "Look OK?" prompt; if not, enter "n" and you will again be presented with the
data entry screen. Once you approve the label's appearance, you will be asked to indicate the position
of the next label.

If you choose to display an already-existing paint-labels file, you will be shown the labels in that file
one at a time. For each label, you will be asked: "Look OK?" If you answer "n" to the "Look OK?"
prompt, you will be presented with the data entry screen so that you may modify the appearance of the
label to your liking.

On-line help is available. If you are puzzled about what should go in a data entry field, just enter
"help" in that field, hit the <ESC> key, and you will be presented with a short description of the field
and what you may enter.
The following is a list of the different fields in the data entry screen and a short description of each.

**TEXT**: The user can enter up to four lines of text.

**SKIP**: yes/no. If no, label will be printed. If yes, the label will be retained in the file but not printed.

**LOCATION**: Determines where the text will be located. The user specifies the easting and northing in map units, and (optionally) specifies a vertical and horizontal offset (in printer pixels) from the specified easting/northing. (The vertical (y) offset will shift the location to the south if positive, north if negative. The horizontal (x) offset will shift the location east if positive, west if negative.) These offsets are provided to allow linear placement of labels.

**RESET LOCATION**: yes/no. If yes, the user will be allowed to use the mouse to select a new location for the label. The mouse buttons will function as follows:

Mouse Buttons
Left: Place Label Here
Middle: Where Am I?
Right: Quit

**PLACEMENT**: Determines which part of the label to which the location refers. This may be specified as:

- lower left (lower left corner of the text)
- lower right (lower right corner of the text)
- lower center (bottom center of the text)
- upper left (upper left corner of the text)
- upper right (upper right corner of the text)
- upper center (top center of the text)
- center (center of the text)

**TEXT SIZE**: Determines the size of the lettering used in the label. Text size (height) is stated in units of (ground) meters; e.g., a text size of 500 sets the height of each line of text equal to 500 ground meters. Thus, text will appear to grow or shrink when displayed, depending on the user’s current geographic region settings.

**TEXT COLOR**: This selects the text color. This color can be specified in one of three ways:

1) By color name:
   - aqua black blue brown cyan gray green grey indigo magenta orange purple red violet white yellow

2) As red, green, blue percentages. For example: .5 .4 .7
   (This form is not supported by d.paint.labels, but see p.map and p.labels.)

3) By printer color number, to get the exact printer color.
   (This form is not supported by d.paint.labels, but see p.map and p.labels.)
Note. If the user sets the text color equal to the background color, the text will not appear on the graphics monitor.

**WIDTH:** This determines the line thickness of the letters. The normal text width should be set to 1. Larger numbers can be used to simulate bold face. (*d.paint.labels* ignores this value and always uses 1.)

**HIGHLIGHT COLOR:** The text can be highlighted in another color so that it appears to be in two colors. The text is drawn first in this color at a wider line width, and then redrawn in the text color at the regular line width. Highlight colors are not shown on the graphics display, they are only shown in the output from *p.labels* and *p.map.*

**HIGHLIGHT WIDTH:** Specifies how far from the text lines (in pixels) the highlight color should extend. Highlight colors are not shown on the graphics display, they are only shown in the output from *p.labels* and *p.map.*

**BACKGROUND COLOR:** Text may be boxed in a solid color by specifying a background color (see **TEXT COLOR** above to specify a color). Specify *none* to use no background.

**OPAQUE TO VECTORS:** *yes/no.* This field only has meaning if a background color is selected. *yes* will prevent vector lines from entering the background. *no* will allow vector lines to enter the background.

**BORDER COLOR:** Select a color for the border around the background. Specify *none* to suppress the border.

**NOTES**

This program is fully interactive and requires no command line arguments.

If the user types the word *help* in a data entry field while entering label information, acceptable field choices will be listed.

Labels must be placed within the current geographic region. If the user attempts to place a label outside of this region, the program will appear to loop endlessly. It is simply failing to display a label positioned beyond the boundaries of the current region; in this event, the user should simply reposition the label.

Labels created by this program are stored in ASCII files under the directory $LOCATION/paint/labels.

d.legend - Displays a legend for a raster map layer in the active frame on the graphics monitor.

(GRASS Display Program)

SYNOPSIS

d.legend
d.legend help
d.legend map=-ane [color=-name] [lines=value]

DESCRIPTION

d.legend displays a legend for a user-specified raster map layer in the active frame on the graphics
monitor. The legend's size is based on the height of the active frame. The user should therefore take
care to create a display frame of suitable dimensions before running d.legend. d.legend will only
obscure those portions of the active frame that directly underlie the legend.

The user can run d.legend either non-interactively or interactively. If the user specifies the name of a
raster map layer on the command line, the program will run non-interactively. Default legend text
color and number of lines will be used unless the user specifies other values on the command line.

Alternately, the user can simply type d.legend on the command line; in this case, the program will
prompt the user for parameter values using the standard GRASS parser interface described in the
manual entry for parser.

Parameters:

map=-name Name of a raster map layer whose legend is to be displayed in the active display
frame.

color=-name Sets the legend text color to the name stated.
Options: red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray,
white, and black.
Default: white

lines=value Number of lines to appear in the map legend.
The number of lines refers to the maximum number of lines of type that can be
displayed given the height of the active display frame. If unspecified by the user,
the program will divide the display frame into the number of lines required to
display all of the category labels and colors associated with the named map. To
decrease the size of the displayed text, increase the number of lines.
Options: 1 - 1000
Default: Set lines value equal to the number of map categories

NOTES

The legend text size is based on the number of lines requested (or, by default, on the number of lines
needed to display the legend). If the user attempts to display a very long legend in a relatively short
display frame, the legend may appear in unreadably small text.

NAME
d.mapgraph - Generates and displays simple graphics on map layers drawn in the active graphics
monitor display frame.
(GRASS Display Program)
SYNOPSIS
d.mapgraph
d.mapgraph help
d.mapgraph [input=\text{name}] [color=\text{name}] [vsize=\text{value}] [hsize=\text{value}]
DESCRIPTION
d.mapgraph draws graphics that are described in standard input (default) or the UNIX input file \text{name}.
If commands are entered via standard input, a \text{ctrl-d} is used to signal the end of input to d.mapgraph.
This program performs essentially the same function as d.graph; however, point locations are specified to d.mapgraph in the geographic coordinate system of the user's current mapset and location (i.e., in
map coordinates), rather than in graphics display screen coordinates.
The program can be run interactively or non-interactively. The user can run the program completely
non-interactively by specifying the name of a file containing d.mapgraph graphics commands and the
values of all needed parameters on the command line. The user can instead elect to run the program
partially interactively, by specifying any/all of the parameters except the graphics input=\text{name}
parameter on the command line. In this case, d.mapgraph will expect the user to input d.mapgraph
graphics commands from standard input (i.e., the keyboard) and will (silently) prompt the user for these
graphics commands. Alternately, the user can simply type d.mapgraph on the command
line, and be prompted for the values of all parameters (the user can still input graphics commands from an input file
using this form.) In this case, the user is presented with the standard GRASS parser interface described
in the manual entry for parser.
Parameters:
\begin{description}
\item[\text{input=\text{name}}] Name of a UNIX file containing graphics instructions. Specify the full path name
of the file if not in the current directory. If no file name is given, commands are
taken from standard input.
\item[\text{color=\text{name}}] Starting color desired for graphics.
Options: red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray,
white, and black.
Default: white
\end{description}
d.mapgraph is used for drawing simple graphics on top of map layers. The coordinate system used by
d.mapgraph is the same as that of the map layer displayed in the active display frame on the graphics
monitor (or that of the user's current region, if no map is displayed).
The graphics language is simple and uses the following commands:
\begin{itemize}
\item \textbf{# comment} \texttt{\# comment} A line of comment which is ignored in the processing.
\item \textbf{move} \texttt{xpos ypos} \texttt{move xpos ypos} The current location is updated to \texttt{xpos ypos} (where these, respectively, are the easting and
northing of geographic coordinates stated in the map coordinate system of the user’s current
GRASS location, falling within the current region and active frame). If unspecified by
the user, the current location becomes \texttt{(0,0)}. If, as most likely, the point \texttt{(0,0)} falls outside of the
user’s current region, graphics drawn there will not appear in the graphics frame.
Note: use \texttt{g.region} to obtain the coordinates of current location. Use \texttt{d.where} to obtain
specific map coordinates of various points on the raster map displayed in the active frame.
Note: there must be a space between \texttt{xpos} and \texttt{ypos}.
\item \textbf{draw} \texttt{xpos ypos} \texttt{draw xpos ypos} A line is drawn in the current color from the current location to the new location \texttt{xpos ypos},
which then becomes the current location. \texttt{xpos} and \texttt{ypos} are (respectively) an easting and
nothing stated in the map coordinate system of the user's current GRASS location, and located within the user's current geographic region and active frame.

Note: there must be a space between \( x_{pos} \) and \( y_{pos} \).

color \( color \)

Sets the current color to that stated. Color options are: red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, white, and black.

size \( x_{per} \) \( y_{per} \)

Subsequent text will be drawn such that the text is \( x_{per} \) percent of the display frame's width and \( y_{per} \) percent of the display frame height. If not specified by the user, the text size becomes 5% of the active frame’s width and 5% of the frame’s height. This is equivalent to entering size 5 5.

text \( line-of-text \)

The stated text is drawn at the current location using the current color and the current size.

icon \( type \) \( size \) \( x \) \( y \)

Draws an icon of types o, x, or + with specified size at location \( x,y \). Note: type o designates a square.

polygon

\( x_{pos} \) \( y_{pos} \)

\( x_{pos} \) \( y_{pos} \)

. .

. .

The map coordinates appearing on lines beneath the word polygon, one pair per line, circumscribe a polygon which is to be filled with the current color.

NOTES

d.mapgraph is identical to the d.graph command, except for the difference in coordinate systems used. d.mapgraph will complain if the user enters something to standard input that it does not understand. Blank lines in the input file will result in this error message.

AUTHOR

James Westervelt, U.S. Army Construction Engineering Research Laboratory
NAME

d.measure – Measures the lengths and areas of features drawn by the user in the active display frame on the graphics monitor.

(GRASS Display Program)

SYNOPSIS

d.measure
d.measure help
d.measure [c1=name] [c2=name]

DESCRIPTION

d.measure provides the user with an interactive way to measure the lengths and areas of lines and polygons drawn by the user in the active frame on the graphics monitor. Lines and polygons are drawn using a pointing device (mouse). Each line segment is drawn in colors c1 and c2. A mouse button menu indicates that the user can find out the geographic coordinates of the cursor location, draw line segments between user-specified vertices, and quit d.measure. Lines and polygons are defined by the series of vertices marked by the user. If more than two successive vertices are drawn, d.measure prints the area encompassed (d.measure will assume the area is closed even if the user has not joined the first and last vertices). Line lengths are stated in the same units as those of the current LOCATION. Areas are stated in hectares, square miles, and square meters.

Lines and polygons drawn using d.measure will overlay (not overwrite) whatever display currently appears in the active frame on the graphics monitor. The user can, for example, run d.rast or d.vect prior to running d.measure, and use raster and/or vector maps as a backdrop.

OPTIONS

The user can specify the colors in which line segments will be drawn by setting the values of c1 and c2 on the command line. Default line colors (see below) will be used if the user does not specify the values of c1 and c2 on the command line.

Parameters:

**c1=name**

The first color in which each line segment is drawn, while being positioned.
Options: red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, white, and black
Default: white

**c2=name**

The second color in which each line segment is drawn, after its vertices are fixed.
Options: Same as c1.
Default: white

NOTES

d.measure uses all segments drawn by the user when computing area. If the user draws an area within another area, the combined area of both regions will be output.

NAME

*d.menu* - Creates and displays a menu within the active frame on the graphics monitor.

*(GRASS Display Program)*

SYNOPSIS

```bash
d.menu

d.menu help

d.menu [bcolor=name] [tcolor=name] [dcolor=name] [size=value]
```

DESCRIPTION

*d.menu* allows the user to create a menu containing a title and options, and to display this menu in the active frame on the graphics monitor. After the menu is displayed in the active frame, the pointing device (mouse) is activated and must be used to select one of the menu options. The number associated with the selected menu option is then printed to standard output and the program exits. This program provides GRASS macro writers with a mouse interface for users.

Parameters can be stated on the command line, from within standard input, or (as illustrated in EXAMPLE) from within a script file.

The user can specify the menu's background, text, and line colors (*bcolor*, *tcolor*, and *dcolor*) and the menu size (*size*) on the command line. If the user sets at least one of these values on the command line, any remaining values that are not specified on the command line will be set (automatically) to their default values (see below). Alternately, the user can simply type *d.menu* on the command line; in this case, the program will prompt the user for the menu colors and text size using the standard GRASS parser interface described in the manual entry for *parser*. The user will then be (silently) prompted to enter the menu's location and contents through standard input (see Menu Information, below).

Parameters:

- **bcolor=name**: Sets the color of the menu background (the rectangle on which the text sits).
  - Options: red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, white, and black.
  - Default: *black*

- **tcolor=name**: Sets the color of the menu text.
  - Options: Same as those for *bcolor*.
  - Default: *white*

- **dcolor=name**: Sets the line color used to divide text lines in the menu.
  - Options: Same as those for *bcolor*.
  - Default: *white*

- **size=value**: Sets the menu's text size to the specified value. Sizes are stated as percentages of the height of the active graphics display frame.
  - Options: 1 - 100
  - Default: 3 (i.e., 3%)

Menu Information:

After the user has (optionally) specified menu colors and size, the program expects the user to enter information about the menu's location and content. The menu will be placed in the lower left corner of the active display frame by default if the user does not position it elsewhere using the .T or .J commands.

The user specifies the menu contents by typing in a menu title followed by the option choices to appear in the menu when displayed. The user *must* enter a menu title and at least one menu option.
.T value

Specifies the menu's distance from the active display frame's top edge (as a percentage of the active frame's height).

Note: Not required

.L value

Specifies the menu's distance from the active display frame's left edge (as a percentage of the active frame's width).

Note: Not required

menu title

A title that describes the type of options listed in the menu, and that will appear at the top of the menu when it is displayed.

option name(s)

The options that will appear in the menu when displayed. Each menu option should appear on a separate line. The user may enter as many options as desired, but must enter at least one menu option.

Note: The user should choose a menu size and location that will allow all menu options to be displayed in the active frame.

If the user enters the menu title and option(s) from standard input (i.e., at the keyboard rather than from a file), the user should enter control-d to end input and display the menu in the active frame on the graphics monitor. (Note: The d.menu program can also be incorporated into UNIX Bourne shell script macros. The below example shows how this might be done.)

EXAMPLE

In the following example, the shell script menu2 calls the shell script color.select, which contains d.menu commands to display a menu in the current frame on the graphics monitor. After the user selects an option from the display menu, the selection number is available for use by menu2.

Contents of file menu2:

```csh
#!/bin/csh -f
set option = 0
set colors = (red green blue black white)
set option = `color.select`
if ($option <= 5) then
    set color = $colors[$option]
    echo $color
    exit
endif
exit
```

Contents of file color.select:

```csh
#!/bin/csh -f
d.menu bcolor=red tcolor=green dcolor=yellow size=5 <<EOF
.T 25
.L 25
Color Choices
Option 1
Option 2
Option 3
Option 4
Option 5
EOF
```

If the user runs menu2, a menu will be displayed on the graphics monitor that has red background, green text, with menu options divided by yellow lines, and a text size of 5% of the active display frame height. The mouse cursor will become active, allowing the user to select (by pointing with the mouse) one of the displayed menu options. Here, these menu options are called Option 1, Option 2, and
Option 3, etc. The first line of text (here, the words Color Choices) contains the title of the menu; this line is not a menu option that can be chosen by the user with the mouse. When the user presses one of the mouse buttons while pointing to the desired menu choice, the number of the option chosen will be available for capture by the shell script menu2. menu2 is a simple example that takes this information and only echoes it to the screen.

NOTES
Although the user can vary text size, all text within the same menu is displayed in a single text size (and font). If the user specifies that items included in the menu's text be displayed in different sizes, all text will be displayed in the size stated last.

NAME

d.mon - To establish and control use of a graphics display monitor.

(Grass Display Program)

SYNOPSIS

d.mon
d.mon help
d.mon [-ILprs] [start=name] [stop=name] [select=name] [unlock=name]

DESCRIPTION

The GRASS program d.mon allows the user to start, select, list, query the status of, release control of,
stop, and unlock control of, available graphics monitors. The user can run this program either
interactively (through a series of menus), or non-interactively by typing the name of the monitor to
start, stop, select, or unlock, and any desired flags on the command line.

Flags:

-I List all monitors
-L List all monitors (with current status)
-p Print name of currently selected monitor
-r Release currently selected monitor
-s Do not automatically select when starting

Parameters:

start=name Name of graphics monitor to start
stop=name Name of graphics monitor to stop
select=name Name of graphics monitor to select
unlock=name Name of graphics monitor to unlock

When the user enters the command d.mon without specifying parameter values,
the below menu appears on the screen:

MONITOR MENU

Making sure that the graphics monitor is running:

1 - Start a graphics monitor
   (also automatically selects this monitor)
2 - Stop a graphics monitor

Choosing a graphics monitor for your graphics:

3 - Select a graphics device for output
   (currently selected monitor: name)
4 - Release control of the graphics driver
   (let someone else use it)
   (option 4 appears only after selection of a monitor)

RETURN quit
These parameters perform the following functions:

1 **Start a Monitor**.
   In order to display on-screen GRASS graphics, the user must **start** and **select** a graphics monitor. By default, the **start** command actually runs two commands, to both start and select whatever monitor is named by the user. (The user can get a list of available monitors by setting the `-1` or `-1` flag on the command line.)

   When a monitor is started, it is therefore also (automatically) **selected** for output, unless the `-s` flag is set by the user; the user can also explicitly **select** a monitor that has been started (see (3) below). After a monitor is started, a blank graphics frame should appear on whatever terminal the user is using to display graphics.

   The desired monitor should be started once and need not be restarted unless it is stopped (option 2) for some reason. A monitor may continue to run for any length of time, even when no GRASS session is being run. The monitor program runs in the background.

2 **Stop a Monitor**.
   Sometimes the monitor program needs to be stopped (terminated). Choosing option 2 will terminate a user-specified monitor program.

   A graphics monitor has two different types of status: monitor program **not running**, and monitor **running**. A monitor that has been started and/or selected will be listed as running; a monitor that has been stopped (or not started) will be listed as not running. The `-l` (list status) flag will list the status of each monitor connected to the system.

3 **Select a Monitor**.
   When the user starts a monitor, it is also (automatically) **selected** for graphics output unless the user sets the `-s` flag. In order to use (direct graphics output to) a monitor, the user must **select** that monitor for use, either by simply starting the monitor without the `-s` flag or by explicitly selecting the monitor for output using option 3. Only running monitors can be selected for graphics output. Once the user has selected a monitor for output, no other user can use this monitor for graphics output until the monitor driver is either **released** (by the user) or **unlocked** (by any user on the system).

   The user can run multiple graphics monitors by simply starting each of the graphics monitor drivers he wishes to direct output to.

4 **Release a Monitor**.
   Once a user has selected a monitor for graphics output, it is locked for use by that user until either: (1) the user voluntarily releases control of the monitor for use by another (option 4), or (2) another GRASS user unlocks the user's control of the monitor. Menu option 4 appears only to the person who has selected the monitor (since only that user can release control of his selected graphics monitor.) If another user wishes to **unlock** the user's control of the monitor, that user must run `d.mon` from the command line and set the unlock=`name` parameter.

   You may choose multiple options within the `d.mon` program. To leave (exit) the `d.mon` menu, press the <RETURN>-key.

**NOTES**

The `d.mon` program can regulate control of graphics monitors both in systems using multiple monitors and in systems using a single graphics monitor.

NAME

d.pain.labels – Displays text labels formatted for use with GRASS paint (p.labels, p.map) output to
the active frame on the graphics monitor.

(GRASS Display Program)

SYNOPSIS

d.paint.labels

d.paint.labels help

d.paint.labels file=\textit{name}

DESCRIPTION

d.paint.labels displays the \textit{paint} label file \textit{name} in the active display frame on the graphics monitor.
This file can be generated by the \textit{labels} option in the \textit{p.labels} program, the \textit{d.labels} program, or
simply created by the user as an ASCII file (using a text editor like \textit{vi}) and placed in the appropriate
\textit{/paint/labels} directory under the user's current mapset and location
(i.e., under $\text{LOCATION/paint/labels}$).

OPTIONS

Parameter:

file=\textit{name}  Name of ASCII file containing paint labels.

This program can be run either non-interactively or interactively. If the user specifies the name of a
paint labels file on the command line, the program will run without interacting with the user.
Alternately, the user can type simply \texttt{d.paint.labels} on the command line; in this case, the program
will prompt the user for the name of a paint labels file using the standard GRASS parser interface
described in the manual entry for \texttt{parser}.

NOTES

Some of the information stored in the label file is unused by \texttt{d.paint.labels}. The unused information
found in a label file is printed to standard output. This extra information is used by such programs as
\texttt{p.labels} and \texttt{p.map}.

SEE ALSO

\texttt{d.display, d.font, d.label, d.labels, d.text, d.title, p.labels, p.map} and \texttt{parser}

James Westervelt, U.S. Army Construction Engineering Research Laboratory
NAME

d.points – Displays point graphics in the active frame on the graphics display monitor.
(GRASS Display Program)

SYNOPSIS

d.points

d.points help

d.points [color=name] [size=value] [type=name] [file=name]

DESCRIPTION

d.points displays points whose coordinate locations are specified by the user and located within the current geographic region in the active display frame on the graphics monitor. Point coordinates are read either from standard input or from a file stated by the file=name option. When entering coordinates through standard input, the user presses control-d to signal the end of input to d.points.

The program can be run interactively or non-interactively. The user can run the program completely non-interactively by specifying the name of a points file (containing the geographic coordinates of icons to be sited) and the values of all needed parameters on the command line. If the name of an input file to d.points is given on the command line, any other parameter values left unspecified on the command line (e.g., the icon color, size, and/or type) are set to their default values.

The user can instead elect to run the program partially interactively, by specifying any/all of the parameters except the points file=name parameter on the command line. In this case, d.points will expect the user to enter icon locations from standard input (i.e., at the keyboard) and will (silently) prompt the user for these locations. Each icon location should be entered as an easting and northing pair separated by a space, followed by a carriage return. Coordinates should be stated in whatever map coordinate system is used by the user’s current GRASS location. The user presses control-d to signal the end of standard input to d.points.

Alternately, the user can simply type d.points on the command line, and be prompted for the values of all parameters (the user can still input icon coordinates from an input file using this form). In this case, the user is presented with the standard GRASS parser interface described in the manual entry for parser.

Parameters:

color=name Sets the current color to the name stated.
Options: red, orange, yellow, green, blue, indigo, violet, gray, white, and black
Default: gray

size=value Size of icon in pixels.
Options: 0-1000 (pixels)
Default: 5 (pixels)

type=name Sets the shape (type) of the icon to be drawn to name.
Options: x, diamond, box, +
Default: +

file=name Take input from the UNIX file name. (Note: This file must be in the user’s current directory or given by its full path name.)
Default: Standard input.
The file contents should consist of a series of geographic coordinates that fit within the boundaries of the current geographic region falling within the active display frame (refer to d.where or g.region for these coordinates). Each icon location should be specified by an easting and northing (in that order) separated by a single blank space, and followed by a carriage return. Eastings and northings should be stated in whatever map coordinate system is being used by the user’s current GRASS location.
d.points  

NOTES

d.points will display a point at the location specified in the active frame, even if the point lies outside the boundaries of the current geographic region.

SEE ALSO

d.frame, d.where, d.sites, g.region, s.out.ascii, and parser

AUTHOR

James Westervelt, U.S. Army Construction Engineering Research Laboratory
NAME  
*d.profiile* - Displays profiles of a user-specified raster map layer.  
(Grass Display Program)

SYNOPSIS  
d.profiile

DESCRIPTION  
This command works only interactively. It clears the entire graphics screen and provides a graphical interaction allowing the selection of transects for which profiles are then generated.

USER PROMPTS  
First, you will be presented with a prompt asking you to choose a raster map layer to be profiled. Once you specify a valid raster map layer name, the map layer will be displayed in the left half of the graphics display, and the right half of the display will be divided into four display frames. There will also be two frames along the top of the display: a mouse-button menu frame on the left, and a status frame on the right.

The mouse-button menu initially offers you three options:

Mouse Buttons:  
Left: Where am I?  
Middle: Mark FIRST Point of Profile Line.  
Right: QUIT this.

You may query the displayed raster map layer by indicating points with the left mouse-button. The coordinates and category value of each point that you indicate will be displayed on in the status frame. If you mark the first point of the profile line you will be presented with the following mouse-button menu:

Mouse Buttons:  
Left: Where am I?  
Middle: Mark SECOND Point of Profile Line.  
Right: QUIT this.

Once you mark the second point of the profile line, the profile line will be labeled (with a letter from A to D) and displayed in one of the four display frames on the right hand side of the screen. You will then be presented with a third mouse-button menu:

Mouse Buttons:  
Left: DO ANOTHER  
Middle: CLEAR DISPLAY  
Right: QUIT this.

If you would like to view another profile, click on the left mouse-button. If you would like to redisplay the raster map layer and clear out the four profile frames, click on the middle mouse button. If you would like to quit, then click on the right button.

NOTES  
Useful enhancements to *d.profiile* would include:

1) Adding an option to display profiles using category colors, like a bar chart.
2) Allowing profile lines to be defined by a series of points, not just two.
3) Allowing profiles to be saved in a file, for later viewing.
4) Allowing the user to enter profile line points by typing coordinates.

NAME

d.rast - Displays and overlays raster map layers in the active display frame on the graphics monitor.

(GRASS Display Program)

SYNOPSIS

d.rast

d.rast help

d.rast [-o] map=name

DESCRIPTION

d.rast displays the raster map layer \textit{name} in the active display frame on the graphics monitor.

The program can be run either non-interactively or interactively. If the user specifies the name of a
raster map layer (\texttt{map=name}) and (optionally) the \texttt{-o} option on the command line, the program will run
non-interactively. Alternatively, the user can type simply \texttt{d.rast} on the command line; in this case, the
program will prompt the user for the flag setting and parameter value using the standard GRASS parser
interface described in the manual entry for \texttt{parser}.

Flag:

\textbf{-o}

Overlay the named raster map layer onto whatever is already displayed in the active
graphics frame. Any zero category value data areas in the named raster map will seem
transparent, and reveal the underlying image previously displayed in the graphics frame.
If the \texttt{-o} flag is set, only cells containing non-zero category values will be displayed
from the overlaid raster map. All other areas (i.e., the portions of the overlaid map
that contain category value zero) will leave the underlying display untouched. If the \texttt{-o}
flag is not set by the user, \texttt{d.rast} will (by default) completely overwrite whatever
appears in the active graphics display frame.

Parameter:

\texttt{map=name}

Name of the raster map to be displayed. If the active graphics frame already contains
text or graphics, and the user does not wish to use the \texttt{-o} option, it is wise to first invoke \texttt{d.erase}
to clear the active graphics frame before running \texttt{d.rast}. After running
\texttt{d.rast}, other \texttt{d}. programs like \texttt{d.vec} and \texttt{d.grid} can be used to enhance the plot.

NOTES

The \texttt{d.rast} raster map overlay option (\texttt{-o}) only works when the color look-up table for the graphics
monitor is set to \texttt{d.colormode fixed}.

NAME

`d.rast.arrow` - Draws arrows representing cell aspect direction for a raster map layer.

(GRASS Display Program)

SYNOPSIS

```
d.rast.arrow

d.rast.arrow help

d.rast.arrow [map=name] [type=name] [arrow_color=name] [grid_color=name]
[x_color=name] [unknown_color=name]
```

DESCRIPTION

`d.rast.arrow` is designed to help users better visualize surface water flow direction, as indicated in an aspect raster map layer. There are two ways to specify the aspect layer the program is to use. The first is to display the aspect map layer on the graphics monitor before running `d.rast.arrow`. The second method involves setting the `map` parameter to the name of the desired aspect map. This allows the arrows to be drawn over any other maps already displayed on the graphics monitor.

`d.rast.arrow` will draw an arrow over each displayed cell to indicate in which direction the cell slopes. An arrow can point in one of eight directions. If the aspect layer has a category value denoting locations of "unknown" aspect, `d.rast.arrow` draws a question mark over the displayed cells of that category. Cells of category 0 (no data) will be marked with an "X".

COMMAND LINE OPTIONS

Parameters:

- **map=name**
  Name of an existing raster map layer to be displayed.

- **type=name**
  Type of existing raster data to be displayed.
  Options: grass, agnps, answers
  Default: grass
  Using this information, `d.rast.arrow` uses internal information to convert category values into appropriate arrow directions.

- **arrow_color=name**
  Color in which arrows will be drawn.
  Options: white, red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, black
  Default: green

- **grid_color=name**
  Color in which grid outlines will be drawn.
  Options: white, red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, black
  Default: gray

- **x_color=name**
  Color in which x’s will be drawn.
  Options: white, red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, black
  Default: white

- **unknown_color=name**
  Color in which unknown information will be displayed.
  Options: white, red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, black
  Default: red

NOTES

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

NAME

d.rast.edit - Program allowing users to interactively edit the cell category values of raster map layers displayed on the graphics monitor.

(GRASS Display Program)

SYNOPSIS

d.rast.edit
d.rast.edit help
d.rast.edit [grid_color=name]

DESCRIPTION

The d.rast.edit program allows users to interactively edit cell category values in a raster map layer displayed to the graphics monitor using a mouse cursor. This program determines the name of the raster map layer currently displayed in the active frame on the selected graphics monitor (if none, program will abort). The user is then prompted for the name of a new raster layer to be created in his mapset. d.rast.edit does not modify the user's original raster map layer.

OPTIONS

Parameter:

grid_color=color Sets the color to be used for a grid drawn during edit mode. A well-selected grid color helps to identify individual cells in the output.

Options: red, orange, yellow, green, blue, indigo, violet, gray, white, and black

Default: black

Geographic Region Concerns

d.rast.edit reads the region definition for the raster map layer being edited from its cell header file. The new, edited copy of the raster layer will be created with the same resolution and region dimensions. If the current region resolution does not match the raster map layer’s resolution, the program will abort. The north, south, east, and west geographic region settings of the current region can be set to any view, as long as they fall within the boundaries of the raster map layer described in its cell header. This is important, since the current view must be such that individual cell locations are easily visible and sufficiently large on the graphics monitor to be pointed at with the mouse cursor. Any mask in place will be ignored when writing the new raster map layer.

Mouse Menus

Cell editing is done using a mouse cursor to choose menu selections and indicate areas on the displayed raster map that are to be edited.

Main Menu options and subsequent functions and sub-menus are described below:

1) Edit

invokes edit mode, during which no graphic menus are used, so that none of the displayed map is hidden. At the start of the edit mode, a grid is drawn over displayed cells to help distinguish cell boundaries. Users can select the color of this grid by setting the grid_color parameter. Interaction with the program during edit mode is done by using the three mouse buttons as follows:

Left Button

what's here. Identify the category value of the cell under the mouse cursor when the button is pressed. The category value of this cell is printed in the text frame.

Middle Button

edit. The current category value of the cell under the mouse cursor is iterated and a prompt for a new cell value appears on the textual command frame. (Remember to move the mouse to the text frame). Enter a new cell category value that is within the range of current category values for the map layer. Note: the edited cell is displayed in the color of the newly-assigned category value, but is hatched with lines of the grid color to indicate it has been edited, since, if the value of the cell is polled (before leaving edit mode), the old category value will be reported.
Right Button

\textbf{exit edit mode}. Command is returned to the \textit{Main Menu} on the graphics monitor. If cell value changes were made during edit mode, they will be saved upon exit.

2) Redraw

\textbf{rediscolds the raster map layer on the graphics monitor.}

3) Zoom

calls the \texttt{d.rast.zoom} program, to allow changing the view of the raster layer. \texttt{Zoom}'s instructions will appear on the text command window. Interaction is conducted using mouse keys.

4) Arrow

This function is available for users editing aspect maps. The \texttt{d.rast.arrow} program is called, which draws arrows over the displayed cells to indicate the down-slope direction of the cell. After selecting the \texttt{arrow} selection from the main menu, sub-menus will appear, allowing input options to be set for the \texttt{d.rast.arrow} program. The first sub-menu selects the type of aspect data displayed (regular \texttt{GRASS} format, as produced by \texttt{r.slope.aspect}; a format prepared as input to the "AGNPS" program; and a format prepared for the "ANSMAP-RS" program). The \texttt{d.rast.arrow} program can accept the name of a layer not drawn on the display for use as input, and an option is given to input the name of that layer, if desired. Otherwise, the currently displayed map layer will be used. Next, the color options of \texttt{d.rast.arrow} may be set via separate menus, or a choice for using default settings may be used.

5) Number

calls the \texttt{d.rast.num} program, which will print the cell category values over the displayed cells on the graphic monitor.

6) Options

\textbf{change the program} options setting for \texttt{grid.color}.

7) Exit

\textbf{QUIT} the \texttt{d.rast.edit} program. If edits have been made, the new raster map layer will be created. Support files are constructed. Category labels and color maps (if any) are copied from the original layer. \texttt{d.rast.edit} rediscolds the original raster map file on the monitor as it exits.

\textbf{NOTES}

\texttt{d.rast.edit} will not create a new raster map layer if the user makes no cell edits while running the program.

Be careful not to cover the graphics monitor window with another frame during the editing process. In some cases, the \texttt{redraw} option will be able to remove traces of other frames; otherwise, the graphics monitor will not be refreshed until after \texttt{d.rast.edit} exits. Further note, however, that this has only been tested on SUN workstations, using a modified SUNVIEW graphics monitor driver.

The primary bane of the \texttt{d.rast.edit} program involves large map layers (with lots of rows and columns) and/or slow computers, since the program must read and write raster map layers row by row for the full size of the map layer as dictated by its region size and resolution. (The current region settings of north, south, east, and west will not limit the size of the edited copy of the map layer, since by use of the \texttt{d.rast.zoom} program, these values may change several times during the editing session). Their effects could be lessened if the program were to create a table of changes that it could incorporate into the new raster file on a forked process started when the user exits, or otherwise allow the user to issue a "save" command when the user has made all desired edits to the raster file. Currently, for instance, if the user needs to use \texttt{d.rast.zoom} to access a different area of the map, the user must wait for a read and write for each entrance and egress of the edit mode.

There is no "undo" command or way to exit edit mode without saving changes.

It would be nice to incorporate a scrollable version of \texttt{d.legend} (such that one could see a legend for files with many categories on a standard size sub-frame). It would be even nicer to be able to select the category values from a graphical legend when editing cell values (thereby saving a trip to the text frame to type in the new value).
Perhaps method(s) for multiple or mass cell edits would be useful. This could be done by providing
modes in which the user may: 1) edit a block of cells to a given value by drawing a box; 2) be able to
choose a given value that then is automatically used as the new value for each cell chosen until a
different value is desired.

There is no interrupt handling. This could leave files in .tmp or (rarely) result in half-baked raster files.
The original file would survive unscathed by an interrupt at most any point in execution, but the
graphics monitor may be left in an indeterminate state (try `d.erase` or `d.mon select=monitor_name` to
bring it back into shape). Beware of exiting the program by means other than using `exit` on the Main
Menu.

Perhaps a `grid_color` option allowing the grid to be turned off is needed, since it may be
inappropriately displayed (i.e., not over the cell edges) in some circumstances.

The program has no method to enter new values beyond the current range of categories, but additional
programming could make it so.

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled
separately by the user.

NAME

d.rast.num - Overlays cell category values on a raster map layer displayed to the graphics monitor.

(Grass Display Program)

SYNOPSIS

d.rast.num

d.rast.num help

d.rast.num [map = name] [grid_color = name]

DESCRIPTION

d.rast.num overlays cell category values onto a raster map layer displayed to the user's graphics monitor. Category values will be displayed in white and/or black, based on the colors in which underlying cells are displayed. A grid outlining each map cell will also be overlaid in a user-specified color.

The user should run d.rast to display the desired map layer on the graphics monitor before running this program.

d.rast.num can be run non-interactively or interactively. If the user specifies the map whose category values are to be displayed and/or the grid color on the command line, the program will run non-interactively. Alternately, the user may simply type d.rast.num on the command line; in this case, the program will prompt the user for parameter values using the standard GRASS user interface described in the manual entry for parser. If no grid color is given the default will be used. If no map layer is specified, the program will use whatever raster map layer is currently displayed in the active frame on the graphics monitor.

COMMAND LINE OPTIONS

Parameters:

map = name
    Name of existing raster map layer whose category values will be displayed.
    Default: (whatever raster map layer is currently displayed)

grid_color = name
    Color in which an overlain grid will be displayed.
    Options: white, red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, black
    Default: gray

NOTES

The user is advised to set the current region to a relatively small area (i.e., less than 100 rows by 100 columns); otherwise, the individual cells being displayed will be small and the category value associated with each will be difficult to see.

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

NAME

d.rast.zoom - To interactively zoom in or zoom out of regions on a raster map displayed in the active frame on the graphics monitor.

(Grass Display Program)

SYNOPSIS

d.rast.zoom

d.rast.zoom help

DESCRIPTION

d.rast.zoom allows the user to zoom in or out of a region of interest on the raster map layer currently displayed in the active frame of the graphics monitor. The user zooms in and out interactively, using a mouse to establish the zoom region. To zoom, click the left mouse button to establish a corner, then drag the mouse to establish the second (diagonal) corner and hit the right mouse button to accept the region. "Unzoom" will move back one step (i.e., to the last modified region). If the user tries to unzoom once again, the zoom region will be set equal to the default region settings. The user can zoom or unzoom any number of times until satisfied.

NOTES

d.rast.zoom is sensitive to the current mask (see r.mask).

This program runs only interactively.

This program remains in alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

NAME
d.rgb - Displays three user-specified raster map layers as red, green, and blue overlays in the active graphics frame.

(GRASS Display Program)

SYNOPSIS
d.rgb
d.rgb help
d.rgb [red=name] [green=name] [blue=name] [out=name]

DESCRIPTION
RGB stands for red, green, and blue. This program visually overlays up to three raster map layers, each displayed in either red, green, or blue. As each overlay is displayed in a single band, the intensity at each point is the average intensity of the red, green, and blue components of the currently active color table. For example, any cell that carries 100% intensity for either red, green, or blue and 0% intensity for the other two colors will be represented at 33% intensity.

WARNING Maps that are using the "color wave" color table appear to be solid grey when using d.rgb. The average intensity of the colors being used is always 33%.

This program sacrifices spatial resolution to provide full color information. Any color that cannot be fully represented at a particular pixel passes the extra color to the next cell right and down. For example, if a cell is to show 50% red, but the closest color available (without showing more than 50%) is 40%, the pixel to the right and the pixel below will be given an extra 5% red each. In this way all the color is provided at the small cost of a slight amount of blurring. The result is very pleasing, especially on high resolution screens.

COMMAND LINE OPTIONS
Parameters:
red=name Name of raster map layer to be used for RED component.
green=name Name of raster map layer to be used for GREEN component.
blue=name Name of raster map layer to be used for BLUE component.
out=name Name of raster map layer to contain results.

NOTES
It produces an image and (optionally) a raster map layer with 1000 colors (10 intensities each of red, green and blue). The image and raster map layers will not display properly if the graphics device does not have at least 1000 colors while the user is running in float colormode. Thus, unless the display device has 1000 colors, it is necessary to run the GRASS program

d.colormode mode=fixed

before running d.rgb. Otherwise, the colors will be incorrect.

The intensity or the saturation layers may be left out. This means that it is possible to have his, hi, or hs images.

NAME
d.rhumbline - Displays the rhumbline joining two user-specified points, in the active frame on the
textual monitor.

(Grass Display Program)

SYNOPSIS
d.rhumbline
  d.rhumbline help
  d.rhumbline coor=lon1,lat1,lon2,lat2 [icolor=name]

DESCRIPTION
A rhumbline is a line following a constant angle of the compass (i.e., a line of constant direction).
There are 32 points on the compass (points are roughly 11 degrees 15 minutes apart).  d.rhumbline
displays the rhumbline joining any two user-specified points in the active frame on the user's graphics
monitor.  The named coordinate locations must fall within the boundaries of the user's current
geographic region.

The user can run this program either interactively or non-interactively.  If the user simply types
d.rhumbline on the command line without specifying parameter values, the mouse will be activated
and the user will be asked to use the mouse to indicate the two endpoints of the rhumbline.  The
rhumbline is then drawn in the default color (white).  The program also outputs the coordinate locations
of the two endpoints on the user's terminal and the number associated with the mouse button depressed
by the user in a format useful for input to other programs.

Alternately, the user can specify the starting and ending longitude/latitude coordinates of the rhumbline
and (optionally) the color in which the rhumbline will be displayed; in this case, the program will run
non-interactively.

COMMAND LINE OPTIONS
Parameters:
  coor=lon1,lat1,lon2,lat2
    Starting and ending coordinates of the rhumbline to be displayed, given as longitudes and
    latitudes.
  icolor=name
    Rhumbline color.
    Options: red, orange, yellow, green, blue, magenta, indigo, violet, gray, white, black
    Default: white

NOTES
This program works only with longitude/latitude data bases.

NAME

d.save - Creates a list of commands for recreating screen graphics.

(GRASS Display Program)

SYNOPSIS

d.save

d.save help

d.save [-ca] [frame=name[,name,...]]

DESCRIPTION

When GRASS display (d) commands are used to generate graphical images on the graphics monitor, some commands are noted in lists that the current graphics driver (see manual entry for d.mon) maintains. This command, d.save, uses this information to create a shell script that can be used to recreate graphics in another frame at another time. The shell script is sent to standard output (the user's terminal). If you wish to save the shell script created by d.save, its output should be redirected to a file; for example:

d.save > script.out

The user can run the program non-interactively by specifying flag settings and parameter values on the command line. If the user types d.save without specifying these program arguments, the user will be prompted for inputs through the standard user interface described in the manual entry for parser.

COMMAND LINE OPTIONS

Flags:

- c
  Shell script will contain only information for regenerating graphics from the active (current) frame. Use of this flag overrides the frame option (below).

- a
  Save information needed to regenerate all the frames on the graphics monitor. The shell script can be used to completely reconstruct the contents of the graphics screen.

Parameter:

frame=[name[,name,...]]
  Names(s) of those display frame(s) to be saved.
  Options: All available frames
  Default: Active frame

NOTES

Display commands used interactively, and those that take their graphic instructions from standard input, will not be saved by d.save.

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

NAME

d.savescreen – Screen capture utility for some MASSCOMP graphics monitors.

(GRASS Display Program)

SYNOPSIS

d.savescreen

DESCRIPTION

d.savescreen captures the image currently displayed on the graphics monitor in a form suitable for later printing by p.screen.

Screen capture is performed in two steps. The displayed image is first captured into a file, and this file then reformatted into the format required by p.screen.

File capture happens interactively. After the user types:

\[ d.savescreen \]

the displayed image is captured into a file and stored under the /tmp directory on the user's machine. The file's name is generated by \[ d.savescreen \] and has the form /tmp/screen### (where ### is a random number). \[ d.savescreen \] reports the name of the /tmp/screen### file to the user after this first step is completed.

File reformatting goes on in the "background" (i.e., the user can do other work at his keyboard while waiting for the image to be reformatted). When the reformat step is completed, the user is notified by mail that the /tmp/screen### file is complete.

The user can then print out the /tmp/screen### file using p.screen. The user must specify the full path of this file to p.screen.

NOTES

This program may not exist on your system; at present, it only works on MASSCOMP systems. MASSCOMP no longer supports this function on 386 DVGA, VEGA, and VDO600 graphics terminals.

This program requires no command line arguments.

\[ d.savescreen \] places its output in a file under the /tmp directory, not under the user's mapset. The user should specify this file by its full path name (i.e., /tmp/screen###) to p.screen when printing it out.

The /tmp/screen### files can be quite large. Users should remove these files after they have been printed. This can be done using the UNIX rm command:

\[ \text{rm /tmp/screen###} \]

SEE ALSO

UNIX Manual entry for \[ \text{rm} \]

\[ d.display, d.save, p.screen, p.select \]
NAME

d.scale - Overlays a bar scale and north arrow for the current geographic region at a user-defined location in the active display frame.

(GRASS Display Program)

SYNOPSIS

d.scale

d.scale help

d.scale [-m] [bcolor = name] [tcolor = name] [at = x,y]

DESCRIPTION

d.scale overlays a bar scale and north arrow for the current geographic region at a user-defined location in the active display frame. The scale and north arrow are proportioned to fit in the active frame when placed along the frame’s left edge.

The user can specify the location of the scale and north arrow interactively (using a mouse), or provide the geographic coordinates at which they will be placed. The scale and north arrow will only overwrite those portions of the graphics display that lie directly beneath them.

The user can also specify the colors in which the scale and north arrow will be drawn. By default, if unspecified by the user, a white scale and north arrow will be displayed on a black background.

OPTIONS

The user can run this program either non-interactively or interactively. The program will be run non-interactively if the user specifies program parameter values and desired flag settings on the command line, using the form:

    d.scale [-m] [bcolor = name] [tcolor = name] [at = x,y]

If at least one parameter value is given on the command line and the -m flag is not set, the program will be run non-interactively; any other parameter values left unspecified on the command line will be set equal to their default values (see below). Alternately, the user can simply type d.scale on the command line, without program arguments. In this case, the user will be prompted for needed parameter values and the flag setting using the standard GRASS parser interface described in the manual entry for parser. If the user sets the -m flag, d.scale will expect the user to designate the scale’s location interactively, using the mouse.

Flag:

-Use the mouse to interactively place the location of the scale and north arrow.

Parameters:

bcolor = name

Set the background color underlying the scale and north arrow to name.

Options: red, orange, yellow, green, blue, indigo, violet, gray, brown, magenta, white, and black

Default: black

tcolor = name

Set the foreground color in which the text, scale, and north arrow are displayed to name.

Options: Same as bcolor colors.

Default: white

at = x,y

The map easting (x) and northing (y) geographic coordinates designating the location at which the upper left corner of the scale is to be placed. The user should choose geographic coordinates located within the current geographic region (see d.where and g.region for these coordinates).

Default: 0,0,0,0
NOTES

d.scale assumes that layer units are in meters.
The scale that d.scale generates is probably not suitable for very tiny maps (in small display frames).

NAME
d.sites - Displays site markers in the active display frame on the graphics monitor.
(GRASS Display Program)

SYNOPSIS
d.sites
d.sites help
d.sites sitefile=name [color=name] [size=value] [type=name]

DESCRIPTION
d.sites displays a GRASS site_lists map using site markers of a color, size, and type specified by the user. Output is displayed in the active frame on the graphics monitor.

This program can be run non-interactively or interactively. If the user gives the name of a GRASS site_lists map and (optionally) specifies other parameter values on the command line the program will be run non-interactively; any parameter values left unspecified are set to their default values (see below). Alternately, the user can type simply d.sites on the command line; in this case, the program will prompt the user for parameter values using the standard GRASS parser interface described in the manual entry for parser.

Parameters:
sitefile=name Name of a GRASS site_lists map in the user's current mapset search path.
color=name Sets the current color to name.
Options: red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, white, and black
Default: gray
size=value Size, in pixels, in which the site icons are to be drawn.
Options: 0-1000
Default: 5
type=name The type of icon to be displayed at site locations.
Options: x, diamond, box, +
Default: x

AUTHOR
James Westervelt, U.S. Army Construction Engineering Research Laboratory
NAME  
\texttt{d.text} – Draws text in the active display frame on the graphics monitor.  
\textit{(GRASS Display Program)}

SYNOPSIS  
\texttt{d.text}  
\texttt{d.text help}  
\texttt{d.text [size=value] [color=name] [line=value]}

DESCRIPTION  
\texttt{d.text} draws text in the active display frame on the graphics monitor. Text can be provided through  
standard input or redirected from a file (using the UNIX redirection mechanism).

Parameters:

size=value  
Height of letters, stated as a percent of the available display frame height.  
Options: 0 - 100  
Default: 5

color=name  
Sets display text color to name.  
Options: red, orange, yellow, green, blue, indigo, violet, gray, white, and black  
Default: gray

line=value  
The screen line number on which the first line of text will be drawn.  
(Line 1 is at the top of the active display frame.)  
Options: 1 - 1000  
Default: 1

In addition to the options provided on the command line, colors, text size, font type, and boldness, can  
be adjusted with commands in the standard input (i.e., if the user invokes \texttt{d.text} without options on the  
command line, and then assigns values to these options on lines within the standard input). In this case,  
the user also sees the standard GRASS parser interface described in the manual entry for \texttt{parser}.

Commands:

\texttt{.C color}  
(where color is one of the available colors) causes text appearing on subsequent lines to be drawn in  
that color.

Text size can be adjusted with the command:

\texttt{.S size}  
(where size is a percentage within the range 0 to 100). Note that a size of 10 would allow 10 lines to  
be drawn in the active display frame, 5 would allow the drawing of 20 lines, and 50 would allow the  
drawing of 2 lines.

Font type can be manipulated using the command:

\texttt{.F font}  
(where font is one of the fonts known by the GRASS program \texttt{dfont}). Available fonts are listed in the  
GRASS manual entry for \texttt{dfont}. The default font type used (if unspecified by the user) is \textit{romans}.  
Run the GRASS macro \texttt{show.fonts.sh} to see what these fonts look like.

The user can also stipulate that text be printed in \texttt{bold} on lines beneath the command:

\texttt{.B 1}  
This command means \texttt{bold on}.  
Similarly, the command:

\texttt{.B 0}  
turns \texttt{bold off} of all text appearing on lines beneath it. (\texttt{Bold off} is used by default, if unspecified by  
the user.)
EXAMPLE

The following command will print the short phrase "This is a test of d.text" in the active display frame using the color yellow, in bold, and using 4/100ths (4%) of the active frame's vertical space per line:

```
d.text
.C yellow
.S 4
.B 1
This is a test of d.text
```

The user presses control-d (the "ctrl" and "d" keys) to end input to d.text.

NOTES

Note that the GRASS command d.title creates map titles in a format suitable for input to d.text.

d.text needs escape sequences that can be used within lines to change colors, boldness, and perhaps size.

SEE ALSO

d.font, d.title, show.fonts.sh, and parser

AUTHOR

James Westervelt, U.S. Army Construction Engineering Research Laboratory
NAME

d.title – Outputs a title for a raster map layer in a form suitable for display by d.text.

(GRASS Display Program)

SYNOPSIS

d.title

d.title help

d.title [-f] map=name [color=name] [size=value]

DESCRIPTION

d.title generates to standard output a string which can be used by d.text to draw a title for the raster map layer name in the active display frame on the graphics monitor. Output created by d.title can be redirected into a file, or piped directly into d.text to display the map title created by d.title. The map title created will include the map layer's name, title, MAPSET, LOCATION_NAME, geographic region boundary coordinates, and cell resolution.

The user can state program arguments on the command line, or type simply d.title on the command line. In the latter case, the program will prompt the user for the parameter values and flag setting using the standard GRASS parser interface described in the manual entry for parser.

Flag:

-f Displays a fancier title.

Parameters:

map=name Name of an existing raster map layer in the user's mapset search path.

color=name Sets the current color to the name stated.

Options: red, orange, green, blue, indigo, violet, black, white, gray, yellow, brown, and magenta

Default: white

size=value Sets the text size as a percentage of the active display frame's height, to value. Floating point values can be used.

Options: 0 - 100

Default: 15.0

EXAMPLE

For example, a user wishing to create a suitable title for the Spearfish, SD soils map layer and to display this title in the active display frame on the graphics monitor might type the following:

\texttt{d.title map=soils color=red size=5 >titlefile}

\texttt{d.text <titlefile}

Alternately, the user might pipe d.title output directly into d.text:

\texttt{d.title map=soils color=red size=5 | d.text}

A file created by d.title can be displayed with d.text. Information contained in this file takes precedence over the color and size parameters for d.text.

NOTES

The text created with d.text will not necessarily fit within the active display frame on the graphics monitor; the user should choose a text size appropriate to this frame.

AUTHORS

James Westervelt, U.S. Army Construction Engineering Research Laboratory

David Gerdes, U.S. Army Construction Engineering Research Laboratory
**NAME**
d.vect - Displays GRASS vector data in the active frame on the graphics monitor.

*(GRASS Display Program)*

**SYNOPSIS**

```
d.vect
```
```
d.vect help
```
```
d.vect map=name [color=name]
```

**DESCRIPTION**

d.vect displays the user-named binary vector file in the active display frame on the graphics monitor, in the user-named color. The vector file must already exist under a mapset listed in the user's current mapset search path.

This program can be run either non interactively or interactively. If the user gives the name of a binary vector map to be displayed and (optionally) specifies a color for vector display, the program will run non-interactively. (If the user gives a vector map name but no vector color on the command line, the named vector map layer will be displayed in the default color *white*.) Alternately, the user can simply type `d.vect` on the command line; in this case, the program will prompt the user for parameter values using the standard GRASS parser interface described in the manual entry for `parser`.

**Parameters:**

- `map=name` Vector map layer to be displayed in the active display frame. Must be binary vector file in the user's current mapset search path.
- `color=name` Sets vector display color to *name*.
  Options: white, red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray, and black
  Default: white

**NOTES**

This program needs to be upgraded with features that would:
1) Allow different line colors, weights, and textures to be assigned to vectors with different category values;
2) Allow different fill patterns and colors to be assigned to areas;
3) Be linked with an associated program identifying these options.

NAME
d.vec.dlg – Displays a USGS Digital Line Graph (DLG-3) binary vector file in the active frame on the
user’s graphics monitor.
(GRASS Display Program)

SYNOPSIS
d.vec.dlg
d.vec.dlg help
d.vec.dlg map=name [color=name]

DESCRIPTION
d.vec.dlg displays a user-specified binary vector digital line graph - level 3 (DLG-3) map in the active
frame on the user’s graphics monitor. The user can (optionally) specify the color in which vectors will
be drawn. The map to be drawn must exist in the user’s current mapset search path.

This program can be run either non-interactively or interactively. The user can run this command non-
interactively by specifying parameter values on the command line. Alternately, the user can simply
type d.vec.dlg on the command line; in this case, the program will prompt the user to enter the name
of a DLG-3 file and a vector color using the standard interface described in the manual entry for
parser.

COMMAND LINE OPTIONS
Parameters:
map=name Name of an existing DLG-3 map layer to be displayed.
color=name Color in which vectors will be drawn.
Options: white, red, orange, yellow, green, blue, indigo, violet, gray, black
Default: gray

NOTES
This program will probably be phased out and is included only to provide some backward compatibility
with previous GRASS versions (e.g., version 2.0).

The command g.list type=vec only lists binary vector files in GRASS format (i.e., dig files); it does
not list binary vector DLG-3 files (bdig files) stored under the user’s mapset. However, the user can
list the DLG-3 files accessible to him by running d.vec.dlg interactively.

James Westervelt, U.S. Army Construction Engineering Research Laboratory
NAME

d.what.rast – Allows the user to interactively query the category contents of multiple raster map layers at user-specified locations within the current geographic region.

(GRASS Display Program)

SYNOPSIS

d.what.rast

d.what.rast help

d.what.rast [-lt] [map=name[,name,...]] [fs=name]

DESCRIPTION

d.what.rast outputs the category values and labels associated with cell(s) at user-specified location(s) on user-named raster map layer(s).

The program will query the contents of raster map layer(s) named by the user on the command line. These map layers must exist in the user's current mapset search path. If the user does not name any raster map layers on the command line, d.what.rast will query the category contents of whatever raster map layer is already displayed in the active frame on the graphics monitor.

The program activates the mouse, and expects the user to indicate the cell location(s) to be queried by depressing a mouse button over desired location(s) within the current geographic region in the active display frame on the graphic monitor.

Flags:

-1 Identify and query just one point location. Only one mouse click is executed. This option is provided for shell scripts and programs that want to obtain only one point from the user.

-t Provide only terse output. This option is provided to simplify the parsing of output by other programs.

Parameters:

map=name Name of existing raster map layer(s). Limit: 15 maps
Default: Query map currently displayed in the active graphics frame.

fs=name Output field separator to be used (in terse mode only).
Default: :

d.what.rast output consists of the geographic coordinates of the location pointed to, and, for each map layer, the map layer name, the category value, and category label in the named raster map layers at this location.

EXAMPLE

It is helpful, but not necessary, to first display a map to be used for reference in the active display frame before running d.what.rast. For example, the user might type the following series of commands and receive the output below.

d.rast map=soils

To first display the soils map in the active frame.

d.what.rast map=soils,aspect

User then moves the mouse to desired location on the displayed soils map layer, and presses the left mouse button to query the category contents of the soils and aspect maps at this geographic location. The program then outputs the below information to the user's terminal.
The first line of output gives the easting (E) and northing (N) coordinates of the geographic location at which the user clicked the mouse. The subsequent two lines give the map name and mapset, map category value (within parentheses), and map category label corresponding to this user-selected map location, for each of the maps queried by the user.

The query may be repeated as often as desired using the left mouse button. The right button on the mouse is used to quit the \texttt{d.what.rast} session.

Users can set the \texttt{-t} flag to obtain a terse output from \texttt{d.what.rast}. This is useful when the user wishes output to be parsed by another program (like \texttt{awk}). If the \texttt{-t} flag is set, users can also select the field separator used (with the \texttt{fs=\textlangle name\textrangle} option), or elect to use the default : field separator. In this case, the command

\begin{verbatim}
d.what.rast -t map=soils_aspect
\end{verbatim}

produces output in the form shown below. The first line of output gives the easting, northing, and the mouse button return value (see \texttt{NOTES}, below). Each subsequent line gives the map name and its mapset, the category value, and category label of the point specified on the user-named raster map layers. The default output field separator, a colon, is used since none was specified on the command line.

\begin{verbatim}
617112:3732014:1
soils@PERMANENT:44:Nunn clay loam, NdC
aspect@PERMANENT:20:15 degrees north of west
\end{verbatim}

Users can also use this program inside of shell scripts that require as input a map category value and a mouse button depressed. Users can choose an option to run \texttt{d.what.rast} only once, and return only the map category value found and the number of the mouse button depressed.

\textbf{NOTES}

Mouse button return values are as follows: 0 indicates no button was pressed, 1 indicates that the left mouse button was pressed, 2 indicates the middle button was pressed, and 3 indicates that the right mouse button was pressed.

\texttt{d.what.rast} will always print its output to the terminal screen. \texttt{d.what.rast} output can be redirected into a file; however, if it is, the output will go both to the screen and to the file. For example:

\begin{verbatim}
d.what.rast map=soils_aspect > what.out
\end{verbatim}

will both send \texttt{d.what.rast} output to the screen and capture its output in the file named \texttt{what.out}.

The maximum number of raster map layers that can be queried at one time is 15.

\texttt{d.what.vect} allows the user to interactively query the category contents of multiple vector map layers at user-specified locations.

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME

*d.what.vect* - Allows the user to interactively query the category contents of a (binary) vector map layer at user-selected locations within the current geographic region.

*(GRASS Display Program)*

SYNOPSIS

```
d.what.vect
```

```
d.what.vect help
```

```
d.what.vect [-1] map=name
```

DESCRIPTION

*d.what.vect* outputs the category value(s) associated with user-specified location(s) in a user-specified vector map layer. This program currently returns only category values for line types in the user-specified vector file.

The program will query the contents of the vector map layer named by the user on the command line. This map layer must exist in the user’s current mapset search path.

The program activates the mouse, and expects the user to indicate the location(s) to be queried by depressing a mouse button over desired location(s) within the current geographic region in the active display frame on the graphic monitor.

Flag:

- `-1` - Identify and query just one point location. Only one mouse click is executed. This option is provided for shell scripts and programs that want to obtain only one point from the user.

Parameter:

```
map=name
```

Name of an existing binary vector map in the user’s mapset search path.

EXAMPLE

A sample *d.what.vect* session is given below. Although it is not necessary that the user first display a vector map to be queried in the active display frame, it is helpful to have a map displayed there for reference.

```
d.vect map=roads.24000
```

Displays the 1:24,000 scale *roads* vector map layer on the graphics monitor.

```
d.what.vect map=roads.24000
```

After typing this, the user moves the mouse to a desired location on the displayed *roads* map layer, and presses the left mouse button to query the category value of the *roads* vector map at this location. The program then outputs the category value of a line type corresponding to this user-selected map location, for the vector map queried by the user.

The query may be repeated as often as desired using the left mouse button. The right button on the mouse is used to quit the *d.what.vect* session.

Users can also use this program inside of shell scripts that require as input a map category value and a mouse button depressed. Users can set the -1 flag to run *d.what.vect* only once, and return only the map category value found and the number of the mouse button depressed. (Mouse button return values are as follows: 0 indicates no button was pressed, 1 indicates that the left mouse button was pressed, 2 indicates the middle button was pressed, and 3 indicates that the right mouse button was pressed.)
**NOTES**

Currently, `d.what.vect` only outputs category values for lines. It does not output category labels for lines, nor output category values or category labels for areas in a vector file.

`d.what.vect` will always print its output to the user's terminal screen. `d.what.vect` output can be redirected into a file; however, if it is, the output will go both to the screen and to the file. For example:

```
d.what.vect map=roads > what.out
```

will both send `d.what.vect` output to the screen and capture its output in the file named `what.out`.

`d.what.rast` can be used to interactively query the map category contents of multiple raster map layers at user-selected locations.

NAME

d.where - Identifies the geographic coordinates associated with point locations in the active frame on the graphics monitor.

(GRASS Display Program)

SYNOPSIS

d.where

d.where help

d.where [-1] [spheroid=name]

DESCRIPTION

d.where is an interactive program that allows the user, using the pointing device (mouse), to identify the geographic coordinates associated with point locations within the current geographic region in the active display frame on the graphics monitor.

If the user runs d.where without specifying the name of a spheroid on the command line, each mouse click will output the UTM easting and northing of the point currently located beneath the mouse pointer. A mouse-button menu is presented so the user knows which mouse buttons to use. The output is always printed to the terminal screen; if the output is redirected into a file it will be written to the file as well.

Flag:

-1 Only one mouse click is executed.

This option is provided for shell scripts and programs which want to obtain only one point from the user. The output is only written to stdout, unless redirected into a file. The geographic location and mouse button pressed are output.

Parameter:

spheroid=name Name of a spheroid (for latitudelongitude coordinate conversion).

Options: australian, bessel, clark66, clark80, everest, international, wgs72, wgs84

NOTES

This program uses the current geographic region setting and active frame. It is not necessary, although useful, to have displayed a map in the current frame before running d.where.

NAME

d.zoom - Allows the user to change the current geographic region settings interactively, with a mouse.  
(GRASS Display Program)

SYNOPSIS

d.zoom

d.zoom help

d.zoom [-q] [action=name]

DESCRIPTION

d.zoom allows the user to interactively adjust the settings of the current geographic region using a pointing device such as a mouse. Like g.region, d.zoom re-defines the settings of the geographic region. However, d.zoom allows the user to change the current region settings interactively, by either outlining the new region perimeter with a mouse or "rotating" latitude/longitude data into the current region. The user should run d.erase after d.zoom is run for the new region settings to affect the graphics display.

Flag:

-q Run quietly, suppressing output of some program messages to standard output.

Parameter:

action=name Allows the user to change the geographic region settings by "rotating" the globe to move a different portion of the globe into the stationary boxed region outline (making this new portion of the globe the new current region), rather than by moving the boxed region outline. This option can only be used with latitude/longitude data bases (although d.zoom will not complain if the user attempts to set this parameter while running on a non-latitude/longitude data base).

Options: zoom, rotate

After the user types the command d.zoom and (optionally) sets the -q flag and type of zoom to be performed, a mouse-button menu will appear, directing the user to: establish the corners of the new geographic region, check its coordinates, and confirm any changes made. When the user accepts new geographic boundaries, d.zoom asks,

Accept new region?  Y / N >

If the user clicks the mouse over the "Y" (yes), the mouse-drawn geographic region is saved as the user's current geographic region. The user is warned that d.erase should be run after d.zoom to make new current region settings affect the graphics display.

If the user clicks the mouse over the "N" (no), the first mouse-drawn geographic region is not saved; instead, d.zoom asks whether or not the user wishes to

Try Again?  Y / N >

The user can then opt to draw a new region with the mouse ("Y"), or opt to exit d.zoom ("N") and leave current region settings unchanged.

To zoom-out to a larger area than was windowed-in on with d.zoom (i.e., to enlarge the current geographic region), the user may run g.region. The user may also alter the current geographic region by running the "region" option of the d.display program.

NOTES

Although it is not necessary that the user display a map in the active display frame before running d.zoom, it is helpful to do this for reference.

Currently, the rubber-banded boundaries of the zoom region drawn by the user are not clearly visible on the graphics monitor. However, whether or not these boundaries are clearly visible when drawn, the drawn region is still correctly zoomed-in on.

NAME

`exit` - Exits the user from the current GRASS session.

SYNOPSIS

`exit`

DESCRIPTION

The `exit` command ends the user's current GRASS session and returns the user to the directory in which he/she was working prior to entering GRASS. When the user exits GRASS, he/she is asked whether he/she wishes to save the files and data stored under his current mapset, and (if maps are present) whether the user wishes to selectively remove map layers, before exiting the system. By default, if the user presses RETURN without responding to these questions, all maps in the user's current mapset are saved. However, because such maps can consume much storage space on the computer, the user should remove any unneeded files before exiting. (The user can also remove data before attempting to exit GRASS using the `g.remove` command.)

Before typing `exit`, the polite user should remember to release the graphics display monitor (using the command `d.mon -r`) for use by other GRASS users. Otherwise, the display device may be locked for use by the user, even though the user has exited GRASS, until another user runs `d.mon` and unlocks this monitor for others' use.

Each time the user re-enters GRASS, the variables described in `g.gisenv` are re-set. If the user wishes to change the mapset, location, or data base on which he/she is working (i.e., those affected by any GRASS programs running during the user's current GRASS session), the user must `exit` GRASS and then re-enter GRASS and specify a different mapset, location, and/or data base location on the GRASS start-up page. When the user re-enters GRASS, these variable settings (the current mapset, location, and data base) are set by default to those used in the user's previous GRASS session, unless changed by the user.

NOTES

This program requires no command line arguments; the user simply types `exit` on the command line to `exit` GRASS.

SEE ALSO

`d.mon`, `g.gisenv`, `g.remove`
NAME

`g.access` - Controls user access to the current GRASS mapset.

(GrASS File Management Program)

SYNOPSIS

`g.access`

DESCRIPTION

This program allows the user to control access to the current mapset. Normally, any user can read data from any GRASS mapset. But sometimes it is desirable to prohibit access to certain sensitive data. The `g.access` command allows a user to restrict read and execute access to the current mapset (see UNIX `chmod` command). `g.access` will not modify write access to the current mapset.

The user may, for example, allow only users in the same UNIX group to read data files in the mapset, or restrict the mapset to personal use only.

After typing `g.access`

the user will be presented with a screen page which reflects the current mapset permissions. The user can then change them. The screen page looks like:

```
LOCATION: spearfish  MAPSET: demo

This program allows you to control access to your mapset by other users.
Access may be granted/removed for everyone, or for everyone in your group.

Mark an 'x' to allow access; erase the field to restrict access.

GROUP:   _x_
OTHER:   _x_

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE:
(OR <Ctrl-C> TO CANCEL)
```

If you remove the x (using the space bar), access will be denied to that class of user (group or other). If you type an x, access will be granted to that class of user.

NOTES

There is no non-interactive version of `g.access`.

Under GRASS version 4.0, access to the mapset PERMANENT must be open to all users. This is because GRASS looks for the user's default geographic region definition settings and the location title in files that are stored under the PERMANENT mapset directory. The `g.access` command, therefore, will not allow you to restrict access to the PERMANENT mapset.

The `g.mapsets` command isn't smart enough to tell if access to a specified mapset is restricted, and the user is therefore allowed to include the names of restricted mapsets in his search path. However, the data in a restricted mapset is still protected; any attempts to look for or use data in a restricted mapset will fail. The user will simply not see any data listed for a restricted mapset.

UNIX manual entries for `chmod` and `group`

`g.mapsets`

AUTHOR

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME

g.ask – Prompts the user for the names of GRASS data base files.

(GRASS File Management Program)

SYNOPSIS

g.ask help

g.ask type=name [prompt="string"] element=name [desc="string"] unixfile=name

DESCRIPTION

g.ask is designed for shell scripts that need to prompt the user for the name of a data base file in the user's current GRASS location. After g.ask is invoked with needed parameters, it will query the user for a file name of the specified type and element. After the user responds to this query, the program will write four lines to the UNIX output file specified by unixfile.

Parameters:

type=name

The type of query. Options for name are old, new, any, and mapset; their functions are given below. “New”, “any”, and “mapset” only look in the user’s current mapset.

old

For existing data files anywhere in the user’s mapset search path.

new

Used to create a new file in the current mapset, which must not already exist there (if a file with this name exists there, it will not be overwritten).

any

Creates a file in the current mapset, which may or may not already exist there. If a file with this name exists in the current mapset, it will be overwritten; if not, a new file with this name will be created.

mapset

For files that must exist in the current mapset. The shell write wants the name of a file that exists in the user’s current mapset. This type would be used instead of “old” if the file is to be modified.

prompt="string"

The prompt to be displayed to the user. If more than one word, the prompt should be enclosed within double quotes (" ").

element=name

The name of the GRASS data base element (i.e., directory under a GRASS mapset) whose files are to be queried.

desc="string"

A short description of the data base element which is meaningful to the user. If description contains more than one word, it should be enclosed within double quotes (" ").

unixfile=name

The name of a UNIX file to store the user’s response. See next section for what is written to this file and how it can be used by shell scripts.

OUTPUT

Upon receiving the user’s response to its request for a file name, g.ask writes four lines to the specified unixfile; this output file is placed in the user’s current working directory, unless otherwise specified, and contains the following lines:

name='some_name'

mapset='some_mapset'

fullname='some_fullname'

file='some_fullpath'

The output is /bin/sh commands to set the variable name to the file name specified by the user (of the element and type requested by g.ask), mapset to the GRASS mapset in which this file resides (or will be created), fullname is the name with the mapset embedded in it, and file to the full UNIX path name identifying this file. These variables may be set in the /bin/sh as follows:

. unixfile

GRASS 4.0 (Summer 1991) U.S. Army CERL 87
The . is a shell command which means read the unifile and execute the commands found there. It is NOT part of the unifile name and MUST be followed by a space.

NOTES
The user may choose to simply hit the return key and not enter a file name. If this happens the variables will be set as follows:

```
name=
mapset=
fullname=
file=
```

The following is a way to test for this case:
```
if [ ! "$file" ]
then
    exit
fi
```

AUTHOR
Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME

g.copy - Copies available data files in the user's current mapset search path and location to the
appropriate element directories under the user's current mapset.

(GRASS File Management Program)

SYNOPSIS

```
g.copy
  g.copy help
  g.copy [rast=from,to] [vect=from,to] [icon=from,to] [labels=from,to] [sites=from,to]
  [region=from,to] [group=from,to]
```

DESCRIPTION

A user may access data stored under the other mapsets listed in his/her mapset search path. However,
the user may only modify data stored under his/her own current mapset. `g.copy` allows the user to
copy existing data files from other mapsets to the user's current mapset ($MAPSET). The files to be
copied must exist in the user's current mapset search path and location; output is sent to the relevant
data element directory(ies) under the user's current mapset.

The user specifies the type(s) of data files he/she wishes to copy (raster, vector, etc.), the name of the
existing file to be copied (i.e., the `from` file name), and the name of the new file copy to be placed in
the user's current mapset (the `to` file name). This information can be given either (non-interactively) on
the command line, or entered in response to program prompts given via the standard parser interface
described in the manual entry for `parser`.

Information can be entered on the command line in the following format:

```
g.copy [rast=from,to] [vect=from,to] [icon=from,to] [labels=from,to] [sites=from,to]
  [region=from,to] [group=from,to]
```

For example, if the user wished to copy the existing raster file `soils` to a file called `soils.ph` and to
copy an existing vector file `roads` to a file called `rds.oid`, the user could type:

```
g.copy rast='soils@wilson',soils vect='roads',rds.oid
```

Data files can also be specified by their mapsets. For example, the below command copies the raster
file named `soils` from the mapset `wilson` to a new file called `soils` to be placed under the user's current
mapset:

```
g.copy rast='soils@wilson',soils
```

If no mapset name is specified, `g.copy` searches for the named `from` map in each of the mapset
directories listed in the user's current mapset search path in the order in which mapsets are listed there
(see `g.mapsets`).

If the user does not enter parameter values but instead types only `g.copy` on the command line the
program will prompt the user for a data type, the name of a file of this data type to copy, and the name
of a new file to hold the copy. After both file names have been entered, the copy is created and the
user is again prompted for a data element to be copied, until the user hits RETURN. When prompted
for file names, the user may enter 'list' to see a list of existing files, or hit RETURN to end the file
listing.
Parameters:

- `rast=from,to` where `from` is an existing raster map layer to be copied, and `to` is the name given to the copy.
- `vect=from,to` where `from` is an existing binary vector map layer to be copied, and `to` is the name given to the copy.
- `icon=from,to` where `from` is an existing paint icon file to be copied, and `to` is the name given to the copy.
- `labels=from,to` where `from` is an existing `/paint/labels` file to be copied, and `to` is the name given to the copy.
- `sites=from,to` where `from` is an existing `site_lists` file to be copied, and `to` is the name given to the copy.
- `region=from,to` where `from` is an existing region definition (`windows`) file to be copied, and `to` is the name given to the copy.
- `group=from,to` where `from` is an existing imagery group file to be copied, and `to` is the name given to the copy.

NOTE

If a file has support files (e.g., as do raster data files), these support files will also be copied.

AUTHOR

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME

`g.filename` - Prints GRASS data base file names.

(GRASS File Management Program)

SYNOPSIS

```
g.filename
```

```
g.filename help
g.filename element=name mapset=name file=name
```

DESCRIPTION

`g.filename` is designed for Bourne shell scripts that need to know the full UNIX file name for raster map layers, vector files, site list files, geographic region definition (windows) files, imagery group files, etc., in the GRASS data base. If the user runs `g.filename` without command line arguments (i.e., simply types `g.filename`), this program will prompt the user for input using the standard parser interface described in the manual entry for `parser`.

Parameters:

- `element=name` The name of a GRASS data base element (i.e., directory within the GRASS mapset location).
- `mapset=name` The name of a GRASS data base mapset. As a convenience, a single dot (.) can be used to designate the current mapset.
- `file=name` The name of a GRASS data base file.

OUTPUT

`g.filename` writes one line to standard output:

```
file='full_file_pathname'
```

The output is a `/bin/sh` command to set the variable specified by the `file` name to the full UNIX path name for the data base file. This variable may be set in the `/bin/sh` as follows:

```
eval `g.filename element=name mapset=name file=name`
```

NOTES

This routine generates the filename, but does not care if the file (or mapset or element) exists or not. This feature allows shell scripts to create new data base files as well as use existing ones.

If the mapset is the current mapset, `g.filename` automatically creates the `element` specified if it doesn’t already exist. This makes it easy to add new files to the data base without having to worry about the existence of the required data base directories. (This program will not create a new mapset, however, if that specified does not currently exist.)

The program exits with a 0 if everything is ok; it exits with a non-zero value if there is an error, in which case `file='full_file_pathname'` is not output.

NAME

\texttt{g.findfile} - Searches for GRASS data base files and sets variables for the shell.
(GRASS File Management Program)

SYNOPSIS

\texttt{g.findfile}
\texttt{g.findfile help}
\texttt{g.findfile element=\textit{name} [mapset=\textit{name}] file=\textit{name}}

DESCRIPTION

\texttt{g.findfile} is designed for Bourne shell scripts that need to search for raster map layer files, vector files, site list files, geographic region definition (windows) files, and imagery group files in the GRASS data base. If the user runs \texttt{g.findfile} without command line arguments, he will be prompted for the names of a GRASS element, file, and mapset, through the standard parser interface (see manual entry for \texttt{parser}).

Parameters:

\begin{itemize}
  \item \texttt{element=\textit{name}} The data base element (i.e., directory within a GRASS mapset) to be searched.
  \item \texttt{mapset=\textit{name}} The mapset in which to search for the specified file \textit{name}. If not specified, all mapsets in the user's GRASS search path are searched. Otherwise, the specified mapset is searched. As a convenience, if specified as a single dot (.) only the current mapset is searched.
  \item \texttt{file=\textit{name}} The name of a GRASS data file (of the stated element type) for which to search.
\end{itemize}

OUTPUT

\texttt{g.findfile} writes three lines to standard output:

\begin{verbatim}
name='\textit{file\_name}'
mapset='\textit{mapset\_name}'
file='unix\_filename'
fullname='grass\_fullname'
\end{verbatim}

The output is /bin/sh commands to set the variable \textit{name} to the GRASS data base file name, \textit{mapset} to the mapset in which the file resides, and \textit{file} to the full UNIX path name for the named file. These variables may be set in the /bin/sh as follows:

\begin{verbatim}
eval `g.findfile element=\textit{name} mapset=\textit{name} name=\textit{name}'
\end{verbatim}

NOTES

If the specified file does not exist, the variables will be set as follows:

\begin{verbatim}
name=
mapset=
fullname=
file=
\end{verbatim}

The following is a way to test for this case:

\begin{verbatim}
if [ ! "\textit{file}\" ]
then
  exit
fi
\end{verbatim}

NAME
  g.gisenv - Outputs the user's current GRASS variable settings.
  (GRASS File Management Program)

SYNOPSIS
  g.gisenv
  g.gisenv [variable_name]

DESCRIPTION
  When a user runs GRASS, certain variables are set specifying the GRASS data base, location, mapset, peripheral device drivers, etc., being used in the current GRASS session. These variable name settings are recognized as long as the user is running a GRASS session.

  No prompts are given to the user when running g.gisenv. If run without arguments, g.gisenv lists all of the user's current GRASS variable settings. Results are sent to standard output, and may look like this:

  GISDBASE=/usr/grass4/data
  LOCATION_NAME=spearfish
  MAPSET=PERMANENT

  In this example, the full path name of the user's current location (i.e., $LOCATION_NAME) is /usr/grass4/data/spearfish, and the full path name of the user's current mapset (i.e., $MAPSET) is /usr/grass4/data/spearfish/PERMANENT.

  If the user specifies a variable_name on the command line (e.g., g.gisenv MAPSET), only the value for that particular GRASS variable is output to standard output. Possible variable names depend on the user's system.

  While other variables may be associated with each GRASS session (e.g., DIGITIZER, PAINTER, DISPLAY, and other variables), those stated below are essential.

  GISDBASE - The $GISDBASE is a directory in which all users' GRASS data are stored. Within the $GISDBASE, data are segregated into subdirectories (called "locations") based on the map coordinate system used and the geographic extent of the data. Each "location" directory itself contains subdirectories called "mapsets"; each "mapset" stores "data base elements" -- the directories (e.g., the cell, cellhd, dig, etc., directories) in which GRASS data files are actually stored.

  LOCATION_NAME - The user must choose to work with the data under a single GRASS location within any given GRASS session; this location is then called the current GRASS location, and is specified by the variable $LOCATION_NAME. The $LOCATION_NAME is the GRASS data base location whose data will be affected by any GRASS commands issued during the user's current GRASS session, and is a subdirectory of the current $GISDBASE. Each "location" directory can contain multiple "mapset" directories (including the special mapset "PERMANENT"). Maps stored under the same GRASS LOCATION_NAME (and/or within the same MAPSET) must use the same coordinate system and typically fall within the boundaries of the same geographic region (aka, "location").

  MAPSET - Each "mapset" contains a set of maps relevant to the LOCATION_NAME: directory in which it appears. Each LOCATION_NAME can contain multiple mapsets. (Mapsets which fall under the same LOCATION_NAME: all contain data geographically relevant to the LOCATION_NAME: and all store data in the same map coordinate system. Frequently, maps are placed into different mapsets to distinguish file ownership -- e.g., each user might have his own mapset, storing any maps that he has created and/or are relevant to his work.) During each
GRASS session, the user must choose one mapset to be the current mapset; the current mapset setting is given by $SMAPSET$, and is a subdirectory of $LOCATION.NAME$. During a single GRASS session, the user can use available data in any of the mapsets stored under the current LOCATION.NAME directory that are in the user's mapset search path and accessible by the user. However, within a single GRASS session, the user only has write access to data stored under the current mapset (specified by the variable $SMAPSET$).

Each "mapset" stores GRASS database elements (i.e., the directories in which GRASS data files are stored). Any maps created or modified by the user in the current GRASS session will be stored here. The MAPSET directory "PERMANENT" is generally reserved for the set of maps that form the base set for all users working under each LOCATION.NAME.

Once within a GRASS session, GRASS users have access only to the data under a single GRASS database directory (the current GRASS data base, specified by the variable $GISDBASE$), and to a single GRASS location directory (the current location, specified by the variable $LOCATION.NAME$). Within a single session, the user may only modify the data in the current mapset (specified by the variable $SMAPSET$), but may use data available under other mapsets under the same LOCATION.NAME.

All of these names must be legal names on the user's current system. For UNIX users, names of fewer than 14 characters and containing no non-printing or space codes are permissible. Examples of permissible names include: one, mymap, VeGe.map, and 1_for_me. The underscore character can safely be used in place of a blank for multiple-word names.

NOTES

The output from g.gisenv when invoked without arguments is directly usable by /bin/sh. The following command will cast each variable into the UNIX environment:

```
eval `g.gisenv`
```

This works only for /bin/sh. The format of the output is not compatible with other UNIX shells.

NAME
   g.help — GRASS help facility.
   (GRASS Help Program)

SYNOPSIS
   g.help

DESCRIPTION
   g.help provides the user with functional information on GRASS programs, a glossary, and access to
   on-line User's Reference Manual entries. The help facility is accessed by simply typing g.help on
   the command line. The user can then wend his way through a series of menus (organized by functional
   area) and key-word searches.

   On-line reference manual entries can also be accessed directly, through the GRASS g.manual
   command.

NAME

`g.list` - Lists available GRASS data base files of the user-specified data type to standard output.

(GRASS File Management Program)

SYNOPSIS

```
g.list

g.list help

g.list [-f] type=datatype [mapset=name]
```

DESCRIPTION

`g.list` allows the user to list user-specified, available and accessible files from `mapsets` under the user's current location. When invoked simply as `g.list`, the program prompts the user for the type of data to be listed from all `mapsets` in the user's current mapset search path. The user can list files from a mapset not listed in the current mapset search path by running the program non-interactively, specifying the (optional) flag setting and parameter values on the command line. Program flag and parameters are described below.

Flag:

- `[-f]` Returns a verbose file listing that includes map titles.

Parameters:

- `type=datatype` The type of data to be listed.
  Options: (listed in bold)
  - `rast` Raster files
  - `vect` Binary vector files
  - `icon` Paint icon files
  - `labels` Paint labels files
  - `sites` Site list files
  - `region` Region definition files
  - `group` Imagery group files

- `mapset=name` The name of a mapset to be searched for files of the specified `type`. Any mapset name under the current location, whether or not it is listed in the user's current mapset search path, can be specified.
  Default: If unspecified, files of the specified `type` from all mapsets in the user's current search path will be listed to standard output.

NOTES

If the user requests that files from a mapset to which access has been restricted be listed (see `g.access`), no files from this mapset will be listed.

NAME

\texttt{g\_manual} – Accesses GRASS User's Reference Manual entries.
\textit{(GRASS File Management Program)}

SYNOPSIS

\begin{itemize}
  \item \texttt{g\_manual}
  \item \texttt{g\_manual help}
  \item \texttt{g\_manual [-laefs] [entries=:name[,name,...]]}
\end{itemize}

DESCRIPTION

The \texttt{g\_manual} command provides user access to the on-line GRASS User's Reference Manual entries. The user may request a list of available manual entries, and may get a manual entry printed to the terminal screen and/or to the line printer.

\texttt{g\_manual} can be run either interactively or non-interactively. If the user types

\begin{itemize}
  \item \texttt{g\_manual}
\end{itemize}

on the command line without program arguments, the program will prompt the user for a manual entry to display. The user may enter "list" to get a section-by-section listing of the manual entries available. Once the user has viewed the desired information, it may be printed by responding to the questions appropriately.

The user can run the program non-interactively, by specifying the appropriate options and/or the \texttt{name(s)} of the manual entries to displayed.

OPTIONS

\begin{itemize}
  \item \texttt{-l} This option will list all manual entries, one per line.
  \item \texttt{-a} This option will list all manual entries in a more appealing format. The manual page list will be separated by manual section.
  \item \texttt{-e} This option tells \texttt{g\_manual} to ignore empty manual sections when printing the listings from the \texttt{-l} or \texttt{-a} options.
  \item \texttt{-f} This option will add formfeeds to output listing when using the \texttt{-a} option.
  \item \texttt{-s} This option will cause \texttt{g\_manual} to run silently. Instead of displaying the manual page it will simply set the exit status to:
    \begin{itemize}
      \item 0 if entry exists, or
      \item 1 if it does not exist.
    \end{itemize}
\end{itemize}

These entries may also be accessed through the \texttt{g\_help} command.

NAME

g.mapsets - Modifies the user's current mapset search path, affecting the user's access to data existing under the other GRASS mapsets in the current location.

(GRASS File Management Program)

SYNOPSIS

g.mapsets
  g.mapsets help
  g.mapsets [-lp] [mapset=name[,name,...]]

DESCRIPTION

A mapset holds a distinct set of data layers, each relevant to the same (or a subset of the same) geographic region, and each drawn in the same map coordinate system. At the outset of every GRASS session, the user identifies a GRASS data base, location, and mapset that are to be the user's current data base, current location, and current mapset for the duration of the session; any maps created by the user during the session will be stored under the current mapset ($MAPSE1) set at the session's outset.

The user can add, modify, and delete data layers that exist under his current mapset. Although the user can also access (i.e., use) data that are stored under other mapsets in the same GRASS location, the user can only make permanent changes (create or modify data) located in the current mapset. The user's mapset search path lists the order in which other mapsets in the same GRASS location can be searched and their data accessed by the user. The user can modify the listing and order in which these mapsets are accessed by modifying the mapset search path; this can be done using the g.mapsets command. This program allows the user to use other's relevant map data without altering the original data layer, and without taking up disk space with a copy of the original map.

g.mapsets shows the user available mapsets under the current GRASS location, lists mapsets to which the user currently has access, and lists the order in which accessible mapsets will be accessed by GRASS programs searching for data files. The user is then given the opportunity to add or delete mapset names from his search path, or modify the order in which mapsets will be accessed.

When the user specifies the name of a data base element file (e.g., a particular vector file, raster file, imagery group file, etc.) to a GRASS program, the program searches for the named file under each of the mapsets listed in the user's mapset search path in the order listed there until the program finds a file of the given name. (Users can also specify a file by its mapset, to make explicit the mapset from which the file is to be drawn; e.g., the command:

  g.copy rast =soils.file@PERMANENT',my.soils

ensures that a new file named my.soils is to be a copy of the file soils.file from the mapset PERMANENT.)

It is common for a user to have the special mapset PERMANENT included in his mapset search path, as this mapset typically contains finished base maps relevant to many applications. Often, other mapsets which contain sets of interpreted map layers will be likewise included in the user's mapset search path. Suppose, for example, that the mapset Soil_Maps contains interpreted soils map layers to which the user wants access. The mapset Soil_Maps should then be included in the user's search path variable.

The mapset search path is saved as part of the current mapset. When the user works with that mapset in subsequent GRASS sessions, the previously saved mapset search path will be used (and will continue to be used until it is modified by the user with g.mapsets).
g.mapsets

Flags:

- List all available mapsets under the user's current location.
-p Print the user's current mapset search path to standard output.

Parameter:

mapset = name[ ,name,...] Name(s) of existing GRASS mapset(s) under the current location.

\texttt{g.mapsets} sets the current mapset search path to the \texttt{mapsets} named on the command line. If \texttt{g.mapsets} is typed but no \texttt{mapset} names are specified by the user on the command line, the program will print the user's current mapset search path, list available mapsets, and prompt the user for a new mapset search path listing.

\textbf{NOTES}

Users can restrict others' access to their mapset files through use of the GRASS program \texttt{g.access}. Mapsets to which access is restricted can still be listed in another's mapset search path; however, access to these mapsets will remain restricted.

g.region

NAME

g.region – Program to manage the boundary definitions for the geographic region.

SYNOPSIS

g.region

DESCRIPTION

The g.region program allows the user to manage the settings of the current geographic region. These regional boundaries can be set by the user directly and/or set from a region definition file (stored under the windows directory in the user's current mapset). The user can create, modify, and store as many geographic region definitions as desired for any given mapset. However, only one of these geographic region definitions will be current at any given moment, for a specified mapset; i.e., GRASS programs that respect the geographic region settings will use the current geographic region settings.

INTERACTIVE PROGRAM USE: MAIN MENU

The main menu consists of an information section listing the current GRASS data base LOCATION, MAPSET, and CURRENT REGION, followed by user options:

```
LOCATION: sample
CURRENT REGION: N=5167600 S=5156755 RES=50 ROWS=216
                  E=729314 W=705924 RES=50 COLS=467
PROJECTION: 1 (UTM)
ZONE: 13

Please select one of the following options

Current Region

1 Modify current region directly
2 Set from default region
3 Set from a database region
4 Set from a raster map
5 Set from a vector map
6 Save current region in the database
7 Create a new region
8 Modify an existing region

RETURN to quit
```

DEFINITIONS

Region:

Here, a region refers to a geographic area with some defined boundaries, based on a specific map coordinate system and map projection. Each region also has associated with it the specific east-west and north-south resolutions of its smallest units (rectangular units called "cells").
The region's boundaries are given as the northernmost, southernmost, easternmost, and westernmost points that define its extent. The north and south boundaries are commonly called *northings*, while the east and west boundaries are called *eastings*.

The region's cell resolution defines the size of the smallest piece of data recognized (imported, analyzed, displayed, stored, etc.) by GRASS programs affected by the current region settings. The north-south and east-west cell resolutions need not be the same, thus allowing non-square data cells to exist.

**Default Region:**
Each GRASS LOCATION_NAME has a fixed geographic region, called the default geographic region (stored in the region file DEFAULT_WIN under the special mapset PERMANENT), that defines the extent of the data base. While this provides a starting point for defining new geographic regions, user-defined geographic regions need not fall within this geographic region.

**Current Region:**
Each mapset has a current geographic region. This region defines the geographic area in which all GRASS displays and analyses will be done. Data will be resampled, if necessary, to meet the cell resolutions of the current geographic region setting.

**Region Data Base:**
Each GRASS MAPSET may contain any number of pre-defined, and named, geographic regions. These region definitions are stored in the user's current mapset location under the *windows* directory (also referred to as the user's data base of region definitions). Any of these pre-defined geographic regions may be selected, by name, to become the current geographic region. Users may also access saved region definitions stored under other mapsets in the current location, if these mapsets are included in the user's mapset search path.

**REGION EDIT PROMPT**
Most of the options will require the user to edit a geographic region, be it the current geographic region or one stored in the user's data base of region definitions (the *windows* directory). A standard prompt is used to perform this edit. An example is shown below:
IDENTIFY REGION

<table>
<thead>
<tr>
<th>DEFAULT REGION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default North: 3402025.00</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>YOUR REGION</th>
</tr>
</thead>
<tbody>
<tr>
<td>North Edge</td>
</tr>
<tr>
<td>West Edge: 233975.00</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>DEF EAST</th>
</tr>
</thead>
<tbody>
<tr>
<td>236025.00</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>DEF SOUTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>3399975.00</td>
</tr>
</tbody>
</table>

| Default South: 3399975.00 |

<table>
<thead>
<tr>
<th>Default GRID RESOLUTION Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>East-West: 50.00</td>
</tr>
<tr>
<td>North-South: 50.00</td>
</tr>
</tbody>
</table>

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE

The fields NORTH EDGE, SOUTH EDGE, WEST EDGE and EAST EDGE, are the boundaries of the geographic region that the user can change. The fields Default North, Default South, Def West and Def East are the boundaries of the default geographic region that are displayed for reference and cannot be changed. The two GRID RESOLUTION Region fields (east-west, and north-south) are the geographic region's cell resolutions that the user can change. The two GRID RESOLUTION Default fields list the resolutions of the default geographic region; these are displayed for reference and cannot be changed here by the user.

REGION MANAGEMENT MENU OPTIONS

1 Modify the current geographic region directly
   Allows the user to edit the current region.

2 Set current geographic region from default region
   Copies the default region to the current geographic region, and then lets the user edit the current geographic region.

3 Set current geographic region from a data base geographic region
   Allows the user to select a geographic region by name from the data base of geographic regions to become the current geographic region, and then lets the user edit the current geographic region.
   Note: geographic region definition files may be selected from other mapsets as well, if accessible and in the user's mapset search path.

4 Set current geographic region from a raster (cell) map layer
   Allows the user to select a raster map layer, copies the cell header for this map layer to the current geographic region, and then lets the user edit the current geographic region. This option is useful when subsequent GRASS operations will be used to produce a raster map layer from one input raster map layer and it is necessary that the result coincide with the input raster map layer.
5 Save the current geographic region (window) in the database

Allows the user to save the current geographic region settings in the user's data base of such settings. These files are stored in the windows directory under the user's current mapset. This option is useful when the current geographic region is set directly using option 2, or even by another GRASS program (e.g., d.display). This option installs an otherwise temporary geographic region setting into the geographic region definition database for recall when needed.

6 Create a new data base geographic region setting

Creates a new geographic region definition in the user's data base of such settings in the windows directory under the current mapset, using the geographic region edit prompt described above. After the geographic region definition is created, the user is asked if this geographic region setting should also be used as the current geographic region.

7 Modify a data base geographic region setting

Modifies a geographic region setting (in the data base of such settings in the windows directory of the current mapset), using the geographic region edit prompt. After the changes have been made, the user is asked if this geographic region setting should also be used as the current geographic region.

NON-INTERACTIVE PROGRAM USE

Alternately, the user can modify the settings of the current geographic region by specifying all needed parameters on the command line. The user enters the command g.region parms, where parms are the following parameters and/or flags:

Flags:
-d Set current region settings equal to default region settings.
-g Print the current region settings (shell script style) in a format that can be given back to g.region on its command line.
-p Print the current region settings.
-u Do not update the current region file settings. Allows the user to temporarily use a different region setting, without saving this setting.

Parameters:
region=name Make current region settings same as the named region file settings
raster=name Make current region settings same as those in the named raster map's cell header. But see zoom=name option, below.
vector=name Make the current region settings the same as those of the named vector map.
sites=name Set the current region to the smallest region encompassing all coordinates in the named site_lists file, aligned with the current region.
n=value Set map coordinate value for the region's northern edge to x
s=value Set map coordinate value for the region's southern edge to x
e=value Set map coordinate value for the region's eastern edge to x
w=value Set map coordinate value for the region's western edge to x
res=value Set grid resolution (both north-south and east-west) to x
nsres=value Set north-south grid resolution value to x
ewres=value Set east-west grid resolution value to x
zoom=name Set current region settings to the smallest region encompassing all non-zero data in the named raster map layer that fall inside the user's current region. If the user also includes the raster=name option on the command line, zoom=name will set the current region settings to the smallest region encompassing all non-zero data in the named raster map layer that fall inside the user's current region.
g.region encompassing all non-zero data in the named zoom map that fall inside the region stated in the cell header for the named raster map.

align=name Set the current resolution equal to that of the named raster map, and align the current region to a row and column edge in the named map. Alignment only moves the existing region edges outward to the edges of the next nearest cell in the named raster map - not to the named map’s edges. To perform the latter function, use the raster=name option.

save=name Save current region settings in the named region file

EXAMPLES

g.region n=7360100 e=699000
will reset the northing and easting for the current region, but leave the south edge, west edge, and the region cell resolutions unchanged.

g.region -dp s=698000
will set the current region from the default region for the GRASS data base location, reset the south edge to 698000, and then print the result.

g.region n=n+1000 w=w+500
The n=value may also be specified as a function of its current value: n=n+value increases the current northing, while n=n-value decreases it. This is also true for s=value, e=value, and w=value. In this example the current region’s northern boundary is extended by 1000 units and the current region’s western boundary is decreased by 500 units.

g.region n=s+1000 e=w+1000
This form allows the user to set the region boundary values relative to one another. Here, the northern boundary coordinate is set equal to 1000 units larger than the southern boundary’s coordinate value, and the eastern boundary’s coordinate value is set equal to 1000 units larger than the western boundary’s coordinate value. The corresponding forms s=n-value and w=e-value may be used to set the values of the region’s southern and western boundaries, relative to the northern and eastern boundary values.

g.region raster=soils
This form will make the current region settings exactly the same as those given in the cell header file for the raster map layer soils.

g.region raster=soils zoom=soils
This form will first look up the cell header file for the raster map layer soils, use this as the current region setting, and then shrink the region down to the smallest region which still encompasses all non-zero data in the map layer soils. Note that if the parameter raster=soils were not specified, the zoom would move to encompass all non-zero data values in the soils map that were located within the current region setting.

g.region -u raster=soils
The -u option suppresses the re-setting of the current region definition. This can be useful when it is desired to only extract region information. In this case, the cell header file for the soils map layer is printed without changing the current region settings.

g.region -u raster=soils zoom=soils save=soils
This will zoom into the smallest region that encompasses all non-zero soils data values, and save the new region settings in a file to be called soils and stored under the windows directory in the user’s current mapset. The current region settings are not changed.
g.region -p

This will print the current region in the format:

projection: 1 (UTM)
zone: 15
north: 4294050.00
south: 4249950.00
east: 526050.00
west: 500950.00
nsres: 100.00
ewres: 100.00
rows: 441
cols: 251

The -g option prints the region in the following format:

n=4294050.00
s=4249950.00
e=526050.00
w=500950.00
nsres=100.00
ewres=100.00

This format does not have the rows and columns, but can be fed back into g.region on its command line.

The -p (or -g) option is recognized last. This means that all changes are applied to the region settings before printing occurs.

NOTE

After all updates have been applied, the current region's southern and western boundaries are (silently) adjusted so that the north/south distance is a multiple of the north/south resolution and that the east/west distance is a multiple of the east/west resolution.

AUTHOR

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME
g.remove – Removes data base element files from the user’s current mapset.
(GRASS File Management Program)

SYNOPSIS

g.remove

g.remove help

g.remove [rast=name[,name,...]] [vect=name[,name,...]] [icon=name[,name,...]] [labels=name[,name,...]]
[sites=name[,name,...]] [region=name[,name,...]] [group=name[,name,...]]

DESCRIPTION

g.remove allows the user to remove specified data base element files from the current mapset. If
g.remove is invoked without arguments on the command line, a menu will appear listing possible data
element types, as below:

1. raster maps
2. vector maps
3. paint icon files
4. paint label files
5. site list files
6. region files
7. imagery group files

RETURN to exit

Once the element type is selected, the user is prompted to name a specific file of this element type for
removal. (This list will vary, depending on what files currently exist in the user’s mapset.) The
specified file is removed, and the user is again prompted for the name of a file of this element type to
be removed. When prompted for a file name, the user may enter list to see a list of existing files of
this element type, or hit RETURN to get back to the above menu.

Alternatively, the user can specify the data base element type and file(s) to be removed on the command
line. Data base element types are specified by the names to the left, below.

Parameters:

rast=name[,name,...] Name(s) of raster file(s) to be removed.
vect=name[,name,...] Name(s) of vector file(s) to be removed.
icon=name[,name,...] Name(s) of paint icon file(s) to be removed.
labels=name[,name,...] Name(s) of paint labels file(s) to be removed.
sites=name[,name,...] Name(s) of site list file(s) to be removed.
region=name[,name,...] Name(s) of region file(s) to be removed.
group=name[,name,...] Name(s) of imagery group file(s) to be removed.

The data base element file(s) named by the user on the command line are subsequently removed from
the user’s current mapset.

EXAMPLE

For example, the below command will cause the raster files named soils, slope, and temp, the vector
files named roads and rail, and the imagery group files named nhap.1 and nhap.2, and these files’
associated support files (e.g., cell header files, category files, etc.), to be removed from the user’s
current mapset.

    g.remove rast=soils,slope,temp vect=roads,rail group=nhap.1,nhap.2
NOTE
If a particular data base element file has support files associated with it (e.g., as is commonly the case with raster files), `g.remove` will remove these support files along with the data base element file specified.
The user can only use `g.remove` to remove data files existing under the user's current mapset.

FILES
`$GISBASE/etc/element_list` lists the element types whose files can be removed by the user.

AUTHOR
Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME

`g.rename` - To rename database element files in the user's current mapset.

(Grass File Management Program)

SYNOPSIS

```
g.rename
```

```
g.rename help
```

```
g.rename [rast=old,new] [vect=old,new] [icon=old,new] [labels=old,new] [sites=old,new]
```

```
[region=old,new] [group=old,new]
```

DESCRIPTION

`g.rename` allows the user to rename database element files in the user's current mapset. The user can specify all necessary information to `g.rename` on the command line, by specifying: the type of database element to be renamed (one or more of: `rast`, `vect`, `icon`, `labels`, `sites`, `region`, and `group`); the specific file element in the current mapset to be renamed (`old`); and the new name to be assigned to this file element (`new`) in the current mapset. The file element `old` is then renamed to `new`.

Users can also simply type `g.rename` without arguments on the command line, to receive a menu of existing database element types and files from which to choose for possible renaming:

```
1 raster maps
2 binary vector maps
3 paint icon files
4 paint label files
5 site list files
6 region definition files
7 imagery group files
```

RETURN to exit

NOTE

If a database element has support files (e.g., as is commonly the case with raster files), these support files also are renamed.

If the user attempts to rename a file to itself by setting the `new` file name equal to the `old` file name (e.g., `g.rename rast=soils,soils`), `g.rename` will not execute the rename, but instead state that no rename is needed. However, `g.rename` will allow the user to overwrite other existing files in the current mapset by making the `new` file name that of an already existing file.

g.tempfile

NAME

* g.tempfile – Creates a temporary file and prints the file name

(Grass File Management Program)

SYNOPSIS

* g.tempfile help

* g.tempfile pid=value

DESCRIPTION

* g.tempfile is designed for shell scripts that need to use large temporary files. GRASS provides a
mechanism for temporary files that does not depend on /tmp. GRASS temporary files are created in the
data base with the assumption that there will be enough space under the data base for large files.
GRASS periodically removes temporary files that have been left behind by programs that failed to
remove them before terminating.

* g.tempfile creates an unique file and prints the name. The user is required to provide a process-id which
will be used as part of the name of the file. Most Unix shells provide a way to get the process id of
the current shell. For /bin/sh and /bin/csh this is $$$. It is recommended that $$ be specified as the
process-id for g.tempfile.

EXAMPLE

* For /bin/sh scripts the following syntax should be used:

    temp1=`g.tempfile pid=$$
    temp2=g.tempfile pid=$$

* For /bin/csh scripts, the following can be used:

    set temp1 = g.tempfile pid=$$
    set temp2 = g.tempfile pid=$$

NOTES

* Each call to g.tempfile creates a different (i.e., unique) name.

Although GRASS does eventually get around to removing tempfiles that have been left behind, the
programmer should make every effort to remove these files. They often get large and take up disk
space. If you write /bin/sh scripts, learn to use the /bin/sh trap command. If you write /bin/csh scripts,
learn to use the /bin/csh onintr command.

NAME

i.build.blk – An imagery function that creates and edits blocks and sub-blocks of imagery groups for
ortho-rectification.
(GRASS Imagery Program)

SYNOPSIS

i.build.blk

DESCRIPTION

An imagery photo block consists of several scanned aerial photographs (raster map layers) of a common
area. An imagery sub-block is a subset of these raster map layers.

i.build.blk allows the user to collect one or more imagery groups by assigning them to a named block
and sub-block. This enables the user to run ortho-rectification programs on a single imagery group
within a sub-block.

The user first creates all of the imagery groups using i.group.

The first menu in the i.build.blk program asks the user to select a block. If the block does not exist,
the user will be asked if he or she would like to create a new block:

This program edits blocks of imagery groups for ortho-rectification.
You may select or create blocks of imagery groups.
You may edit blocks of existing imagery groups.
You may create sub-blocks of imagery groups within the block.
You may select a TARGET location for the ortho-rectified blocks.
You may select an elevation data raster file from the TARGET location.
You may select a camera reference file for the block.

Please enter the block to be created/modified

BLOCK: __________ (enter 'list' for a list of existing blocks)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO EXIT)

If the word list is entered, blocks that have already been created in the current LOCATION and
MAPSET(S) will be displayed.

The second menu in i.build.blk provides the user with the following options:

1. Select a different block
2. Edit block title
3. Select a TARGET location
4. Select an elevation data layer
5. Select a camera reference file
6. Include new imagery groups in the block
or remove imagery groups from the block
7. Create a new sub-block within the block
The options are described as follows:

Select a different block
If option number 1 is chosen, the following menu is displayed:

Please enter the block to be created/modified

BLOCK: ___________ (enter 'list' for a list of blocks)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO EXIT)

If the word 'list' is entered, blocks that have already been created in the current LOCATION and MAPSET(S) will be displayed.

Edit block title
If option number 2 is selected, an entry space is provided to type in the block title. This title is useful in identifying each block:

TITLE

This option offers an opportunity to go back and change the entry if it is not correct by asking: Look ok? (y/n).

Select a TARGET location
If option number 3 is selected, an entry space is provided to type in the TARGET location and mapset were the ortho-rectified raster files are to reside.

The following menu asking for the target LOCATION and MAPSET is displayed:

Please select the target LOCATION and MAPSET for block <block_name>

CURRENT LOCATION: location_________
CURRENT MAPSET: mapset_________
TARGET LOCATION:_________
TARGET MAPSET:_________

(enter list for a list of locations or mapsets within a location)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)
If the word *list* is entered, the list of available LOCATION(S) and MAPSET(S) will be displayed.

**Select an elevation data layer**

If option number 4 is selected, an entry space is provided to type in the name of an existing raster file within the TARGET location that is to be used as the elevation data during ortho-rectification.

The following menu asking a raster file in the TARGET location to be used for elevation data is displayed:

```
Please select an elevation raster file for block <block_name>
```

```
Elevation raster file: ______________________
(enter list for a list of raster files in the TARGET location)
```

**AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE**

**(OR <Ctri-C> TO CANCEL)**

If the word *list* is entered, a list of raster files within the TARGET location will be displayed.

**NOTE:** It is assumed that the category values of the selected elevation raster map layer are represented in METERS. *r.mapcalc* may be used to convert other data conventions, as well as replace any cells with category value zero (no-data) with another value.

**Select a camera reference file**

If option number 5 is selected, an entry space is provided to type in the name of an existing camera reference file within the CURRENT location that is to be used for data during ortho-rectification.

The following menu asking for an existing camera reference file is displayed:

```
Please select a camera reference file for block <block_name>
```

```
Camera reference file: ______________________
(enter list for a list of existing camera reference files)
```

**AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE**

**(OR <Ctri-C> TO CANCEL)**

If the word *list* is entered, a list of existing camera reference files be displayed.

**NOTE:** The GRASS program *i.mod.camera* may be used to create camera reference files.

**Include or remove imagery groups from the block**
When choosing option number 6, the following menu is displayed:

LOCATION: location  BLOCK: demo  MAPSET: mapset

If you wish to delete an imagery group from block [demo], remove the 'x' from in front of the file name.

  x.  group13 in mapset
  x.  group14 in mapset

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR Ctrl-C> TO CANCEL)

Next, a menu listing all the other imagery groups present in the current MAPSET(S) will be displayed:

LOCATION: location  BLOCK: demo  MAPSET: mapset

Please mark an 'x' by the imagery groups to be added in block [demo]

  MAPSET: mapset
  x.:group21 in mapset
  x.:group22 in mapset

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR Ctrl-C> TO CANCEL)

If more than one MAPSET is selected, menus for those mapsets will also be displayed. All imagery groups selected with an 'x' will be included in the block being updated.

The user will then have the opportunity to check the contents of the block that was just modified:

Block [demo] references the following raster files

    group13 in mapset
    group14 in mapset
    group21 in mapset
    group22 in mapset

Look ok? (y/n)

If the user responds with the letter y then the following sentence is displayed on the screen:

Block [demo] updated!
And the main menu for `i.build.blk` returns.

If the user responds `n`, the menu containing the block files after it was modified will be displayed and the user will be asked to place an `x` in front of those imagery groups that are to be removed from the block. Then, a menu listing all of the other imagery groups in the current MAPSET will be displayed again, and the user will be again asked to place an `x` in front of imagery groups to be included in the block. This gives the user the opportunity to correct mistakes or make changes in the choice of files to be selected in a block without exiting `i.build.blk`.

Create a new sub-block within the block

The following menu enables the user to create a sub-block out of a single imagery group in the block. Any number of sub-blocks may be created by repeating the option.

```
LOCATION: location
MAPSET: mapset

BLOCK: demo
SUBBLOK: ________ ('list' will show available sub-blocks)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)
```

After selecting or creating a sub-block, this menu is displayed:

```
Mark an 'x' by only one imagery group to form sub-block [13]

   x_ group13 in mapset
      --- group14 in mapset
      --- group21 in mapset
      --- group22 in mapset

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)
```

The user is then given the opportunity to check the contents of the sub-block:

```
Subblock [13] references the following raster file

   group13 in mapset

Look ok? (y/n)
```

If the user responds with the letter `n`, the block menu will appear again enabling the user to select another file to form the sub-block.
NOTES
The i.build.blk options are only available for imagery groups in the current LOCATION.

The ortho-rectification programs in i.rectify.blk currently are designed as single photo rectifications. Hence, only a single imagery group may be selected for each sub-block. In the future multi-photo rectification may become available.

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

NAME
i.camera - An imagery function that establishes a camera reference file for an imagery group, and runs interactively.

(Grass Image Processing Program)

SYNOPSIS
i.camera

DESCRIPTION
i.camera selects a camera reference file to be used with an imagery group. In the imagery programs i.ortho.reference, i.ortho.control, and i.ortho.rectify, a camera reference file is required for computation of reference points and ortho-rectification parameters. i.camera enables the user to specify an existing camera reference file for a selected imagery group.

i.camera is fully interactive. The program first prompts the user for the name of the imagery group that requires a camera reference file. This imagery group must already exist under the user's current MAPSET (see i.group).

The program next asks the user for the name of an existing camera reference file to be used with the imagery group selected above. The GRASS program i.mod.camera can be used to create this camera reference file.

NOTES
This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

NAME
i. cca – Canonical components analysis (cca) program for image processing.
(Grass Image Processing Program)

SYNOPSIS
i. cca
i.cca help
i.cca group=name subgroup=name signature=name output=name

DESCRIPTION
i.cca is an image processing program that takes from two to eight (raster) band files and a
signature file, and outputs the same number of raster band files transformed to provide maximum
separability of the categories indicated by the signatures. This implementation of the canonical
components transformation is based on the algorithm contained in the LAS image processing system.

Typically the user will use the i.class program to collect a set of signatures and then pass those
signatures along with the raster band files to i.cca. The raster band file names are specified on the
command line by giving the group and subgroup that were used to collect the signatures.

The output raster map names are built by appending a ".1", ".2", etc. to the output raster map name
specified on the command line.

Parameters:
group=name Name of the imagery group to which the 2 to 8 raster band files used belong.
subgroup=name Name of the imagery subgroup to which the 2 to 8 raster band files used belong.
signature=name Name of an ASCII file containing spectral signatures.
output=name Output raster file prefix name. The output raster map layer names are built by
appending a ".1", ".2", etc. onto the output name specified by the user.

NOTES
i.cca respects the current geographic region definition and the current mask setting while performing
the transformation.

NAME

*i.class* - An imagery function that generates spectral signatures for an image by allowing the user to outline regions of interest. The resulting signature file can be used as input for *i.maxlik* or as a seed signature file for *i.cluster*.

*(GRASS Image Processing Program)*

SYNOPSIS

```
i.class
```

DESCRIPTION

*i.class* performs the first pass in the GRASS two-pass supervised image classification process; the GRASS program *i.maxlik* executes the second pass. Both programs must be run to generate a classified map in GRASS raster format.

*i.class* is an interactive program that allows the user to outline a region on the screen and calculate the spectral signature based on the cells that are within that region. During this process the user will be shown a histogram of the region for each image band. The user can also display the cells of the image bands which fall within a user-specified number of standard deviations from the means in the spectral signature. By doing this, the user can see how much of the image is likely to be put into the class associated with the current signature.

The spectral signatures that result are composed of region means and covariance matrices. These region means and covariance matrices are used in the second pass (*i.maxlik*) to classify the image.

Alternatively, the spectral signatures generated by *i.class* can be used for seed means for the clusters in the *i.cluster* program.

USER INPUTS

The first screen in the program *i.class* asks the user for the imagery group and subgroup to be analyzed:

```
LOCATION: location        SUPERVISED CLASSIFIER MAPSET: demo
Please select the group and subgroup to be analyzed

GROUP: spot (list will show available groups)
SUBGROUP: 123 (list will show available subgroups)
```

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

The *group* should contain the imagery bands that the user wishes to classify. The *subgroup* is a subset of this group. The user must create a group and a subgroup by running the GRASS program *i.group* before running *i.class*. The subgroup should contain only the image bands that the user wishes to classify. Note that this subgroup must contain more than one band.

After the first screen, the program asks the user for the name of the resulting signature file. The signature file is both the output file for *i.class* and the required input file for the GRASS program *i.maxlik*. It contains the region means and covariance matrices that are used to classify an image in *i.maxlik*.

After entering the resulting signature file name, the user is asked to enter the name of a seed signature file. This is optional. A "seed" signature file is a previously created signature file. Such a seed signature file may be the result of an earlier run of *i.class*. The seed signature file is copied into the new resulting signature file before any new signatures are added by *i.class*. In this way, you can collect the work from several sessions with *i.class* into one signature file.
Next, the user is asked to enter the name of the raster map to be displayed during the process of outlining regions. Typically, the user will want to enter the name of a color composite previously created by \textit{i.composite}. However, the user can enter the name of any existing raster map. This leaves the potential for using a raster map not directly derived from the image as a backdrop on which the user can outline the classes of interest.

At this point the \textit{i.class} graphics screen will be drawn on the graphics monitor and the user will be directed to use the mouse. From this point on the user will primarily work with the mouse, selecting options from the menus and outlining regions on the screen. The only time that the user will need to return to the text terminal is to enter names for the signatures created.

**THE DISPLAY FRAMES**

The display frame layout that \textit{i.class} uses is represented below for reference.

```
+-----------------------------+--------------- ------------------------ +
|                            | Map Display Frame |
+-----------------------------+-------------------+
| Histogram Display Frame     |                   |
+-----------------------------+-------------------+
| Zoom Display Frame          |                   |
| Menu Frame                  |                   |
```

**THE MENUS**

All of the menus in the \textit{i.class} program are displayed across the bottom of the graphics monitor in the Menu Frame. To select an option from one of these menus, simply place the cursor over your selection and press any button on the mouse. Each of the menus is discussed in the following paragraphs.

**The Command Menu**

The Command Menu includes the following selections:

- **Zoom** - This command allows the user to outline a rectangular region in either the Map or Zoom Display Frames and the region is displayed, magnified, to fit in the Zoom Display Frame. A red rectangle is drawn in the Map Display Frame, indicating what area the Zoom Display Frame shows.

  To outline the rectangular region, simply use any mouse button to anchor the first corner of the border and then use any button to choose the other corner.

- **Define region** - This selection takes the user to the Region Menu. This menu includes the options that allow the user to outline a region of interest on the displayed raster map.

- **Redisplay map** - This selection takes the user to the Redisplay Menu. The Redisplay Menu allows the user to redraw map display frames.
*Analyze region* - This selection starts the process of analyzing the currently defined region. A histogram of the defined region will be displayed for each band. On the histogram for each band, the mean, standard deviation, minimum cell value and maximum cell value are marked. The histograms are automatically scaled in an attempt to fit the data into the space available, but it is possible that all of the data will not fit. In this case, as much of the data as possible, centered around the mean, will be displayed. After the histograms are displayed, the user will be given the Signature Menu.

*Quit* - The user should make this selection to end the session with *i.class*.

**The Region Menu**

The Region Menu contains the following selections:

*Erase region* - This selection erases any currently defined region.

*Draw region* - This selection allows the user to use the mouse to draw a region on either the Map or Zoom Display Frame. An explanation of which mouse buttons to use is displayed in the Menu Frame. The user does not need to try to complete the region boundary. The last line of the region will be added when the user selects the Complete region option on the Region Menu.

*Restore last region* - This selection restores the last region that was drawn. After a region is completed, it will be saved to be restored later. Only one previous region is saved.

*Complete region* - This selection completes the region that is currently being drawn. As noted above, it saves the complete region to be restored later, if needed. Once the user has made a complete region, it can be analyzed with the Analyze Region selection on the Command Menu.

*Done* - Use this selection to return to the Command Menu.

**The Redisplay Map Menu**

The Redisplay Map Menu has the following selections, which are useful to redraw the raster maps displayed in the Map and Zoom Display Frames.

*Map geographic region* - This selection causes the raster map in the Map Display Frame to be redrawn.

*Zoom region* - This selection causes the Zoom Display Frame to be redrawn.

*Both* - This selection causes both the Map and Zoom Display Frames to be redrawn.

*Cancel* - Use this selection if you do not want to redisplay either of the above regions. The user will be returned to the Command Menu.

**The Analyze Region Menu**

The Analyze Region Menu contains the Signature Menu, which allows the user to set the number of standard deviations and the display color, and then to display (as an overlay) the cells that match the signature within the number of standard deviations specified. Note that once the matching cells are displayed, the Map Display Frame must be redisplayed to see only the original raster map again. The following selections are available on the Signature Menu:

*Set std dev's* - This selection allows the user to set the number of standard deviations from the mean for the maximum and minimum range. The maximum and minimum range is used when finding the cells that "match" the signature. The user is presented with a menu of typical choices and an "Other" option. If the "Other" option is selected, enter the number of standard deviations from the keyboard on the text terminal. Otherwise, the selected option will be used. When the number of standard deviations is set, the histograms for each band will be redrawn with the maximum and minimum range marked.
Note that the number in parentheses on this selection is the current number of standard deviations.

**Set color** - This selection allows the user to set the color for the display of cells that "match" the current signature. The user is presented with a menu of color choices. The color selected will be used when the Display Matches Menu selection is made.

Note that the color in parentheses on this selection is the current color for display.

**Display matches** - This selection displays the cells that "match" the current signature in the current color. A cell "matches" the current signature if the cell value in each band is between the minimum range and maximum range for that band defined by the number of standard deviations currently set.

**Done** - When this selection is chosen, the user will be asked whether or not he/she would like to save the current signature. If the user answers with the "Yes" selection, he/she will be asked to enter a description for the resultant signature file on the text terminal keyboard. The saved signature file description will be used by `i.maxlik` to name the category that is created from the current signature. After either a "No" answer or the signature description is entered, the user is returned to the Command Menu.

**NOTES**

*i.class* uses the current MASK to generate the overlay for cells that match a signature. As a result, if a MASK already exists it will be removed during the execution of this program.

The cell values in the image bands cannot fall outside of the range of 0 to 255. *i.class* will report an error if they do.

*i.class*, like some of the other imagery programs, does not use the standard GRASS display frames. After running *i.class*, you will need to create a display frame (e.g., using `d.frame` or `d.erase`) before you can use most of the GRASS display (d.) commands.

*i.group* must be run before *i.class* to create an imagery group and a subgroup containing the image bands to be classified.

The user can perform a supervised image classification by running *i.class* followed by *i.maxlik*. The user can perform an unsupervised classification by running *i.cluster* followed by *i.maxlik*.

*i.class* is interactive and requires no command line arguments. The user must be running a graphics display monitor (see `d.mon`) to run this program.

NAME

*i.cluster* - An imagery function that generates spectral signatures for land cover types in an image using a clustering algorithm. The resulting signature file is used as input for *i.maxlik*, to generate an unsupervised image classification.

(GRASS Image Processing Program)

SYNOPSIS

*i.cluster*

DESCRIPTION

*i.cluster* performs the first pass in the GRASS two-pass unsupervised classification of imagery, while the GRASS program *i.maxlik* executes the second pass. Both programs must be run to complete the unsupervised classification.

*i.cluster* is a clustering algorithm that reads through the (raster) imagery data and builds pixel clusters based on the spectral reflectances of the pixels. The pixel clusters are imagery categories that can be related to land cover types on the ground. The spectral distributions of the clusters (which will be the land cover spectral signatures) are influenced by six parameters set by the user. The first parameter set by the user is the initial number of clusters to be discriminated. *i.cluster* starts by generating spectral signatures for this number of clusters and "attempts" to end up with this number of clusters during the clustering process. The resulting number of clusters and their spectral distributions, however, are also influenced by the range of the spectral values (category values) in the image files and the other parameters set by the user. These parameters are: the minimum cluster size, minimum cluster separation, the percent convergence, the maximum number of iterations, and the row and column sampling intervals.

The cluster spectral signatures that result are composed of cluster means and covariance matrices. These cluster means and covariance matrices are used in the second pass (*i.maxlik*) to classify the image. The clusters or spectral classes that result can be related to land cover types on the ground.

USER INPUTS

The first menu in the program *i.cluster* asks the user for the imagery group and subgroup to be analyzed:

LOCATION: location   CLUSTER   MAPSET: demo

Please select the group/subgroup to be analyzed

GROUP:  spot
SUBGROUP:  123

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE

(OR <Ctrl-C> TO CANCEL)

The group should contain the imagery files that the user wishes to classify. The subgroup is a subset of this group. The user must create a group and subgroup by running the GRASS program *i.group* before running *i.cluster*. The subgroup should contain only the imagery band files that the user wishes to classify. Note that this subgroup must contain more than one band file. The purpose of the group and subgroup is to collect map layers for classification or analysis.

The first prompt inside the program asks the user for the name of the resulting signature file. The signature file is both the output file for *i.cluster* and can be used as the required input file for the GRASS program *i.maxlik*. It contains the cluster means and covariance matrices that are used to classify an image in *i.maxlik* for an unsupervised classification.
After entering the signature file name, the user is asked to enter the name of a seed signature file. This is optional. Seed signatures are signatures that contain cluster means and covariance matrices that were calculated prior to the current run of `i.cluster`. They may be acquired from a previous run of `i.cluster` or from a supervised classification signature training site selection (e.g., using the signature file output by `i.class`). The purpose of seed signatures is to optimize the cluster decision boundaries (means) for the number of clusters specified.

The final menu asks the user for the clustering parameters. The default values in the menu are the suggested values based upon the total number of rows and columns in the image files. This menu also informs the user of the number of rows and columns of the image files that are included in the current geographic region. Make sure that this geographic region is large enough to include the portion of the image files that you wish to classify.

Please set the following information

- **Number of initial classes**: 15
- **Minimum class size**: 17
- **Minimum class separation**: 0.50
- **Percent convergence**: 98.00
- **Maximum number of iterations**: 30

Your current geographic region contains 100 rows and 100 cols (1000 cells)

Please set the sampling intervals

- **Row interval**: 2
- **Col interval**: 2

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE (OR <Ctrl-C> TO CANCEL)

**Number of initial classes**
This is the number of clusters that will initially be identified in the clustering process before the iterations begin.

**Minimum class size**
This is the minimum number of pixels that will be used to define a cluster, and is therefore the minimum number of pixels for which means and covariance matrices will be calculated.

**Minimum class separation**
This is the minimum separation below which clusters will be merged in the iteration process. This is an image-specific number (a "magic" number) that depends on the image data being classified and the number of final clusters that are acceptable. Its determination requires experimentation. Note that as the minimum class (or cluster) separation is increased, the maximum number of iterations should also be increased to achieve this separation with a high percentage of convergence (see **percent convergence**).

**Percent convergence**
A high percent convergence is the point at which cluster means become stable during the iteration process. When clusters are being created, their means constantly change as pixels are assigned to them and the mean is recalculated to include the new pixel. After all clusters have been created, `i.cluster` begins iterations that change cluster means by maximizing the distances between them. As these means shift, a higher and higher convergence is approached. Because means will never become totally static, a percent convergence and a maximum number of...
iterations is supplied to stop the iterative process. The percent convergence should be reached before the maximum number of iterations. If the maximum number of iterations is reached, it is probable that the desired percent convergence was not reached. The number of iterations is reported in the cluster statistics in mail (see NOTES).

**Maximum number of iterations**

This is a number which is greater than the number of iterations predicted to achieve the optimum percent convergence. If the number of iterations reaches the maximum designated by the user, the user may want to rerun `i.cluster` with a higher number of iterations (see NOTES).

**Row and column sampling intervals**

These numbers are based on the size of the data set.

**NOTES**

`i.cluster` will run in the background and notify the user by mail when it is complete. The mail message will contain the results, i.e., the statistics for each cluster. Also included in the mail message are the resulting percent convergence for the clusters, the number of iterations that were required to achieve the convergence, and the separability matrix.

`i.group` must be run before `i.cluster` to create an imagery group and a subgroup containing the image band files to be classified.

This program is interactive and requires no command line arguments.

NAME

`i.colors` - An imagery function that creates colors for imagery groups.

(Grass Image Processing Program)

SYNOPSIS

`i.colors`

DESCRIPTION

`i.colors` allows the user to interactively assign red, green, and blue colors to the band files in an imagery group while viewing the display of the combined bands on the graphics monitor.

The user is asked to select an imagery group. Band files in the group that are currently assigned to the red, green, and blue color bands are displayed along the left edge of the user's graphics display frame, and a composite image of these bands is displayed in the right portion of the display frame. A small matrix appears in the lower left portion of the display frame, and reflects current red, green, and blue band file color assignments. Red, green, and blue color boxes appear next to the names of the image band files to which they are currently assigned. The user can change current color assignments by clicking the mouse cursor beside desired color assignments.

A menu along the bottom of the graphics display frame indicates that the user can also replot and enlarge the composite image on display, or quit the program, by clicking the mouse cursor on the desired option.

The Grass program `i.group` can also be used to assign red, green, and blue colors to imagery group band files.

NOTES

This program is not yet complete. To assign colors to an imagery group, use the Grass program `i.group`.

This program is interactive and requires no command line arguments. The user must be running a graphics monitor to use this program.

**NAME**

`i.composite` - An imagery function that creates a color composite image from three imagery band files specified by the user.

*(GRASS Image Processing Program)*

**SYNOPSIS**

`i.composite`

**DESCRIPTION**

`i.composite` creates a color composite image from three band files specified by the user. The user specifies the bands to be used by assigning a red, blue, and/or green color to each band. The resulting image is a raster map layer of raw spectral data composed of the three bands chosen by the user. The color composite can then be displayed, painted, or manipulated as would any raster map layer in GRASS.

The first prompt asks the user for the imagery group whose files are to be used.

The following menu is then displayed:

```
Please indicate which files to use for red, green, and blue colors. You may leave any color out. You may specify more than one color per file. However, each color may only be specified once. For example, to get a full color image, specify r,g,b for 3 different files. To get a grey scale image, specify rgb for a single file.

    b_  spot.1
    g_  spot.2
    r_  spot.3
    __  spotclass
    __  spotreject

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)
```

The user is then allowed to check the choice of bands:

```
Colors assigned as follows:

RED:    spot.3@mapsetname
GREEN:  spot.2@mapsetname
BLUE:   spot.1@mapsetname

Look ok? (y/n) [y]
```

The color table that is created has 1000 colors (10 saturation levels (or shades) per primary color (blue, green, red)). The number of colors that can be displayed at one time on a color graphics monitor will depend on the graphics monitor being used. For example, if the graphics monitor can only display 512 colors at one time, then the user must run the GRASS command `d.colormode mode=fixed` before displaying the raster map layer. The colors that cannot be displayed will be assigned to the nearest displayable color, and the raster map layer will retain its relative color accuracy. If the user is in `float` colormode, however, the raster map layer displayed on the graphics monitor will not accurately reflect the map's real color assignments.
The user is then asked to name the composite image raster map layer. The percentage completed is echoed to the screen and \textit{r.support} files are created automatically.

\textbf{NOTES}

The user should always check the geographic region settings before running most imagery commands. It is very easy for the boundaries of the geographic region to be completely off the image. Before running \textit{i.composite}, or other imagery commands, the user should probably set the geographic region to match that of the raster map layers to be read. This can be accomplished using option 4 of the \textit{g.region} command.

This program is interactive and requires no command line arguments.

NAME
i.fft - Fast Fourier Transform (FFT) for image processing.
(GRASS Image Processing Program)

SYNOPSIS
i.fft
i.fft help
i.fft input_image = name real_image = name imaginary_image = name [range = value]

DESCRIPTION
i.fft is an image processing program based on the algorithm given by Press (1988), with enhancements by Vali (1990), that processes a single input raster map layer (input_image) and constructs the real and imaginary Fourier components in frequency space.

Parameters:
input_image = name Input raster map layer on which the fast Fourier transform is run.
real_image = name Output real part arrays stored as raster map layer.
imaginary_image = name Output imaginary part arrays stored as raster map layer.
range = value Range of values used during fast Fourier transformation.

The real and imaginary components are stored as arrays of doubles in the cell_misc directory (for use in the inverse transform program, i.ifft), and are also scaled and formatted into the real_image and imaginary_image raster map layers for inspection, masking, etc. In these raster map layers the low frequency components are in the center and the high frequency components are toward the edges. The input_image need not be square; before processing, the X and Y dimensions of the input_image are padded with zeroes to the next highest power of two in extent (i.e., 256 x 256 is processed at that size, but 200 x 400 is padded to 256 x 512). The cell category values for viewing, etc., are calculated by taking the natural log of the actual values then rescaling to 255, or whatever optional range is given on the command line, as suggested by Richards (1986). A color table is assigned to the resultant map layer.

The current geographic region and mask settings are respected when reading the input file. The presence of a mask will, in general, make the resulting fast Fourier transform invalid, or at least difficult to interpret.

   *i.grey.scale* – An interactive imagery function that assigns a histogram contrast stretch grey scale color table to a raster map layer.

   *(GRASS Image Processing Program)*

SYNOPSIS

   *i.grey.scale*

DESCRIPTION

   *i.grey.scale* is an interactive imagery function that assigns a histogram contrast stretch grey scale color table to a raster map layer. The histogram contrast stretch expands the original range of digital (category) values to utilize the full range of the user’s graphics monitor.

   The user is asked for the name of the raster map layer that needs a grey scale. When the raster map layer is displayed, it will be displayed with a grey scale color scheme.

NOTES

   This program is interactive and requires no command line arguments.

NAME

i.group - An imagery function that creates and edits groups and subgroups of (raster) imagery files.

(GRASS Image Processing Program)

SYNOPSIS

i.group

DESCRIPTION

i.group allows the user to collect raster map layers in an imagery group by assigning them to user-named subgroups or other groups. This enables the user to run analyses on any combination of the raster map layers in a group. The user creates the groups and subgroups and selects the raster map layers that are to reside in them. Imagery analysis programs like i.points, i.rectify, i.ortho.rectify and others ask the user for the name of an imagery group whose data are to be analyzed. Imagery analysis programs like i.cluster and i.maxlik ask the user for the imagery group and imagery subgroup whose data are to be analyzed.

The first menu in the i.group program asks the user to select a group. If the group does not exist, the user will be asked if he or she would like to create a new group.

This program edits imagery groups. You may add raster map layers to, or remove such layers from, an imagery group. You may also create new groups.

Please enter the group to be created/modified

GROUP: (enter 'list' for a list of groups)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE

(OR <Ctrl-C> TO EXIT)

If the word list is entered, groups that have already been created in the user's current LOCATION_NAME: and MAPSET(S) will be listed. The second menu in i.group provides the user with the following options:

1. Select a different group
2. Edit group title
3. Include new raster (cell) files in the group
   or remove raster (cell) files from the group
4. Assign colors to the group
5. Create a new subgroup within the group

RETURN to exit
The options are described as follows:

Select a different group

If option number 1 is chosen, the following menu is displayed:

Please enter the group to be created/modified

GROUP: _______________ (enter 'list' for a list of groups)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO EXIT)

If the word list is entered, groups that have already been created in the current LOCATION_NAME and MAPSET(S) will be displayed.

Edit group title

If option number 2 is selected, an entry space is provided to type in the group title. This title is useful in identifying each group:

TITLE__________________________

This option offers an opportunity to go back and change the entry if it is not correct by asking: Look ok? (y/n).

Include new raster (cell) files in the group or remove raster (cell) files from the group

When choosing option number 3, the following menu is displayed:

LOCATION: location  GROUP: spot  MAPSET: demo

If you wish to delete a file from group [spot], remove the 'x' from in front of the file name.

x_ spot.1 in demo
x_ spot.2 in demo
x_ spot.3 in demo

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR Ctrl-C TO CANCEL)
Next, a menu listing all the other raster map layers present in the current MAPSET(S) will be displayed:

LOCATION: location   GROUP: spot   MAPSET: demo

Please mark an 'x' by the files to be added in group [spot]

MAPSET: demo

x_ composite1
x_ spotclass1
  spotclass2

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR Ctrl-C TO CANCEL)

If more than one MAPSET is selected, menus for those mapsets will also be displayed. All raster map layers selected with an 'x' will be included in the group being updated.

The user will then have the opportunity to check the contents of the group that was just modified:

Group [spot] references the following raster files

<table>
<thead>
<tr>
<th>File</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>spot.1</td>
<td>in demo</td>
</tr>
<tr>
<td>spot.2</td>
<td>in demo</td>
</tr>
<tr>
<td>spot.3</td>
<td>in demo</td>
</tr>
<tr>
<td>composite</td>
<td>in demo</td>
</tr>
<tr>
<td>spotclass1</td>
<td>in demo</td>
</tr>
</tbody>
</table>

Look ok? (y/n)

If the user responds with the letter y, then the following sentence is displayed on the screen:

Group [spot] updated!

And the main menu for i.group returns.

If the user responds n, the menu containing the group files after it was modified will be displayed and the user will be asked to place an x in front of those raster map layers that are to be removed from the group. Then, a menu listing all of the other raster map layers in the current MAPSET will be displayed again, and the user will be again asked to place an x in front of raster map layers to be included in the group. This gives the user the opportunity to correct mistakes or make changes in the choice of raster map layers to be selected in a group without exiting i.group.
Assign colors to the group

Option number 4 provides the following menu:

Please indicate which files to use for red, green, and blue colors. You may leave any color out. You may specify more than one color per file. However, each color may only be specified once. For example, to get a full color image, specify r,g,b for 3 different files. To get a grey scale image, specify rgb for a single file.

```
b_    spot.1
 g_    spot.2
  r_    spot.3
   _    composite1
   _    spotclass1
```

<<<r,g,b can only be specified once >>>

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

This menu allows you to select a color for each imagery band or for each file for display. Note, however, that composite images and classified images are already assigned colors during their creation.

An opportunity to change the choice of colors is offered after escaping the menu by:

```
Look ok? (y/n)
```

Create a new subgroup within the group

The following menu enables the user to create a subgroup out of any combination of raster map layers in the group. Any number of subgroups may be created by repeating the option.

```
LOCATION: location
MAPSET: spot

GROUP: spot1
SUBGROUP: __________ ('list' will show available subgroups)
```

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

After selecting or creating a subgroup, this menu is displayed:
Mark an 'x' by the files to form subgroup [J23]

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>spot.1</td>
</tr>
<tr>
<td>x</td>
<td>spot.2</td>
</tr>
<tr>
<td>x</td>
<td>spot.3</td>
</tr>
<tr>
<td></td>
<td>composite1</td>
</tr>
<tr>
<td></td>
<td>spotclass1</td>
</tr>
</tbody>
</table>

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

The user is then given the opportunity to check the contents of the subgroup:

Subgroup [J23] references the following raster (cell) files

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>spot.1</td>
<td>in demo</td>
</tr>
<tr>
<td>spot.2</td>
<td>in demo</td>
</tr>
<tr>
<td>spot.3</td>
<td>in demo</td>
</tr>
</tbody>
</table>

Look ok? (y/n)

If the user responds with the letter n, the group menu will appear again enabling the user to select raster map layers to form the subgroup.

NOTES
The i.group options are only available for imagery map layers in the current LOCATION_NAME.
Subgroup names may not contain more than 12 characters.
This program is interactive and requires no command line arguments.

NAME

*i.his.rgb* - Hue-intensity-saturation (his) to red-green-blue (rgb) raster map color transformation function.

*(GRASS Image Processing Program)*

SYNOPSIS

```
i.his.rgb
i.his.rgb help
i.his.rgb hue_input=name intensity_input=name saturation_input=name
       red_output=name green_output=name blue_output=name
```

DESCRIPTION

*i.his.rgb* is an image processing program that processes three input raster map layers as hue, intensity and saturation components and produces three output raster map layers representing the red, green and blue components of this data. The output raster map layers are created by a standard hue-intensity-saturation (his) to red-green-blue (rgb) color transformation. Each output raster map layer is given a linear gray scale color table. The current geographic region and mask settings are respected.

Parameters:

- **hue_input=name** Name of input raster map layer representing *hue*.
- **intensity_input=name** Name of input raster map layer representing *intensity*.
- **saturation_input=name** Name of input raster map layer representing *saturation*.
- **red_output=name** Output raster map layer representing the *red* component in the data.
- **green_output=name** Output raster map layer representing the *green* component in the data.
- **blue_output=name** Output raster map layer representing the *blue* component in the data.

NOTES

It is not possible to process three bands with *i.his.rgb* and then exactly recover the original bands with *i.rgb.his*. This is due to loss of precision because of integer computations and rounding. Tests have shown that more than 70% of the original cell values will be reproduced exactly after transformation in both directions and that 99% will be within plus or minus 1. A few cell values may differ significantly from their original values.

i.ifft  - Inverse Fast Fourier Transform (ifft) for image processing.

( Misc Image Processing Program)

SYNOPSIS

i.ifft  
.i.ifft help 
.i.ifft real_image=name imaginary_image=name output_image=name

DESCRIPTION

i.ifft is an image processing program based on the algorithm given by Press (1988), and modified by Vali (1990), that converts real and imaginary frequency space images (produced by i.fft) into a normal image.

Parameters:

real_image=name  Input raster map layer for inversion fast Fourier transform, real part.
imaginary_image=name  Input raster map layer for inversion fast Fourier transform, imaginary.
output_image=name  Output inversion raster map layer after fast Fourier transformation.

The current mask is respected when reading the real and imaginary component files; thus, r.mask become a primary program for selecting the portion of the frequency space data to be included in the inverse transform. The GRASS program d-digit can be used to create .mask while viewing the real or imaginary component image. When i.ifft is executed, it (automatically) uses the same GRASS region definition setting that was used during the original transformation done with i.fft.

The real and imaginary components are read from arrays of doubles in the cell.misc directory (produced by the forward transform program, i.fft), and the reconstructed image will preserve the cell value scaling of the original image processed by i.fft. No color table is assigned to the output map; one should be created before viewing the output_image.

NAME

*i.maxlik* - An imagery function that classifies the cell spectral reflectances in imagery data based on the spectral signature information generated by either *i.cluster* or *i.class.*

*(GRASS Image Processing Program)*

SYNOPSIS

*i.maxlik*

DESCRIPTION

*i.maxlik* is a maximum-likelihood discriminant analysis classifier. It can be used to perform the second step in either an unsupervised or a supervised image classification.

Both image classification methods are performed in two steps. The first step in an unsupervised image classification is performed by *i.cluster*, while the first step in a supervised classification is executed by the GRASS program *i.class*. In both cases, the second step in the image classification procedure is performed by *i.maxlik*.

In an unsupervised classification, the maximum-likelihood classifier uses the cluster means and covariance matrices from the *i.cluster* signature file to determine to which category (spectral class) each cell in the image has the highest probability of belonging. In a supervised image classification, the maximum-likelihood classifier uses the region means and covariance matrices from the spectral signature file generated by *i.class*, based on regions (groups of image pixels) chosen by the user, to determine to which category each cell in the image has the highest probability of belonging.

In either case, the raster map layer output by *i.maxlik* is a classified image in which each cell has been assigned to a spectral class (i.e., a category). The spectral classes (categories) can be related to specific land cover types on the ground.

The first screen asks the user for the *group* and *subgroup* to be classified:

```
Please select the group/subgroup containing the signatures to be used in the classification

GROUP:  spot
SUBGROUP:  123
```

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

This group should contain the subgroup to be classified. The subgroup should contain the band files that were used to create the signature file in the program *i.cluster* or *i.class*.

The user is then prompted for the name of the signature file to be used for the classification. The signature file contains the cluster and covariance matrices that were calculated by the GRASS program *i.cluster* (or the region means and covariance matrices generated by *i.class*, if the user runs a supervised classification). These spectral signatures are what determine the categories (classes) to which image pixels will be assigned during the classification process.

The next prompt asks the user to assign a name to the classified raster map layer that will be generated by *i.maxlik*. This new raster map layer will contain categories that can be related to land cover categories on the ground.
Next, the user is asked to assign a name to the reject threshold raster map layer that is also generated by `i.maxlik`. After classifying the image, `i.maxlik` runs a chi square test on each discriminant result at various threshold levels of confidence to determine the confidence level associated with each cell class (category). This is the reject threshold map layer. It contains one calculated confidence level for each classified cell in the classified image. One of the possible uses for this map layer is as a mask, to identify cells in the classified image that have the lowest probability of being assigned to the correct class.

Next, the following menu is displayed:

**COLOR CONFIGURATION FOR CLASSIFIED LAYER [spotclass1]**

Please indicate which raster map layers to use for red, green, and blue colors. You may leave any color out. You may specify more than one color per color file. However, each color may only be used once.

For example, to get a full color image, specify r,g,b for 3 different files. To get a grayscale image, specify rgb for a single file.

```
b___  spot.1 in demo
g___  spot.2 in demo
r___  spot.3 in demo
```

**AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE**
**(OR <Ctrl-C> TO CANCEL)**

More than three bands (raster map layers) can be classified, but since only three bands can be displayed on most color graphics monitors at one time, only three bands are assigned a color in the above menu. This subgroup, therefore, could have more than three bands in it.

`i.maxlik` runs in the background and the user is notified by mail when it is complete.

**NOTES**

The maximum-likelihood classifier assumes that the spectral signatures for each class (category) in each band file are normally distributed (i.e., Gaussian in nature). Clustering algorithms, however, can create signatures that are not normally distributed. If this occurs, `i.maxlik` will reject them and display an error message.

This program is interactive and requires no command line arguments.

NAME

*i.median* – An interactive imagery function that creates a raster map layer whose color table is based on the red, green, and blue color values present in existing, user-specified imagery group files.

*GRASS Image Processing Program*

SYNOPSIS

i.median

DESCRIPTION

*i.median* is an interactive imagery function that allows the user to create a new raster map layer whose color table values are based on the red, green, and blue color values present in (as many as) three raster map layers in an imagery group.

The user is first asked to enter the name of the imagery group from whose map layers red, green, and blue color values are to be extracted. The user is then shown a listing of imagery files in the specified group, and is asked to indicate which files in the group are to be used for red, green, and blue colors in the new map layer. Each color (red, green, and blue) must be specified once and only once.

The user is also asked to assign a name to the new raster map layer output.

NOTES

This program is interactive and requires no command line arguments.
The input files must ALL be within the range of 0-255.

i.mod.camera - An imagery function that creates or modifies entries in a camera reference file.

(Grass Image Processing Program)

SYNOPSIS

i.mod.camera

i.mod.camera help

DESCRIPTION

i.mod.camera creates or modifies entries in a camera reference file. In the imagery programs
i.ortho.reference, i.ortho.control, and i.ortho.rectify, a camera reference file is required for
computation of reference points and ortho-rectification parameters. The program i.camera, which
selects a camera reference file to be used with an imagery group, also requires an existing camera
reference file.

This program runs interactively. It first prompts the user for the name of the camera reference file to
be created or modified.

The following menu is then displayed:

Please provide the following information

Camera Name: 
Camera Identification: 
Calibrated Focal Length mm.: 
Point of Symmetry: X-coordinate mm.: 
Point of Symmetry: Y-coordinate mm.: 
Maximum number of fiducial or reseau marks:

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

The user is then asked to enter the X and Y photo coordinates of each fiducial as follows:
Please provide the following information

<table>
<thead>
<tr>
<th>Fid#</th>
<th>Fid ID</th>
<th>Xf</th>
<th>Yf</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>2</td>
<td></td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>4</td>
<td></td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>5</td>
<td></td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>6</td>
<td></td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>7</td>
<td></td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>8</td>
<td></td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>9</td>
<td></td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>10</td>
<td></td>
<td>0.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>

next: end_

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

The input display is repeated until the maximum number of fiducials specified by the user is reached.

NOTES
This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

FILES
Camera reference files are stored under the directory
\$GISDBASE/LOCATION_NAME/5MAPSET/camera. (This is the same as LOCATION/camera, the /camera directory under the user's current mapset.)

NAME

i.pca - Principal components analysis (pca) program for image processing.
(GRASS Image Processing Program)

SYNOPSIS

i.pca
i.pca help
i.pca input1=name input2=name [input3=name] [input4=name] [input5=name]
   [input6=name] [input7=name] [input8=name] output=name

DESCRIPTION

i.pca is an image processing program based on the algorithm provided by Vali (1990), that processes \( n \) (2 \( \leq n \leq 8 \)) input raster map layers and produces \( n \) output raster map layers containing the principal components of the input data in decreasing order of variance ("contrast"). The output raster map layers are assigned names with .1, .2, ... .n suffixes. The current geographic region definition and mask settings are respected when reading the input raster map layers.

Parameters:

- input1=name: Name of first input raster map layer.
- input2=name: Name of second input raster map layer.
- input3=name: Name of third input raster map layer.
- input4=name: Name of fourth input raster map layer.
- input5=name: Name of fifth input raster map layer.
- input6=name: Name of sixth input raster map layer.
- input7=name: Name of seventh input raster map layer.
- input8=name: Name of eighth input raster map layer.
- output=name: The output raster map layer name to which suffixes are added. Each output raster map layer is assigned this user-specified name with a numerical (.1, .2, ... .n) suffix.

Richards (1986) gives a good example of the application of principal components analysis (pca) to a time series of LANDSAT images of a burned region in Australia.

*i.points* An imagery function that enables the user to mark coordinate system points on an image to be rectified and then input the coordinates of each point for creation of a coordinate transformation matrix. The transformation matrix is needed as input for the GRASS program *i.rectify.*

*(GRASS Image Processing Program)*

SYNOPSIS

*i.points*

DESCRIPTION

*i.points* is an imagery function that enables the user to mark points on a (raster) image to be rectified and then input the geographic coordinates of each point for calculation of a coordinate transformation matrix. *i.points* must be followed by use of the GRASS program *i.rectify,* which rectifies the image using the transformation matrix coefficients calculated by *i.points.*

Rectification is the mapping (transformation) of an image from one coordinate system to another. The geometry of an image extracted into a GRASS LOCATION having an x,y coordinate system is not planimetric. To create a planimetric image, that is, to convert the x,y coordinate system into a standard coordinate system (for example, the UTM coordinate system or the State Plane coordinate system), points from a map having the standard coordinates must be associated with the same points on the image to be rectified. *i.points* enables the user to mark points on an image and input the standard coordinates for that point. *i.points* then calculates a least squares regression using the two coordinate systems (x,y and standard) for the marked points. A matrix containing transformation coefficients is the output file for *i.points.*

During the process of marking points and entering map coordinates, the user can compute the RMS (root mean square) error for each point entered. *i.points* does this by calculating the transformation equation (the same one that is calculated in the GRASS program *i.rectify*), and then plugging these results into an equation for RMS error.

*i.points* offers a zoom option to locate precisely the point to be marked on an image. This program also offers the user the option of acquiring standard coordinates for a marked point from a map layer in the target data base.

*i.target* must be run before running *i.points* to enable the PLOT RASTER option to be used and to identify a target data base LOCATION NAM: and MAPSET for the rectified image. To run *i.points,* a graphics monitor is required.

The procedure for marking points, entering coordinates, and calculating RMS error is described below.

The first prompt in the program asks the user for the imagery group to be registered. Note that if *i.target* is not run before *i.points,* the *i.points* program will display the following error message:

```
ERROR: Target information for group [spot] missing
Please run i.target for group [spot]
```

After entering the group to be registered the terminal screen displays the message:

```
Use mouse now...
```
The graphics monitor displays the following screen:

<table>
<thead>
<tr>
<th>imagery filename (mag)</th>
<th>target filename (mag)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

QUIT ZOOM PLOT RASTER ANALYZE

A pop-down menu like that shown below will be superimposed on the left half of the screen:

Double click on raster map layer to be plotted
Double click here to cancel

<table>
<thead>
<tr>
<th>Mapset demo</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>spotclass</td>
<td>spot.1</td>
<td></td>
</tr>
<tr>
<td>composite</td>
<td>spot.2</td>
<td></td>
</tr>
<tr>
<td>spot.3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Any single raster map layer in the imagery group may be used on which to mark points, and the user can mark points on more than one raster map layer in the imagery group to accumulate the suggested minimum number of 12 points. Any raster map layer in the imagery group can be rectified (using \texttt{i.rectify}) based on the transformation matrix computed from these points.

The imagery file chosen by the user is displayed in the upper left quadrant of the screen.

**ZOOM**

To magnify the displayed file, the user must place the mouse cross hairs on the word ZOOM. The following menu will then be displayed at the bottom of the screen:
The user has the option of identifying the zoom region either by using the mouse to make a box, or by using the mouse to mark the two diagonal points of the desired region. The terminal screen will display a mouse button menu to guide the user in identifying the corner points of the region.

**MARKING POINTS**
To mark the points on the image that correspond to the points on a standard coordinate system map, the user must place the mouse cross hairs on the corresponding location on the image to be marked and press the left hand button on the mouse. A diamond shaped symbol will be marked on the image. The user’s terminal will display the following menu:

<table>
<thead>
<tr>
<th>Point 1 marked on the image at</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>East: 1023.77</td>
<td></td>
</tr>
<tr>
<td>North: -164.41</td>
<td></td>
</tr>
</tbody>
</table>

Enter coordinates as east north:

The user then enters the easting and northing (separated by a space) for the point marked on the image. If the user wishes not to enter a coordinate, he or she may simply hit RETURN to return control to the mouse; the marked point then disappears.

**PLOT RASTER**
In addition to acquiring reference points from a standard map, the user has the option of acquiring the reference points from a raster map layer in the target data base LOCATION_NAME. The data base raster map layer is displayed by placing the mouse cross hairs on the words PLOT RASTER. The following line is then displayed at the bottom of the graphics monitor:

| Cancel | Indicate which side should be plotted |

Which side of the graphics monitor is to be plotted is indicated by placing the mouse cross hairs on the half of the graphics monitor screen that the user would like to use, and pressing the left mouse button. The following pop-down menu will be superimposed on the half of the screen that was chosen.
Double click on raster (cell) map layer to be plotted
Double click here to cancel

<table>
<thead>
<tr>
<th>Mapset demo</th>
</tr>
</thead>
<tbody>
<tr>
<td>tm.rectified</td>
</tr>
<tr>
<td>tm.classified</td>
</tr>
</tbody>
</table>

Mapset PERMANENT

elevation  geology
slope  soils
aspect
roads
streams
airfields

After the raster map layer is displayed, the following message appears at the bottom of the graphics monitor:

input method --> keyboard screen

If the user wishes to use the plotted raster map layer only as a comparative reference, then the keyboard can be chosen as the means to input coordinates corresponding to the marked points on the image. This is done by placing the mouse cross hairs on the word KEYBOARD and pressing the left button on the mouse.

If the user selects the SCREEN option, then points marked on the image will automatically be associated with the coordinates from the corresponding points on the target data base map layer. In this option, when the user marks a point on the image, the following menu is displayed at the terminal:

Point 5 marked on the image at
East: 1023.77
North: -164.41

Point located at
East: 679132.57
North: 4351080.67

use mouse now...
The user then uses the mouse to mark a corresponding point on the displayed image from the target data base. The coordinates for the target data base map layer are automatically saved as the coordinates corresponding to the marked point on the image.

**ANALYZE**

After a number of points have been marked (4 to 7), the user can check the RMS error of the points marked on the image. This is done by placing the mouse cross hairs on the word ANALYZE at the bottom of the graphics monitor. An error report resembling that shown below is superimposed on the graphics monitor:

<table>
<thead>
<tr>
<th>#</th>
<th>error</th>
<th>image</th>
<th>target</th>
<th>east</th>
<th>north</th>
<th>east</th>
<th>north</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.0</td>
<td>-0.9</td>
<td>1.0</td>
<td>1048.5</td>
<td>-144.8</td>
<td>679132.5</td>
<td>4351080.6</td>
</tr>
<tr>
<td>2</td>
<td>0.4</td>
<td>1.0</td>
<td>1.3</td>
<td>2153.1</td>
<td>-567.2</td>
<td>684314.7</td>
<td>4399014.4</td>
</tr>
<tr>
<td>3</td>
<td>-1.2</td>
<td>-0.5</td>
<td>0.6</td>
<td>1452.8</td>
<td>-476.5</td>
<td>567841.4</td>
<td>3457682.8</td>
</tr>
<tr>
<td>4</td>
<td>1.1</td>
<td>0.5</td>
<td>1.3</td>
<td>1034.0</td>
<td>-109.2</td>
<td>677573.8</td>
<td>4352626.4</td>
</tr>
<tr>
<td>5</td>
<td>-2.7</td>
<td>14.0</td>
<td>14.2</td>
<td>1048.6</td>
<td>-144.9</td>
<td>679132.6</td>
<td>4351080.7</td>
</tr>
</tbody>
</table>

**overall rms error:** 4.46

The following menu then appears at the bottom of the graphics monitor:

**DONE | PRINT FILE | Double click on point to be included/excluded**

The RMS error for the image is given under the column titled "error" and subtitled "row" and "col." In the above report, point number 1 is 0.0 rows and -0.9 columns from the predicted location calculated from the transformation equation. The RMS error for the target raster map layer is listed under the heading "target." This is the RMS error for the east and north coordinates of the target map layer, but it is presented in the table using one general value. The overall RMS error is displayed at the bottom of the screen in meters. Points that create high RMS error are displayed in red on the graphics monitor (represented here in italics).

The location of the point marked on the imagery group file is given under the heading "image," the subheadings "east" and "north." The location of the point in the target data base is given under the heading "target," and the subheadings "east" and "north." If the user would like to exclude or include a point, this can be accomplished by placing the mouse cross hairs on the point number to be included (if the point is absent) or excluded (if the point is displayed) and pressing the left button on the mouse twice. When a point is excluded, it is not afterwards included in the calculation of the RMS error, or included in the final transformation matrix. However, it can be retrieved within i.points at any time by double clicking with the mouse as described above.

**QUIT**

To end the i.points program place the mouse cross hairs on the word QUIT; the marked points (including coordinates) will be saved.

**NOTES**

A good rule of thumb is to mark at least 12 to 15 points that are evenly distributed over the entire imagery group file in order to obtain an accurate transformation equation for the rectification process. The RMS error may increase with more points added, but the transformation equation will be more accurate.
An RMS error of less than or equal to approximately one resolution unit (pixel or cell) for the image being rectified is generally considered acceptable.

In order to use a digitizer with i.points, at least one digitizer driver besides "none" (the on-screen digitizer) must be available in the digitcap file.

This program is interactive and requires no command line arguments.

AUTHOR

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME

i.rectify – An imagery function that rectifies an image by computing a coordinate transformation for each cell (pixel) in the image using the transformation coefficient matrix created by the GRASS program i.points.

(GRASS Image Processing Program)

SYNOPSIS

i.rectify

DESCRIPTION

i.rectify rectifies an image by using the transformation coefficient matrix created by i.points. Rectification is the process by which the geometry of an image is made planimetric. This is accomplished by mapping (transforming) an image from one coordinate system to another. In i.rectify, the coefficients computed by i.points are used in an equation to convert x,y coordinates to standard map coordinates for each cell in the image. The result is an image with a standard map coordinate system. Upon completion of the program the rectified image is deposited in a previously targeted GRASS LOCATION_NAME and MAPSET.

The first prompt in the program asks the user for the name of the group containing the raster map layers to be rectified.

The user is then asked to select the map layer(s) within the group to be rectified:

Please select the file(s) to rectify by naming an output file

spot.1 in demo ..........
spot.2 in demo ..........
spot.3 in demo ..........
spotclass in demo spotrectify..
spotreject in demo ..........

(Enter list by any name to get a list of existing raster files)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

More than one raster map layer may be rectified at a time. Each raster map layer should have a unique output file name.

Next the user is asked to select one of two geographic region settings:

Please select one of the following options
1. Use the current geographic region definition (window) in the target location
2. Determine the smallest geographic region definition (window) which covers the image

i.rectify will only rectify that portion of the image that occurs within the chosen geographic region setting. Only that portion will be relocated in the target data base. It is therefore important to check the current geographic region settings in the target location if choice number one is selected.
NOTES

*i.rectify* will run in the background and notify the user by mail when it is finished. The process may take an hour or more depending on the size of the image, the number of files, and the size of the geographic region definition.

The rectified (raster) image will be located in the target LOCATION when the program is completed. The original unrectified raster map layers are not modified or removed.

This program is interactive and requires no command line arguments.

NAME
i.rectify.blk - An imagery function that ortho-rectifies an imagery group file.

SYNOPSIS
i.rectify.blk

DESCRIPTION
i.rectify.blk allows the user to ortho-rectify an imagery group file. An imagery photo block consists of several scanned aerial photographs (raster files) of a common area. An imagery sub-block is a subset of these raster files. Block and sub-blocks of imagery groups are created by the GRASS imagery program i.build.blk.

i.rectify.blk guides the user through the steps required to ortho-rectify a single sub-block of imagery groups contained in a block.

The first menu in the i.rectify.blk program asks the user to select an existing block and sub-block. If the block and sub-block do not yet exist, the user should run i.build.blk before running i.rectify.blk.

If the word list is entered, blocks or sub-blocks that have already been created in the current LOCATION_NAME and MAPSET will be listed.

The next menu in i.rectify.blk provides the user with the following options:

1. Select another sub-block
2. Compute image-to-photo transformation
3. Initialize exposure station parameters
4. Compute ortho-rectification parameters
5. Ortho-rectify the selected imagery sub-block files

RETURN to exit

These options can be described as follows:

Select another sub-block
If option number 1 is chosen, the following menu is displayed:

Please enter the sub-block to be selected

BLOCK: block.1
SUB-BLOCK: _______ ___ (enter 'list' for a list of sub-blocks)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

If the word list is entered, sub-blocks that have already been created in the current block will be displayed.
Compute image-to-photo transformation
If option number 2 is selected, image-to-photo transformation parameters of the imagery group in the selected sub-block are computed. The user associates reference points (fiducials, reseau marks, etc.) with their known photo coordinates. The user must be running the graphics monitor. Complete documentation for this option is available under the manual entry i.ortho.reference. (The user must select one imagery group in the sub-block to initialize the camera. i.camera must be used to create a camera reference file, and i.build.blk must be run to select a camera reference file for the block, before this option can be used.)

Select initial exposure station parameters
If option number 3 is selected, initial camera exposure station parameters are selected or modified. Complete documentation for this option is available under the manual entry i.ortho.initial.

Compute ortho-rectification parameters
If option number 4 is selected, ortho-rectification parameters for the imagery sub-block are computed. Here control points are marked on one or more sub-block imagery raster files and associated with their known UTM coordinates. Complete documentation for this option is available under the manual entry i.ortho.control.

ortho-rectify selected sub-block
If option number 5 is chosen, the raster files referenced by the imagery sub-block are ortho-rectified. Rectified raster files will be created in the target location. Complete documentation for this option is available under the manual entry i.ortho.rectify.

NOTES
The i.rectify.blk options are only available for imagery files stored under the user's current LOCATION.

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

i.rgb.his - Red-green-blue (rgb) to hue-intensity-saturation (his) function for image processing.

(GRASS Image Processing Program)

SYNOPSIS

i.rgb.his
i.rgb.his help
i.rgb.his red_input=name green_input=name blue_input=name
hue_output=name intensity_output=name saturation_output=name

DESCRIPTION

i.rgb.his is an image processing program that processes three input raster map layers as red, green, and blue components and produces three output raster map layers representing the hue, intensity, and saturation of the data. The output raster map layers are created by a standard red-green-blue (rgb) to hue-intensity-saturation (his) color transformation. Each output raster map layer is given a linear gray scale color table. The current geographic region definition and mask settings are respected.

Parameters:

red_input=name Input raster map layer representing the red component.
green_input=name Input raster map layer representing the green component.
blue_input=name Input raster map layer representing the blue component.
hue_output=name Output raster map layer representing hue.
intensity_output=name Output raster map layer representing intensity.
saturation_output=name Output raster map layer representing saturation.

NAME
i.tape.mss - An imagery function that extracts Multispectral Scanner (MSS) imagery data from half-inch tape.
(GRASS Image Processing Program)

SYNOPSIS
i.tape.mss

DESCRIPTION
i.tape.mss is a program that extracts Multispectral Scanner (MSS) imagery data from tape.

This program must be run in a LOCATION_NAME with a x,y coordinate system (i.e., a coordinate system with projection 0). For further information regarding this LOCATION_NAME refer to the manual entry for imagery.

The first prompt in i.tape.mss asks the user for the tape device name. This is sometimes /dev/rmt0 (for a half-inch tape with a tape density of 1600), but this varies with each machine.

The next prompt is:

Please mount and load tape, then hit RETURN -->

IMAGE IDENTIFICATION MENU
The first menu in the program asks the user for information about the data.

please enter the following information

Tape Identification: —

Image Description: —

Title for the Extracted Raster (Cell) Files: —

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

This program automatically enters the scene ID number and the date of the image into the field for Tape Identification. The sun angles are automatically entered into the field for Image Description.
The second menu is:

**MSS TAPE EXTRACTION**

*please select the desired tape window (geographic region definition) to extract*

- **first row:** (1-2984)
- **last row:** (1-2984)
- **first col:** (1-3548)
- **last col:** (1-3548)

*After completing all answers, hit <ESC> to continue (or <Ctrl-C> to cancel)*

The numbers in parentheses are the total number of rows and columns on the tape including filler (zeros). This information and additional information can also be obtained by running the GRASS program `i.tape.mss.h`, which reads the header information on an MSS tape. Any subset of the image on tape may be extracted. For a discussion of row and column extraction, see the subheading titled ROW AND COLUMN EXTRACTION below.

The next menu is:

*please make an x by the bands you want extracted*

- 1
- 2
- 3
- 4

*After completing all answers, hit <ESC> to continue (or <Ctrl-C> to cancel)*

MSS imagery has 4 bands, but the user may want to extract only a subset of these bands. See the subheading in this entry titled ROW AND COLUMN EXTRACTION.

The user then is asked to enter the prefix/group for the band files to be created. This name will precede each band file extracted into GRASS. For example, if three bands are extracted the following three (raster) band files will result:

```
prefixname.1
prefixname.2
prefixname.3
```

Whatever `prefixname` is specified will also automatically become the name for the imagery group file being created. Each image (i.e., each run of `i.tape.mss`) should be given a unique prefix/group name.

The extraction process will begin by first skipping the number of specified files, advancing to the starting row, and then reading the tape. The percent completion of the extraction is displayed on the screen. If more than one tape is required to store the image, the program will pause and inform the user to mount the next tape.

The extracted (raster) band files will be listed as raster map layers available in the current MAPSET and may be displayed using the GRASS commands `d.display`, `d.rast` or `r.points`
NOTES
After extracting an image from tape, the geographic region definition in the x,y coordinate LOCATION_NAME will be set based upon the extracted rows and columns from the tape. The relationship between the image rows and columns and the geographic coordinates of the region is discussed in the manual entry for imagery.

This program is interactive and requires no command line arguments.

ROW AND COLUMN EXTRACTION
The display options in GRASS allow the user to locate rows and columns on the digital image. If enough disk space is available, one band of an entire image, or one band of a portion of an image known to contain the area of interest, can be extracted and displayed. The measurements option in d.display, or d.where (following the use of d.rast) will echo x and y coordinates to the screen. (These coordinates will display negative numbers in the north-south direction, but ignoring the negative sign will yield the row number.) See the imagery manual entry for further explanation.

If a photograph of the digital image is available, the rows and columns to be extracted can be determined from it by associating inches with the total number of known rows and columns in the scene. For example, if the total length of the photograph is 12 inches, the total number of rows on the tape is 2000, and the northwest corner of the area of interest begins 2 inches from the top of the photo, then:

\[
12 \text{ in.} / 2000 \text{ rows} = 2 \text{ in.} / x \text{ rows} \\
x = \frac{333.333}{2}
\]

The northwest corner of the area of interest starts at row 333. The starting row, ending row, starting column, and ending column can be calculated in this manner.

NAME
i.tape.mss.h - An imagery function that extracts header information from LANDSAT Multispectral Scanner (MSS) imagery data stored on half-inch tape.

(Grass Image Processing Program)

SYNOPSIS
i.tape.mss.h
i.tape.mss.h help
i.tape.mss.h tape_drive_name

DESCRIPTION
i.tape.mss.h reads the header information on a Multispectral Scanner (MSS) tape. This program reads the specified input file (the computer-compatible tape tape_drive_name), and by default displays the output to the user's terminal. The user may redirect output to a file by using the UNIX redirection mechanism. For example:

i.tape.mss.h /dev/rdmt0 > h.out

The name of the tape drive depends on the computer being used.

This program can be run either non-interactively or interactively. The user can run the program by specifying program arguments on the command line. Alternately, the user can simply type i.tape.mss.h on the command line, without program arguments. In this event, the program will prompt the user to enter a tape device name using the standard user interface described in the manual entry for parser.

*i.tape.other* - An imagery function that extracts scanned aerial imagery (NHAP, etc.) and SPOT imagery from half-inch tape.

(Grass Image Processing Program)

SYNOPSIS

*i.tape.other*

DESCRIPTION

*i.tape.other* is a generic program that extracts imagery from tape using the tape description that is input by the user.

This program must be run in a LOCATION_NAME with a x,y coordinate system (i.e., a coordinate system with projection 0). For further information regarding this LOCATION_NAME refer to the manual entry for *imagery*.

The first prompt in *i.tape.other* asks the user for the tape device name. This is sometimes /dev/hrmt0 (for a density of 1600), but this varies with each machine.

The next prompt is:

*Please mount and load tape, then hit RETURN -->*

IMAGE IDENTIFICATION MENU

The first menu in the program asks the user for information about the data.

*please enter the following information*

Tape Identification: --

Image Description: --

Title for the Extracted Raster (Cell) Files: --

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE (OR <Ctrl-C> TO CANCEL)

TAPE LAYOUT MENU

The next menu asks for the physical layout of the tape.
GENERIC TAPE EXTRACTION

number of tape files to be skipped
If there are files at the beginning of the tape that are not image data, they can be skipped. Sometimes information that comes with a tape will indicate the number of header files or records on the tape. The GRASS utility `examine.tape` will also provide this information. The record length is the number of columns in the image, while the number of records is the number of rows in the image. NHAP imagery and usually most scanned aerial imagery do not have tape header files, but this should be checked. SPOT imagery has two files that should be skipped on the first tape, and one file to be skipped on the second tape (of a two tape set).

number of records in the remaining files to be skipped
If the files that contain the image begin with non-image data, these records can also be skipped. This is usually zero for most data types. SPOT imagery stored in 1600bpi has one header record in the image file on each tape that should be skipped.

number of bands on the tape
Most aerial imagery have three bands, but satellite simulator data may have more. SPOT has three bands as a standard. The total number of bands on the tape should be specified here, not just the number that will be extracted.

data format
The two formats that imagery data are most commonly stored in are called band interleaved format (BIL) and band sequential format (BSQ). In BIL format, each record on the tape contains one line for one band of data. If the data contains three bands, then the first five records will look like this:

```
band 1, line 1
band 2, line 1
band 3, line 1
band 1, line 2
band 2, line 2
```
In BSQ format, all lines of one band are stored together on a tape, followed by all lines of another band, followed by all lines of the next band, etc. These data are stored as if they were in a one band BIL format:

band 1, line 1  
band 1, line 2  
band 1, line 3  

band 2, line 1  
band 2, line 2  

band 2, line 156  
band 2, line 157  

Each pixel contains one byte and there is one line per record. BSQ format is the format that is usually created by optical scanning devices when they scan photographs, but not all digitized aerial imagery are stored in this format. The format of the data is usually written on the exterior of the tape; this should be checked.

_length (in bytes) of the longest record on the tape_

This must be set to the number of bytes in the longest data record. It is used to determine how large a buffer to use for reading the tape. This value can be obtained using *m.examine.tape*.

**BAND EXTRACTION MENU**

The user is then asked to mark an x beside the bands to be extracted. See the subheading in this entry entitled ROW AND COLUMN EXTRACTION.

please mark an x by the bands you want extracted

____ 1
____ 2
____ 3
____ 4

**AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE**

(OR <Ctrl-C> TO CANCEL)

**PREFIX/GROUP NAME**

The user is asked to enter the prefix/group for the (raster) band files to be created. This name will precede each band file extracted into GRASS. For example, if three bands are extracted, the following three band files will result:

prefixname.1
prefixname.2
prefixname.3

The specified *prefixname* will also automatically become the name for the imagery group file being created. Each image (i.e., each run of *i.tape.other*) should be given a unique prefix/group name.
ROW AND COLUMN MENU

Finally, the starting row, ending row, starting column and ending column are required. This allows the user to extract any subset of the image from the tape.

EXTRACT
please select desired tape window (geographic region definition) to extract

start row:_0_
end row:_0_

start col:_0_
end col:_0_

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

The extraction process will begin by first skipping the number of specified files, advancing to the starting row, and then reading the tape. The percent completion of the extraction is displayed on the screen.

Following the extraction, the extracted band files will be listed as raster map layers available in the current MAPSET. These raster map layers may be displayed individually using the GRASS commands d.display, d.rast or i.points.

NOTES

After extracting an image from tape, the geographic region in the xy coordinate LOCATION_NAME will be set, based upon the extracted rows and columns from the tape. The relationship between the image rows and columns and the coordinates bounding the geographic region is discussed in the imagery manual entry.

This program is interactive and requires no command line arguments.

ROW AND COLUMN EXTRACTION

The display options in GRASS allow the user to locate rows and columns on the digital image. If enough disk space is available, one band of an entire image, or one band of a portion of an image known to contain the area of interest, can be extracted and displayed. The measurements option in d.display, or d.where (following a run of d.rast) will echo x and y coordinates to the screen. (These coordinates will display negative numbers in the north-south direction but ignoring the negative sign will yield the row number. See the imagery manual entry for further explanation.)

If a photograph of the digital image is available, the rows and columns to be extracted can be determined from it by associating inches with the total number of known rows and columns in the scene. For example, if the total length of the photograph is 12 inches, the total number of rows on the tape is 2000, and the northwest corner of the area of interest begins 2 inches from the top of the photo, then:

12 in. / 2000 rows = 2 in. / x rows
x = 333.333

The northwest corner of the area of interest starts at row 333. The starting row, ending row, starting column, and ending column can be calculated in this manner.

AUTHOR

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME
\texttt{i.tape.tm} – An imagery function that extracts LANDSAT Thematic Mapper (TM) imagery from half-inch tape.
\textit{(GRASS Image Processing Program)}

SYNOPSIS
\texttt{i.tape.tm}

DESCRIPTION
\texttt{i.tape.tm} is a program that extracts LANDSAT Thematic Mapper (TM) imagery from half-inch tape.

This program must be run in a LOCATION_NAME with a x,y coordinate system (i.e., a coordinate system with projection C). For further information regarding this LOCATION_NAME refer to the \textit{imagery} manual entry.

The first prompt in \texttt{i.tape.tm} asks the user for the tape device name. This is sometimes /dev/rmt0 (for a half-inch tape having a density of 1600 bpi), but this varies with each machine.

The next prompt is:

\texttt{Please mount and load tape, then hit RETURN -->}

IMAGE IDENTIFICATION MENU
The first menu in the program asks the user for information about the data.

\texttt{please enter the following information}

\begin{itemize}
  \item \textbf{Tape Identification:} \\
  \item \textbf{Image Description:} \\
  \item \textbf{Title for the Extracted Raster (Cell) Files:}
\end{itemize}

\textbf{AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE (OR <Ctrl-C> TO CANCEL.)}

This program automatically enters the scene ID number into the field for Tape Identification. The mission, path, row, quadrant, date, and whether the image is corrected is automatically entered into the field for Image Description.
The second menu is:

THEMATIC MAPPER EXTRACT
please select the desired tape window (geographic region definition) to extract

first row: ______ (1-2984)
last row: ______ (1-2984)

first col: ______ (1-4220)
last col: ______ (1-4220)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

The numbers in parentheses are the total number of rows and columns on the tape including zeros (filler). This information and additional information can also be obtained by running the program m.examine.tape. m.examine.tape will read any tape and provide the user with the number of files on a tape, the number of records on a tape, and the record lengths. Any subset of the image on the tape may be extracted. For a discussion of row and column extraction see the subheading entitled ROW AND COLUMN EXTRACTION below.

The next menu is:

please make an x by the bands you want extracted

1
2
3
4
5
6
7

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

TM imagery has seven bands, but the user may want to extract only a subset of these bands. See the subheading in this entry entitled ROW AND COLUMN EXTRACTION.

The user then is asked to enter the prefix/group for the raster band files to be created. This name will precede each band file extracted into GRASS. For example, if three bands are extracted the following three band files will result:

prefixname.1
prefixname.2
prefixname.3

The specified prefixname will also automatically become the name for the imagery group file being created. Each image or quad (i.e., each run of i.tape.tm) should be given a unique prefix/group name.
The extraction process will begin by first skipping the number of specified files, advancing to the first band requested, and then reading the tape. After extracting the requested rows and columns for each band, the program creates support files for the raster band map layer. The percent completion of the extraction is displayed on the screen. Because TM imagery is divided into four quads and is stored in multiple tape sets, the program is designed to read one quad at a time. The number of tapes required to store one quad depends on the number of bytes per inch in which the data is stored. If more than one tape is required to store one quad, the program will pause and inform the user to mount the next tape.

The extracted band files will be listed as raster map layers available in the current MAPSET and may be displayed using the GRASS commands `d.display`, `d.rast` or `i.points`.

NOTES
After extracting an image from tape the geographic region definition in the x,y coordinate LOCATION_NAME will be set based upon the extracted rows and columns from the tape. The relationship between the image rows and columns and the coordinates of the geographic region is discussed in the `imagery` manual entry.

This program is interactive and requires no command line arguments.

ROW AND COLUMN EXTRACTION
The display options in GRASS allow the user to locate rows and columns on the digital image. If enough disk space is available, one band of an entire image or, one band of a portion of an image known to contain the area of interest, can be extracted and displayed. The `measurements` option in `d.display`, or `d.where` (following use of `d.rast`) will echo x and y coordinates to the screen. (These coordinates will display negative numbers in the north-south direction, but ignoring the negative sign will yield the row number.) See the `imagery` manual entry for further explanation.

Each quad of a TM image contains filler on both the left and right sides of the quad. The user may want to identify the row and column numbers in order to exclude the filler. This filler will otherwise be extracted with the image and take up unnecessary disk space.

If a photograph of the digital image is available, the rows and columns to be extracted can be determined from it by associating inches with the total number of known rows and columns in the scene. For example, if the total length of the photograph is 12 inches, the total number of rows on the tape is 2000, and the northwest corner of the area of interest begins 2 inches from the top of the photo, then:

\[ \frac{12 \text{ in.}}{2000 \text{ rows}} = \frac{2 \text{ in.}}{x \text{ rows}} \]

\[ x = 333.333 \]

The northwest corner of the area of interest starts at row 333. The starting row, ending row, starting column, and ending column can be calculated in this manner.

NAME
i.target - An interactive imagery function that establishes a GRASS target location and mapset for an imagery group.

(GRASS Image Processing Program)

SYNOPSIS
i.target

DESCRIPTION
i.target targets an imagery group to a GRASS data base location name and mapset. During the imagery program i.rectify, a location name and mapset are required into which to transfer the rectified file just prior to completion of the program; i.target enables the user to specify this location. i.target must be run before i.points and i.rectify.

The first prompt in the program asks the user for the name of the imagery group that needs a target. The imagery group must be present in the user's current mapset.

The following menu asking for the target LOCATION NAME and MAPSET is displayed:

Please select the target LOCATION and MAPSET for group <pot>

CURRENT LOCATION: location
CURRENT MAPSET: demo
TARGET LOCATION: 
TARGET MAPSET: 

(Enter list for a list of location names or mapsets within a location)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <CtrI-C> TO CANCEL)

An imagery group may be targeted to any GRASS location.

NOTES
This program is interactive and requires no command line arguments.

**NAME**

*i.zc* - Zero-crossing "edge detection" raster function for image processing.

(Grass Image Processing Program)

**SYNOPSIS**

```
i.zc
i.zc help
i.zc input_map=name zc_map=name [width=value] [threshold=value] [orientations=value]
```

**DESCRIPTION**

*i.zc* is an image processing program used for edge detection. The raster map produced shows the location of "boundaries" on the input map. Boundaries tend to be found in regions of changing cell values and tend to run perpendicular to the direction of the slope. The algorithm used for edge detection is one of the "zero-crossing" algorithms and is discussed briefly below.

This program will be run interactively if the user types *i.zc* without program arguments on the command line. In this event, the program will prompt the user for parameter values using the standard interface described in the manual entry for parser. Alternately, the user can run the program non-interactively by specifying program parameter values on the command line.

**Parameters:**

- **input_map=name** Name of input raster map layer.
- **zc_map=name** Name of raster map layer to be used for zero-crossing values.
- **width=value** This parameter determines the x-y extent of the Gaussian filter. The default value is 9; higher and lower values can be tested by the user. Increasing the width will result in finding "edges" representing more gradual changes in cell values.
  Default: 9
- **threshold=value** This parameter determines the "sensitivity" of the Gaussian filter. The default value is 10; higher and lower values can be tested by the user. Increasing the threshold value will result in fewer edges being found.
  Default: 10
- **orientations=value** This value is the number of azimuth directions the cells on the output raster map layer are categorized into (similar to the aspect raster map layer produced by the *r.slope.aspect* program). For example, a value of 16 would result in detected edges being categorized into one of 16 bins depending on the direction of the edge at that point.
  Default: 1

The current region definition and mask settings are respected when reading the input map.

**NOTES**

The procedure to find the "edges" in the image is as follows: 1) The Fourier transform of the image is taken. 2) The Fourier transform of the Laplacian of a two-dimensional Gaussian function is used to filter the transformed image. 3) The result is run through an inverse Fourier transform. 4) The resulting image is traversed in search of places where the image changes from positive to negative or from negative to positive. 5) Each cell in the map where the value crosses zero (with a change in value greater than the threshold value) is marked as an edge and an orientation is assigned to it. The resulting raster map layer is output.

NAME
m.datum.shift - Datum shift program.
(GRASS Data Import/Processing Program)

SYNOPSIS
m.datum.shift lat=dd.mm.ss{N|S} lon=dd.mm.ss{E|W} is=input_spheroid os=output_spheroid
 dx=xshift dy=yshift dz=zshift

DESCRIPTION
m.datum.shift returns geographic coordinates based on a different spheroid (and datum) than the one
used to obtain the original coordinates.

The input and output spheroids, is and os, are the spheroids for two different datums. The input
spheroid is the one on which the original coordinates are based. The output spheroid is that on which
the resultant coordinates will be based. The shifting occurs between the two datums. The shift
values, dx, dy, and dz, are constants. They indicate the mean differences between points in the second
datum versus the first as measured in meters.

The list of spheroids available is somewhat dynamic. It may not contain exactly the ones listed below.
To determine the current list of possible spheroids, type in the command:

m.datum.shift lat=0n lon=0w dx=0 dy=0 dz=0 is=help os=help

A list of available spheroids will be printed on the screen. If the spheroid desired is not on the list, the
values for the semi-major axis and the eccentricity squared for the spheroid may be entered in place of
a spheroid name in the following format:

s=a=semi-major_axis,e=eccentricity_squared

SOME POSSIBLE SPHEROIDS
(The on-line listing includes only the spheroid names)

<table>

</tbody>
</table>

EXAMPLE
m.datum.shift lat=0n lon=175w is=clark66 os=wgs72 dx=-22 dy=-157 dz=-176

Results:
lat=0.00005729999N
lon=174.59.55.0041333W

NOTES
Essentially, the program follows these steps. The original point, as defined by a latitude and a
longitude, is converted to geocentric coordinates. The shift values are added to the geocentric
coordinates. The summed values are then converted to latitude and longitude based on the output
spheroid.

For a brief discussion of spheroids and datums see m.ll2u. For a brief discussion of geocentric
coordinates see m.ll2gc.
This remains under testing and is still an experimental program. It is part of an initial effort to incorporate geographic coordinates into GRASS.

m.dem.examine - Provides a terse description of USGS Digital Elevation Model (DEM) data files stored on half-inch magnetic tape.

(Grass Data Import/Processing Program)

SYNOPSIS
m.dem.examine input = name blocksize = value

DESCRIPTION
m.dem.examine reads Digital Elevation Model (DEM) terrain elevation data produced and supplied by the USGS from the input file specified by name, in the block size specified by value. If no input file is named on the command line, the program assumes that /dev/rmt0 is the input file. The information provided to the user comes from each file included on tape. Included are the maximum and minimum elevation values and the approximate UTM boundaries of each file. The program assumes unlabeled tapes in ASCII format with no header or trailer files.

SEE ALSO
  g.region, m.dem.extract, m.examine.tape, r.rescale, r.support

AUTHOR
  Andrew Heekin, U.S. Army Construction Engineering Research Laboratory
NAME
m.dem.extract – Extracts USGS Digital Elevation Model (DEM) data from half-inch magnetic tape.
(GRASS Data Import/Processing Program)

SYNOPSIS
m.dem.extract
m.dem.extract help
m.dem.extract input = name output = name blocksize = value

DESCRIPTION
m.dem.extract extracts USGS Digital Elevation Model (DEM) elevation data that fits into the user's current geographic region from the input file input, in blocks of blocksize bytes. If no input file is specified by the user, input is taken from /dev/rmt0, by default. Results are placed in the named output file, and stored beneath the cell directory of the user's current mapset. m.dem.extract will only extract data that fall within the boundaries of the user's current geographic region. Data falling outside this region will be ignored. m.dem.extract will not complain if the input file does not cover the entire geographic region. The program assumes unlabeled tapes in ASCII format with no header or trailer tiles. The user should run m.dem.examine prior to running m.dem.extract to determine the size of the geographic region needed. If the block size is unknown, run the command m.examine.tape.

The user can run this program either non-interactively or interactively. The program will be run non-interactively if the user specifies program arguments on the command line, using the form:

m.dem.extract input = name output = name blocksize = value

Alternately, the user can simply type m.dem.extract on the command line, without program arguments. In this case, the user will be prompted for needed parameter values using the standard GRASS interface described in the manual entry for parser.

Parameters:
input = name The full path name of the half-inch tape device from which DEM data are to be extracted.
Default: /dev/rmt0

output = name The name to be assigned to the output file containing raster DEM data extracted from half-inch tape.

blocksize = value The physical block size (record length) of each record, in bytes. m.examine.tape can be used to determine block size.

NOTES
The user should check the boundaries and resolution of the current region setting (see g.region) BEFORE extracting data, since m.dem.extract will only extract the data that falls within these boundaries and only use the set resolution during extraction.

Improvements to program code were made for GRASS 4.0 by
David Satnik, Central Washington University
**NAME**
m.dmaUSGSread - Extracts digital terrain elevation data (DTED) produced by the Defense Mapping Agency (DMA) but supplied by the USGS (in a different tape format) on half-inch magnetic tape.

**SYNOPSIS**
```
dd [if=tapedev] ibs=input-block-size | m.dmaUSGSread top=value bottom=value left=value right=value output=name logfile=name
```

**DESCRIPTION**
m.dmaUSGSread extracts digital terrain elevation data (DTED) that was produced by the Defense Mapping Agency (DMA) but bought from the USGS; these two agencies distribute the same data in slightly different tape formats. This program requires the use of the UNIX command dd to read the half-inch magnetic tape. m.dmaUSGSread should be used prior to using the GRASS programs mor90 and r.in.ll.

Parameters for the UNIX dd command are listed below:
- **if=tapedev** The path name of the tape drive from which input will be taken (usually /dev/rmt0).
- **ibs=input-block-size** The physical blocking value of the data on tape, usually written on the tape spool. If this value is unknown, run m.examine.tape prior to running m.dmaUSGSread.

Parameters for m.dmaUSGSread are listed below:
- **top=value** Beginning row number of data.
  Options: 1-1201
- **bottom=value** Ending row number of data.
  Options: 1-1201
- **left=value** Beginning column number of data.
  Options: 1-1201
- **right=value** Ending column number of data.
  Options: 1-1201
- **output=name** Name of the output file to hold the extracted DEM data.
- **logfile=name** Name of a file to hold related information about the extracted data.

**EXAMPLE:**
For example, the command:
```
    dd if=/dev/rmt0 ibs=10240 |
    m.dmaUSGSread top=1 bottom=400 left=1 right=500 |
    output=dem logfile=log
```
will extract data from /dev/rmt0 and put the first 400 rows and first 500 columns into the file `dem` located in the user's current directory.

NAME
m.dted.examine - Provides a terse description of level 1 and 2 digital terrain elevation data (DTED) files produced and distributed by the Defense Mapping Agency (DMA) on half-inch magnetic tapes.
(GRASS Data Import/Processing Program)

SYNOPSIS
m.dted.examine [tapedev]

DESCRIPTION
m.dted.examine scans digital terrain elevation data (DTED - Levels 1 and 2) that was produced and supplied by the Defense Mapping Agency (DMA) on half-inch magnetic tape from the tape device specified by tapedev, and prints to the screen a terse description of each file.

If the user specifies no tapedev on the command line the program assumes that input is coming from /dev/rmt0. The information provided by m.dted.examine includes the UTM borders, cell resolution, and number of elevation profiles in each file.

BUGS
The header file for DTED Level 1 and 2 data was changed in 1987. m.dted.examine and m.dted.extract operate only on DTED data containing pre-1987 headers. DTED data containing the pre-1987 headers may be purchased from the Defense Mapping Agency (DMA) upon request.

NAME
m.dted.extract - Extracts digital terrain elevation data (DITED - levels 1 and 2) produced and supplied by the Defense Mapping Agency (DMA) on half-inch magnetic tapes.
(GRASS Data Import/Processing Program)

SYNOPSIS
m.dted.extract if=tapedev of=outfile hf=headfile n=lat s=lat e=lon w=lon

DESCRIPTION
m.dted.extract extracts DITED (Levels 1 and 2) digital terrain elevation data produced by the Defense Mapping Agency (DMA) from half-inch magnetic tapes obtained from DMA. Data is read from the input file (if) specified by tapedev. If the user does not specify any file name on the command line, the program assumes that input is coming from /dev/rmt0. The extracted data is placed in the output file (of) specified by outfile. This program should be used in conjunction with the programs m.rot90 and r.in.ll to convert DITED data to GRASS raster format.

if The pathname of the tape device where the raw DITED data exists (default is /dev/rmt0)
of The full pathname of the output file into which the extracted tape data is to be copied
hf The full pathname of a file to contain descriptive information about the extracted data; should be placed in the same directory as the output file
n North latitude value defining the boundaries of the extraction geographic region (format: dd.mm.ss[ns])
s South latitude value defining the extraction geographic region (format: dd.mm.ss[ns])
ea East longitude value defining the extraction geographic region (format: dd.mm.ss[ew])
w West longitude value defining the extraction geographic region (format: dd.mm.ss[ew])

The n s e and w parameters define a geographic region that should completely encompass the data set. dd.mm.ss are degree, minute, and second values. Only data that falls within this defined geographic region will be extracted from the tape.

EXAMPLE
The command line:
    m.dted.extract if=/dev/rmt0 of=dted.out hf=dted.head n=37.30.00n s=37.15.00n e=103.30.00w w=103.45.00w

will extract DITED data from /dev/rmt0, store it in a file named dted.out, and store some supporting information in the file dted.head. Only data that falls within the geographic region defined by the coordinates n s e and w will be extracted.

NOTE
The user should examine the contents of the header file produced by this program; it contains information needed as inputs to the data rotation and raster file import programs m.rot90 and r.in.ll, respectively.

BUGS
The format of the header file for DITED Level 1 and 2 data was changed in 1987. m.dted.extract and m.dted.examine only operate on DITED data containing pre-1987 headers. DITED data containing the pre-1987 headers may be purchased from the DMA upon request.

DIAGNOSTICS
Invalid requests are so designated.

NAME
m.examine.tape – Provides a description of the files on half-inch magnetic tape. 
(Grass File Management Tool)

SYNOPSIS
m.examine.tape

DESCRIPTION
m.examine.tape is a convenient tool for previewing a tape and obtaining block size values. After the
user enters the command

m.examine.tape

the program will prompt the user for the full path name of the tape device on which the tape is
mounted. In most cases, this will be /dev/nnt0. However, the user must enter this, as there is no
default value for the tape device name. The user is then prompted to enter the buffer size to be used
when reading the tape. The buffer size is the amount of memory allocated to read one physical record
of the tape. If the user hits RETURN, the program will assume a default buffer size of 32767 bytes.
m.examine.tape reads the tape specified by the user and reports back the block size (record length) and
the number of blocks for each file contained on the tape. m.examine.tape can be used on any half-
inch magnetic tape. The user has the option of sending the output into a file or viewing the output on
the terminal screen.

NOTES
The buffer size is the amount of memory allocated to read one physical record on the tape. Magnetic
tape devices will accept a request to read more bytes than actually exist in any given record on a tape.
However, m.examine.tape reads only as many bytes as physically exist on the tape and returns the
number of bytes actually read. The user is allowed to alter the buffer size in order to request smaller
reads for tape devices unable to handle requests this large (32767 bytes), or to request larger reads for
tapes with larger record sizes read on drives able to handle larger record sizes.

Note that m.examine.tape cannot be used to examine the content of either ordinary files or one-
quarter-inch tape cartridges.

NAME

*m.flip* - Flips elevation data extracted from systems that retrieve data by rows from south to north.

(GRASS Data Import/Processing Program)

SYNOPSIS

```
  m.flip
  m.flip help
  m.flip [-q] input=name output=name rows=value cols=value bpc=value
```

DESCRIPTION

*m.flip* is similar to *m.rot90*. However, rather than rotating a raster file, *m.flip* flips the contents of the raster generated by tape extraction programs about the east-west axis. Flipping may be necessary to compensate for the orientation of the data read from tape. This program can be used in conjunction with the program *r.in.ii* to convert this rotated data into GRASS raster format.

*m.flip* requires five inputs to be entered by the user. These parameters and the optional flag setting are described below.

Flag:

- `-q` Run quietly, suppressing output of messages on program progress to standard output.

Parameters:

- `input=name` The full pathname of an existing file containing the data to be flipped.
- `output=name` The full pathname of the output file in which the rotated data are to be stored.
- `rows=value` The number of rows of data in the `input` file. Values must be positive integers.
- `cols=value` The number of columns of data in the `input` file. Values must be positive integers.
- `bpc=value` The number of bytes per cell (i.e., per data value) in the `input` file. Values must be positive integers.

EXAMPLE

The following command:

```
  m.flip input=/amp/foo.out output=/amp/flip.out rows=301 cols=358 bpc=2
```

will rotate the `foo.out` file and place the rotated file in `/amp/flip.out`. Here, the input file is 301 rows by 358 columns, at 2 bytes per data value.

NOTES

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

NAME

m.gc2ll - Converts geocentric to geographic coordinates.
(GRASS Data Import/Processing Program)

SYNOPSIS

m.gc2ll x=# y=# z=# s=spheroid

DESCRIPTION

m.gc2ll returns geographic coordinates for geocentric ones supplied by the user. It performs the
reverse operation of the GRASS program m.ll2gc. The x, y and z values are the three dimensions
needed to locate a point in three-dimensional space. The values that are printed include the latitude,
the longitude and the height above (or distance below) the spheroid.

The list of spheroids available is somewhat dynamic. It may not contain exactly the ones listed below.
To determine the current list of possible spheroids, simply type in:

m.gc2ll x=0 y=0 z=0 s=help

A list of available spheroids will be printed on the screen. If the spheroid desired is not on the list, the
values for the semi-major axis and the eccentricity squared for the spheroid may be entered in place of
a spheroid name in the following format:

s=a=semi-major_axis,e=eccentricity_squared

SOME POSSIBLE SPHEROIDS
(The on-line listing includes only the spheroid names)

NAME

*ml2gc* - Converts geographic coordinates to geocentric coordinates.

(Grass Data Import/Processing Program)

SYNOPSIS

```
ml2gc lat=dd.mm.ss{n|s} lon=dd.mm.ss{e|w} [h=height] s=spheroid
```

DESCRIPTION

*ml2gc* returns geocentric coordinates for geographic coordinates (latitude and longitude). Geographic coordinates are in degrees, minutes, and seconds and must include designation of north or south \{n|s\} and east or west \{e|w\}. The spheroid on which they are based must also be entered. The height (in meters) above the spheroid is optional.

The list of spheroids available is somewhat dynamic. It may not contain exactly the ones listed below. To determine the current list of possible spheroids, type in:

```
ml2gc lat=0n lon=0w s=help
```

A list of available spheroids will be printed on the screen. If the spheroid desired is not on the list, the values for the semi-major axis and the eccentricity squared for the spheroid may be entered in place of a spheroid name in the following format:

```
s=a=semi-major_axis,e=eccentricity_squared
```

SOME POSSIBLE SPHEROIDS

*The online listing includes only the spheroid names*

</tr>
</tbody>
</table>

EXAMPLE

```
ml2gc lat=0n lon=90w s=wgs72
```

Results:

```
x=6378135.0
y=0.0
z=0.0
```

The distances designated by "x," "y," and "z" are in meters from the center of the earth. Because the sample point is on the equator and is at 90 degrees west, two of the three parameters have a value of zero (i.e., the point is at the origin of those two dimensions).

NOTES

For a brief discussion of spheroids see *ml2p2*

Geographic coordinates (latitude/longitude) describe the location of a point on the earth relative to the equator in the north/south direction and relative to Greenwich in the east/west directions. The same point will have different coordinates depending on the spheroid used as the approximation of the shape of the earth. The geocentric coordinates given here describe the point on the basis of the Earth's spheroid, but they use the center of the spheroid as their origin. This can be thought of as being the
center of the earth, which is why they are called "geocentric." Describing the location of a point in a spheroid requires three points: \(x, y,\) and \(z;\) these are measured out from the center along three different axes. The distances given are in meters.

This is an experimental program. It is part of initial efforts to incorporate geographic coordinates into GRASS.

AUTHOR

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME

m.l12u - Converts geographic coordinates to Universal Transverse Mercator (UTM) coordinates.
(GRASS Data Import/Processing Program)

SYNOPSIS

m.l12u
m.l12u help
m.l12u [-rwoz] spheroid=name [zone=value] [input=name] [output=name]

DESCRIPTION

m.l12u converts geographic coordinates (i.e., latitudes and longitudes) to Universal Transverse Mercator
(UTM) eastings and northings. The user must specify the spheroid on which to base the UTM
conversion. The user may optionally specify the UTM zone; however, the program can determine this
from the geographic coordinates submitted.

The list of spheroids available is somewhat dynamic. At the time of this release, available spheroids
included: airy, australian, bessel, clark66, everest, grs80, hayford, international, krasovsky, wgs66,
wgs72, and wgs84 (see table below).

This command can be run either non-interactively or interactively. The user can run the program non-
interactively by entering desired flag settings and parameter values on the command line using the
following format:

m.l12u [-rwoz] spheroid=name [zone=value] [input=name] [output=name]

Alternately, the user can simply type:

m.l12u

on the command line. In this case, the user will be prompted for parameter values and flag settings
through the standard interface described in the manual entry for parser.

Input can be entered from the keyboard or from an input file. In either case, input should be entered
with one longitude and latitude pair per line, in the form:

degrees:minutes:seconds{W} degrees:minutes:seconds{S}
degrees:minutes:seconds{E} degrees:minutes:seconds{S}
degrees:minutes:seconds{W} degrees:minutes:seconds{S}
degrees:minutes:seconds{W} degrees:minutes:seconds{N}

end

If the user sets the r flag, m.l12u will expect the order of the coordinates to be reversed, and stated as
latitude, longitude pairs, rather than as longitude, latitude pairs.

Similarly, the user can elect to send output to an output file or to standard output (the
user's terminal screen). If the user sets the w flag, output will be printed in a format suitable for input
to programs like d.ponts. Example input and output are shown below (see EXAMPLES).

Program flag settings and parameters have the following meanings.

Flags:

-r  The order of coordinates is reversed in the input, and will be reversed later.
-w  Do not treat a line having no input values as errors.
-o  Do not treat input lines as errors.
-z  Suppress printing of the UTM zone in the output stream. This will produce
    output in a format suitable for editing input to programs like d.ponts.

Parameters:

- **spheroid** = *name*
  - Reference spheroid (ellipsoid).
  - Options: airy, australian, bessel, clark66, everest, grs80, hayford, international, krasovsky, wgs66, wgs72, wgs84

- **zone** = *value*
  - UTM zone number (results will be forced into this UTM zone).
  - Options: 1-60

- **input** = *name*
  - Name of an existing input file containing longitude, latitude coordinates to be converted.

- **output** = *name*
  - Name to be assigned to the output file containing UTM coordinates and zone designations.

### AVAILABLE SPHEROIDS

</tr>
<tr>
<td>wgs84</td>
<td>a=6378137</td>
<td>f=1/298.257</td>
<td>worldwide coverage</td>
</tr>
</tbody>
</table>

**EXAMPLE**

Assume the user has input the command:

```
m.ll2u spheroid=wgs72 input=Ulnfile output=utm.output
```

where the input file *Ulnfile* contains the following longitude, latitude values:

```
155:30:00W 19:35:00N
165:30:00W 19:35:00N
145:30:00W 20:00:00N
135:30:00W 21:00:00N
```

Output would then be sent to the output file *utm.output*, containing the below Easting and Northing coordinate values and UTM zone designations:

```
237740.85270818 2167292.10762315
447560.64349407 2165450.19058338
656921.61734802 2212183.40032627
448035.11644906 2322228.30381678
```

**NOTES**

Spheroids, the solids associated with an ellipse, are also known as ellipsoids. They are used as the best possible model to simulate the shape of the earth with its flattened poles and bulging equator. They are the mathematical means for establishing control points to use as a reference when determining exact locations on the earth. A cohesive set of these control points is called a datum.
The spheroids listed above have been used as the basis for a number of different datums. The North American Datum of 1927 (NAD 27) was based on the Clark 1866 ("clark66") spheroid. This was a recent current standard datum for North America. Be aware, however, that a new datum, NAD 83, has been developed using the Geodetic Reference System 1980 spheroid; this is now available in m.112u as the "grs80" spheroid. The "wgs66", "wgs72", and "wgs84" spheroids are for worldwide use. The "wgs72" spheroid has been used fairly widely by the Department of Defense (DOD) and is the basis for the World Geodetic System 1972 datum. This datum has also been recently replaced; the new DOD datum is WGS 84 (wgs84). Both datums are available within m.112u.

To use spheroids other than those listed here, the user can add lines to the ellipsoid parameter definition file in $GISBASE/etc/ellipse.table.

Read the marginalia of your source map to determine which spheroid was used to produce the map on which you are working.

This program has received only limited testing. It should be used with some caution.

FILES
See ellipsoid parameter definition file in $GISBASE/etc/ellipse.table.

AUTHOR
Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME
m.lulc.USGS - Creates raster map layers from a Composite Theme Grid (CTG) file created by m.lulc.read. m.lulc.read extracts the CTG data from an ASCII landuse/landcover (lulc) CTG format file supplied by the USGS. (GRASS Data Import/Processing Program)

SYNOPSIS
m.lulc.USGS input_file

DESCRIPTION
m.lulc.USGS creates the following raster map layers from the CTG file created by m.lulc.read, and places them into the user's current mapset:

1. Land Use & Land Cover
2. Political Units
3. Census Units
4. Hydrologic Units
5. Federal Land Ownership

Since the CTG file may not contain all of layers listed above, m.lulc.USGS will extract only the raster map layers that exist in the CTG file.

The CTG file contains all of the geographic region definition information necessary for creating the raster map layers, including:

1. Grid Zone
2. Projection Type (UTM)
3. Cell Resolution (ew_res = nw_res)
4. Multi-byte data formation
5. Geographic region coordinates.

m.lulc.USGS will use the geographic region information definition supplied with the CTG file and NOT the geographic region definition currently set for the user's mapset; (note that this is different than in the case with many of the other GRASS map development commands).

When m.lulc.USGS is executed, it will check the file for a specified layer and then ask the user if he wishes to extract the associated raster map layer. The user is then prompted for the name of a new raster file in which output is to be placed. m.lulc.USGS will then create this raster file and all supporting (e.g., category, cell header, color table, etc.) files.

EXAMPLE
In the example below, raster data is extracted from a CTG file (named lulc) that contains only LAND USE/LAND COVER data:

m.lulc.USGS lulc

MAP TITLE: DODGE CITY, KS 1:250,000 LU, PB, CN, HU, FO
The Composite Theme Grid file contains <1 >overlays
and has a map code type of <01 >

Do you Wish to Create <LAND USE/LAND COVER >Raster File (y/n) [y] y

Enter File Name for LAND USE/LAND COVER Overlay
Enter 'list' for a list of existing raster files
Hit RETURN to cancel request
>landuse
Creating <landuse> from <LAND USE/LAND COVER> Overlay: 95%
Number of Categories: 76 (UNLABELED)
Writing Cell Header Information
Writing Color Table Information

Conversion is Complete

BUGS

m.lulc.USGS does not currently extract Census unit data. Also, only the cataloging unit is extracted from the CTG file (see the Land Use and Land Cover Data User’s Guide supplied by the USGS).

NAME

m.lulc.read - Extracts Landuse/Landcover data in the ASCII Composite Theme Grid (CTG) data format distributed by the USGS into a working file for m.lulc.USGS.

(GRASS Data Import/Processing Program)

SYNOPSIS

dd [if=tapedev] ibs=input block_size cbs=80 conv=unblock | m.lulc.read argl

DESCRIPTION

m.lulc.read extracts USGS Land Use/Land Cover data distributed in the ASCII CTG format. Extracted data is placed into a file specified by argl. m.lulc.read should be used prior to using the GRASS program m.lulc.USGS.

m.lulc.read reads the data from standard input, allowing the user to pipe in the data from a file.

Data can also be read directly from the half-inch magnetic tape distributed by USGS, by using the UNIX command dd.

Parameters:

if=tapedev
  the pathname of the input tape drive (usually /dev/rmt0)

ibs=input
  the physical blocking value of the data on tape, usually written on the tape spool. If this value is unknown, run m.examine.tape prior to m.lulc.read.

cbs
  this is the conversion blocking factor for ASCII CTG file and is by default set to 80.

conv
  set conv to unblock when extracting ASCII CTG data

argl
  the name of the output file where the data will be stored in binary format.

EXAMPLES

READING FROM A FILE:

m.lulc.read outfile <infile

The above command will read the data from infile and place the results into outfile. Note that infile must be extracted from the USGS CTG half-inch magnetic tape using the UNIX dd command:

dd if=/dev/rmt0 of=infile ibs=32000 cbs=80 conv=unblock

READING DIRECTLY FROM HALF-INCH MAGNETIC TAPE:

dd if=/dev/rmt0 ibs=32000 cbs=80 conv=unblock | m.lulc.read outfile

The above command will extract data with a blocksize of 32000 from /dev/rmt0, and put the results in the file outfile.

NAME

\texttt{m.region.ll} - Converts Universal Transverse Mercator (UTM) coordinates falling within the current geographic region from UTM coordinates to geographic (latitude/longitude) coordinates.

\textit{(GRASS Data Import/Processing)}

SYNOPSIS

\texttt{m.region.ll}  
\texttt{m.region.ll help}  
\texttt{m.region.ll spheroid=name}

DESCRIPTION

\texttt{m.region.ll} takes current geographic region settings in UTM coordinates, and converts them to geographic coordinates (i.e., latitudes and longitudes). It also prints the length (in meters) of one arc-second at each of the four edges of the geographic region. The user must enter the spheroid upon which to base the geographic coordinates.

The list of spheroids available is somewhat dynamic. It may not contain exactly the ones listed below. To determine the current list of possible spheroids, simply type in:

\texttt{m.region.ll help}

A list of available spheroids will be printed on the screen.

AVAILABLE SPHEROIDS

NAME

m.rot90 - Rotates elevation data extracted by either m.dted.extract or m.dmaUSGSread
(GRASS Data Import/Processing Program)

SYNOPSIS

m.rot90
m.rot90 help
m.rot90 [-q] input=name output=name rows=value cols=value bpc=value

DESCRIPTION

m.rot90 is used as a companion program to the DTM and DFM digital elevation data tape extraction
programs m.dted.extract and m.dmaUSGSread. m.rot90 rotates the contents of the output files
generated by these tape extraction programs 90 degrees. Rotation is necessary to compensate for the
orientation of the data read from tape. This program can be used in conjunction with the program
r.in.ill to convert this rotated data into GRASS raster map layer form.

m.rot90 requires five inputs to be entered by the user. These parameters and the optional flag setting
are described below.

Flags:
- q Run quietly, suppressing output of messages on program progress to standard
output.

Parameters:

input = name The full pathname of an already-existing file containing the data to be rotated. This input
file is usually the output file created by m.dted.extract or m.dmaUSGSread.

output = name Name to be assigned to the resultant, rotated output file. The full pathname of the
output file in which the rotated data are to be stored.

rows = value The number of rows of data in the input file.

cols = value The number of columns of data in the input file.

bpc = value The number of bytes per cell in the input file.

EXAMPLE

The following command:

m.rot90 input = /Amp/dma.out output = /Amp/rot.out rows = 301 cols = 358 bpc = 2

will rotate the file /Amp/dma.out, and place the rotated file in /Amp/rot.out. Here, the input file is 301
rows by 358 columns, at 2 bytes per data value.

NOTES

The user should note that since the output file is rotated 90 degrees from the original input file, the
rows and columns have been interchanged. Hence, in the above example, the number of rows (301),
and columns (358) stated by the user on the command line were those present in the input file. The
output file, however, will have 358 rows and 301 columns.

NAME

`m.tiger.region` - Finds geographic region information for U.S. Census Bureau TIGER input data.

(Grass Data Import/Processing Program)

SYNOPSIS

```
m.tiger.region
m.tiger.region help
m.tiger.region infile=name [zone=value] [spheroid=name]
```

DESCRIPTION

`m.tiger.region` is a program designed to evaluate a file of raw type 1 Census (TIGER) data and determine the geographic region covered by that input file. Output is sent to standard out, and gives the east, west, north, and south boundaries for the given input data file.

If the user specifies the input file name and (optionally) the zone number or spheroid to be used on the command line, the program will run non-interactively; if no zone number or spheroid name is given, the default(s) will be used (see below). Alternately, the user may simply type `m.tiger.region` on the command line; in this case, the program will prompt the user for parameter values using the standard GRASS parser interface described in the manual entry for `parser`.

COMMAND LINE OPTIONS

Parameters:

- **infile=name**
  
  Input file name in which raw TIGER data (type 1) are stored.

- **zone=value**
  
  Universal Transverse Mercator (UTM) zone for this county.
  
  Options: -60 - 60
  
  Default: 0

- **spheroid=name**
  
  Name of spheroid to be used.
  
  Default: clark66

  Available spheroids are:

  - australian
  - bessel
  - clark66
  - clark80
  - everest
  - international
  - wgs72
  - wgs84

  It is recommended that the user choose the clark66 (default) spheroid when dealing with TIGER data as it is the most consistent with the original data.

EXAMPLES

If the user typed simply:

```
m.tiger.region infile=inputfilename
```

program output would look similar to this:

Number of calculated zones is: 2

INFO FOR ZONE 1:

zone number: 13

percentage of data points
in this zone: 0.799489
regional spread of points within this zone:
north: 5092049.155918
south: 5049238.983803
east: 734139.517650
west: 732514.747908

INFO FOR ZONE 2:
zone number: 14
percentage of data points in this zone: 99.200508
regional spread of points within this zone:
north: 5092041.463966
south: 5036134.342322
east: 398030.217441
west: 265527.656108

If the user does not input the UTM zone number, it is calculated for them. Then the zone number and region information are output, and if the program finds that the input data contains information in more than one UTM zone, then the output is given for all applicable zones.

If instead the user supplies the UTM zone number, the output would look like that shown below:

REGION FOR THIS DATA FILE:
north border: 5092049.155918
south border: 5036134.342322
east border: 398030.217441
west border: 265527.656108
(zone number: 14)

NOTES
This command must be compiled separately. It resides in the src.alpha directory and will not automatically be included in the compile of the main GRASS code. Although m.tiger.region does not need a FORTRAN compiler, it is used to support other TIGER data functions (like v.db.rim, v.in.tiger, and rim) that do require access to a FORTRAN compiler.

TIGER data are presented in latitude/longitude format, and are converted to UTM coordinates using coordinate conversion routines contained in the GRASS library. If no UTM zone number is supplied by the user, the program calculates the appropriate zone(s) based on the input data provided. The output then provides the UTM zone numbers found (if more than one), the geographic region covered within each zone, and the percentage of data points found in each zone. The user must then decide which of these UTM zones contains the major or most important portion of data values, so that the zone number can be supplied in creating the GRASS location to hold the imported data and can be provided to the importing program (v.in.tiger). Zone edges will be extended (reasonably) to include data values lying outside the chosen zone. If desired, m.tiger.region can be re-run, supplying the chosen zone number, in order to evaluate the region edges of the input data set (with the extended zone).

FILES
Source code for RIM is located under $GISBASE/src/related/rim
Source code for v.db.rim is located under $GISBASE/src/garden/grass.rim/v.db.rim

NAME

\texttt{m.u2ll} – Converts Universal Transverse Mercator (UTM) coordinates to geographic (latitude/longitude) coordinates.

(\textit{GRASS Data Import/Processing Program})

SYNOPSIS

\begin{verbatim}
m.u2ll
m.u2ll help
m.u2ll [-srwo] spheroid=name [zone=value] [input=name] [output=name]
\end{verbatim}

DESCRIPTION

\texttt{m.u2ll} converts Universal Transverse Mercator (UTM) northings and eastings to geographic coordinates (i.e., latitudes and longitudes). The user must specify the UTM coordinates to be converted and the spheroid on which the geographic coordinates will be based. The program also needs to know the UTM zone in which the input coordinates are located. However, if the user is running GRASS from a UTM data base LOCATION, \texttt{m.u2ll} will use this data base's UTM zone designation, if no zone is specified by the user.

The GRASS program \texttt{m.il2u} performs the reverse operation, converting geographic coordinates to UTM coordinates.

The list of spheroids available is somewhat dynamic. At the time of this release, available spheroids included: airy, australian, bessel, clark66, everest, grs80, hayford, international, krasovsky, wgs66, wgs72, and wgs84 (see table below).

This command can be run either non-interactively or interactively. The user can run the program non-interactively by entering desired flag settings and parameter values on the command line using the following format:

\begin{verbatim}
m.u2ll [-srwo] spheroid=name [zone=value] [input=name] [output=name]
\end{verbatim}

Alternately, the user can simply type:

\begin{verbatim}
m.u2ll
\end{verbatim}

on the command line. In this case, the user will be prompted for parameter values and flag settings through the standard interface described in the manual entry for parser.

Input can be entered from the keyboard or from an input file. In either case, input should be entered with one UTM easting and northing pair per line, in the format shown below:

\begin{verbatim}
easting northing
  easting northing
  easting northing
  
  end
\end{verbatim}

If the user sets the -r flag, \texttt{m.u2ll} will expect the order of the coordinates to be reversed, and stated as northing, easting pairs, rather than as easting, northing pairs. This is useful for passing ASCII GRASS vector (\texttt{dig}) files, whose coordinates are stated as northing, easting pairs, directly through \texttt{m.u2ll}.

Similarly, the user can elect to send output to an output file or (by default) to standard output (the user's terminal screen). Example input and output are shown below (see EXAMPLE).

Program flag settings and parameters have the following meanings.
Flags:

- `s` Specified UTM zone is in the southern hemisphere.
- `r` The order of coordinates is reversed in the input, and entered as: north east.
  This option allows the user to pass an ascii vector file through m.u21.
- `w` Do not flag invalid east, north input lines as errors.
- `o` Flag other invalid input lines as errors.

Parameters:

- `spheroid=name` Reference spheroid (ellipsoid).
  Options: airy, australian, bessel, clark66, everest, grs80, hayford, international,
  krasovsky, wgs66, wgs72, wgs84
- `zone=value` UTM zone in which UTM coordinates are located.
  Options: 1-60
- `input=name` Name of input file containing UTM values to be converted.
- `output=name` Name to be assigned to output file containing longitude and latitude values.

**AVAILABLE SPHEROIDS**
(The on-line listing includes only the spheroid names.)

<table>
<thead>
<tr>
<th>Spheroid</th>

<td>f=1/298.26</td>
<td>worldwide coverage</td>
</tr>
<tr>
<td>wgs84</td>
<td>a=6378137</td>
<td>f=1/298.257223563</td>
<td></td>
</tr>
</tbody>
</table>

**EXAMPLE**

Assume the user has input the command:

```
m.u21 -s spheroid=wgs72 zone=4 input=utm.infile output=ll.outfile
```

where the input file `utm.infile` contains the following easting and northing UTM coordinate values and zone designations:

<table>
<thead>
<tr>
<th>Easting</th>
<th>Northing</th>
</tr>
</thead>
<tbody>
<tr>
<td>237740.85</td>
<td>2167292.10</td>
</tr>
<tr>
<td>238740.00</td>
<td>2167000.00</td>
</tr>
<tr>
<td>239000.00</td>
<td>2167100.00</td>
</tr>
<tr>
<td>237100.00</td>
<td>2166000.00</td>
</tr>
</tbody>
</table>

Output would then be sent to the output file `ll.outfile`, containing the below longitude and latitude coordinate values:

```
166:02:25.645137W 70:27:46.615528S
166:00:53.237056W 70:27:59.692673S
166:00:27.23258W 70:27:57.454281S
166:03:41.428895W 70:28:25.61617S
```
NOTES

Users can add information to the ellipsoid parameter definition file on their systems (located in $GISBASE/etc/ellipse.table) to add spheroids not now among those supported by GRASS.

See m.ll2u for a brief discussion of spheroids.

The UTM zone designation determines what area of the earth a point is found. The same UTM coordinates will be found in each different UTM zone. Look at the marginalia of your source map to determine into which UTM zone your UTM coordinates fall. Although the user can permissibly omit specification of a UTM zone when running this program under a UTM data base LOCATION, it is safer to specify it (see DESCRIPTION, above).

m.u2ll converts the first pair of coordinates on each line of input and leaves anything else on the line alone. If a line begins:

```
xxxxxx.xx xxxxxxxx.xx
```
then the xxxxxxxx xxxxxxx.xx UTM coordinate pair is converted to a longitude, latitude pair. Any other information appearing on the line is left alone. If the line doesn’t begin with a pair of coordinates in the above format, then the line is left as it is.

FILES

p.chart

NAME

p.chart – Prints the color chart of the currently selected printer.

(GRASS Hardcopy Output Program)

SYNOPSIS

p.chart

DESCRIPTION

This function prints the color chart of the user's hardcopy color printer. The colors in the chart are numbered with the (device-dependent) number associated with each color. This function is useful both for the p.colors command as well as for color selection with p.map.

The user must select a printer using p.select before running this command.

SEE ALSO

d.colors, p.colors, p.map, p.select, r.colors

AUTHOR

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME
p.colors - Allows the user to develop a color table that associates map categories with user-specified printer colors.
(GRASS Hardcopy Output Program)

SYNOPSIS
p.colors

DESCRIPTION
This function allows the user to modify a color table for a raster map layer, by assigning colors to the categories in the raster map layer based on printer color numbers (instead of red, green, blue percentages).

The user will need to have the printer color chart available to properly select the colors (see manual entry for p.chart).

The p.colors function allows the user to exercise perfect control over the colors that appear in the hardcopy image.

NOTES
If the user assigns a printer color number outside of the printer's range, p.colors will not complain, but will not save the out-of-range printer color number to the raster map layer's color table.

This command modifies the color table associated with a map layer, and will therefore also affect the colors in which a map layer is displayed on the user's graphics monitor. (See map color table files stored under $LOCATION/colr and $LOCATION/colr2.)

\texttt{\textit{p.labels}} \textit{Create labels for hardcopy maps.}

\textit{(GRASS Hardcopy Output Program)}

SYNOPSIS

\texttt{p.labels}

DESCRIPTION

This module allows the user to create or modify labels files. These labels files, which are stored in the database, define text information for printing with \texttt{p.map} and for graphics display with \texttt{d.paint.labels}. Each labels file contains components which determine the text, the location of the text on the image, its size, and the background for the text.

The interface is a screen-oriented input/edit layout. Each label is entered with a single screen. After filling in the required information (described below), the user hits \texttt{<ESC>}, to accept the label and start a new one. After the last label has been accepted, the user then hits the \texttt{<ESC>}, one more time (on an empty label screen) to exit the module and save the labels.

SCREEN LAYOUT

The screen layout for the labels looks like this:

```
PAINT LABELS: labelfile new labels [1]
TEXT: SKIP: no
LOCATION: EAST: OFFSET: NORTH: OFFSET: PLACEMENT: center
FONT: standard
TEXT SIZE: TEXT COLOR: black WIDTH: 1 HIGHLIGHT COLOR: none WIDTH: 0
BACKGROUND COLOR: white BORDER COLOR: black OPAQUE TO VECTORS: yes
```

AFTER COMPLETING ALL ANSWERS, HIT \texttt{<ESC>} TO CONTINUE
(OR \texttt{<Ctri-C>} TO CANCEL)

The label information that must be provided is:

TEXT: Up to four lines of text. Lines in multiple line labels will appear one above the next.

SKIP: yes/no. If \textit{no}, the label will be printed. If \textit{yes}, the label will be retained in the file but not printed.

LOCATION: Determines where the text will be located on the image. The user specifies the location.
and northing, and (optionally) specifies a vertical and horizontal offset (in printer pixels) from the specified easting/northing. (The vertical offset will shift the location to the south if positive, north if negative. The horizontal offset will shift the location east if positive, west if negative.) These offsets are provided to allow finer placement of labels.

**PLACEMENT:** Determines which part of the label to which the location refers. If placement is unspecified, the label is centered (*center*), by default. Label placement may be specified as:

- **lower left** (lower left corner of the text)
- **lower right** (lower right corner of the text)
- **lower center** (bottom center of the text)
- **upper left** (upper left corner of the text)
- **upper right** (upper right corner of the text)
- **upper center** (top center of the text)
- **center** (center of the text)

**FONT:** This specifies the font to use. The following fonts are available:

- **cyrillic**
- **gothtg**
- **gothc**
- **greekc**
- **greeks**
- **italicc**
- **italiccs**
- **italict**
- **roman**
- **romanb**
- **romanc**
- **romans**
- **romand**
- **romans**
- **romanb**
- **romanb**
- **scriptc**
- **scripts**

The word *standard* can be used to specify the default font (which is *roman*.)

**TEXT SIZE:** This determines the size of the letters. The size specifies the vertical height of the letters in meters on the ground. Thus text will grow or shrink depending on the scale at which the map is drawn. The default text size, if none is specified, is **500**.

**TEXT COLOR:** This selects the text color. If unspecified, the label’s text is drawn in *black*, by default. The text color can be specified in one of four ways:

1) By color name:
   - aqua
   - black
   - blue
   - brown
   - cyan
   - gray
   - green
   - grey
   - indigo
   - magenta
   - orange
   - purple
   - red
   - violet
   - white
   - yellow

2) As red, green, blue percentages. for example: *5 4 7*
   (This form is not supported by *d.paint.labels.*)

3) By printer color number to get the exact printer color.
   (This form is not supported by *d.paint.labels.*)

4) Specify *none* to suppress the lettering.

**WIDTH:** This determines the line thickness of the letters. The normal text width should be set to 1. Larger numbers can be used to simulate bold face. (*d.paint.labels* ignores this value and always uses 1. 1 is also the default width to which the width is set by *paint*, if none is specified by the user.)

**HIGHLIGHT COLOR:** The text can be highlighted in another color so that it appears to be in two colors. The text is drawn first in this color at a wider line width, and then redrawn in the text color at the regular line width. No highlight color (*none*) is used, by default, if unspecified by the user. To specify use of no highlight color, specify *none*. (See TEXT COLOR above for a list of permissible color names.)
**HIGHLIGHT WIDTH:** Specifies how far from the text lines (in units of pixels) the highlight color should extend. The default highlight width is set to 0 (i.e., no highlight color).

**BACKGROUND COLOR:** Text may be boxed in a solid color by specifying a background color. Specify `none` for no background. The default background color setting, if unspecified by the user, is `white`. (See TEXT COLOR above for a list of permissible color names).

**BORDER COLOR:** Select a color for the border around the background. Specify `none` to suppress the border. The default border color used, if unspecified, is `black`. (See TEXT COLOR above for a list of permissible color names.)

**OPAQUE TO VECTORS:** `yes` | `no`. This field only has meaning if a background color is selected. `yes` will prevent vector lines from entering the background. `no` will allow vector lines to enter the background. The default setting, if unspecified by the user, is `yes`.

NAME

p.map - Hardcopy color map output utility.

(GRASS Hardcopy Output Program)

SYNOPSIS

p.map
p.map help
p.map [input=name] [scale=mapscale]

DESCRIPTION

p.map produces hardcopy color map products on your system's color output device. Output can include a raster map, any number of vector overlays, site data, text labels, and other spatial data.

This program has 2 distinct modes of operation. The command-line mode requires the user to prepare a file of mapping instructions describing the various spatial and textual information to be printed prior to running p.map. The interactive mode (i.e., no command-line arguments) will prompt the user for items to be mapped and does not require the user to prepare a file of instructions.

The command-line parameters are:

input = name File containing mapping instructions. (or enter input = to enter from keyboard).
These instructions are described in detail below.

scale = mapscale Scale of the output map, e.g., 1:25000
Default: ipanel
This parameter is provided as a convenience. It is identical to the scale mapping instruction described below.

Note: the user must select an output device using p.select before running p.map. Also, the preview device can be selected to view the output from p.map on the graphics monitor instead of sending it to a paper printer.

MAPPING INSTRUCTIONS

The mapping instructions allow the user to specify various spatial data to be plotted. These instructions are normally prepared in a regular text file using a system editor. Some instructions are single line instructions while others are multiple line. Multiple line instructions consist of the main instruction followed by a subsection of one or more additional instructions.

colormode

Selects the appropriate method to color raster map layers and images.

USAGE: colormode approx | best

There are two methods: approximate and best. From a user perspective, approximate can be used for raster map layers with few categories, such as soils, and best should be used for images like LANDSAT images or NHAP photos, or maps with many categories. The approximate mode treats each pixel independently, giving it the printer color that best approximates the true color. The best mode "blends" colors from pixel to pixel using a dithering technique to simulate more colors than the printer can actually print. The default, if unspecified, is best.

This example would select the approximate colormode. The assumption is that the raster map layer being printed has few colors or that the colors would not look good dithered.

EXAMPLE: colormode approx
colortable

Includes the color table for the raster map layer in the legend below the map.

Usage:  colortable [y|n]

The color table will display the colors for each raster map layer category value and the category label. To get a color table, you must have previously requested a raster map layer. Omitting the colortable instruction would result in no color table. Note: Be careful about asking for the color table for a raster map layer that contains many categories, like an elevation layer; this could result in the printing of an extremely long color table.

This example would print a color table as part of the legend to the map.
Example:  colortable

comments

Prints comments beneath the map. You may submit comment text line by line during p.map execution or via a prepared comments file.

Usage:  comments [commentfile]

Example:  comments

This example prints the comment "This is a comment" in the legend below the map.
Example:  comments

This example prints whatever is in the file veg.comments in the legend below the map.
Example:  raster vegetation

comments veg.comments

This example prints whatever is in the file veg.comments in the legend below the map. Presumably, the file veg.comments contain comments pertaining to the raster map layer vegetation, such as "This map was created by classifying a LANDSAT TM image."

defpat

Defines area fill patterns to be used in the setpat instruction.

Usage:  defpat name

pattern

color #color

end

The pattern is given a name on the defpat instruction line. The pattern which follows is composed of a sequence of numbers 0-9 (and blanks, which are equivalent to 0). The blanks or zeros indicate holes in the pattern where the normal category color would show thru. The other numbers 1-9 indicate pattern pixels and can be assigned any color. The default color for all the digits will be black unless specified with the color instruction. The color option will begin by entering the word color followed by one of the digits (1-9) in the pattern, followed by one of the NAMED COLORS. This should be repeated for each of the digits specified to avoid using black. The instruction end terminates the pattern definition.
Of course, the user can define more patterns by entering more \textit{defpat} instructions.

\textbf{NOTE:} Do NOT indent the pattern. Leading blank spaces will be interpreted as 0's.

This example creates a black horizontal line pattern.
\textbf{EXAMPLE}: \texttt{defpat horiz}
\begin{verbatim}
  1
  0
  0
  0
  \textbf{color} 1 \texttt{black}
  \textbf{end}
\end{verbatim}

This example creates a green vertical line pattern.
\textbf{EXAMPLE}: \texttt{defpat vert}
\begin{verbatim}
  1000
  \textbf{color} 1 \texttt{green}
  \textbf{end}
\end{verbatim}

This example creates a red diagonal line pattern.
\textbf{EXAMPLE}: \texttt{defpat diag}
\begin{verbatim}
  00001
  0001
  001
  01
  1
  \textbf{color} 1 \texttt{red}
  \textbf{end}
\end{verbatim}

This example creates a two-toned tree pattern with orange trunks and green leaves.
\textbf{EXAMPLE}: \texttt{defpat tree}
\begin{verbatim}
  2
  222
  22122
  22 1 22
  1
  2
  222
  22122
  22 1 22
  1
  \textbf{color} 1 \texttt{orange}
  \textbf{color} 2 \texttt{black}
  \textbf{end}
\end{verbatim}

\texttt{grid}

Overlays a coordinate grid onto the output map.

\textbf{USAGE}: \texttt{grid \textbf{spacing}}
\begin{verbatim}
  \textbf{color} \texttt{color}
  \textbf{numbers} \#\texttt{[color]}
  \textbf{end}
\end{verbatim}
The **spacing** of the grid is given (in the geographic coordinate system units) on the main instruction line. The subsection instructions allow the user to specify the **color** of the grid lines, whether coordinate **numbers** should appear on the grid lines, and if they should appear on every grid line (1), every other grid line (2), etc., and what color the numbers should be. The defaults are black grid lines, unnumbered.

This example would overlay a green grid with a spacing of 10000 meters (for a metered database, like UTM) onto the output map. Alternate grid lines would be numbered with red numbers.

**EXAMPLE:**
```
grid 10000
  color green
  numbers 2 red
end
```

**labels**

Selects a labels file for output (see manual entry for `p.labels`).

**USAGE:**
```
labels labelfile|file|
```

This example would paint labels from the labels file called `town.names`. Presumably, these labels would indicate the names of towns on the map.

**EXAMPLE:**
```
labels town.names
```

**line**

Draws lines on the output map.

**USAGE:**
```
line east north east north
  line x% y% x% y%
  color color
  width #
  masked [y|n]
end
```

The beginning and ending points of the line are entered on the main instruction. These points can be defined either by map coordinates or by using percentages of the geographic region. The user may also specify line **color**, **width** in pixels, and if the line is to be **masked** by the current mask. (See manual entry for `r.mask` for more information on the mask.)

This example would draw a yellow line from the point $x=10\%$, $y=80\%$ to the point $x=30\%$, $y=70\%$. This line would be 2 pixels wide and would appear even if there is a mask.

**EXAMPLE:**
```
line 10% 80% 30% 70%
  color yellow
  width 2
  masked n
end
```

Of course, multiple lines may be drawn with multiple **line** instructions.
outline

Outlines the areas of a raster map layer with a specified color.

**USAGE:**

```
outline
color color
d
```

Distinct areas of the raster map will be separated from each other visually by drawing a border (or outline) in the specified `color` (default: black). Note: it is important the user enter the instruction `end` even if a color is not chosen. (It is hoped that in the future the outline of a different raster map layer other than the one currently being painted may be placed on the map.)

This example would outline the category areas of the `soils` raster map layer in grey.

**EXAMPLE:**

```
raster soils
  outline
color grey
d
```

point

Places additional points or icons on the output map.

**USAGE:**

```
point east north
point x% y%
color color
tcml iconfile list
size 
masked [y|n]
d
```

The point location is entered in the main instruction line by giving either the map coordinates or by using percentages of the geographic region. The user may also specify the point `color`, the `tcml` file to be used to represent the point location (see the the manual entry for `p.icon`), the `size` of the icon in integer multiples of the pattern in the icon file, and whether the point is to be masked by the current mask. (See manual entry for `r.mask` for more information on the mask.)

This example would place a purple diamond (from icon file `diamond`) at the point (E456000 N7890000). This diamond would be the same size it is in the diamond icon file and would not be masked by the current mask.

**EXAMPLE:**

```
point 456000 7890000
color purple
tcml diamond:size 1
masked n
d
```

Of course, multiple points may be drawn with multiple `point` instructions.

raster

Selects a raster map layer for output.
USAGE: raster mapname|list

For each p.map run, only one raster map layer can be requested. If no raster map layer is requested, a completely white map will be produced. It can be useful to select no raster map layer to provide a white background for vector images.

This example would paint a map of the raster map layer soils.
EXAMPLE: raster soils

read

Provides p.map with a previously prepared input stream.

USAGE: read previously prepared UNIX file

Mapping instructions can be placed into a file and read into p.map.

Note: p.map will not search for this file. The user must be in the correct directory or specify the full path on the read instruction. (Note to bin/csh users: ~ won’t work with this instruction).

This example reads the UNIX file pmap.roads into p.map. This file may contain all the p.map instructions for placing the vector map layer roads onto the output map.

EXAMPLE: read pmap.roads

The user may have created this file because this vector map layer is particularly useful for many p.map outputs. By using the read option, the user need not enter all the input for the vector instruction, but simply read the previously prepared file with the correct instructions.

region

Places the outline of a smaller geographic region on the output.

USAGE: region regionfile|list
color color
width #
end

Geographic region settings are created and saved using g.region. The p.map region option can be used to show an outline of a smaller region which was printed on a separate run of p.map on other user-created maps.

The user can specify the color and the width (in pixel units) of the outline. The default is a black border of one pixel width.

This example would place a white outline, 2 pixels wide, of the geographic region called fire.zones onto the output map. This geographic region would have been created and saved using g.region.

EXAMPLE: region fire.zones
color white
width 2
end
scale

Selects a scale for the output map.

**USAGE:**

```
scale scale
```

The scale can be selected either as:
- a relative ratio, e.g., 1:25000;
- an absolute width of the printed map, e.g., 10 inches;
- the number of printed paper panels, e.g., 3 panels;
- the number of miles per inch, e.g., 1 inch equals 4 miles.

This example would set the scale of the map to 1 unit = 25000 units.

**EXAMPLE:**

```
scale 1:25000
```

**setcolor**

Overrides the color assigned to one or more categories of the raster map layer.

**USAGE:**

```
setcolor cat(s) color
```

This example would set the color for categories 2, 5, and 8 of the raster map layer `watersheds` to white and category 10 to green. (NOTE: no spaces are inserted between the category values.)

**EXAMPLE:**

```
raster watersheds
setcolor 2,5,8 white
setcolor 10 green
```

Of course, `setcolor` can be requested more than once to override the default color for additional categories. More than one category can be changed for each request by listing all the category values separated by commas (but with no spaces).

**setpat**

Assigns a (previously defined) pattern on a raster map layer category.

**USAGE:**

```
setpat cat name
or
setpat builtin
or
setpat all
```

The user can choose to use: the name of a specific pattern created using `defpat` (see above); the patterns built into `p.map`; or all the patterns the user may have created.

This example assigns the vertical pattern created using `defpat` (see example in `defpat` above) to category 3 of the raster map layer `vegetation` and the tree pattern (see example in `defpat` above) to category 10.

**EXAMPLE:**

```
raster veg
setpat 3 vert
setpat 10 tree
```

This example reads a previously prepared UNIX file `horiz.pat` with the correct `defpat` instructions for creating a black horizontal pattern (see example in `defpat` above) and assigns that pattern to category 5 of the raster map layer `soils` via the `setpat` instruction.
EXAMPLE:
```
raster soils
read horiz.pat
setpat 5 horiz
```

To select the builtin patterns:
EXAMPLE:
```
raster soils
setpat builtin
```

To select individual builtin patterns:
EXAMPLE:
```
raster soils
setpat 5 #1
setpat 10 #2
```

```sites```
Selects sites data to be placed on the output map (see manual entry for `s.menu`).

USAGE: sites sitemap/list
color color
icon iconfile/list
size #
desc [y|n]
end

The user may specify the color of the sites (see section on NAMED COLORS below); the icon to be used to represent the presence of a site (see the manual entry for `p.icons`); the size of the icon (number of times larger than the size it is in the icon file); and whether or not the description associated with each site is also to be printed.

This example would paint a sites map with blue windmills (from an icon file created by the user using the `p.icons` GRASS command) placed at all windmill locations (from a sites list). These windmills would be two times larger than the size of the icon in the icon file and have descriptions from the sites list file printed beside them.

EXAMPLE: sites windmills
color blue
icon windmill
size 2
desc y
end
```
```
```
```text```
Places text on the map.

USAGE: text east north text
text x% y% text
font fontname
color color|none
width #
hecolor color|none
hwidth #
background color|none
border color|none
size #
ref reference point
xoffset #
The user specifies where the text will be placed by providing map coordinates or percentages of the geographic region map. The text follows these coordinates on the same instruction line. More than one line of text can be specified by noting the end of a line with \n (e.g. USA\nCERL).

The user can then specify various text features:

- **font**: cyrilc gothgbt gothgrt gothitt greekc greeks greekp goeks greekc gothc gothicc gothp greeks gothicc gothp greekp greekc (The default font is romans);
- **color** (see NAMED COLORS);
- **width** of the lines used to draw the text (to make thicker letters);
- **size** as the vertical height of the letters in meters on the ground (text size will grow or shrink depending on the scale at which the map is painted);
- the highlight color (**bcolor**) and the width of the highlight color (**bwidth**);
- the text-enclosing-box **background** color; the text box **border** color;
- **ref**. This reference point specifies the text handle - what part of the text should be placed on the location specified by the map coordinates. Reference points can refer to: [lower|upper|center] [left|right|center] of the text to be printed;

**yoffset**, which provides finer placement of text by shifting the text a vertical distance in pixels from the specified north. The vertical offset will shift the location to the south if positive, north if negative;

**xoffset**, which shifts the text a horizontal distance in pixels from the specified east. The horizontal offset will shift the location east if positive, west if negative;

whether or not the text should be **opaque** to vectors. Entering no to the opaque option will allow the user to see any vectors which go through the text's background box. Otherwise, they will end at the box's edge.

This example would place the text *SPEARFISH LAND COVER* at the coordinates E650000 N7365000. The text would be a total of 3 pixels wide (2 pixels of red text and 1 pixel black highlight), have a white background enclosed in a red box, and be 500 meters in size. The lower right corner of the text would be centered over the coordinates provided. All vectors on the map would stop at the border of this text.

**EXAMPLE**: text 650000 7365000 SPEARFISH LAND COVER

- **font** romans
- **color** red
- **width** 2
- **bcolor** black
- **bwidth** 1
- **background** white
- **border** red
- **size** 500
The user can specify the color of the vectors; the width of the vectors lines in pixels; the highlight color for the vector lines; the width of the highlight color in pixels; whether or not the raster map layer is to be masked by the current mask (see manual entry r.mask for more information on the mask); and the line style. The line style allows the vectors to be dashed in different patterns and colors. This is done by typing a series of numbers (0-9) in a desired sequence or pattern. Colors for the numbers (1-9) can be assigned using the color instruction. Blanks and non-digit characters are recognized as 0's. Using 0 would allow the colors of the raster map layer (or the background color if no raster map layer was selected) to show through.

This example would paint a map of the vector map layer named streams. These streams would be a total of 3 pixels wide (the inner two pixels blue and the outer highlight pixel white). The map would not show streams outside of the current mask.

EXAMPLE:
```
vector streams
  color blue
  width 2
  hcolor white
  hwidth 1
  masked y
  style 0-9
  end
```

This example would paint a map of the vector map layer roads. These roads would be 2 pixels wide and would be dashed blank-black-red (the blank areas would show what lies under the roads). This map would show roads inside and outside of the current mask.

EXAMPLE:
```
vector roads
    width 2
    style 001122
    color 1 black
    color 2 red
    masked n
    end
```

verbose
Changes the amount of talking p.map will do.
USAGE: `verbose [0|1|2]`

A higher value implies more chatter. The default is 2. This example sets the amount of chatter to a minimum.

EXAMPLE: `verbose 0`

`end`

Terminates input and begin painting the map.

USAGE: `end`

NAMED COLORS

The following are the colors that are accepted by `p.map`:

- aqua
- black
- blue
- brown
- cyan
- gray
- green
- grey
- indigo
- magenta
- orange
- purple
- red
- violet
- white
- yellow

ICONS VS. PATTERNS

Icons and patterns as used in `p.map` are not the same thing. Patterns are defined and are normally used to cover those extended areas covered by a raster map layer category. A pattern will repeat above, below and adjacent to itself. Icons are used to represent a single point.

Patterns are supported directly within `p.map` using the `defpat` instruction, while icons must be created using the `p.icons` program.
EXAMPLE p.map INPUT FILE
The following is an example of a p.map script file. The file has been named spear.soils. For the purposes of illustration, the file is in two columns. This script file can be entered at the command line:

```
p.map input=spear.soils
```

```
raster soils
defpat diag
vector streams
  color blue
  width 2
  bcolor white
  bwidth 1
  masked y
end
vector roads
  width 2
  style 001122
text 608000.00 3476004.73 SPEARFISH SOILS MAP
color 1 black
color 2 red
masked n
end
labels town.names
region sub.region
  color white
  width 2
end
grid 10000
color green
numbers 2 red
end
outline
color black
end
colortable y
comments
  This is a comment
end
scale 1:25000
setcolor 6,8,9 white
setcolor 10 green
```

INTERACTIVE MODE
If the user simply enters p.map without arguments, then a simple prompting session occurs. Some, but not all of the non-interactive requests are available at this level.

**NAME**

*p.ppm* - Reads portable pixmap (ppm) files created by PPM utilities.

(Grass Paint/Print Program)

**SYNOPSIS**

```
p.ppm
p.ppm help
p.ppm [-f] [input=name]
```

**DESCRIPTION**

This program, *p.ppm*, reads a user-specified portable pixmap (ppm) file and outputs it to the currently selected printer (see `p.select`). The input ppm file should be one that has been created using the PPM utilities developed by Jeff Poskanzer. These utilities can import various image formats (including SUN raster, X Windows pixmaps, and others) into the PPM formats *ppm* (color pixmaps), *pgm* (grey scale maps), and *pbm* (black and white bit-maps).

If the image doesn't fit the output device, it won't get printed. If you want the image printed (but clipped), use the *p.ppm* -f option, or scale the input using *ppmscale*, or rotate the image using *ppmrotate* (if it will fit that way -- otherwise you might have to scale it as well). If the image doesn't fit, *p.ppm* will tell you what scaling value to enter to *ppmscale* that will make it fit.

**EXAMPLES**

If the user is running GRASS on a SUN machine, the following command could be used to send a monitor screen image to the printer:

```
screendump | rasttoppm | p.ppm
```

If you are running suntools, the user might type:

```
sleep 10; screendump | rasttoppm | ppmrotate 90 | p.ppm
```

The UNIX `sleep` command allows you time to arrange the frames before the screen dump starts. The `ppmrotate` is usually needed because the SUN screens are wider than they are long (and wider than 1024 pixels - which is the width of most of our printers).

If you are running X, the user might type:

```
xwd | xwdtoppm | ppmrotate 90 | p.ppm
```

**NOTES**

This program only supports the ppm binary format (P6).

Maximum color level is 255. If the ppm file has more color levels, use *ppmscale* to reduce the number of colors.

No scaling is done. Use *ppmscale* to change image size.

No rotation is done. Use *ppmrotate* to rotate the image.

**SEE ALSO**

See also:

The PPM utilities
- `ppmrotate` (rotates ppm images),
- `ppmscale` (scales ppm images for printing),
- `rasttoppm` (converts a SUN raster file to ppm format), and
- `xwdtoppm` (converts an X Windows dump file to ppm format).

The SUN program `screendump` (dumps the image on the color graphics monitor into a file in SUN raster file format).
The X program `xwd` (dumps the image in an X window into a file in X window dump [xwd] format).

The GRASS programs `d.save`, `d.savescreen`, `p.map`, `p...lect`, and `parser`.

This program uses the PPM utilities developed by Jeff Poskanzer.
NAME

p.screen – Prints a graphics monitor display image file that has been saved by d.savescreen.
(GRASS Paint/Print Output Program)

SYNOPSIS

p.screen
p.screen help
p.screen [-r] input=name [bg=value] [scale=value[pl]]

DESCRIPTION

p.screen prints the graphics monitor screen image file created by d.savescreen to a color printer.

Flag:

- Select black and white reversal. Whatever is specified as black in the original graphics monitor display image is printed ("painted") in white, and whatever was white in the screen image is printed in black.

Parameters:

input=name Name of a file containing a graphics screen image.

bg=value Data (category) value representing the background color Enables user to set the background color to white without having to reverse all black and white. For example, -w0 will set color 0 to white.

scale=valuep or scale=valuei Image scaling factor. If not specified by the user, the graphics monitor screen image is scaled to fill the width of the printer (i.e., 1p, 1 panel wide). It outputs the graphics monitor screen image at the ratio of 1 image pixel to printer pixels (i.e., 4 will print the graphics monitor screen image at a ratio of 1 image pixel = 4 printer pixels). This or on is useful if the resampling of the screen image must be controlled. Since rescaling often entails dropping some input pixels or repeating some input pixels more often than others, linear elements in the screen image may be distorted. This effect can be eliminated by specifying 1 as the scaling factor.

p Outputs the graphics monitor screen image at # panels wide (i.e., 3p will print the graphics monitor screen image at 3 panels wide).

i Outputs the graphics monitor screen image at # inches wide (i.e., 8.5i will print the screen image 8.5 inches wide).

If no arguments are given on the command line, the user will be prompted for the input file name, the background data value, the image scaling factor, and the black-white reversal flag setting.

NOTES

The input file to p.screen is generated by the program d.savescreen. At present, d.savescreen only exists for MAASCOMP systems. If you do not have a MAASCOMP, you probably will not be able to save screens to be painted by p.screen.

NAME

`p.select` - Selects a device (printer) for GRASS hardcopy output.

*(GRASS Hardcopy Output Program)*

SYNOPSIS

```
p.select
p.select help
p.select [-lpq] [painter=name]
```

DESCRIPTION

`p.select` allows the user to select the device for GRASS hardcopy output. The user must select a device *before* running the other GRASS hardcopy output functions (e.g., `p.map`, `p.labels`, `p.chart`).

COMMAND LINE OPTIONS

Flags:

- `-l` List all available painters.
- `-p` Print name of currently selected painter.
- `-q` Quietly select painter.

Parameter:

`painter=name` Name of painter to select.

Options: (this will be a list of available hardcopy output devices, and also `preview`, the user's graphics monitor)

INTERACTIVE MODE

If the user runs `p.select` without specifying program arguments on the command line, the program will prompt the user for the name of a hardcopy output device to select.

NAME

r.average -- Finds the average of values in a values map within areas assigned the same category value in a user-specified base map.

(GRASS Raster Program)

SYNOPSIS

r.average
r.average help
r.average [-c] base=name values=name result=name

DESCRIPTION

r.average calculates the average value of data contained in a values raster map layer for areas assigned the same category value in the user-specified base raster map layer. These averaged values are stored in the category labels file associated with a new result map layer.

The values to be averaged are taken from a user-specified values map. The category values for the values map will be averaged, unless the -c flag is set. If the -c flag is set, the values that appear in the category labels file for the values map will be averaged instead (see example below).

The result map is actually a reclass of the base map (see r.reclass), and will have exactly the same category values as the base map. The averaged values computed by r.average are stored in the result map's category labels file.

If the user simply types r.average on the command line, the user is prompted for the flag setting and parameter values through the standard parser interface (see parser manual entry).

Alternately, the user can supply all needed flag settings and parameter values on the command line.

Flag:

-c  Take the average of the values found in the category labels for the values map, rather than the average of the value map's category values.

Parameters:

base=name  An existing raster map layer in the user's current mapset search path. For each group of cells assigned the same category value in the base map, the values assigned these cells in the values map will be averaged.

values=name  An existing raster map layer containing the values (in the form of cell category values or cell category labels) to be averaged within each category of the base map.

result=name  The name of a new map layer to contain program output (a reclass of the base map). Averaged values will be stored in the result map's category labels file under the user's $LOCATION/cats directory.
EXAMPLE

Assume that `farms` is a map with seven farms (i.e., seven categories), and that `soils.Kfactor` is a map of soil K factor values with the following category file:

<table>
<thead>
<tr>
<th>category</th>
<th>category value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>label</td>
</tr>
<tr>
<td>0</td>
<td>no soil data</td>
</tr>
<tr>
<td>1</td>
<td>0.10</td>
</tr>
<tr>
<td>2</td>
<td>0.15</td>
</tr>
<tr>
<td>3</td>
<td>0.17</td>
</tr>
<tr>
<td>4</td>
<td>0.20</td>
</tr>
<tr>
<td>5</td>
<td>0.24</td>
</tr>
<tr>
<td>6</td>
<td>0.28</td>
</tr>
<tr>
<td>7</td>
<td>0.32</td>
</tr>
<tr>
<td>8</td>
<td>0.37</td>
</tr>
<tr>
<td>9</td>
<td>0.43</td>
</tr>
</tbody>
</table>

Then

```
r.average -c base=farms values=soils.Kfactor result=K.by.farm
```

will compute the average soil K factor for each farm, and store the result in the resultant map `K.by.farm`, which will be a reclass of `farms` with category labels as follows (example only):

<table>
<thead>
<tr>
<th>category</th>
<th>category value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>label</td>
</tr>
<tr>
<td>1</td>
<td>0.1023</td>
</tr>
<tr>
<td>2</td>
<td>0.1532</td>
</tr>
<tr>
<td>3</td>
<td>0.172</td>
</tr>
<tr>
<td>4</td>
<td>0.3872</td>
</tr>
<tr>
<td>5</td>
<td>0.003</td>
</tr>
<tr>
<td>6</td>
<td>0.28</td>
</tr>
<tr>
<td>7</td>
<td>0.2345</td>
</tr>
</tbody>
</table>

NOTES

The `-c` option requires that the category label for each category in the `values` map be a valid number, integer, or decimal. To be exact, if the first item in the label is numeric, then that value is used. Otherwise, zero is used. The following table covers all possible cases:

<table>
<thead>
<tr>
<th>category label</th>
<th>value used by @</th>
</tr>
</thead>
<tbody>
<tr>
<td>.12</td>
<td>0.12</td>
</tr>
<tr>
<td>.80 KF</td>
<td>0.8</td>
</tr>
<tr>
<td>no data</td>
<td>0</td>
</tr>
</tbody>
</table>

(This operator is very similar to the `@` operator in `r.mapcalc`, and the user is encouraged to read the manual entry for `r.mapcalc` to see how it works there.)

The user should use the results of `r.average` with care. Since this utility assigns a value to each cell which is based on global information (i.e., information at spatial locations other than just the location of the cell itself), the resultant map layer is only valid if the geographic region and mask settings are the same as they were at the time that the result map was created.

Results are affected by the current region settings and mask.

NAME

*r.basins.fill* - Generates a raster map layer showing watershed subbasins.

*(GRASS Raster Program)*

SYNOPSIS

```
r.basins.fill
r.basins.fill help
r.basins.fill number=value e_map=name t_map=name result=name
```

DESCRIPTION

*r.basins.fill* generates a raster map layer depicting subbasins, based on input raster map layers for the coded stream network (where each channel segment has been "coded" with a unique category value) and for the ridges within a given watershed. The raster map layer depicting ridges should include the ridge which defines the perimeter of the watershed. The coded stream network can be generated as part of the *r.watershed* program, but the map layer of ridges will need to be created by hand, either through digitizing done in *v-digit*, or through the on-screen digitizing option accessible within *d.display* or *d.digit*.

The resulting output raster map layer will code the subbasins with category values matching those of the channel segments passing through them. A user-supplied number of passes through the data is made in an attempt to fill in these subbasins. If the resulting map layer from this program appears to have holes within a subbasin, the program should be rerun with a higher number of passes.

The user can run *r.basins.fill* either interactively or non-interactively. If the user simply types *r.basins.fill* without other arguments on the command line, the program will prompt the user for the needed parameters using the standard GRASS parser interface (see manual entry for parser).

If the user wishes to run the program non-interactively, the following parameter values must be specified on the command line:

**Parameters:**

- `number=value` - The number of passes to be made through the dataset.
- `e_map=name` - The coded stream network file name.
- `t_map=name` - The thinned ridge network file name.
- `result=name` - The resultant watershed partition file name.

**NOTES**

The current geographic region setting is ignored. Instead, the geographic region for the entire input stream's map layer is used.

**SEE ALSO**

See Appendix A of the GRASS Tutorial: *r.watershed* for further details on the combined use of *r.basins.fill* and *r.watershed*.

*d-digit*, *d.display*, *r.watershed*, *v-digit*, and *parser*

NAME

r.binfer - Bayesian expert system development program.

(GRASS Raster Program)

SYNOPSIS

r.binfer
r.binfer help
r.binfer [-v] input=name [output=name]

DESCRIPTION

r.binfer is an expert system shell containing an inference engine based on Bayesian statistics (reasoning from past experience). It is designed to assist human experts in a field develop computerized expert systems for land use planning and management. These expert systems are designed to aid non-experts make decisions about land use.

In Bayesian expert system programs like r.binfer, the system bases the probable impacts of a future land use action on the conditional probabilities about the impact of similar past actions.

COMMAND LINE OPTIONS

Flags:
-v Run verbosely, displaying messages on debugging output to standard output. Includes a listing of the symbol table used by r.binfer.

Parameters:

input=name Name of an existing file containing analysis instructions.
output=name Name to be assigned to the file to contain program output.

Default: binfer.out

Using appropriate r.binfer syntax, the human expert structures an input knowledge/control script with an appropriate combination of map layer category values (GRASS raster map layers that contain data on soil texture, slope, density, etc.) and attributes relevant to decision-making (e.g., rainfall, temperature, season, subjective judgement, etc.). Options exist for specifying a user interface and a data base containing prior and conditional probabilities necessary to infer the value of a goal attribute. The expert also specifies the format for display of end results (raster map layers) in the input script. New raster map layers -- one for each possible inferred attribute value -- are created that contain the probability of the inferred attribute value occurring in each grid cell.

Alternately, a single new map layer called r.binfer (or whatever output name is specified by the user) is also output. This map shows, for each grid cell, the inferred attribute value that has the highest probability of occurring in each grid cell, given the values of the input raster map layer and contextual attributes.

r.binfer scripts are typed into a file by the user using a system editor like vi, and then input to r.binfer as the input file named on the command line. For a complete description of the input syntax, see the document GRASS Tutorial: r.binfer (forthcoming). For example r.binfer scripts see the EXAMPLES section below. The results are used to generate the new raster map layers in the user's current mapset.

As stated above, r.binfer scripts contain descriptions of two types of input attributes. The map layer type attributes are actual GRASS raster map layers, with the values defined to be ranges of the categories within that raster map layer. For example, if the user chooses slope as one of the layer attributes, the possible values for the slope attribute might be the following:

- flat (slopes between 0 and 5 degrees)
- low (slopes between 6 and 10 degrees)
- medium (slopes between 11 and 30 degrees)
- steep (slopes greater than 31 degrees)
The contextual attributes are those that do not represent raster map layers, but rather, information that reflects criteria relevant to the specific decision being contemplated. For example, if the user chooses "rainfall amount" as one of the contextual attributes, possible values assigned to the "rainfall amount" attribute might be the following:

- low: (rainfall amounts less than 1 inch)
- medium: (rainfall amounts between 1 and 3 inches)
- high: (rainfall amounts greater than 3 inches)

The inferred attribute values are specified along with a prior probability and a table of conditional probabilities that indicate the probability of that inferred attribute value occurring given that an input attribute value has occurred.

`r.binfer` will determine the value of contextual attributes by prompting the user for input. It will then open each of the raster map layers corresponding to each map layer attribute. `r.binfer` then determines the values for all map layer attributes in each grid cell. Using the conditional probability tables, the prior probabilities, and Bayes' theorem, `r.binfer` calculates the output probabilities for each inferred value and writes its probability of occurrence as a percentage. It also determines which value is most likely to occur in that cell and writes that to the output file name.

**EXAMPLES**

The two sample scripts shown below illustrate only the use of `r.binfer` to: (1) estimate the probability that an avalanche will occur, and (2) infer the probability of finding pine mountain beetles, at each cell across a landscape, given the input map layer attributes shown below. The author makes no claims as to the correctness of using these criteria to infer either event.

**Some Notes on Script Construction.**

1. **No Data** (or what to do with category zero).

   If category zero is excluded from the ranges of any layer attribute value, it is treated as "no data" and the resulting probability and combined maps will reflect this.

   Otherwise, category zero is treated just like any other cell value.

2. **Category ranges for layer attributes.**

   The category ranges are specified using `r.reclass` rules.

   For example, a value list for slope might look like this:

   (flat [0 thru 3], gentle [4 thru 8], moderate [9 thru 15], other [16 thru 89]).

3. **Question Attachments.**

   Question attachments can be supplied for and context attribute or attribute value. If names are chosen cleverly, the default menu should be sufficient.

4. **Determinant List.**
At this time the determinant list serves no real purpose. Planned extensions to binfer will make use of this list, so just don't use it for now.

5. Probabilities.

The conditional probability table is very important, try to be sure of its accuracy.

NAME

`r.buffer` - Creates a raster map layer showing buffer zones surrounding cells that contain non-zero category values.

*GRASS Raster Program*

SYNOPSIS

```
  r.buffer
  r.buffer help
  r.buffer input=name outputt=name distances=value[,value,...] [units=name]
```

DESCRIPTION

`r.buffer` creates a new raster map layer showing buffer (aka, "distance" or "proximity") zones around all cells that contain non-zero category values in an existing raster map layer. The distances of buffer zones from cells with non-zero category values are user-chosen. Suppose, for example, that you want to place buffer zones around roads. This program could create the raster map layer shown below on the right based on road information contained in the raster map layer shown on the left.

```
Category 0: No roads
Category 1: Roads
Category 2: Buffer Zone 1 around roads
Category 3: Buffer Zone 2 around roads
```

INTERACTIVE PROGRAM USE

The user can run the program interactively by simply typing `r.buffer` without program arguments on the command line. The program then prompts the user for parameter values.

(1) You are requested to identify the existing raster map layer from which distance-from calculations shall be based, and a name (of your choice) for the new raster map layer which will contain the results.

(2) Then, identify the units of measurement in which buffer (distance) zones are to be calculated, and the distance of each buffer zone from each non-zero cell in the input map. The user has the option of identifying up to 60 continuous zones. The zones are identified by specifying the upper limit of each desired zone (`r.buffer` assumes that 0 is the starting point). ("Continuous" is used in the sense that each category zone's lower value is the previous zone's upper value. The first buffer zone always has distance 0 as its lower bound.) Distances can be entered in one of four units: `meters`, `kilometers`, `feet`, and `miles`.

(3) Last, calculate distances from cells containing user-specified category values, using the "fromcell" method. [The "fromcell" method goes to each cell that contains a category value from which distances are to be calculated, and draws the requested distance rings around them. This method works very fast when there are few cells containing the category values of interest, but works slowly when there are numerous cells containing the category values of interest spread throughout the area.]

The `r.buffer` program now runs the process in "background" and returns keyboard control to the user. These processes can occasionally take up to an hour or more to finish; however, because they run in the background, you are free to do other things with the computer in the interim.
NON-INTERACTIVE PROGRAM USE

The user can run \texttt{r.buffer} specifying all parameter values on the command line, using the form:

\begin{verbatim}
r.buffer input=name output=name distances=value[,value,...] [units=name]
\end{verbatim}

Parameters:

- \texttt{input=name}
  - The name of an existing raster map layer whose non-zero category value cells are to be surrounded by buffer zones in the \texttt{output} map.

- \texttt{output=name}
  - The name assigned to the new raster map layer containing program output. The \texttt{output} map will contain buffer zones at the user-specified \texttt{distances} from non-zero category value cell in the \texttt{input} map.

- \texttt{distances=value[,value,...]}
  - The distance of each buffer zone from cells having non-zero category values in the \texttt{input} map.

- \texttt{units=name}
  - The unit of measurement in which distance zone values are to be calculated. Possible choices for \texttt{name} are: meters, kilometers, feet, and miles. The default units used, if unspecified by the user, are meters.

EXAMPLE

In the example below, the buffer zones would be (in the default units of meters): 0-10, 11-20, 21-30, 31-40 and 41-50.

Format:

\begin{verbatim}
r.buffer input=name output=name distances=value[,value,...] [units=name]
\end{verbatim}

Example:

\begin{verbatim}
r.buffer input=map.in output=map.out distances=10,20,30,40,50 units=meters
\end{verbatim}

NOTES

\texttt{r.buffer} measures distances from center of cell to center of cell using Euclidean distance measure for planimetric databases (like UTM) and using ellipsoidal geodesic distance measure for latitude/longitude databases.

\texttt{r.buffer} calculates distance zones from all cells having non-zero category values in the \texttt{input} map. If the user wishes to calculate distances from only selected \texttt{input} map layer category values, the user should run (for example) \texttt{r.reclass} prior to \texttt{r.buffer}, to reclass all categories from which distance zones are not desired to be calculated into category zero.

NAME

r.cats - Prints category values and labels associated with user-specified raster map layers.
(GRASS Raster Program)

SYNOPSIS

r.cats
r.cats help
r.cats map=name [cats=range[,...]] [fs=character | space | tab]

DESCRIPTION

r.cats prints the category values and labels for the raster map layer specified by map=name to standard output.

The user can specify all needed parameters on the command line, and run the program non-interactively. If the user does not specify any categories (e.g., using the optional cats=range[,range,...] argument), then all the category values and labels for the named raster map layer that occur in the map are printed. The entire map is read, using r.describe, to determine which categories occur in the map. If a listing of categories is specified, then the labels for those categories only are printed. The cats may be specified as single category values, or as ranges of values. The user may also (optionally) specify that a field separator other than a space or tab be used to separate the category value from its corresponding category label in the output, by using the fs=character | space | tab option (see example below). If no field separator is specified by the user, a tab is used to separate these fields in the output, by default.

The output is sent to standard output in the form of one category per line, with the category value first on the line, then an ASCII TAB character (or whatever single character or space is specified using the fs parameter), then the label for the category.

If the user simply types r.cats without arguments on the command line the program prompts the user for parameter values using the standard GRASS parser interface described by parser.

EXAMPLES

r.cats map=soils
prints the values and labels associated with all of the categories in the soils raster map layer;

r.cats map=soils cats=10,12,15-20
prints only the category values and labels for soils map layer categories 10, 12, and 15 through 20; and

r.cats map=soils cats=10,20 fs=:
prints the values and labels for soils map layer categories 10 and 20, but uses ":" (instead of a tab) as the character separating the category values from the category values in the output.

Example output:

10:Dumps, mine, Cc
20:Kyle clay, KaA

NOTES

Any ASCII TAB characters which may be in the label are replaced by spaces.

The output from r.cats can be redirected into a file, or piped into another program.

NAME

r.clump - Recategorizes data in a raster map layer by grouping cells that form physically discrete areas into unique categories.

(GRASS Raster Program)

SYNOPSIS

r.clump
r.clump help
r.clump [-q] input=name output=name [title="string"]

DESCRIPTION

r.clump finds all areas of contiguous cell category values in the input raster map layer name. It assigns a unique category value to each such area ("clump") in the resulting output raster map layer name. If the user does not provide input and output map layer names on the command line, the program will prompt the user for these names, using the standard parser interface (see manual entry for parser).

Category distinctions in the input raster map layer are preserved. This means that if distinct category values are adjacent, they will NOT be clumped together. (The user can run r.reclass prior to r.clump to recategorize cells and reassign cell category values.)

Flag:

-q Run quietly, without printing messages on program progress to standard output.

Parameters:

input=name Name of an existing raster map layer being used for input.
output=name Name of new raster map layer to contain program output.
title="string" Optional title for output raster map layer, in quotes. If the user fails to assign a title for the output map layer, none will be assigned it.

ALGORITHM

r.clump moves a 2x2 matrix over the input raster map layer. The lower right-hand corner of the matrix is grouped with the cells above it, or to the left of it. (Diagonal cells are not considered.)

NOTES

r.clump works properly with raster map layers that contain only "fat" areas (more than a single cell in width). Linear elements (lines that are a single cell wide) may or may not be clumped together depending on the direction of the line -- horizontal and vertical lines of cells are considered to be contiguous, but diagonal lines of cells are not considered to be contiguous and are broken up into separate clumps.

A random color table and other support files are generated for the output raster map layer.

NAME
r.coin - Tabulates the mutual occurrence (coincidence) of categories for two raster map layers.
(Grass Raster Program)

SYNOPSIS
r.coin
r.coin help
r.coin [-qw] map1=name map2=name units=name

DESCRIPTION
r.coin tabulates the mutual occurrence of two raster map layers' categories with respect to one another.
This analysis program respects the current geographic region and mask settings.
The user can run the program non-interactively by specifying all needed flag settings and parameter
values on the command line, in the form:

r.coin [-qw] map1=name map2=name units=name

Flags:
-q Run quietly, and suppress the printing of program status messages to standard output.
-w Print a wide report, in 132 columns (default: 80 columns)

Parameters:
map1=name Name of first raster map layer.
map2=name Name of second raster map layer.
units=name Units of measure in which to output report results.

Options: c, p, x, y, a, h, k, m

Alternately, the user can run r.coin interactively by simply typing r.coin without command line
arguments; in this case, the user will be prompted for the names of the two raster map layers which will
be the subjects of the coincidence analysis. r.coin then tabulates the coincidence of category values
among the two map layers and prepares the basic table from which the report is to be created. This
tabulation is followed by an indication of how long the coincidence table will be. If the table is
extremely long, the user may decide that viewing it is not so important after all, and may cancel the
request at this point. Assuming the user continues, r.coin then allows the user to choose one of eight
units of measure in which the report results can be given. These units are:
c cells
p percent cover of region
x percent of <map name> category (column)
y percent of <map name> category (row)
a acres
h hectares
k square kilometers
m square miles

Note that three of these options give results as percentage values: "p" is based on the grand total
number of cells; "x" is based on only column totals; and "y" is based on only row totals. Only one unit
of measure can be selected per report output. Type in just one of the letters designating a unit of
measure followed by a <RETURN>. The report will be printed to the screen for review. After
reviewing the report on the screen, the user is given several options. The report may be saved to a file
and/or sent to a printer. If printed, it may be printed with either 80 or 132 columns. Finally, the user
is given the option to rerun the coincidence tabulation using a different unit of measurement.
Below is a sample of tabular output produced by *r.coin*. Here, map output is stated in units of square miles. The report tabulates the coincidence of the Spearfish sample database's *owner* and *road* raster map layers' categories. The *owner* categories in this case refer to whether the land is in private hands (category 1) or is owned by the U.S. Forest Service (category 2). The *roads* map layer categories refer to various types of roads (with the exception of category value "0", which indicates "no data"; i.e., map locations at which no roads exist). *r.coin* does not report category labels. The user should run *r.report* or *r.cats* to obtain this information.

The body of the report is arranged in panels. The map layer with the most categories is arranged along the vertical axis of the table; the other, along the horizontal axis. Each panel has a maximum of 5 categories (9 if printed) across the top. In addition, the last two columns reflect a cross total of each column for each row. All of the categories of the map layer arranged along the vertical axis are included in each panel. There is a total at the bottom of each column representing the sum of all the rows in that column. A second total represents the sum of all the non-zero category rows. A cross total (Table Row Total) of all columns for each row appears in a separate panel.

Note how the following information may be obtained from the sample report. In the Spearfish database, in area not owned by the Forest Service, there are 50.63 square miles of land not used for roads. Roads make up 9.27 square miles of land in this area. Of the total 102.70 square miles in Spearfish, 42.80 square miles is owned by the Forest Service. In total, there are 14.58 square miles of roads. There are more category 2 roads outside Forest Service land (2.92 mi. sq.) than there are inside Forest land boundaries (0.72 mi. sq.).

Following is a sample report.

NOTES
It is not a good idea to run *r.coin* on a map layer which has a monstrous number of categories (e.g., unclassed elevation). Because *r.coin* reports information for each and every category, it is better to reclassify those categories (using *reclass*) into a more manageable number prior to running *r.coin* on the reclassified raster map layer.

*r.coin* calculates the coincidence of two raster map layers. Although *r.coin* allows the user to rerun the report using different units, it is not possible to simply rerun the report with different map layers. In order to choose new map layers, it is necessary to rerun *r.coin*.

r.colors  

NAME  
\texttt{r.colors} - Creates/Modifies the color table associated with a raster map layer.  
\textit{(GRASS Raster Program)}  

SYNOPSIS  
\begin{verbatim}  
r.colors  
r.colors help  
r.colors [-wq] map=name color=type  
\end{verbatim}  

DESCRIPTION  
\texttt{r.colors} allows the user to create and/or modify the color table for a raster map layer. The map layer  
(specified on the command line by \texttt{map=\textit{name}}) must exist in the user's current mapset search path.  
The color table specified by \texttt{color=\textit{type}} must be one of the following:

<table>
<thead>
<tr>
<th>color type</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aspect</td>
<td>(aspect oriented grey colors)</td>
</tr>
<tr>
<td>grey</td>
<td>(grey scale)</td>
</tr>
<tr>
<td>grey.eq</td>
<td>(histogram-equalized grey scale)</td>
</tr>
<tr>
<td>gyr</td>
<td>(green through yellow to red colors)</td>
</tr>
<tr>
<td>rainbow</td>
<td>(rainbow color table)</td>
</tr>
<tr>
<td>ramp</td>
<td>(color ramp)</td>
</tr>
<tr>
<td>random</td>
<td>(random color table)</td>
</tr>
<tr>
<td>ryg</td>
<td>(red through yellow to green colors)</td>
</tr>
<tr>
<td>wave</td>
<td>(color wave)</td>
</tr>
<tr>
<td>rules</td>
<td>(create new color table based on user-specified rules)</td>
</tr>
</tbody>
</table>

If the user specifies the \texttt{-w} flag, the current color table file for the input map will not be overwritten.  
This means that the color table is created only if the \texttt{map} does not already have a color table. If this  
option is not specified, the color table will be created if one does not exist, or modified if it does.  

If the user sets the \texttt{-q} flag, \texttt{r.colors} will run quietly, without printing numerous messages on its  
progress to standard output.

Color table types \texttt{aspect}, \texttt{grey}, \texttt{grey.eq} (histogram-equalized grey scale), \texttt{gyr} (green-yellow-red),  
\texttt{rainbow}, \texttt{ramp}, \texttt{ryg} (red-yellow-green), \texttt{random}, and \texttt{wave} are pre-defined color tables that \texttt{r.colors}  
knows how to create without any further input.

The \texttt{rules} color table type will cause \texttt{r.colors} to read color table specifications from standard input  
(stdin) and will build the color table accordingly.

Using color table type \texttt{rules}, there are three ways to build a color table: by color list, by category  
values, and by "percent" values.

Building a customized color table by color list is the simplest of the three rules methods: just list the  
colors you wish to appear in the color table in the order that you wish them to appear. Use the  
standard GRASS color names: white, black, red, green, blue, yellow, magenta, cyan, aqua, grey, gray, orange, brown, purple, violet, and indigo.

For example, to create a color table for the raster map layer \texttt{elevation} that assigns greens to low map  
category values, browns to the next larger map category values, and yellows to the still larger map  
category values, one would type:

\begin{verbatim}  
r.colors map=elevation color=rules  
\end{verbatim}
To build a color table by category values' indices, the user should determine the range of category values in the raster map layer with which the color table will be used. Specific category values will then be associated with specific colors. Note that a color does not have to be assigned for every valid category value because \texttt{r.colors} will interpolate a color ramp to fill in where color specification rules have been left out. The format of such a specification is as follows:

\begin{verbatim}
category_value color_name
category_value color_name
  ...

category_value color_name
end
\end{verbatim}

Each category value must be valid for the raster map layer, category values must be in ascending order and only use standard GRASS color names (see above).

Colors can also be specified by color numbers each in the range 0-255. The format of a category value color table specification using color numbers instead of color names is as follows:

\begin{verbatim}
category_value red_number green_number blue_number
category_value red_number green_number blue_number
  ...

category_value red_number green_number blue_number
end
\end{verbatim}

Specifying a color table by "percent" values allows one to treat a color table as if it were numbered from 0 to 100. The format of a "percent" value color table specification is the same as for a category value color specification, except that the category values are replaced by "percent" values, each from 0-100, in ascending order. The format is as follows:

\begin{verbatim}
percent_value% color_name
percent_value% color_name
  ...

percent_value% color_name
end
\end{verbatim}

Using "percent" value color table specification rules, colors can also be specified by color numbers each in the range 0-255. The format of a percent value color table specification using color numbers instead of color names is as follows:

\begin{verbatim}
percent_value% red_number green_number blue_number
percent_value% red_number green_number blue_number
  ...

percent_value% red_number green_number blue_number
end
\end{verbatim}
Note that you can also mix these three methods of color table specification; for example:

0 black
10% yellow
78 blue
magenta
purple
brown
100% 0 255 230
end

EXAMPLES
(1) The below example shows how you can specify colors for a three category map, assigning red to category 1, green to category 2, and blue to category 3. Start by using a text editor, like vi, to create the following rules specification file. Save it with the name rules.file.

1 red
2 green
3 blue
end

The color table can then be assigned to map threecats by typing the following command at the GRASS> prompt:

cat rules.file | r.colors map=threecats color=rules

(2) To create a natural looking LUT for true map layer elevation, use the following rules specification file. It will assign light green shades to the lower elevations (first 20% of the LUT), and then darker greens (next 15%, and next 20%) and light browns (next 20%) for middle elevations, and darker browns (next 15%) for higher elevations, and finally yellow for the highest peaks (last 10% of LUT).

0% 0 230 0
20% 0 160 0
35% 50 130 0
55% 120 100 30
75% 120 130 40
90% 170 160 50
100% 255 255 100

NAME

\textit{r.comb2} - Allows category values from several raster map layers to be combined. (\textit{GRASS Raster Program})

SYNOPSIS

\texttt{r.comb2}

\texttt{r.comb2 <inputfile}}

DESCRIPTION

\texttt{r.comb2} accepts commands that are similar to those used for boolean combinations (AND, OR, NOT) in order to overlay user-selected groups of categories from different raster map layers. After the \texttt{r.comb2} program is started, the users are asked if they want the graphic output to go to a color graphics monitor. If a color graphics monitor is not used, the graphic output is displayed on the terminal screen. This display is, of course, quite rough. It consists of numerals representing the various categories that result from the \texttt{r.comb2} analysis. The user will see a [1]: following this question. This is the first prompt, and indicates that \texttt{r.comb2} is ready to receive input from the user.

The following commands perform operations in \texttt{r.comb2}:

<table>
<thead>
<tr>
<th>Command</th>
<th>Alias</th>
<th>Followed by</th>
<th>Such as</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>[name]</td>
<td>name for raster map output</td>
<td>sandstone</td>
</tr>
<tr>
<td>GROUP</td>
<td>[group]</td>
<td>category values and a raster map</td>
<td>1-40 (elevation.255)</td>
</tr>
<tr>
<td>AND</td>
<td>[and]</td>
<td>expression describing a raster map and categories</td>
<td>(grp 4 (soils)) (grp 2 (owner))</td>
</tr>
<tr>
<td>OR</td>
<td>[or]</td>
<td>expression describing a raster map and categories</td>
<td>(grp 4 (soils)) (grp 2 (owner))</td>
</tr>
<tr>
<td>NOT</td>
<td>[not]</td>
<td>expression describing a raster map and categories</td>
<td>(grp 2 3 (roads))</td>
</tr>
<tr>
<td>OVER</td>
<td>[overlay]</td>
<td>existing raster map and color</td>
<td>sandstone yellow</td>
</tr>
<tr>
<td>COVER</td>
<td>[cover]</td>
<td>existing raster map</td>
<td>sandstone</td>
</tr>
</tbody>
</table>

\texttt{r.comb2} uses the same colors for all the operating commands. This is the \texttt{r.comb2} color table:

- 0 black
- 1 red
- 2 yellow
- 3 orange
- 4 blue
- 5 purple
- 6 green
- 7 white
- 8 grey
- 9 red/grey
- 10 yellow/grey
- 11 orange/grey
- 12 blue/grey
- 13 purple/grey
- 14 green/grey
- 15 dark grey

The user may enter commands either line-by-line from within \texttt{r.comb2}, or by typing the commands into a file that is then read into \texttt{r.comb2} using the UNIX redirection symbol <. The command format is the same for the two methods. The line-by-line method, however, does not allow as much flexibility as does use of an input file. If a line containing a syntax error is entered on the \texttt{r.comb2} command line, it is cleared; the line must then be re-entered in its entirety. Input files containing mistakes, however, can easily be modified (rather than recreated). An input file is especially advantageous when a more complex series of statements is input to \texttt{r.comb2}.
r.combine uses two types of commands: those that perform operations, and those that have some other function.

r.combine can probably best be learned by following examples, so pay special attention to those included below with the operating command descriptions. Notice two things in particular:

1) All parentheses must be closed. A raster map layer name must often be enclosed within parentheses; each time one of the above commands is used, it and its appropriate companions must also be enclosed within parentheses.

2) Certain spaces are important. Generally, r.combine requires at least one space before an opening parenthesis (except when it is the first character in an expression). r.combine ignores extra spaces and tab characters.

OPERATING COMMANDS
Below is a summary of the syntax of the operating commands, a description of each command, and examples using the Spearfish sample data base.

NAME
(NAME: new_map_name (Expression))
Allows graphic output to be saved in the raster map layer new_map_name, so that it is available for additional analysis or for future viewing. The results of performing the expression in parentheses is then placed into the named output raster map layer (here, new_map_name). Note that this means that r.combine may be used to create new raster map layers from existing ones. r.combine automatically creates a color table for the new raster map layers; however, the user should run the GRASS program r.support to fill in category assignments and history information if the new raster map layer is to be saved for future use in the mapset.

Example:
(NAME sandstone (GROUP 4 (geology)))
The above command will result in the creation of a new raster map layer named sandstone, noting the locations of cells with geology category value 4. You must then run the GRASS program r.support in order to label the categories present in the new raster map layer.

Resultant categories:
0 - black: other than sandstone
1 - red: sandstone

GROUP
(GROUP category_values (existing raster map layer))
Selects out categories of the desired values from the existing raster map layer which is indicated in parentheses directly after the category grouping. It also works to select out just one category from the map layer. Any of the following are legal category groupings:

2
1-18
1 2 5-7

Example:
(GROUP 1-40 (elevation.255))
Depicts only the area with elevation 1187 meters or less (i.e., elevation map layer category values 1 through 40 only).
Resultant categories:
0 - black: elevation > 1187 m
1 - red: elevation <= 1187 m

Example:
(NAME low_hi (GROUP 1-40 238-255 (elevation.255)))
Depicts only those areas with elevations of either 1187 meters or less, or in excess of 1787 meters (elevation categories 1-40, and 238-255). The graphic output is saved in the new raster map layer called low_hi.

Resultant categories:
0 - black: elevation > 1187 m and < 1787 m
1 - red: elevation <= 1187 m and >= 1787 m

AND

(AND (Expression A) (Expression B))
Combines two map layers and creates a new one: when both of the category values associated with the same given cell location in the two combined map layers are non-zero, a category value of 1 is assigned to that cell in the new map layer. If, however, either map layer assigns a category value of zero to the same given cell location, the category value associated with this cell's location in the resultant map layer also becomes zero.

Example:

```
AND (GROUP 4 7-9 (geology)) (GROUP 2 (owner))
```
Depicts the occurrences of categories 4, 7, 8, and 9 from the map layer geology whenever they occur on U.S. Forest Service property. Results are displayed to the terminal screen.

Resultant categories:
0 - black: no data occurred in one or the other of the raster map layers
1 - red: the AND condition is met

Note that if neither map layer contained any areas of "no data," the resultant raster map layer would include only 1's.

Example:

```
(NAME sand (AND (GROUP 4 7-9 (geology)) (GROUP 2 (owner))))
```
Same as above, except the results are saved in the map layer sand.

OR

(OR (Expression A) (Expression B))
Combines two map layers and creates a new one: when EITHER of the category values associated
with the same given cell location in the two combined map layers is non-zero, a category value of 1 is assigned to that cell in the new map layer. If, however, both map layers assign a category value of zero to the same given cell location, the category value of this cell in the resultant map layer also becomes zero. Only two map layers may be combined at one time. For example:

```
raster map 1 2 2 0
   2 1 0
   0 0 0       1 1 1 results
   or --> 1 1 0
raster map 2 1 0 1
   1 1 0
   1 1 0
```

Example:

```
(OR (GROUP 4 7-9 (geology)) (GROUP 2 (owner)))
```

Depicts all occurrences of categories 4, 7, 8, and 9 from the map layer `geology` as well as showing all the land which is U.S. Forest Service property. Results are displayed to the terminal screen.

Resultant categories:
0 - black: this area has neither the values of 4, 7, 8, or 9
nor is it on U.S. Forest Service property
1 - red : this area meets one or the other of the conditions noted above

Note that no distinction is made between those places where conditions are met in both map layers and where they are met in only one. See the `r.combine` command `OVER` if it is necessary to make that distinction.

**NOT**  

```
(NOT (Expression))
```

Negates `Expression` in order to define a new map layer which contains the opposite of what is defined by `Expression`. The new raster map layer will contain category values of either 0 or 1. 0 values would indicate that the NOT conditions were not met. Cell values of 1 would indicate that the NOT conditions were met. In order to specify the map layer in which to save the output from NOT, use the `r.combine` command `NAME`.

Example:

```
(NAME rds (NOT (GROUP 0 (roads))))
```

Areas containing category zero in the existing map layer `roads` indicate those locations within the database where roads do not exist. Negating that expression leaves us with all other areas - i.e., those locations at which roads do exist. Here, the graphic output is saved in the raster map layer named `rds`.

Resultant categories:
0 - black: no roads
1 - red : roads

The same results could have been obtained with: `(NAME rds (GROUP 1-5 (roads)))`. NOT is most useful in those cases where it is simpler to define something on the basis of what it is not than on the basis of what it is.

**OVER**  

```
(OVER color (Expression)) or (OVER existing_rastermap color (Expression))
```

Performs a transparent overlay operation. This means that when a map layer that depicts some feature
in blue is overlaid with one that depicts a feature in yellow, the resulting raster map layer will show
areas of overlap in green; areas in the two raster map layer that do not overlap other areas maintain
their original colors (i.e., yellow or blue).

OVER may be run with or without an existing map layer name. If the user does not specify an existing
raster map layer name, OVER applies the color specified to the expression in parentheses and displays
the results. If an existing raster map layer name is specified, OVER applies the color to the expression
(just as before) and then overlays the results on top of the existing raster map layer. In order to make
sense of the colors which result, use only those existing map layers created using OVER.

OVER allows the user to specify just four colors:

<table>
<thead>
<tr>
<th>color value</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>red</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>yellow</td>
<td>2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>blue</td>
<td>4</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>grey</td>
<td>8</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

These four colors are then combined to form other colors. The number of progressive overlays allowed
is limited to four (one for each of the basic colors above). The actual number of colors on the resultant
raster map layer, however, varies depending on the distribution of the features and on the interaction of
the features from the different map layers which are overlaid. When two or more of these colors are
overlaid, new colors are created. The numerical values associated with the colors above are significant,
in that the values of any additional colors created reflect the sum of two or more of the four above.
These overlaid color values appear on the resultant overlay as cell (category) values. The user should
know what these values represent in order to know what category information is to be associated with
the new map layer (entered using the GRASS rsupport command), and to know the significance of
this and subsequent analyses involving the new map layer.

Any of these colors and category values may result from OVER. Note that this is the same as the
r.combine color table listed above.

<table>
<thead>
<tr>
<th>0 black</th>
<th>4 blue</th>
<th>8 grey</th>
<th>12 blue/grey</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 red</td>
<td>5 purple</td>
<td>9 red/grey</td>
<td>13 purple/grey</td>
</tr>
<tr>
<td>2 yellow</td>
<td>6 green</td>
<td>10 yellow/grey</td>
<td>14 green/grey</td>
</tr>
<tr>
<td>3 orange</td>
<td>7 white</td>
<td>11 orange/grey</td>
<td>15 dark grey</td>
</tr>
</tbody>
</table>

The syntax for OVER makes no provision for a new raster map layer name. It is necessary to use the
r.combine operator NAME to specify a new raster map layer name in which to save the graphic output
generated by OVER. If the user runs OVER without specifying an output raster map layer name,
output is displayed to the terminal. However, this output is available for future use only if it is saved
using the NAME command.

Example:

(NAME park.or.priv (OVER red (GROUP 1 (owner))))

The new raster map layer park.or.priv displays private land (i.e., category 1 of the raster map layer
owner) in red, and displays U.S. Forest Service land (i.e., "no data" areas within the owner map layer)
as black.

Resultant categories:

0 - black: park
1 - red : private land

Example:

(NAME roads.or.not (OVER park.or.priv yellow (GROUP 0 (roads))))
Category 0 in the map layer *roads* is overlaid in yellow on top of the *park.or.priv* map layer created above. The output is placed in a new map layer named *roads.or.not*.

Resultant categories in *roads.or.not* are:

- 0 - black : park; road
- 1 - red : private; road
- 2 - yellow : park; no road
- 3 - orange : private; no road

Example:

```
(NAME low.elev (OVER park.or.priv blue (GROUP 1-19 (elevation.255))))
```

The elevation categories of 1123 meters or less from the map layer *elevation.255* are assigned the color blue and then overlaid on *park.or.priv* (generated in the previous example).

Resultant categories in the new map layer *low.elev* are:

- 0 - black : park; >1123 m
- 1 - red : private; >1123m
- 4 - blue : park; <= 1123 m
- 5 - purple : private; <= 1123 m

Note how category 5 is the sum of red (1) + blue (4) (i.e., the intersection of areas containing low elevations and private lands with roads).

**COVER**

```
(COVER existing_map (Expression))
```

Performs an *opaque* overlay operation. This means that where the top map layer contains "holes" (cell category values of 0), the bottom map layer will show through. Where the top map layer contains information on a feature, it will cover (substitute its category value for) whatever is below it. The top map layer is that which is defined by *Expression*. The bottom map layer is *existing_map*; this map layer must already exist.

The user does not specify colors with COVER. COVER uses the default color table that is listed above with OVER. Colors are assigned starting with the lower map layer. The category values are assigned the color from the table that corresponds with that value. For example, 1 would be red; 2, yellow; 3, orange, etc. Moving to the upper map layer COVER starts wherever it left off after the lower one. If the highest value of the lower map layer was 5, then all non-zero (i.e., places where a feature exists) cells of the upper map layer would be assigned the value of 6 (green). Note that if, in this case, the upper map layer did not have any cells of value zero, then the entire resulting new map layer would be green. The upper map layer would have been assigned the value 6 and would have completely covered that which was below it.

This is what happens:

```
Expression  1 1 1 0
(top raster map)  1 1 0 0
0 0 0 0 6 6 6 0 result
---> 6 6 2 0
oldmap  2 5 0 0 5 5 2 2
(bottom raster map) 0 5 2 0
5 5 2 2
```

As many map layers may be overlaid as is desired. However, there is a practical limit on the number of map layers that can be used while still generating sensible output. That number depends on the
features involved in each map layer, and how many cells within the upper (overlying) map layers contain category values of zero (holes through which underlying data can be seen).

COVER has no provision for saving graphic output. Use the r.combine command NAME to save output in a raster map layer.

Example:

(NAME lo.elev (COVER owner (GROUP 1-19 (elevation.255))))

The categories that indicate elevation of 1123 meters or less are placed on top of the existing map layer owner. Output is saved in lo.elev.

Resultant categories:
1 - red : private ownership; elev > 1123 m
2 - yellow : park property; elev > 1123 m
3 - orange : park or private; elev <= 1123 m

Example:

(NAME sand.lo (COVER lo.elev (GROUP 4 (geology))))

Category 4 of geology (sandstone) is placed on top of lo.elev, the raster map layer created in the previous example. The output is saved in sand.lo.

Resultant categories:
1 - red : private ownership; elev > 1123 m; no sandstone
2 - yellow : park property; elev > 1123 m; no sandstone
3 - orange : park or private; elev <= 1123 m; no sandstone
4 - blue : park or private; any elev; sandstone

ADDITIONAL COMMANDS

r.combine also contains a number of commands which are not used for operations, but serve a variety of other functions. Additional commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Alias</th>
<th>Followed By</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUIT</td>
<td></td>
<td>exit bye</td>
</tr>
<tr>
<td>CATS</td>
<td>categories</td>
<td>existing raster map</td>
</tr>
<tr>
<td>EXP</td>
<td>expr</td>
<td>number of an expression</td>
</tr>
<tr>
<td></td>
<td></td>
<td>shell command e.g., vi comb.1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>existing input file</td>
</tr>
<tr>
<td>WINDOW</td>
<td>window</td>
<td>existing raster map layer</td>
</tr>
<tr>
<td>HISTORY</td>
<td>hist</td>
<td></td>
</tr>
<tr>
<td>HELP</td>
<td>help</td>
<td>combine command for which help is needed</td>
</tr>
<tr>
<td>ERASE</td>
<td>erase</td>
<td></td>
</tr>
</tbody>
</table>

QUIT

Allows the user to exit from r.combine while remaining within the GRASS session.

CATS      CATS raster map

Gives user an on-line listing of categories and labels for the map layer specified. For example:

[1]:CATS owner

EXP      EXP expression number

During an r.combine session, each completed expression and command is assigned a number. This number may be used to reference the expression to which it is assigned;
this means that the user can substitute the number of the expression for the expression itself.

For example:

\[4\]: (GROUP 5 (geology))
\[5\]: (NAME limestone (EXP 4))

Use the UNIX history mechanism (explained below) to determine the specific numbers associated with particular expressions in your current r.combine session.

! shell command
Allows user to temporarily suspend r.combine and go run another command, as in the two examples below:

!vi input
ligt list type=rast

Unless otherwise specified by the user, when a file is created using a system editor (like vi) from within r.combine, this file will be placed in the user's mapset under the COMBINE directory. After the command is completed, control returns to r.combine.

< <input filename
Takes input from the specified filename containing r.combine commands. The user, of course, must previously have entered the commands into this named input file. If no pathname is given, the input file is assumed to be in the user's mapset under the COMBINE directory. For example, the user would perform the following steps to redirect input from the file combin into the r.combine program (while within r.combine):

First, the user would create the file: 

Second, the user would direct r.combine to take its input from the file: <combin

WINDOW WINDOW raster_map
Gives on-line geographic region (window) information about the raster map layer specified.

HISTORY
Provides a listing of all previously completed expressions used within the current r.combine session, and the numbers associated with the execution of these commands.

HELP HELP command
An on-line help facility for r.combine commands only. Type in the name of the r.combine command for which help is needed, to see the entry for that command.

ERASE
Will cause the color graphics monitor to clear.
NOTES

In all of the above examples, only a single line of input was provided to \texttt{r.comb}ine. However, since \texttt{r.comb}ine conveniently ignores extra spaces and tabs, it is possible to type input to \texttt{r.comb}ine in the manner outlined below. Users may find this to more clearly exhibit the relationships involved and parentheses needed. This can be typed as shown below either directly at the \texttt{r.comb}ine command line, or redirected into \texttt{r.comb}ine from an already existing file.

Example:

\begin{verbatim}
(NAME good.place
   (AND
    (OR
     (GROUP 1 2 5 (geology))
     (GROUP 1-5 (elevation.255))
    )
    (NOT
     (GROUP 1-4 (landuse))
    )
   )
)
\end{verbatim}

Such involved input to \texttt{r.comb}ine might conveniently be typed into an input file, and then input to \texttt{r.comb}ine using the UNIX redirection mechanism <.

NAME

r.compress - Compresses and decompresses raster files.

(GRASS Raster Program)

SYNOPSIS

r.compress
r.compress help
r.compress [-u] map=name[,name,...]

DESCRIPTION

The GRASS program r.compress can be used to compress and decompress raster map layers.

During compression, this program reformats raster files using a run-length-encoding (RLE) algorithm. Raster map layers which contain very little information (such as boundary, geology, soils and land use maps) can be greatly reduced in size. Some raster map layers are shrunk to roughly 1% of their original sizes. Raster map layers containing complex images such as elevation and photo or satellite images may increase slightly in size. GRASS uses a new compressed format, and all new raster files are now automatically stored in compressed form (see FORMATS below). GRASS programs can read both compressed and regular (uncompressed) file formats. This allows the use of whichever raster data format consumes less space.

As an example, the Spearfish data base raster map layer owner was originally a size of 26600 bytes. After it was compressed, the raster file became only 1249 bytes (25351 bytes smaller).

Raster files may be decompressed to return them to their original format, using the -u option of r.compress. If r.compress is asked to compress a raster file which is already compressed (or to decompress an already decompressed file), it simply informs the user of this and asks the user if he wishes to perform the reverse operation.

PROGRAM OPTIONS

r.compress can be run either non-interactively or interactively. In non-interactive use, the user must specify the name(s) of the raster map layer(s) to be compressed (or decompressed) on the command line, using the form map=name[,name,...] (where each name is the name of a raster map layer to be compressed or decompressed). To decompress a map, the user must include the -u option on the command line. If the -u option is not included on the command line, r.compress will attempt to compress the named map layer(s).

If the user simply types r.compress without specifying any map layer name(s) on the command line, r.compress will prompt the user for the names of the map layers to be compressed/decompressed. This program interface is the standard GRASS parser interface described in the manual entry for parser.

Flags:

-u

If set, r.compress converts a compressed map to its uncompressed format. If not set, r.compress will attempt to compress the named map layer(s).

Parameters:

map=name[,name,...] The name(s) of raster map layer(s) to be compressed or decompressed.

FORMATS

Conceptually, a raster data file consists of rows of cells, with each row containing the same number of cells. A cell consists of one or more bytes. The number of bytes per cell depends on the category values stored in the cell. Category values in the range 0-255 require 1 byte per cell, while category values in the range 256-65535 require 2 bytes, and category values in the range above 65535 require 3 (or more) bytes per cell.
The decompressed raster file format matches the conceptual format. For example, a raster file with 1-byte cells that is 100 rows with 200 cells per row, consists of 20,000 bytes. Running the UNIX command `ls -I` on this file will show a size of 20,000. If the cells were 2-byte cells, the file would require 40,000 bytes. The map layer category values start with the upper left corner cell followed by the other cells along the northern boundary. The byte following the last byte of that first row is the first cell of the second row of category values (moving from left to right). There are no end-of-row markers or other syncing codes in the raster file. A cell header file (`cellhdf`) is used to define how this string of bytes is broken up into rows of category values.

The compressed format is not so simple, but is quite elegant in its design. It not only requires less disk space to store the raster data, but often can result in faster execution of graphic and analysis programs since there is less disk I/O. There are two compressed formats: the pre-version 3.0 format (which GRASS programs can read but no longer produce), and the version 3.0 format (which is automatically used when new raster map layers are created).

**PRE-3.0 FORMAT:**

First 3 bytes (chars) - These are a special code that identifies the raster data as compressed.

Address array (long) - array (size of the number of rows + 1) of addresses pointing to the internal start of each row. Because each row may be a different size, this array is necessary to provide a mapping of the data.

Row by row, beginning at the northern edge of the data, a series of byte groups describes the data. The number of bytes in each group is the number of bytes per cell plus one. The first byte of each group gives a count (up to 255) of the number of cells that contain the category values given by the remaining bytes of the group.

**POST-3.0 FORMAT:**

The 3 byte code is not used. Instead, a field in the cell header is used to indicate compressed format.

The address array is the same.

The RLE format is the same as the pre 3.0 RLE, except that each row of data is preceded by a single byte containing the number of bytes per cell for the row, and if run length encoding the row would not require less space than non run length encoding, then the row is not encoded.

These improvements give better compression than the pre 3.0 format in 99% of the raster data layers. The kinds of raster data layers which get bigger are those in which each row would be larger if compressed (e.g., imagery band files). But even in this case the raster data layer would only be larger by the size of the address array and the single byte preceding each row.

NAME

r.cost - Outputs a raster map layer showing the cumulative cost of moving between different geographic locations on an input raster map layer whose cell category values represent cost.

(GRASS Raster Program)

SYNOPSIS

r.cost
r.cost help
r.cost input=name output=name [coordinate=x,y[x,y,...]]

DESCRIPTION

r.cost determines the cumulative cost of moving to each cell on a cost surface (the input raster map layer) from other user-specified cell(s) whose locations are specified by their geographic coordinate(s). Each cell in the original cost surface map will contain a category value which represents the cost of traversing that cell. r.cost will produce an output raster map layer in which each cell contains the lowest total cost of traversing the space between each cell and the user-specified points. (Diagonal costs are multiplied by a factor that depends on the dimensions of the cell.) This program uses the current geographic region settings.

OPTIONS

r.cost can be run either non-interactively or interactively. The program will be run non-interactively if the user specifies the names of raster map layers and any desired options on the command line, using the form:

r.cost input=name output=name [coordinate=x,y[x,y,...]]

where the input name is the name of a raster map layer representing the cost surface map, the output name is the name of a raster map layer of cumulative cost, and each x,y coordinate pair gives the geographic location of a point from which the transportation cost should be figured.

Alternatively, the user can simply type r.cost on the command line, without program arguments. In this case, the user will be prompted for parameter values using the standard GRASS parser interface described in the manual entry for parser.

r.cost can be run with two different methods of identifying the starting point(s). One or more points (geographic coordinate pairs) can be provided on the command line. In lieu of command line coordinates, a map of starting point (e.g., start.pt.map) may already exist. Primarily filled with zeros, this map contains non-zero values at the starting cell(s). To submit the start.pt.map, set output=start.pt.map. Beware: doing this will overwrite start.pt.map with the results of the calculations. If start.pt.map does exist and points are also given on the command line, the start.pt.map is ignored and the coordinates given on the command line are used instead.

Parameters:

input=name Name of input raster map layer whose category values represent surface cost.

output=name Name of raster map layer to contain output. Also can be used as the map layer of the input starting points. If so used, the input starting point map will be overwritten by the output.

coordinate=x,y[x,y,...] Each x,y coordinate pair gives the easting and northing (respectively) geographic coordinates of a starting point from which to figure cumulative transportation costs for each cell.

As many points as desired can be entered by the user.
EXAMPLE
Consider the following example:

Input: Cost Surface
```
  . 2 2 1 1 5 5 5
  . . . . . . .
  . 2 2 8 8 5 2 1
  . . . . . . .
  . 7 1 1 8 2 2 2
  . . . . . . .
  . 8 7 8 8 7 5 5
  . . . . . . .
  . . . . . . .
```

Output: Cumulative Cost Surface
```
  . 22 20 18 17 19 17 16
  . . . . . . .
  . 22 21 26 22 16 12 11
  . . . . . . .
  . 26 19 18 19 11 10 11
  . . . . . . .
  . 28 20 18 17 13 8 10
  . . . . . . .
  . . . . . . .
  . . . . . . .
```

The user-provided ending location in the above example is the boxed 3 in the left-hand map. The costs in the output map represent the total cost of moving from each box ("cell") to one or more (here, only one) starting location(s). This output map can be viewed, for example, as an elevation model in which the starting location(s) is/are the lowest point(s). Outputs from `r.cost` can be used as inputs to `r.drain`, in order to trace the least-cost path given in this model between any given cell and the `r.cost` starting location(s). The two programs, when used together, generate least-cost paths or corridors between any two map locations (cells).

NOTES
If you submit the starting point map on the command line by specifying:
```
output=start_pt_map
```
the starting point map will be overwritten by the calculated output. It is wise to copy or rename (e.g., using `g.copy` or `g.rename`) the map of starting points to another name before submitting it to `r.cost`; otherwise, its contents will be overwritten.

Sometimes, when the differences among cell category values in the `r.cost` cumulative cost surface output are small, this cumulative cost output cannot accurately be used as input to `r.drain` (`r.drain` will output bad results). This problem can be circumvented by making the differences between cell category values in the cumulative cost output bigger. It is recommended that, if the output from `r.cost` is to be used as input to `r.drain`, the user multiply the input cost surface map to `r.cost` by the value of the map's cell resolution, before running `r.cost`. This can be done using `r.mapcalc` or other programs. The map resolution can be found using `g.region`.

NAME

`r.covar` - Outputs a covariance/correlation matrix for user-specified raster map layer(s).

(Grass Raster Program)

SYNOPSIS

```
 r.covar
 r.covar help
 r.covar [-m rqj] map=name[name,...]
```

DESCRIPTION

`r.covar` outputs a covariance/correlation matrix for user-specified raster map layer(s). The output can be printed, or (if run non-interactively) saved by redirecting output into a file. The output is an N x N symmetric covariance (correlation) matrix, where N is the number of raster map layers specified on the command line. For example,

```
 r.covar map=layer.1,layer.2,layer.3
```

would produce a 3x3 matrix (values are example only):

<table>
<thead>
<tr>
<th></th>
<th>462.876649</th>
<th>480.411218</th>
<th>281.758307</th>
</tr>
</thead>
<tbody>
<tr>
<td>480.411218</td>
<td>513.015646</td>
<td>278.914813</td>
<td></td>
</tr>
<tr>
<td>281.758307</td>
<td>278.914813</td>
<td>336.326645</td>
<td></td>
</tr>
</tbody>
</table>

OPTIONS

The program will be run non-interactively, if the user specifies the names of raster map layers and any desired options on the command line, using the form

```
 r.covar [-m rqj] map=name[name,...]
```

where each `name` specifies the name of a raster map layer to be used in calculating the correlations, and the (optional) flags `-m`, `-r`, and `-q` have meanings given below. If these flags are not specified on the command line, their answers default to "no."

Flags:

- `-m` Include zero values in the correlation calculations, due to the mask.
- `-r` Print out the correlation matrix.
- `-q` Run quietly (without comments on program progress).

Parameters:

```
 map=name[name,...]
```

Existing raster map layer(s) to be included in the covariance/correlation matrix calculations.

Alternately, the user can simply type `r.covar` on the command line, without program arguments. In this case, the user will be prompted for flag settings and parameter values using the standard GRASS parser interface described in the manual entry for `parser`.

PRINCIPLE COMPONENTS

This module can be used as the first step of a principle components transformation. The covariance matrix would be input into a system which determines eigen values and eigen vectors. An N x N covariance matrix would result in N real eigen values and N eigen vectors (each composed of N real numbers). In the above example, the eigen values and corresponding eigen vectors for the covariance matrix are:
The component corresponding to each vector can be produced using \texttt{r.mapcalc} as follows:

\begin{verbatim}
\texttt{r.mapcalc 'pc.1 = 0.691002*layer.1 + 0.720528*layer.2 + 0.480511*layer.3'}
\texttt{r.mapcalc 'pc.2 = 0.711939*layer.1 - 0.635820*layer.2 - 0.070394*layer.3'}
\texttt{r.mapcalc 'pc.3 = 0.226584*layer.1 + 0.347470*layer.2 - 0.846873*layer.3'}
\end{verbatim}

Note that based on the relative sizes of the eigen values, \texttt{pc.1} will contain about 88\% of the variance in the data set, \texttt{pc.2} will contain about 1\% of the variance in the data set, and \texttt{pc.3} will contain about 11\% of the variance in the data set.

Also, note that the range of values produced in \texttt{pc.1}, \texttt{pc.2}, and \texttt{pc.3} will not (in general) be the same as those for \texttt{layer.1}, \texttt{layer.2}, and \texttt{layer.3}. It may be necessary to rescale \texttt{pc.1}, \texttt{pc.2} and \texttt{pc.3} to the desired range (e.g., 0-255). This can be done with \texttt{r.rescale}.

\textbf{NOTES}

If your system has a FORTRAN compiler, then the program \textit{meigen} in srccontrib can be compiled and used to generate the eigen values and vectors.

NAME

r.cross - Creates a cross product of the category values from multiple raster map layers.

(GRASS Raster Program)

SYNOPSIS

r.cross

r.cross help

r.cross [-qz] input = name, name [, name,...] output = name

DESCRIPTION

r.cross creates an output raster map layer representing all unique combinations of category values in
the raster input layers (input = name, name, name, ...). At least two, but not more than ten, input map
layers must be specified. The user must also specify a name to be assigned to the output raster map
layer created by r.cross.

OPTIONS

The program will be run non-interactively if the user specifies the names of between 2-10 raster map
layers be used as input, and the name of a raster map layer to hold program output, using the form:

r.cross [-qz] input = name, name [ , name,...] output = name

where each input name specifies the name of a raster map layer to be used in calculating the cross
product, the output name specifies the name of a raster map layer to hold program output, and the
options -q and -z respectively specify that the program is to run quietly and exclude zero data values.
Alternatively, the user can simply type r.cross on the command line, without program arguments. In this
case, the user will be prompted for needed input and output map names and flag settings using the
standard GRASS parser interface described in the manual entry for parser.

Flags:

-q

Run quietly. Suppresses output of program percent-complete messages. If this flag is not used, these
messages are printed out.

-z

Do not cross zero data values. This means that if a zero category value occurs in
any input data layer, the combination is assigned to category zero in the resulting
map layer, even if other data layers contain non-zero data. In the example given
above, use of the -z option would cause 3 categories to be generated instead of 5.

If the -z flag is not specified, then map layer combinations in which not all
category values are zero will be assigned a unique category value in the resulting
map layer.

Parameters:

input = name, name [ , name,...]

The names of between two and ten existing raster map layers to be used as input.
Category values in the new output map layer will be the cross-product of the
category values from these existing input map layers.

output = name

The name assigned to the new raster map layer created by r.cross, containing
program output.
EXAMPLE
For example, suppose that, using two raster map layers, the following combinations occur:

```
map1  map2 | output
0     1   | 1
0     2   | 2
1     1   | 3
1     2   | 4
2     4   | 5
```

`r.cross` would produce a new raster map layer with 5 categories:

```
map1  map2  output
0     1   1
0     2   2
1     1   3
1     2   4
2     4   5
```

Note: The actual category value assigned to a particular combination in the result map layer is dependent on the order in which the combinations occur in the input map layer data and can be considered essentially random. The example given here is illustrative only.

SUPPORT FILES
The category file created for the output raster map layer describes the combinations of input map layer category values which generated each category. In the above example, the category labels would be:

```
category | category
value    | label
1        | layer1(0) layer2(1)
2        | layer1(0) layer2(2)
3        | layer1(1) layer2(1)
4        | layer1(1) layer2(2)
5        | layer1(2) layer2(4)
```

A random color table is also generated for the output map layer.

NOTES
When run non-interactively, `r.cross` will not protect existing files in the user's mapset. If the user specifies an output file name that already exists in his mapset, the existing file will be overwritten by the new `r.cross` output.

`r.corr`, `r.covar`, `r.stats`, and `parser`

AUTHOR
Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME
r.describe - Prints terse list of category values found in a raster map layer.
(GRASS Raster Program)
SYNOPSIS
r.describe
r.describe help
r.describe [-lrd] map=name
DESCRIPTION
r.describe prints a terse listing of category values found in a user-specified raster map layer.

The program will be run non-interactively, if the user specifies the name of a raster map layer and any desired flags on the command line, using the form

\[ \textit{r.describe [-lrd] map=name} \]

where the map \textit{name} is the name of a raster map layer whose categories are to be described, and the (optional) flags -l, -r, -q, and -d have the meanings described below.

Alternately, the user can simply type \textit{r.describe} on the command line, without program arguments. In this case, the user will be prompted for needed flag settings and the parameter value using the standard GRASS parser interface described in the manual entry for \textit{parser}.

PROGRAM USE
The user can select one of the following two output reports from \textit{r.describe}:

(1) RANGE: A range of category values found in the raster map layer will be printed. The range is divided into three groups: negative, positive, and zero. If negative values occur, the minimum and maximum negative values will be printed. If positive values occur, the minimum and maximum positive values will be printed. If zero occurs, this will be indicated.

(2) FULL LIST: A list of all category values that were found in the raster map layer will be printed.

The following sample output from \textit{r.describe}:

\[ 0 2-4 10-13 \]

means that category data values 0, 2 through 4, and 10 through 13 occurred in the named map layer.

The user must choose to read the map layer in one of two ways:

(1) DIRECITY. The current geographic region and mask are ignored and the full raster map layer is read. This method is useful if the user intends to \textit{reclassify} or \textit{rescale} the data, since these functions (\textit{r.reclass} and \textit{r.rescale}) also ignore the current geographic region and mask.

(2) REGIONED and MASKED. The map layer is read within the current geographic region, masked by the current mask.
NON-INTERACTIVE PROGRAM USE

*r.describe* examines a user-chosen raster map layer. If run non-interactively, the layer name must be supplied on the command line.

A compact list of category values that were found in the data layer will be printed.

Following is a sample output:

0 2-4 10-13

-1     Print the output one value per line, instead of the default short form. In the above example, the -1 option would output:

0
2
3
4
10
11
12
13

-r     Only print the range of the data. The highest and lowest positive values, and the highest and lowest negative values, are output. In the above example, the -r option would output:

0 2 13

If the -1 option is also specified, the output appears with one category value per line.

-q     Quiet. The -q option will tell *r.describe* to be silent while reading the raster file. If not specified, program percentage-completed messages are printed.

-d     Use the current geographic region settings. Normally, *r.describe* will read the data layer directly, ignoring both the current region settings and mask. The -d option tells *r.describe* to read the map layer in the current region masked by the current mask (if any).

NOTES

The range report will generally run faster than the full list.

AUTHOR

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
r.drain - Traces a flow through an elevation model on a raster map layer.

(Grass Raster Program)

SYNOPSIS

r.drain
r.drain help
r.drain input=name output=name [coordinate=x,y[x,y,...]]

DESCRIPTION

r.drain traces a flow through a least-cost path in an elevation model. The elevation surface (a raster map layer input) might be the cumulative cost map generated by the r.cost program. The output result (also a raster map layer) will show one or more least-cost paths between each user-provided location(s) and the low spot (low category values) in the input model.

The program will be run non-interactively, if the user specifies the names of raster map layers and any desired options on the command line, using the form

r.drain input=name output=name [coordinate=x,y[x,y,...]]

where the input name is the name of a raster map layer to be used in calculating drainage, the output name is the name of the raster map layer to contain output, and each x,y coordinate pair is the geographic location of a point from which drainage is to be calculated.

Alternately, the user can simply type r.drain on the command line, without program arguments. In this case, the user will be prompted for needed parameter values using the standard Grass parser interface described in the manual entry for parser.

OPTIONS

Program parameters are as follows.

Parameters:

input=name Name of raster map layer containing cell cost information.
output=name Name of raster map layer to contain program output.
coordinate=x,y[x,y,...] Each x,y pair is the easting and northing (respectively) of a starting point from which a least-cost corridor will be developed. As many points as desired can be input. (But, see Bugs below.)

EXAMPLE

Consider the following example:

Input:
Elevation Surface

<table>
<thead>
<tr>
<th></th>
<th>18</th>
<th>15</th>
<th>10</th>
<th>10</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>19</td>
<td>17</td>
<td>16</td>
<td>16</td>
<td>16</td>
</tr>
<tr>
<td>18</td>
<td>18</td>
<td>24</td>
<td>18</td>
<td>15</td>
<td>12</td>
</tr>
<tr>
<td>22</td>
<td>16</td>
<td>16</td>
<td>18</td>
<td>10</td>
<td>10</td>
</tr>
<tr>
<td>17</td>
<td>15</td>
<td>15</td>
<td>10</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>24</td>
<td>16</td>
<td>8</td>
<td>7</td>
<td>8</td>
<td>0</td>
</tr>
<tr>

<td>16</td>
<td>8</td>
<td>7</td>
<td>8</td>
<td>0</td>
</tr>
<tr>
<td>17</td>
<td>9</td>
<td>8</td>
<td>7</td>
<td>8</td>
<td>6</td>
</tr>
</tbody>
</table>

The user-provided starting location in the above example is the boxed 19 in the left-hand map. The
path in the output shows the least-cost corridor for moving from the starting box to the lowest (smallest) possible point. This is the path a raindrop would take in this landscape.

BUGS
Currently, *r.drain* will not actually provide output for more than one pair of input coordinates stated on the command line.

*r.drain* also currently finds only the lowest point (the cell having the smallest category value) in the input file that can be reached through directly adjacent cells that are less than or equal in value to the cell reached immediately prior to it; therefore, it will not necessarily reach the lowest point in the input file. It currently finds *pits* in the data, rather than the lowest point present.

Only one least-cost path is currently printed to the output file for the user.

Sometimes, when the differences among cell category values in the *r.cost* cumulative cost surface output are small, this cumulative cost output cannot accurately be used as input to *r.drain* (*r.drain* will output bad results). This problem can be circumvented by making the differences between cell category values in the cumulative cost output bigger. It is recommended that, if the output from *r.cost* is to be used as input to *r.drain*, the user multiply the input cost surface map to *r.cost* by the value of the map resolution, before running *r.cost*. This can be done using *r.mapcalc* or other programs. The map resolution can be found using *g.region*.

NAME

r.grow - Generates an output raster map layer with contiguous areas grown by one cell (pixel).

(GRASS Raster Program)

SYNOPSIS

r.grow
r.grow help
r.grow [-bq] input=name output=name

DESCRIPTION

r.grow adds one cell around the perimeters of all areas in a user-specified raster map layer and stores the output in a new raster map layer.

An area consists of any contiguous clump of cells with non-zero category values. No distinction is made between differing category values within an area. Rather, a border is grown around the outside of each entire contiguous set of non-zero cells.

The output raster map layer will not go outside the boundaries set in the current geographic region. Thus, if a contiguous area in the input raster map layer extends to the geographic edge of the current map layer, no new border cells can be added to that side of the area.

Growth around a rectangular area in the input raster map layer will occur straight out from each edge, but not diagonally from the corners of the rectangle. Thus, the "grown" border area will contain lines along the edge of the original rectangle, but the corners of the border will not be squared off. Instead, the lines of the border that go along each side of the original rectangle will touch only at the corners of the cells at the end of each line.

OPTIONS

The user can run r.grow either interactively or non-interactively. The program is run interactively if the user types r.grow without specifying flag settings and parameter values on the command line. In this case, the user will be prompted for input.

Alternately, the user can run r.grow non-interactively, by specifying the names of an input and output map layer, and including any desired flags, on the command line.

Flags:

-b

Output a binary raster map layer having only zero-one category values, regardless of the category values in the input map layer. In this case, all cells with a non-zero category value in the input map layer are assigned to category 1 in the output map layer. If the -b flag is not used, these cells will retain their original non-zero category values. In either case, all cells whose category value is changed from 0 during the growing process are assigned a category value of 1 in the output map.

-q

Run quietly, suppressing printing of information about program progress to standard output.

Parameters:

input=name

Name of an existing raster map layer in the user's current mapset search path containing areas to be "grown."

output=name

Name of the new raster map layer to contain program output. This map will be binary if the user sets the -b flag. Otherwise, input map cells having non-zero category values will retain their original values. In either case, all cells whose values changed during growth will be assigned category value 1 in the output map.
NOTES

The `r.grow` command can be used to represent the boundary of one or more areas. In this case, the zero-one (binary) output option should NOT be used. Then the input map layer can be subtracted from the output map layer using the `r.mapcalc` command. All original non-zero category values will be subtracted out, leaving the boundary areas only. This resulting zero-one boundary depiction can be displayed over other related raster map layers using the overlay option of `d.rast`.

If the resolution of the current geographic region does not agree with the resolution of the input raster map layer, unintended resampling of the original raster map layer may occur. The user should be sure that the current geographic region is set properly.

NAME
r.in.ascii - Convert an ASCII raster text file into a (binary) raster map layer.
(GRASS Raster Data Import Program)

SYNOPSIS
r.in.ascii
r.in.ascii help
r.in.ascii input=name output=name [title="phrase"]

DESCRIPTION
r.in.ascii allows a user to create a (binary) GRASS raster map layer from an ASCII raster input file
with (optional) title.

COMMAND LINE OPTIONS
Parameters:
input=name Name of an existing ASCII raster file to be imported.
output=name Name to be assigned to resultant binary raster map layer.
title="phrase" Title to be assigned to resultant raster map layer.

The input file has a header section which describes the location and size of the data, followed by the
data itself.
The header has 6 lines:

north: xxxxxxx.xx
south: xxxxxxx xx
east: xxxxx.xx
west: xxxxxxx
rows: r
cols: c

The north, south, east, and west field values entered are the coordinates of the edges of the geographic
region. The rows and cols field values entered describe the dimensions of the matrix of data to follow.
The data which follows is r rows of c integers.

EXAMPLE
The following is a sample input file to r.in.ascii:
NOTES
The geographic coordinates north, south, east, and west describe the outer edges of the geographic region. They run along the edges of the cells at the edge of the geographic region and NOT through the center of the cells at the edges.

The data (which follows the header section) must contain r x c integers, but it is not necessary that all the data for a row be on one line. A row may be split over many lines.

NAME

r.inll - Converts raster data referenced using latitude and longitude coordinates to a UTM-referenced map layer in GRASS raster format.

(GRASS Raster Data Import Program)

SYNOPSIS

r.inll
r.inll help
r.inll [-s] input=name output=name bpc=value corner=corner,lat,lon dimension=rows,cols
res=laires,lonres spheroid=name

DESCRIPTION

This program converts raster data referenced using latitude and longitude coordinates to a UTM-referenced map layer in GRASS raster format. r.inll is primarily used as the final program in converting UTMED and DEM digital elevation data to GRASS raster format, but is not limited to this use. r.inll uses the user's current geographic region settings. Only data that falls within the current geographic region will appear in the final raster map layer.

r.inll requires the user to enter the following information:

COMMAND LINE OPTIONS

Flags:
-s Signed data (high bit means negative value).

Parameters:
input=name Name of an existing input raster map layer.
output=name Name to be assigned to the output raster map layer.
bpc=value Number of bytes per cell.

One corner latitude and longitude of the input.
Format: {nw|ne|sw|se},dd:mm:ss{N|S},ddd:mm:ss{E|W}

The latitude and longitude are specified as dd,mm,ssH where dd is degrees, mm is minutes, ss is seconds, and H is the hemisphere (N or S for latitudes, E or W for longitudes).

For example, to specify the southwest corner: corner=sw,37:13N,103:45W

Note: the latitude and longitude specified are for the center of the corner cell.

dimension=rows,cols
Number of rows and columns in the input file.

res=laires,lonres Resolution of the input (in arc seconds).

spheroid=name Name of spheroid to be used for coordinate conversion.

Options: airy, australian, bessel, clark66, everest, gds80, hayford, international, krasowsky, wgs66, wgs72, wgs84

EXAMPLE

The command line:

r.inll input=rot.out output=import.out dimension=358,301 bpc=2 res=3,3
corner=sw,37:13N,103:45W spheroid=wgs72
reads data from the file `rot.out`, converts the data, and stores them in the file `import.out`. The data to be converted are made up of 358 rows and 301 columns, and have a resolution of 3x3 arc seconds.

**NOTES**

In the conversion of DTED and DEM elevation data to raster map layer format, `r.in.ll` follows execution of the data rotation program `m.rot90`. Because the user can glean information on the number of rows and columns, the resolutions of the latitude and longitude, and the number of bytes per column from the header file produced by the tape extraction programs `mdted.extract` and `mdmaUSGSread`, the user should recall that `m.rot90` has rotated the files produced by the tape extraction programs 90 degrees; this means that the user should INTERCHANGE the numbers of rows and columns present in the header file for input to `r.in.ll`. The number of rows shown in the tape extract header file now become the number of columns in the `m.rot90` output file; the number of columns shown in the tape extract header file are now the number of rows present in the `m.rot90` output file.

The user should also note that the raster map layer imported into GRASS will be based on the current geographic region settings. The boundaries of this geographic region should therefore be checked before importing the raster map layer. Data outside of the geographic region will not be imported and missing data will be assigned the category value "no data."

**SEE ALSO**

NAME

r.in.sunrast - Converts a SUN raster file to a GRASS raster file.

(GRASS Raster Data Import Program)

SYNOPSIS

r.in.sunrast

DESCRIPTION

This program converts a SUN raster file that has been created by SUN's "screendump" utility to a GRASS raster file. Output is placed in the /cell directory under the user's current GRASS mapset.

The program prompts the user to enter the name of the SUN raster file to be converted and the name to be assigned to the GRASS raster file to contain the resultant image.

It is recommended that this program be used in an x,y database (as opposed to, for example, a UTM data base), since the cell header is created with nonsense coordinates (i.e., coordinates designed only to specify the number of rows and columns in the image). Of course, the user can adjust the cell header after import using r.support.

The user must, of course, first create the SUN raster file to be converted, either by running the SUN "screendump" utility (to capture a displayed image) or by some other means (e.g., from a scanning system that produces SUN raster file format).

NOTES

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

AUTHOR

Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME

*r.infer* - Outputs a raster map layer whose category values represent the application of user-specified criteria (rules statements) to other raster map layers' category values.

*GRASS Raster Program*

SYNOPSIS

```
 r.infer
 r.infer help
 r.infer [-vt] rulesfile=name
```

DESCRIPTION

*r.infer* is an inference engine which applies a set of user-specified rules to named raster map layers. A new raster map layer named *infer* is created as output, whose category values reflect the ability of each cell in the named input layers to satisfy the named conditions.

*r.infer* commands (conditions and consequences) are typed into a file by the user using a system editor like *vi*, and then input to *r.infer* as the *rulesfile* named on the command line. The results are used to generate a new raster map layer named *infer* in the user's current mapset. This program performs analyses similar to *r.combine*, but uses a (possibly) more pleasing syntax and approach.

OPTIONS

The program will be run non-interactively if the user specifies the name of a rules file and any desired flags on the command line, using the form:

```
 r.infer [-vt] rulesfile=name
```

where *name* is the name of an ASCII file containing valid input rules to *r.infer*, and the (optional) flags 

*vt* have the meanings described in the OPTIONS section, below.

Alternately, the user can simply type *r.infer* on the command line, without program arguments. In this case, the user will be prompted for the needed parameter value and flag settings using the standard GRASS parser interface described in the manual entry for *parser*.

Flags:

- **-t** Allows the user to run *r.infer* in test mode. The user is questioned about the truth of each condition named in the file. *r.infer* then outputs the value that would be placed in the new layer *infer* for a cell meeting conditions specified by the user. When no sets of conditions stated in the input file are satisfied (based upon the user's answers), cell values of zero are output. Test mode is used to test the accuracy of the user's logic. Users are encouraged to run *r.infer* in test mode prior to actually creating map layers.

- **-v** Makes *r.infer* run verbosely, giving information about each cell as it is analyzed according to the statement conditions.

Parameter:

**rulesfile=name**

Allows the user to input rules to *r.infer* from an ASCII file, rather than from standard input. This rulesfile must exist in the user's current working directory or be given by its full pathname. File rules statements take the same form as those given on the command line. Examples of valid rules statements are given in the sections below.
COMMANDS AND STATEMENTS

The following commands are available in \texttt{r.infer}:

<table>
<thead>
<tr>
<th>Command</th>
<th>Aliases</th>
<th>Followed By</th>
<th>Such As</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFMAP</td>
<td>ANDIFMAP</td>
<td>cellmap cat#</td>
<td>geology 2</td>
</tr>
<tr>
<td></td>
<td>ANDIFMAP</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IFNOTMAP</td>
<td>ANDNOTMAP</td>
<td>cellmap cat#</td>
<td>geology 2</td>
</tr>
<tr>
<td>THENMAPHYYP</td>
<td></td>
<td>cat#[statement]</td>
<td>3 nice vacation spot</td>
</tr>
<tr>
<td>THEN</td>
<td></td>
<td>statement condition</td>
<td>No sandstone</td>
</tr>
<tr>
<td>IF</td>
<td>AND</td>
<td>predefined condition</td>
<td>No sandstone</td>
</tr>
<tr>
<td></td>
<td>ANDIF</td>
<td>statement condition</td>
<td></td>
</tr>
</tbody>
</table>

These five commands may be used to formulate statements with functions ranging from a simple reclassification to a more complex expert system application. Statements are composed of one or more conditions followed by one or more hypotheses and/or conclusions. The use of aliases is provided to allow for the use of a command which has an English meaning consistent with the logic at that point.

Following is a description of each of the five commands. The map layers used in the examples are in the Spearfish sample data base.

**IFMAP**

*Map condition.*

Map conditions are questions to each cell about the presence of specified map layer category values. \texttt{r.infer} questions each cell in the named map layer (here, \texttt{geology}) about its contents (i.e., category value). Cells which satisfy the named condition(s) stated by IFMAP (i.e., here, those cells which contain \texttt{geology} map layer category values 4 or 5) will be assigned the subsequently-stated map conclusion or hypothesis (category), in the new map layer \texttt{infer}. Cells which fail to satisfy named map condition(s) will continue to move down through the user's \texttt{rulesfile} (searching for conditions it is able to satisfy) if any additional conclusions/hypotheses are stated in the file, or will be assigned category zero in the new map layer \texttt{infer} (if no additional conclusions/hypotheses are possible in this \texttt{rulesfile}).

Example: \texttt{IFMAP geology 4 5}

**IFNOTMAP**

*Map condition.*

Like IFMAP, but instead questions each cell about the absence of specified map layer categories. Cells which meet the IFNOTMAP conditions (i.e., below, those cells which do NOT include owner map layer category value 2) will be assigned the named conclusion/hypothesis, in the new map layer \texttt{infer}.

Example: \texttt{IFNOTMAP owner 2}

**THENMAPHYYP**

*Map conclusion.*

Assigns each cell a specified category value in the new map layer \texttt{infer} based on the cell's ability or failure to meet conditions named above this THENMAPHYYP statement in the \texttt{rulesfile}. The user should note that although the user can specify a uniquely-named \texttt{rulesfile}, \texttt{r.infer} always directs its output to a file named \texttt{infer} in the current mapset (overwriting whatever is currently in this file). Therefore, if the user wishes to save this file for future use, this file should be renamed before the user next runs \texttt{r.infer} (e.g., using the GRASS command \texttt{g.rename}).
It is important to realize that \texttt{r.infer} runs through the conditions stated in the named \texttt{rulesfile} one cell at a time, moving from the top of the raster input file to the bottom of the raster input file. As soon as the cell currently being examined by \texttt{r.infer} satisfies a set of conditions, it is assigned a category value in the new map layer \texttt{infer}. \texttt{r.infer} does NOT check to see if that same cell satisfies other conditions named further down in the input file, too. Instead it moves on to the next cell, and begins anew with the conditions named at the top of the input file. Essentially, this means that conclusions made higher-up in the input file have precedence over conditions named further down in the input file.

\textbf{example: } \texttt{IFMAP density 1}
\texttt{THENMAPHYP 1 no trees}

In the above example, all cells having a category value of 1 (non-forest) in the map layer \texttt{density}, are assigned a category value of 1 in the resultant map layer \texttt{infer}. The trailing text "no trees" is entered into the category support file for category 1 in the new map layer \texttt{infer}.

\textbf{THEN Statement hypothesis.}
At the conclusion of one or several condition statements, instead of making a map conclusion as with \texttt{THENMAPHYP}, the conditions are used to create a hypothesis. This may then be referenced in later statements using the \texttt{IF} command. The trailing text at the end of the \texttt{THEN} statement is used as the means with which to reference the hypothesis. An example follows the description of \texttt{IF} below.

\textbf{IF Statement condition.}
States a condition based on an hypothesis that was created by a previous \texttt{THEN} statement. \texttt{IF} may be used only after a \texttt{THEN} has set up the group of statements that are to be referenced later.

\textbf{example: } \texttt{IFMAP elevation.255 170-255}
\texttt{ANDIFMAP density 3 4}
\texttt{THEN high elevation with trees !}
\texttt{IF high elevation with trees}
\texttt{ANDIFMAP owner 2}
\texttt{THENMAPHYP 1 this is the place}

The above example queries each cell for the presence of \textit{both} elevations greater than 1580 meters (i.e., for \texttt{elevation.255} category values 170-255) and a medium to high density of trees (i.e., density category values 3 4). All areas (i.e., cells) that satisfy these criteria are assigned to the hypothesis "high elevation with trees." The "!" simply tells \texttt{r.infer} to ignore whatever appears on that line (a comment statement), and is used here for readability.

The \texttt{IF} statement then references cells having "high elevation with trees" (i.e., those cells that satisfied both of the above condition, named by the \texttt{IFMAP} and \texttt{ANDIFMAP} statements). If a cell \textit{both} has "high elevations with trees" and \textit{owner} map layer category 2 (areas owned by the Forest Service), it is assigned by the \texttt{THENMAPHYP} statement to category 1 in the new map layer \texttt{infer}. The trailing text "this is the place" is automatically entered into the category support file for the new map \texttt{infer}. Cells failing to meet all of the conditions stated in this input file will be assigned category 0 in the new map layer \texttt{infer}.

NAME

`r.info` - Outputs basic information about a user-specified raster map layer.

(GRASS Raster Program)

SYNOPSIS

`r.info`

`r.info help`

`r.info map=name`

DESCRIPTION

`r.info` reports some basic information about a user-specified raster map layer. This map layer must exist in the user's current mapset search path. Information about the map's boundaries, resolution, projection, data type, category number, data base location and mapset, and history are put into a table and written to standard output. The types of information listed can also be found in the `leasts`, `icellhd`, and `hist` directories under the mapset in which the named map is stored.

The program will be run non-interactively if the user specifies the name of a raster map layer on the command line, using the form:

```
r.info map = name
```

where `name` is the name of a raster map layer on which the user seeks information. The user can save the tabular output to a file by using the UNIX redirection mechanism (`>`); for example, the user might save a report on the `soils` map layer in a file called `soil.rpt` by typing:

```
r.info map=soils > soil.rpt
```

Alternately, the user can simply type `r.info` on the command line, without program arguments. In this case, the user will be prompted for the name of a raster map layer using the standard GRASS parser interface described in the manual entry for `parser`. The user is asked whether he wishes to print the report and/or save it in a file. If saved, the report is stored in a user-named file in the user's home directory. Below is the report produced by `r.info` for the raster map `geology` in the Spearfish sample data base.

NAME

r.line - Makes a new binary GRASS vector file by extracting line features from a thinned raster file.
(GRASS Raster Program)

SYNOPSIS

r.line
r.line help
r.line input=name output=name [type=name]

DESCRIPTION

r.line scans the named raster map layer (input=name) and extracts thinned linear features into the
named vector file (output=name). r.line assumes that the input map has been thinned using r.thin.

OPTIONS

The user can run this program either non-interactively or interactively. The program will be run non-
interactively if the user specifies program arguments on the command line, using the form:

\[ r.line \ input=name \ output=name \ [type=name] \]

If the user specifies input raster and output vector map names on the command line, any other
parameter values left unspecified on the command line will be set to their default values (see below). Alternately, the user can simply type r.line on the command line, without program arguments. In this
case, the user will be prompted for parameter values using the standard GRASS parser interface
described in the manual entry for parser.

Parameters:

input=name Name of existing raster file to be used as input.
output=name Name of new vector file to be output.
type=name Line type of the extracted vectors: either line or area. Specifying line will type
extracted vectors as linear edges. Specifying area will type extracted vectors as
area edges.

Options: line or area
Default: type=line

NOTES

r.line extracts vectors (aka, "arcs") from a raster file. These arcs may represent linear features (like
roads or streams), or may represent area edge features (like political boundaries, or soil mapping units).
The attribute type option allows the user to establish the use of either linear or area edge attributes for
all of the extracted vectors.

r.poly may be used to extract vectors that represent area features (like soil mapping units, elevation
ranges, etc.) from a raster file.

The user must run v.support on the resultant vector (v.digit) files to build the dig_.plus information.

r.thin and r.line may create excessive nodes at every junction, and may create small spurs or "dangling
lines" during thinning and vectorization. These nodes and spurs may be removed using v.trim.

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled
separately by the user.

BUGS

The input raster file MUST be thinned by r.thin; if not, r.line may crash.

Michael Baba, DBA Systems, Inc., 10560 Arrowhead Drive, Fairfax, Virginia 22030
NAME

\texttt{r.los} -- Line-of-sight raster analysis program.

\textit{(GRASS Raster Program)}

SYNOPSIS

\texttt{r.los}
\texttt{r.los help}
\texttt{r.los input=name output=name coordinate=x,y [patt_map=name] [obs_elev=value] [max_dist=value]}

DESCRIPTION

\texttt{r.los} generates a raster map output in which the cells that are visible from a user-specified observer location are marked with integer values that represent the vertical angle (in degrees) required to see those cells.

The program can be run either non-interactively or interactively. To run \texttt{r.los} non-interactively, the user must specify at least an \texttt{input} file name, \texttt{output} file name, and the geographic \texttt{coordinate} of the user's viewing location on the command line; any remaining parameters whose values are unspecified on the command line will be set to their default values (see below). Non-interactive usage format is:

\texttt{r.los input=name output=name coordinate=x,y [patt_map=name] [obs_elev=value] [max_dist=value]}

Alternatively, the user can type simply \texttt{r.los} on the command line; in this case, the program will prompt the user for parameter values using the standard GRASS interface described in the manual entry for \texttt{parser}.

Parameters:

- \texttt{input=name} Name of a raster map layer containing elevation data, used as program input.
- \texttt{output=name} Name assigned to the file in which the raster program output will be stored.
- \texttt{coordinate=x,y} Geographic coordinates (i.e., easting and northing values) identifying the desired location of the viewing point.
- \texttt{patt_map=name} Name of a binary (1/0) raster map layer in which cells within the areas of interest are assigned the category value '1', and all other cells are assigned the category value '0'. If this parameter is omitted, the analysis will be performed for the whole area within a certain distance of the viewing point inside the geographic region boundaries. Default: assign all cells that are within the \texttt{max_dist} and within the user's current geographic region boundaries a value of 1.
- \texttt{obs_elev=value} Height of the observer (in meters) above the viewing point's elevation. Default: 1.75 (meters)
- \texttt{max_dist=value} Maximum distance (in meters) from the viewing point inside of which the line of sight analysis will be performed. The cells outside this distance range are assigned the category value '0'. Options: 0-999999 (stated in map units) Default: 100

NOTES

For accurate results, the program must be run with the resolution of the geographic region set equal to the resolution of the data (see \texttt{g.region}).

It is advisable to use a 'pattern layer' that identifies the areas of interest in which the line of sight analysis is required. Such a measure will reduce the time taken by the program to run.

NAME

\texttt{r.mapcalc} - Raster map layer data calculator.

(\textit{GRASS Raster Program})

SYNOPSIS

\texttt{r.mapcalc}
\texttt{r.mapcalc [result=expression]}

DESCRIPTION

\texttt{r.mapcalc} performs arithmetic on raster map layers. New raster map layers can be created that are
arithmetic expressions involving existing raster map layers, integer or floating point constants, and
functions.

PROGRAM USE

If used without command line arguments, \texttt{r.mapcalc} will read its input, one line at a time, from
standard input (which is the keyboard, unless redirected from a file or across a pipe). Otherwise, the
expression on the command line is evaluated. \texttt{r.mapcalc} expects its input to have the form:

\begin{verbatim}
result = expression
\end{verbatim}

where \texttt{result} is the name of a raster map layer to contain the result of the calculation and \texttt{expression}
is any legal arithmetic expression involving existing raster map layers, integer or floating point constants,
and functions known to the calculator. Parentheses are allowed in the expression and may be nested to
any depth. \texttt{result} will be created in the user's current mapset.

The formula entered to \texttt{r.mapcalc} by the user is recorded both in the \texttt{result} map title (which appears
in the category file for \texttt{result}) and in the history file for \texttt{result}.

Some characters have special meaning to the command shell. If the user is entering input to \texttt{r.mapcalc}
on the command line, expressions should be enclosed within single quotes. See NOTES, below.

OPERATORS AND ORDER OF PRECEDENCE

The following operators are supported:

\begin{center}
\begin{tabular}{|c|c|c|c|}
\hline
Operator & Meaning & Type & Precedence \\
\hline
\% & modulus (remainder upon division) & Arithmetic & 4 \\
/ & division & Arithmetic & 4 \\
\* & multiplication & Arithmetic & 4 \\
+ & addition & Arithmetic & 3 \\
- & subtraction & Arithmetic & 3 \\
== & equal & Logical & 2 \\
!= & not equal & Logical & 2 \\
> & greater than & Logical & 2 \\
>= & greater than or equal & Logical & 2 \\
< & less than & Logical & 2 \\
<= & less than or equal & Logical & 2 \\
\&\& & and & Logical & 1 \\
\| & or & Logical & 1 \\
\hline
\end{tabular}
\end{center}

The operators are applied from left to right, with those of higher precedence applied before those with
lower precedence. Division by 0 and modulus by 0 are acceptable and give a 0 result. The logical
operators give a 1 result if the comparison is true, 0 otherwise.
RASTER MAP LAYER NAMES

Anything in the expression which is not a number, operator, or function name is taken to be a raster map layer name. Examples:

\[ \text{elevation } \times 3 \ 3d\text{his} \]

Most GRASS raster map layers meet this naming convention. However, if a raster map layer has a name which conflicts with the above rule, it should be quoted. For example, the expression

\[ x = a - b \]

would be interpreted as: \( x \) equals a minus b, whereas

\[ x = "a-b" \]

would be interpreted as: \( x \) equals the raster map layer named \( a-b \)

Also

\[ x = 3107 \]

would create \( x \) filled with the number 3107, while

\[ x = "3107" \]

would copy the raster map layer \( 3107 \) to the raster map layer \( x \).

Quotes are not required unless the raster map layer names look like numbers or contain operators, or unless the program is run non-interactively. Examples given here assume the program is run interactively. See NOTES, below.

\texttt{r.mapcalc} will look for the raster map layers according to the user's current mapset search path. It is possible to override the search path and specify the mapset from which to select the raster map layer. This is done by specifying the raster map layer name in the form:

\texttt{name@mapset}

For example, the following is a legal expression:

\[ \text{result} = x@\text{PERMANENT} / y@\text{SOILS} \]

The mapset specified does not have to be in the mapset search path. (This method of overriding the mapset search path is common to all GRASS commands, not just \texttt{r.mapcalc}.)

THE NEIGHBORHOOD MODIFIER

Maps and images are data base files stored in raster format, i.e., two-dimensional matrices of integer values. In \texttt{r.mapcalc}, maps may be followed by a \textit{neighborhood} modifier that specifies a relative offset from the current cell being evaluated. The format is \texttt{map[r,c]}, where \( r \) is the row offset and \( c \) is the column offset. For example, \texttt{map[1,2]} refers to the cell one row below and two columns to the right of the current cell, \texttt{map[-2,-1]} refers to the cell two rows above and one column to the left of the current cell, and \texttt{map[0,1]} refers to the cell one column to the right of the current cell. This syntax permits the development of neighborhood-type filters within a single map or across multiple maps.
Raster Map Layer Values From The Category File

Sometimes it is desirable to use a value associated with a category's contents instead of the category value itself. If a raster map layer name is preceded by the @ operator, then the labels in the category file for the raster map layer are used in the expression instead of the category value.

For example, suppose that the raster map layer soil.ph (representing soil pH values) has a category file with labels as follows:

<table>
<thead>
<tr>
<th>cat</th>
<th>label</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no data</td>
</tr>
<tr>
<td>1</td>
<td>1.4</td>
</tr>
<tr>
<td>2</td>
<td>2.4</td>
</tr>
<tr>
<td>3</td>
<td>3.5</td>
</tr>
<tr>
<td>4</td>
<td>5.8</td>
</tr>
<tr>
<td>5</td>
<td>7.2</td>
</tr>
<tr>
<td>6</td>
<td>8.8</td>
</tr>
<tr>
<td>7</td>
<td>9.4</td>
</tr>
</tbody>
</table>

Then the expression:

```
result = @soils.ph * 10
```

would produce a result with category values 0, 14, 24, 35, 58, 72, 88 and 94.

Note that this operator may only be applied to raster map layers and produces a floating point value in the expression. Also the category label must start with a valid number. Missing labels, or labels that do not start with a number will (silently) produce a 0 value for that category.

Grey-Scale Equivalents And Color Separates

It is often helpful to manipulate the colors assigned to map categories. This is particularly useful when the spectral properties of cells have meaning (as with imagery data), or when the map category values represent real quantities (as when category values reflect true elevation values). Map color manipulation can also aid visual recognition, and map printing.

The # operator can be used to either convert map category values to their grey-scale equivalents or to extract the red, green, or blue components of a raster map layer into separate raster map layers.

```
result = #map
```

converts each category value in map to a value in the range 0-255 which represents the grey scale level implied by the color for the category. If the map has a grey-scale color table, then the grey level is what #map evaluates to. Otherwise, it is computed as:

```
.18 * red + .81 * green + .01 * blue
```

The # operator has three other forms: r#map, g#map, b#map. These extract the red, green, or blue components in the named raster map, respectively. The GRASS shell script blend.sh extracts each of these components from two raster map layers, and combines them by a user-specified percentage. These forms allow color separates to be made. For example, to extract the red component from map and store it in the new 0-255 map layer red, the user could type:

```
red = r#map
```

To assign this map grey colors type:

```
r.colors map=red color=none
black
white
```
To assign this map red colors type:

\[ r.colors \text{ map=} \text{red color=} \text{rules} \]
\[ \text{black} \]
\[ \text{red} \]

**FUNCTIONS**

The functions currently supported are listed in the table below. The type of the result is indicated in the last column. F means that the functions always results in a floating point value, I means that the function gives an integer result, and * indicates that the result is float if any of the arguments to the function are floating point values and integer if all arguments are integer.

<table>
<thead>
<tr>
<th>function</th>
<th>description</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs(x)</td>
<td>return absolute value of x</td>
<td>*</td>
</tr>
<tr>
<td>atan(x)</td>
<td>inverse tangent of x (result is in degrees)</td>
<td>F</td>
</tr>
<tr>
<td>cos(x)</td>
<td>cosine of x (x is in degrees)</td>
<td>F</td>
</tr>
<tr>
<td>exp(x)</td>
<td>exponential function of x</td>
<td>F</td>
</tr>
<tr>
<td>exp(x,y)</td>
<td>x to the power y</td>
<td>F</td>
</tr>
<tr>
<td>float(x)</td>
<td>convert x to floating point</td>
<td>F</td>
</tr>
<tr>
<td>if</td>
<td>decision options:</td>
<td>*</td>
</tr>
<tr>
<td>if(x)</td>
<td>1 if x not zero, 0 otherwise</td>
<td></td>
</tr>
<tr>
<td>if(x,a)</td>
<td>a if x not zero, 0 otherwise</td>
<td></td>
</tr>
<tr>
<td>if(x,a,b)</td>
<td>a if x not zero, b otherwise</td>
<td></td>
</tr>
<tr>
<td>if(x,a,b,c)</td>
<td>a if x &gt;0, b if x is zero, c if x &lt;0</td>
<td></td>
</tr>
<tr>
<td>int(x)</td>
<td>convert x to integer [ truncates ]</td>
<td>I</td>
</tr>
<tr>
<td>log(x)</td>
<td>natural log of x</td>
<td>F</td>
</tr>
<tr>
<td>log(x,b)</td>
<td>log of x base b</td>
<td>F</td>
</tr>
<tr>
<td>max(x,y[,z...])</td>
<td>largest value of those listed</td>
<td>*</td>
</tr>
<tr>
<td>min(x,y[,z...])</td>
<td>smallest value of those listed</td>
<td>*</td>
</tr>
<tr>
<td>round(x)</td>
<td>round x to nearest integer</td>
<td>I</td>
</tr>
<tr>
<td>sin(x)</td>
<td>sine of x (x is in degrees)</td>
<td>F</td>
</tr>
<tr>
<td>sqrt(x)</td>
<td>square root of x</td>
<td>F</td>
</tr>
<tr>
<td>tan(x)</td>
<td>tangent of x (x is in degrees)</td>
<td>F</td>
</tr>
</tbody>
</table>

**FLOATING POINT VALUES IN THE EXPRESSION**

Floating point numbers are allowed in the expression. A floating point number is a number that contains a decimal point:

2.3 12. .81

Floating point values in the expression are handled in a special way. With arithmetic and logical operators, if either operand is float, the other is converted to float and the result of the operation is float. This means, in particular that division of integers results in a (truncated) integer, while division of floats results in an accurate floating point value. With functions of type * (see table above), the result is float if any argument is float, integer otherwise.

However, GRASS raster map layers can only store integer values. If the final value of the expression is a floating point value, this value is rounded to the nearest integer before storing it in the result raster map layer.

Note that raster map layers in the expression are considered to be integers.
EXAMPLES

To compute the average of two raster map layers \(a\) and \(b\):

\[
\text{ave} = (a + b)/2
\]

To form a weighted average:

\[
\text{ave} = (5\times a + 3\times b)/8.0
\]

To produce a binary representation of the raster map layer \(a\) so that category 0 remains 0 and all other categories become 1:

\[
\text{mask} = a/a
\]

This could also be accomplished by:

\[
\text{mask} = \text{if}(a)
\]

To mask raster map layer \(b\) by raster map layer \(a\):

\[
\text{result} = \text{if}(a,b)
\]

REGION/MASK

The user must be aware of the current geographic region and current mask settings when using \textit{r.mapcalc}. All raster map layers are read into the current geographic region masked by the current mask. If it is desired to modify an existing raster map layer without involving other raster map layers, the geographic region should be set to agree with the cell header for the raster map layer. For example, suppose it is determined that the elevation raster map layer must have each category value increased by 10 meters. The following expression is legal and will do the job:

\[
\text{new_elevation} = \text{elevation} + 10
\]

Since a category value of zero is used in GRASS for locations that do not exist in the raster map layer, the new raster map layer will contain the category value 10 in the locations that did not exist in the original elevation. Therefore, in this example, it is essential that the boundaries of the geographic region be set to agree with the cell header. However, if there is a current mask, then the resultant raster map layer is masked when it is written; i.e., zero category values in the mask force zero values in the output.

NOTES

Extra care must be taken if the expression is given on the command line. Some characters have special meaning to the UNIX shell. These include, among others:

\[
* ( ) >& |
\]

It is advisable to put single quotes around the expression; e.g.:

\[
\text{result} = '\text{elevation} + 2'
\]

Without the quotes, the \(*\), which has special meaning to the UNIX shell, would be altered and \textit{r.mapcalc} would see something other than the \(*\).

If the input comes directly from the keyboard and the \textit{result} raster map layer exists, the user will be asked if it can be overwritten. Otherwise, the \textit{result} raster map layer will automatically be overwritten if it exists.
Quoting \textit{result} is not allowed. However, it is never necessary to quote \textit{result} since it is always taken to be a raster map layer name.

For formulas that the user enters from standard input (rather than from the command line), a line continuation feature now exists. If the user adds \textbackslash to the end of an input line, \texttt{r.mapcalc} assumes that the formula being entered by the user continues on to the next input line. There is no limit to the possible number of input lines or to the length of a formula.

If the \texttt{r.mapcalc} formula entered by the user is very long, the map title will contain only some of it, but most (if not all) of the formula will be placed into the history file for the \textit{result} map.

When the user enters input to \texttt{r.mapcalc} non-interactively on the command line, the program will not warn the user not to overwrite existing map layers. Users should therefore take care to assign program outputs raster tile names that do not yet exist in their current mapsets.

r.mask — Establishes or removes the current working mask.

(Grass Raster Program)

**DESCRIPTION**

The *r.mask* program allows the user to block out certain areas of a map from analysis, by "hiding" them from sight of other Grass programs. This is done by establishing a mask. While a mask exists, most Grass programs will operate only on data falling inside the masked area, and ignore any data falling outside of the mask.

Because the mask is actually only a reclass file called "MASK" that is created when the user identifies a mask using *r.mask*, it can be copied, renamed, removed, and used in analyses, just like other Grass raster map layers. The user should be aware that a mask remains in place until a user renames it to something other than "MASK", or removes it using *r.remove* or *g.remove*.

**r.mask** provides the following options:

1. Remove the current mask
2. Identify a new mask
3. Return Exit from program

The user establishes a new mask by choosing option (2). The user will be asked to name an existing raster map layer from among those available in the current mapset search path. Once done, the user is shown a listing of this map's categories, and is asked to assign a value of "1" or "0" to each map category. Areas assigned category value "1" will become part of the mask's surface, while areas assigned category value "0" will become "no data" areas in the MASK file.

If a category is not assigned category value "1" it will automatically be assigned the category value "0" in the resulting MASK file. Any cells falling in category "0" will fall outside the newly formed mask, and their presence will be ignored by Grass programs run later on, as long as the MASK file remains in place.

**NOTES**

The above method for specifying a "mask" may seem counterintuitive. Areas inside the mask are not hidden; areas outside the mask will be ignored until the MASK file is removed.

This program actually creates a raster map layer (reclass type) called *MASK*, which can be manipulated (renamed, removed, copied, etc.) like any other raster map layer.

Somewhat similar program functions to those performed by *r.mask* can be done using *r.mapcalc*, *g.region*, and other programs.

This program can only be run interactively.

NAME
r.mfilter - Raster file matrix filter.

(GRASS Raster Program)

SYNOPSIS
r.mfilter
r.mfilter help
r.mfilter [-qzp] input=name output=name filter=name [repeat=value] [title="phrase"]

DESCRIPTION
r.mfilter filters the raster input to produce the raster output according to the matrix filter designed by the user (see FILTERS below). The filter is applied repeat times (default value is 1). The output raster map layer can be given a title if desired. (This title should be put in quotes if it contains more than one word.)

OPTIONS
The program can be run either non-interactively or interactively. To run r.mfilter non-interactively, the user should specify desired flag settings and parameter values on the command line, using the form:
r.mfilter [-qzp] input=name output=name filter=name [repeat=value] [title="phrase"]

If the user specifies input, output, and filter file names on the command line, other parameters whose values are unspecified on the command line will be set to their default values (see below).

Alternatively, the user can simply type r.mfilter on the command line, without program arguments. In this case, the user will be prompted for flag settings and parameter values using the standard GRASS parser interface described in the manual entry for parser.

Flags:
-q r.mfilter will normally print messages to indicate what it is doing as it proceeds. If the user specifies the -q flag, the program will run quietly.
-z The filter is applied only to zero category values in the input raster map layer. The non-zero category values are not changed. Note that if there is more than one filter step, this rule is applied to the intermediate raster map layer -- only zero category values which result from the first filter will be changed. In most cases this will NOT be the desired result. Hence -z should be used only with single step filters.

Parameters:
input=name The name of an existing raster file containing data values to be filtered.
output=name The name of the new raster file to contain filtered program output.
filter=name The name of an existing, user-created UNIX ASCII file whose contents is a matrix defining the way in which the input file will be filtered. The format of this file is described below, under FILTERS.
repeat=value The number of times the filter is to be applied to the input data.
Options: integer values
Default: 1

title="phrase" A title to be assigned to the filtered raster output map. If the title exceeds one word, it should be quoted.
Default: (none)
FILTERS
The filter file is a normal UNIX ASCII file designed by the user. It has the following format:

- **TITLE**: title
- **MATRIX**: \( n \times n \)
- **DIVISOR**: \( d \)
- **TYPE**: S/P

**TITLE**: A one-line title for the filter. If a title was not specified on the command line, it can be specified here. This title would be used to construct a title for the resulting raster map layer. It should be a one-line description of the filter.

**MATRIX**: The matrix \( (n \times n) \) follows on the next \( n \) lines. \( n \) must be an odd integer greater than or equal to 3. The matrix itself consists of \( n \) rows of \( n \) integers. The integers must be separated from each other by at least 1 blank.

**DIVISOR**: The filter divisor is \( d \). If not specified, the default is 1. If the divisor is zero (0), then the divisor is dependent on the category values in the neighborhood (see HOW THE FILTER WORKS below).

**TYPE**: The filter type. S means sequential, while P means parallel. If not specified, the default is S.

Sequential filtering happens in place. As the filter is applied to the raster map layer, the category values that were changed in neighboring cells affect the resulting category value of the current cell being filtered.

Parallel filtering happens in such a way that the original raster map layer category values are used to produce the new category value.

More than one filter may be specified in the filter file. The additional filter(s) are described just like the first. For example, the following describes two filters:

**EXAMPLE FILTER FILE**

- **TITLE**: 3x3 average, non-zero data only, followed by 5x5 average
- **MATRIX**: 3
  
  | 1 | 1 | 1 |
  | 1 | 1 | 1 |
  | 1 | 1 | 1 |

- **DIVISOR**: 0
- **TYPE**: P

- **MATRIX**: 5
  
  | 1 | 1 | 1 | 1 | 1 |
  | 1 | 1 | 1 | 1 | 1 |
  | 1 | 1 | 1 | 1 | 1 |
  | 1 | 1 | 1 | 1 | 1 |
  | 1 | 1 | 1 | 1 | 1 |

- **DIVISOR**: 25
- **TYPE**: P
HOW THE FILTER WORKS
The filter process produces a new category value for each cell in the input raster map layer by multiplying the category values of the cells in the n x n neighborhood around the center cell by the corresponding matrix value and adding them together. If a divisor is specified, the sum is divided by this divisor, rounding to the nearest integer. (If a zero divisor was specified, then the divisor is computed for each cell as the sum of the MATRIX values where the corresponding input cell is non-zero.)

If more than one filter step is specified, either because the repeat value was greater than one or because the filter file contained more than one matrix, these steps are performed sequentially. This means that first one filter is applied to the entire input raster map layer to produce an intermediate result; then the next filter is applied to the intermediate result to produce another intermediate result; and so on, until the final filter is applied. Then the output cell is written.

NOTES
If the resolution of the geographic region does not agree with the resolution of the raster map layer, unintended resampling of the original data may occur. The user should be sure that the geographic region is set properly.

NAME

\texttt{r.neighbors} — Makes each cell category value a function of the category values assigned to the cells around it, and stores new cell values in an output raster map layer.

\textit{(GRASS Raster Program)}

SYNOPSIS

\texttt{r.neighbors} \\
\texttt{r.neighbors help} \\
\texttt{r.neighbors [-aq] input\_name output\_name method\_name size=value [title=\"phrase\"]}

DESCRIPTION

\texttt{r.neighbors} looks at each cell in a raster input file, and examines the category values assigned to the cells in some user defined "neighborhood" around it. It outputs a new raster map layer in which each cell is assigned a category value that is some (user-specified) function of the values in that cell’s neighborhood. For example, each cell in the output layer might be assigned a category value equal to the average of the category values appearing in its 3 x 3 cell “neighborhood” in the input layer.

The program will be run non-interactively if the user specifies program arguments (see OPTIONS) on the command line. Alternately, the user can simply type \texttt{r.neighbors} on the command line, without program arguments. In this case, the user will be prompted for flag settings and parameter values.

OPTIONS

The user must specify the names of the raster map layers to be used for \texttt{input} and \texttt{output}, the \texttt{method} used to analyze neighborhood category values (i.e., the neighborhood function or operation to be performed), and the \texttt{size} of the neighborhood. Optionally, the user can also specify the \texttt{title} to be assigned to the raster map layer \texttt{output}, elect to not align the resolution of the output with that of the input (the \texttt{-a} option), and elect to run \texttt{r.neighbors} quietly (the \texttt{-q} option). These options are described further below.

\textit{Neighborhood Operation Methods:} The \texttt{neighborhood} operators determine what new category value a center cell in a neighborhood will have after examining category values inside its neighboring cells. Each cell in a raster map layer becomes the center cell of a neighborhood as the neighborhood window moves from cell to cell throughout the map layer. \texttt{r.neighbors} can perform the following operations:

\begin{itemize}
  \item \texttt{average} — The average category value within the neighborhood. In the following example, the result would be:
    \[(7 \times 4 + 6 + 5 + 4 \times 3)/9 = 5.66\]
    The result is rounded to the nearest integer (in this case 6).
  \item \texttt{median} — The category value found half-way through a list of the neighborhood's category values, when these are ranged in numerical order.
  \item \texttt{mode} — The most frequently occurring category value in the neighborhood.
  \item \texttt{minimum} — The minimum category value within the neighborhood.
  \item \texttt{maximum} — The maximum category value within the neighborhood.
\end{itemize}

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|c|}
\hline
Raw Data & Operation & New Data \\
\hline
7 & 7 & 5 & & \\
4 & 7 & 4 & average & 6 \\
7 & 6 & 4 & \\
\hline
\end{tabular}
\end{table}

\begin{itemize}
  \item \texttt{diversity} — The number of different category values within the neighborhood. In the above example, the diversity is four.
  \item \texttt{interception} — The percentage of cells containing categories which differ from the category
assigned to the center cell in the neighborhood, plus 1. In the above example, the
interspersion is:

\[ \frac{5}{8} \times 100 + 1 = 63.5 \]

The result is rounded to the nearest integer (in this case 64).

**Neighborhood Size:** The neighborhood size specifies which cells surrounding any given cell fall into
the neighborhood for that cell. The size must be an odd integer. Options are: 1, 3, 5, 7, 9, 11, 13, 15,
17, 19, 21, 23, and 25. For example,

```
  ___
 /   \
|     |
|     |
|     |
|   _ _|
```

3 x 3 neighborhood --->
```
/   \
|     |
|   _ _|
```

- **-a** If specified, `r.neighbors` will not align the output raster map layer with that of the input raster
  map layer. The `r.neighbors` program works in the current geographic region. It is
  recommended, but not required, that the resolution of the geographic region be the same as that
  of the raster map layer. By default, if unspecified, `r.neighbors` will align these geographic
  region settings.

- **-q** If specified, `r.neighbors` will run relatively quietly (i.e., without printing to standard output
  notes on the program's progress). If unspecified, the program will print messages to standard
  output by default.

**NOTES**

The `r.neighbors` program works in the current geographic region with the current mask, if any. It is
recommended, but not required, that the resolution of the geographic region be the same as that of the
raster map layer. By default, `r.neighbors` will align these geographic region settings. However, the
user can elect to keep original input and output resolutions which are not aligned by specifying this
(e.g., using the `a` option).

`r.neighbors` copies the GRASS `color` files associated with the input raster map layer for those output
map layers that are based on the neighborhood average, median, mode, minimum, and maximum.
Because diversity and interspersion are indices, rather than direct correspondents to input category
values, no `color` files are copied for these map layers. (The user should note that although the `color`
file is copied for averaged neighborhood function output, whether or not the `color` file makes sense for
the output will be dependent on the input data values.)

NAME

_r.out.ascii_ - Converts a raster map layer into an ASCII text file.

(GRASS Raster Data Export Program)

SYNOPSIS

_r.out.ascii_

_r.out.ascii help_

_r.out.ascii [-h] map=name [digits=value]_

DESCRIPTION

_r.out.ascii_ converts a user-specified raster map layer (map=name) into an ASCII text file suitable for export to other computer systems. The digits=value option (where value is a number of the user's choice) can be used to request that numbers in the output be equally-spaced (i.e., columnar output). Each category value in the ASCII map layer will then take up value number of spaces. However, to use this, the user should know the maximum number of digits that will occur in the output file, and add one to this number (to leave a space between each column). The user can find the maximum number of digits occurring in the output file by running _r.out.ascii_ without the digits=value option.

The GRASS program _r.in.ascii_ can be used to perform the reverse function, converting an ASCII file in suitable format to GRASS raster file format.

Flag:

-h Suppress printing of header information.

Parameters:

map=name Name of an existing raster map layer.

digits=value The minimum number of digits (per cell) to be printed.

_r.out.ascii_ can be run either non-interactively or interactively. The program will be run non-interactively if the user specifies the name of a raster map layer and (optionally) a value for digits, using the form

_r.out.ascii map=name [digits=value]_

where name is the name of a raster map layer to be converted to ASCII format, and value is the minimum number of digits (per cell) to be printed to output. The user can also specify the -h option to suppress the output of file header information.

Alternately, the user can simply type _r.out.ascii_ on the command line, without program arguments. In this case, the user will be prompted for parameter values using the standard GRASS parser interface described in the manual entry for parser.

NOTES

The output from _r.out.ascii_ may be placed into a file by using the UNIX redirection mechanism; e.g.: _

_r.out.ascii map=soils >out.file_

The output file out.file can then be printed or copied onto a magnetic tape or floppy disk for export purposes.

r.patch

NAME

r.patch - Creates a composite raster map layer by using known category values from one (or more) map layer(s) to fill in areas of "no data" in another map layer.

(GRASS Raster Program)

SYNOPSIS

r.patch
r.patch help
r.patch [-q] input=name[.name,...] output=name

DESCRIPTION

The GRASS program r.patch allows the user to assign known data values from other raster map layers to the "no data" areas (those assigned category value 0) in another raster map layer. This program is useful for making a composite raster map layer from two or more adjacent map layers, for filling in "holes" in a raster map layer's data (e.g., in digital elevation data), or for updating an older map layer with more recent data.

The program will be run non-interactively if the user specifies program arguments on the command line, using the form

r.patch [-q] input=name[.name,...] output=name

where each input name is the name of a raster map layer to be patched, the output name is the name assigned to the new composite raster map layer containing the patched result, and the (optional) -q flag directs r.patch to run quietly.

The first name listed in the string input=name,name,name,... is the name of the base map whose zero data values will be attempted to be filled by non-zero data values in the second through tenth input name maps listed. The second through tenth input name maps will be used to supply missing (zero) category values for the first input map name, based on the order in which they are listed in the string input=name,name,name,...

Alternately, the user can simply type r.patch on the command line, without program arguments. In this case, the user will be prompted for the flag setting and parameter values using the standard GRASS parser interface described in the manual entry for parser.

Flag:

-q

Directs that r.patch run quietly, suppressing output of messages on program progress to standard output.

Parameters:

input=name,name,...

The name(s) of between one and ten existing raster map layers to be patched together. The first of the ten maps listed will be used as a base map, and the second through tenth maps listed will be used to supply missing (zero) category values for the first map.

output=name

The name of the new raster map to contain the resultant patched output.

EXAMPLE

Below, the raster map layer on the far left is patched with the middle (patching) raster map layer, to produce the composite raster map layer on the right.

```
111022200 001100000 111122200
110222200 001100000 111222200
333322200 000000000 333332200
333330000 444444444 333334444
333300000 444444444 333344444
000000000 444444444 444444444
```
Switching the *patched* and the *patching* raster map layers produces the following results:

```
00110000 11102200 11112200
00110000 11022200 11112200
00000000 33332200 33332200
44444444 33330000 44444444
44444444 33330000 44444444
44444444 00000000 44444444
```

**NOTES**

Frequently, this program is used to patch together adjacent map layers which have been digitized separately. The programs *v.mkquads* and *v.mkgrid* can be used to make adjacent maps align neatly.

The user should check the current geographic region settings before running *r.patch*, to ensure that the region boundaries encompass all of the data desired to be included in the composite map.

Use of *r.patch* is generally followed by use of the GRASS programs *g.remove* and *g.rename*; *g.remove* is used to remove the original (un-patched) raster map layers, while *g.rename* is used to then assign to the newly-created composite (patched) raster map layer the name of the original raster map layer.

*r.patch* creates support files for the patched, composite output map.

NAME

r.poly - Extracts area edges from a raster map layer and converts data to GRASS vector format.

(GRASS Raster Program)

SYNOPSIS

r.poly
r.poly help
r.poly [-1] input=name output=name

DESCRIPTION

r.poly scans the named input raster map layer, extracts area edge features from it, converts data to
GRASS vector format, and smooths vectors.

r.poly first traces the perimeter of each unique area in the raster map layer and creates vector data to
represent it. The cell category values for the raster map layer will be used to create attribute
information for the resultant vector area edge data.

A true vector tracing of the area edges might appear blocky, since the vectors outline the edges of
raster data that are stored in rectangular cells. To produce a better-looking vector map, r.poly
smoothes the corners of the vector data as they are being extracted. At each change in direction (i.e.,
each corner), the two midpoints of the corner cell (half the cell’s height and width) are taken, and the
line segment connecting them is used to outline this corner in the resultant vector file. (The cell’s
cornernost node is ignored.) Because vectors are smoothed by this program, the resulting vector map
will not be "true" to the raster map from which it was created. The user should check the resolution of
the geographic region (and the original data) to estimate the possible error introduced by smoothing.

OPTIONS

The user can run this program either non-interactively or interactively. The program will be run non-
interactively if the user specifies program arguments and flag settings on the command line, using:

r.poly [-1] input=name output=name

Alternately, the user can simply type r.poly on the command line without program arguments. In this
case, the user will be prompted for parameter values and flag settings using the standard GRASS parser
interface described in the manual entry for parser.

Flag:

-1 Smooth corners.

Parameters:

input=name Use the existing raster map name as input.
output=name Set the new vector output file name to name.

NOTES

r.poly extracts only area edges from the named raster input file. If the raster file contains other data
(i.e., line edges, or point data), the output may be wrong.

The user must run v.support on the resultant file to build the needed topology information stored in the
dig_plus file.

Modified program for smoothed lines: David Satnik, Central Washington University, WA
NAME

`r.profile` - Outputs the raster map layer values lying on user-defined line(s).

(Grass Raster Program)

SYNOPSIS

```bash
r.profile
r.profile help
r.profile map=name [result=type] [width=value]
    line=east,north,east,north[,...]
```

DESCRIPTION

This program outputs, in ASCII, the values assigned to those cells in a raster map layer that lie along
one or more lines ("profiles"). The lines are described by their starting and ending coordinates. The
profiles may be single-cell wide lines, or multiple-cell wide lines. The output, for each profile, may be
the category values assigned to each of the cells, or a single aggregate value (e.g., average or median
value).

COMMAND LINE OPTIONS

Parameters:

- `map=name` Raster map to be queried.
- `result=type` Type of result to be output.
  - Options: raw, median, average
  - Default: raw

Raw results output each of the category values assigned to all cells along the
profile. Median and average output a single value per profile: average outputs the
average category value of all cells under the profile; median outputs the median
cell category value.

- `line=east,north,east,north[,...]`
  - The geographic coordinates of the starting and ending points that define each
    profile line, given as easting and northing coordinate pairs. The user must stat:
    the starting and ending coordinates of at least one line, and may optionally
    include starting and ending coordinates of additional lines.

- `width=value` Profile width, in cells (odd number).
  - Default: 1

Wider profiles can be specified by setting the width to 3, 5, 7, etc. The profiles
are then formed as rectangles 3, 5, 7, etc., cells wide.

OUTPUT FORMAT

The output from this command is printed to the standard output in ASCII. The format of the output
varies slightly depending on the type of result. The first number printed is the number of cells
associated with the profile. For raw output, this number is followed by the individual cell values. For
average and median output, this number is followed by a single value (i.e., the average or the median
value).

These examples are for the `elevation.dem` raster map layer in the `spearfish` sample data set distributed
with Grass 4.0:

Single cell profile:

```
r.profile map=elevation.dem line=593655,4917280,593726,4917351
```

```
4 1540 1551 1557 1550
```
3-cell wide profile:
```
r.profile map=elevation.dem line=-593655,4917280,593726,4917351 width=3
```

```
22 1556 1538 1525 1570 1551 1528 1578 1565 1551 1536 1523 1569 1557 1546 1533
1559 1550 1542 1552 1543 1548
```

(Output appears as multiple lines here, but is really one line)

3-cell wide profile average:
```
r.profile map=elevation.dem line=-593655,4917280,593726,4917351 width=3 result=average
```

```
22 1548.363636
```

3-cell wide profile median:
```
r.profile map=elevation.dem line=-593655,4917280,593726,4917351 width=3 result=median
```

```
22 1549.000000
```

NAME

*r.random* - Creates a raster map layer and site list file containing randomly located sites.

*(GRASS Raster Program)*

SYNOPSIS

```
r.random
r.random help
r.random [-qz] input=name nsites=number[\%] [raster_output=name] [sites_output=name]
```

DESCRIPTION

The program *r.random* allows the user to create a raster map layer and a site list file containing geographic coordinates of points whose locations have been randomly determined. The program locates these randomly-generated sites within the current geographic region and mask (if any), on non-zero category value data areas within a user-specified raster map layer. If the user sets the -z flag, sites will be randomly generated across all cells (even those assigned category value 0).

The *raster_output* raster map layer is created in the user's current mapset. The category values and corresponding category names already associated with the random site locations in the *input* map layer are assigned to these sites in the *raster_output* map layer. A color table, designed to contrast with that assigned to the *input*, is generated for the *raster_output*.

The *site_lists* file created by *r.random* contains a listing of the sites' geographic coordinates; these coordinates are the center points of the randomly-selected cells.

OPTIONS

The user may specify the quantity of random locations to be generated either as a *positive integer* (e.g., 10), or as a *percentage of the raster map layer's total area* (e.g., 10\%, or 3.05\%). If unspecified, the number of sites is set to '0' by default. If stated as a percentage of the raster map's total size, the number of random locations generated will be set equal to the number of cells contained within the stated percentage of the raster map layer. Options are 0-100; percentages less than one percent may be stated as decimals. The default percentage value used, if unspecified by the user, is '0'. (Note that choosing 1\% of a raster map's cells frequently produces an abundance of random locations.)

*r.random* can be run interactively or non interactively. The user may provide program arguments on the command line, specifying an input map layer name (*input=name*), output raster map layer name (*raster_output=name*), output site list file name (*sites_output=name*), and (optionally) give the number of sites to be randomly generated as a total number of sites (*nsites=number*) or as a percentage of the map's size (*nsites=number\%*). The user can also direct that *r.random* run quietly (using the -q option), and/or direct *r.random* to also generate random site locations against cells containing category zero (using the -z option).

Alternately, the user can simply type *r.random* on the command line without program arguments. In this case, the user will be prompted for needed inputs and option choices using the standard GRASS user interface described in the manual entry for *parser*.

Flags:

- **-q**
  Run quietly. *r.random* will normally print output messages to standard output as it runs. The -q option will suppress the printing of these messages.

- **-z**
  Include areas assigned a category value of zero within the pool of areas within which *r.random* will randomly generate site locations. If the -z option is specified, sites that fall in areas assigned a category value of zero in the input map layer will be assigned to a newly-created category in the output raster map layer. If the -z flag is not set, cells having category value zero in the output layer will represent the areas at which randomly located sites were not placed.
Parameters:

input=name
An existing raster map layer in the user's current mapset search path. \texttt{r.random} will randomly generate sites on a user-specified portion of the cells in this \texttt{input} raster map.

nsites=\texttt{number} or \texttt{nsites=number\%}
Allows the user to specify the quantity of sites to be randomly generated as either a positive integer, or as a percentage value of the number of cells in the \texttt{input} map layer. If stated as a positive integer, \texttt{number} is the number of sites (i.e., number of cells) to appear in the \texttt{raster_output} layer and/or \texttt{sites_output} file. Options: Non-percentage values should be given as positive integer values less than or equal to the number of cells in the input map layer. Percentage values given should be within the range 0.00 - 100.00 (decimal values are allowed).

\texttt{raster_output}=name
The new raster map layer to hold program output. This map will contain the sites randomly generated by \texttt{r.random}. If the -z flag is not set, all sites will be assigned whatever category values were assigned these cell locations in the \texttt{input} raster map layer. If the -z flag is set, all sites except those falling on cells assigned category value 0 in the \texttt{input} value will be assigned the category values assigned these cells in the input layer; sites falling on cells assigned category value 0 in the \texttt{input} layer will be assigned to a newly created category in the \texttt{raster_output} layer.

\texttt{sites_output}=name
The new GRASS site lists file to hold program output. If no \texttt{sites_output} file name is given on the command line, no site lists file will be created by \texttt{r.random}. (See \texttt{raster_output} parameter description, above.)

Note. Although the user need not request that \texttt{r.random} output both a raster map layer (\texttt{raster_output}) and a site list file (\texttt{sites_output}), the user must specify that at least one of these outputs be produced.

NOTES
To create random site locations within some, but not all, non-zero categories of the input raster map layer, the user must first create a reclassified raster map layer of the original raster map layer (e.g., using the GRASS program \texttt{r.reclass}) that contains only the desired categories, and then use the reclassed raster map layer as input to \texttt{r.random}.

\texttt{g.region}, \texttt{r.mask}, \texttt{r.reclass}, and \texttt{parser}

AUTHOR
Dr. James Hinthorne, GIS Laboratory, Central Washington University
NAME
r.reclass - Creates a new map layer whose category values are based upon the user's reclassification of categories in an existing raster map layer.

(SRASS Raster Program)

SYNOPSIS
r.reclass
r.reclass help
r.reclass input＝name output＝name [title＝name]

DESCRIPTION
r.reclass creates an output map layer based on an input raster map layer. The output map layer will be a reclassification of the input map layer based on reclass rules input to r.reclass, and can be treated in much the same way that raster files are treated. A title for the output map layer may be (optionally) specified by the user.

The reclass rules are read from standard input (i.e., from the keyboard, redirected from a file, or piped through another program).

The program will be run non-interactively if the user specifies the name of the raster map layer to be reclassified, the name of an output layer to hold reclass rules, and (optionally) the name of a title for the output map:

r.reclass input＝name output＝name [title＝name]

After the user types in the above information on the command line, the program will (silently) prompt the user for reclass rules to be applied to the input map layer categories. The form of these rules is described in further detail in the sections on non-interactive program use reclass rules and examples, below.

Alternately, the user can simply type r.reclass on the command line, without program arguments. In this case, the user will be prompted for all needed inputs.

Before using r.reclass one must know the following:

1. The new categories desired; and, which old categories fit into which new categories.
2. The names of the new categories.

INTERACTIVE PROGRAM USE: EXAMPLE
Suppose we want to reclassify the raster map layer roads, consisting of five categories, into the three new categories: paved roads, unpaved roads, and railroad tracks. The user is asked whether the reclass table is to be established with each category value initially set to 0, or with each category value initially set to its own value. A screen like that shown below then appears, listing the categories of the roads raster map layer to be reclassified and prompting the user for the new category values to be assigned them.
### ENTER NEW CATEGORY NUMBERS FOR THESE CATEGORIES

<table>
<thead>
<tr>
<th>OLD CATEGORY NAME</th>
<th>OLD NUM</th>
<th>NEW NUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>no data</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Hard Surface, 2 lanes</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Loose Surface, 1 lane</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Improved Dirt</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>Unimproved Dirt Trail</td>
<td>4</td>
<td>0</td>
</tr>
<tr>
<td>Railroad, single track</td>
<td>5</td>
<td>0</td>
</tr>
</tbody>
</table>

**AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE (OR <Ctrl-C> TO CANCEL)**

In the following screen the new category values have been entered beside the appropriate old category names. Cells assigned category values 2, 3, and 4 in the old raster map layer are now assigned the new category value 2 in the reclassed map; cell data formerly assigned to category value 5 in the old raster map are now assigned the new category value 3 in the reclassed map.

### ENTER NEW CATEGORY NUMBERS FOR THESE CATEGORIES

<table>

<td>Railroad, single track</td>
</tr>
</tbody>
</table>

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

Based upon the information supplied by the user in the above sample screens, the new output map, supporting category, color, history, and header files are created.

NON-INTERACTIVE PROGRAM USE: RECLASS RULES

In non-interactive program use, the names of an input map, output map, and output map title are given on the command line. However, the reclass rules are still read from standard input (i.e., from the keyboard, redirected from a file, or piped through another program).

Once the user has specified an input raster map layer, output map layer name, and (optionally) output map layer title by typing

```
r.reclass input=name output=name [title=name]
```

Each line of input must have the following format:

```
input_categories=output_category [label]
```

where the input lines specify the category values in the input raster map layer to be reclassified to the new output_category category value. Specification of a label to be associated with the new output map layer category is optional. If specified, it is recorded as the category label for the new category value. The equal sign = is required. The input_categories may consist of single category values or a range of such values in the format "low thru high." The word "thru" must be present.

A line containing only the word end terminates the input.

NON-INTERACTIVE PROGRAM USE: EXAMPLES

The following examples may help clarify the reclass rules.

1. This example reclassifies categories 1, 3, and 5 in the input raster map layer to category 1 with category label "poor quality" in the output map layer, and reclassifies input raster map layer categories 2, 4, and 6 to category 2 with the label "good quality" in the output map layer.

```
1 3 5 = 1  poor quality
2 4 6 = 2  good quality
```

2. This example reclassifies input raster map layer categories 1 thru 10 to output map layer category 1, input map layer categories 11 thru 20 to output map layer category 2, and input map layer categories 21 thru 30 to output map layer category 3, all without labels.

```
1 thru 10 = 1
11 thru 20 = 2
21 thru 30 = 3
```

3. Subsequent rules override previous rules. Therefore, the below example reclassifies input raster map layer categories 1 thru 19 and 51 thru 100 to category 1 in the output map layer, input raster map layer categories 20 thru 24 and 26 thru 50 to the output map layer category 2, and input raster map layer category 25 to the output category 3.
1 thru 100 = 1  poor quality
20 thru 50 = 2  medium quality
25 = 3  good quality

4 The previous example could also have been entered as:

1 thru 19  51 thru 100 = 1  poor quality
20 thru 24  26 thru 50 = 2  medium quality
25 = 3  good quality

or as:

1 thru 19 = 1  poor quality
51 thru 100 = 1
20 thru 24 = 2
26 thru 50 = 2  medium quality
25 = 3  good quality

The final example was given to show how the labels are handled. If a new category value appears in
more than one rule (as is the case with new category values 1 and 2), the last label which was specified
becomes the label for that category. In this case the labels are assigned exactly as in the two previous
examples.

NOTES
In fact, the r.reclass program does not generate any new raster map layers (in the interests of disk
space conservation). Instead, a reclassification table is stored which will be used to reclassify the original
raster map layer each time the new (reclassed) map name is requested. As far as the user (and
programmer) is concerned, that raster map has been created. Also note that although the user can
generate a r.reclass map which is based on another r.reclass map, the new r.reclass map map will be
stored in GRASS as a reclass of the original raster map on which the first reclassed map was based.
Therefore, while GRASS allows the user to provide r.reclass map layer information which is based on
an already reclassified map (for the user's convenience), no r.reclass map layer (i.e., reclassification table)
will ever be stored as a r.reclass of a r.reclass.

To convert a reclass map to a regular raster map layer, set your geographic region settings to match the
settings in the header for the reclass map (an ASCII file found under the cellhd directory, or viewable
by running r.support) and then run r.resample.

r.mapcalc can also be used to convert a reclass map to a regular raster map layer:

```
r.mapcalc raster_map=reclass_map
```

where raster_map is the name to be given to the new raster map, and reclass_map is an existing
reclass map.

BEWARE
Because r.reclass generates a table referencing some original raster map layer rather than creating a
reclassed raster map layer, a r.reclass map map layer will no longer be accessible if the original raster map
layer upon which it was based is later removed.

A r.reclass map is not a true raster map layer. Rather, it is a table of reclassification values which
reference the input raster map layer. Therefore, users who wish to retain reclassified map layers must
also save the original input raster map layers from which they were generated.

Category values that are not explicitly reclassified to a new value by the user are reclassified to zero.

NAME

r.report - Reports statistics for raster map layers.

(GRASS Raster Program)

SYNOPSIS

r.report
r.report help
r.report [-hmfq] map=name[.name,...] [units=nname[.name,...]] [pl=value] [pw=value] [output=name]

DESCRIPTION

r.report allows the user to set up a series of report parameters to be applied to a raster map layer, and creates a report. If invoked with command line arguments, the report will print out to the screen only. However, output may be redirected to a file or another program using the UNIX redirection mechanism. If invoked without command line arguments, the user is given the option of printing out each report and/or saving output to a file.

The program will be run non-interactively, if the user specifies the names of raster map layers and any desired options on the command line, using the form

\[ r.report [-hmfq] map=name[.name,...] [units=nname[.name,...]] [pl=value] [pw=value] \]

where each map name is the name of a raster map layer on which to report, each unit name is a unit of measure in which results are to be reported, the pl value gives the page length, the pw value gives the page width, and the (optional) flags -h, -m, -f, and -q have the meanings stated below.

Flags:

- Suppress the print-out of page headers.
- Report on zero values, because a mask is being used.
- Use formfeeds between pages when printing report output.
- Run quietly, without printing program messages to standard output.

Parameters:

map=name,name,... Names of raster map(s) on which to report.
units=nname Units of measure in which results are to be reported. These units are based on the number of cells in the user's area of interest (i.e., cells within the current geographic region definition, and the current mask [if any]). These are established with the programs g.region and r.mask, respectively.

Options: Possible units of measurement are:

mi (cover measured in square miles)
me (cover measured in square meters)
k (cover measured in square kilometers)
a (cover measured in acres)
h (cover measured in hectares)
c (the number of cells in the area of interest)
p (the percent cover, excluding no data areas)

pl=value Page length, in lines, in which report will be output. Default: 0 (lines)
pw=value Page width, in characters, in which report will be output. Default: 79 (characters)
output=name The name of a file to store the report in. If not specified, the report is printed on the terminal screen.
Alternately, the user can simply type `r.report` on the command line, without program arguments. In this case, the user will be prompted for program flag settings and parameter values.

The report itself consists of two parts, a header section and the main body of the report.

The header section of the report identifies the raster map layer(s) (by map layer name and title), location, mapset, report date, and the region of interest. The area of interest is described in two parts: the user's current geographic region is presented, and the mask is presented (if any is used).

The main body of the report consists of from one to three tables which present the statistics for each category and the totals for each unit column.

Note that, unlike `r.stats`, `r.report` allows the user to select the specific units of measure in which statistics will be reported.

Following is the result of a `r.report` run on the raster map layer `geology` (located in the Spearfish, SD sample data base), with the units expressed in square miles and acres. Here, `r.report` output is directed into the file `reportfile`.

**EXAMPLE:**

```
r.report map=geology units=miles,acres > reportfile
```

**NOTES**

If the user runs `r.report` interactively and saves the report output in a file, this file will be placed into the user's current working directory.

If the user runs `r.report` non-interactively, report output can be saved by redirecting it to a file or a printer using the UNIX redirection mechanism.

NAME

r.resample – GRASS raster map layer data resampling capability.

(GRASS Raster Program)

SYNOPSIS

r.resample
r.resample help
r.resample [-q] input=name output=name

DESCRIPTION

r.resample resamples the data values in a user-specified raster input map layer name (bounded by the current geographic region and masked by the current mask), and produces a new raster output map layer name containing the results of the resampling. The category values in the new raster output map layer will be the same as those in the original, except that the resolution and extent of the new raster output map layer will match those of the current geographic region settings (see g.region).

The program will be run non-interactively if the user specifies program arguments on the command line, using the form

r.resample [-q] input=name output=name

where the input name is the name of the raster map layer whose data are to be resampled, the output name is the name of the raster map layer to store program output, and the -q option, if present, directs that r.resample run quietly (supressing the printing of program messages to standard output).

Alternately, the user can simply type r.resample on the command line, without program arguments. In this case, the user will be prompted for needed inputs and option choices using the standard GRASS parser interface described in the manual entry for parser.

NOTES

The method by which resampling is conducted is "nearest neighbor" (see r.neighbors). The resulting raster map layer will have the same resolution as the resolution of the current geographic region (set using g.region).

The resulting raster map layer may be identical to the original raster map layer. The r.resample program will copy the color table, category file, and history file associated with the original raster map layer for the resulting raster map layer.

When the user resamples a GRASS reclass file, a true raster file is created by r.resample.

NAME

r.rescale - Rescales the range of category values in a raster map layer.

(GRASS Raster Program)

SYNOPSIS

```
rxescale
r.rescale help
r.rescale [-q] input=name [from=min,max] output=name [to=min,max] \\
| [title="phrase"]
```

DESCRIPTION

The `r.rescale` program rescales the range of category values appearing in a raster map layer. A new raster map layer, and an appropriate category file and color table based upon the original raster map layer, are generated with category labels that reflect the original category values that produced each category. This command is useful for producing representations with a reduced number of categories from a raster map layer with a large range of category values (e.g., elevation). Rescaled map layers are appropriate for use in such GRASS programs as `r.stats`, `r.report`, and `r.coin`.

`r.rescale` will be run non-interactively if the user specifies program arguments on the command line, using the form:

```
r.rescale [-q] input=name [from=min,max] output=name [to=min,max] \\
| [title="phrase"]
```

Alternately, the user can simply type:

```
r.rescale
```

on the command line without program arguments. In this case, the user will be prompted for parameter values using the standard GRASS user interface described in the manual entry for `parser`.

Flag:

-q  Run quietly, without printing messages on program progress to the user's terminal.

Parameters:

input=name  The name of the raster map layer whose category values are to be rescaled.

from=min,max  The input map range to be rescaled.

Default: The full range of the input map layer.

output=name  The name of the new, rescaled raster map layer.

to=min,max  The output map range (after rescaling).

Default: 1,255

title="phrase"  Title for new output raster map layer.

EXAMPLE

To rescale an elevation raster map layer with category values ranging from 1090 meters to 1000 meters into the range 1-255, the following command line could be used:

```
r.rescale input=elevation from=1090,1800 output=elevation.255 to=1,255
```

NOTES

The rescaled category value range is actually unlimited, but the category value range 1 to 255 is frequently used due to limitations of color graphics monitors.

Category values that fall beyond the input range will become zero. This allows the user to select a subset of the full category value range for rescaling if desired. This also means that the user should know the category value range for the input raster map layer. The user can request the `r.rescale`
program to determine this range, or can obtain it using the \textit{r.describe} command. If the category value range is determined using \textit{r.rescale}, the input raster map layer is examined, and the minimum and maximum non-zero category values are selected as the input range.

NAME

*r.slope.aspect* - Generates raster map layers of slope and aspect from a raster map layer of true elevation values.

*(GRASS Raster Program)*

SYNOPSIS

```
 r.slope.aspect
 r.slope.aspect help
 r.slope.aspect [-aqz] elevation=name [slope=name] [aspect=name]
```

DESCRIPTION

*r.slope.aspect* generates raster map layers of slope and aspect from a raster map layer of true elevation values. The user must specify the input elevation file name and at least one output file name to contain the slope or aspect data.

The program will be run non-interactively if the user specifies program inputs and any desired options on the command line, using the form

```
 r.slope.aspect [-aq] elevation=name [slope=name] [aspect=name]
```

If the user runs:

```
 r.slope.aspect
```

without command line arguments, the program will prompt the user for flag settings and parameter values.

Flags:

- `-a` Do not align the settings of the current geographic region (to which the output slope and aspect map layers will be set) to those of the elevation layer. See NOTES.

- `-q` Run quietly, and suppress the printing of information on program operations during execution.

- `-z` Assume that zero values in the elevation map layer represent true elevation values, not areas of "no data."

Parameters:

```
elevation=name
slope=name
aspect=name
```

Name of the raster map layer of true elevation values to be used as input.

Name of a raster map layer of slope values created from the elevation map.

Name of a raster map layer of aspect values created from the elevation map.

Resulting raster map layers of slope and aspect are named by the user and placed in the current mapset.

ELEVATION RASTER MAP

The raster elevation map layer specified by the user must contain true elevation values, not rescaled or categorized data.

ASPECT RASTER MAP

The raster aspect map layer which is created indicates the direction that slopes are facing. The aspect categories are as follows:
r.slope.aspect

GRASS Reference Manual

r.slope.aspect

0 no data
1 east facing
2 15 degrees north of east
3 30 degrees north of east
4 northeast facing
5 30 degrees east of north
6 15 degrees east of north
7 north facing
8 15 degrees west of north
9 30 degrees west of north
10 northwest facing
11 30 degrees north of west
12 15 degrees north of west
13 west facing
14 15 degrees south of west
15 30 degrees south of west
16 southwest facing
17 30 degrees west of south
18 15 degrees west of south
19 south facing
20 15 degrees east of south
21 30 degrees east of south
22 southeast facing
23 30 degrees south of east
24 15 degrees south of east
25 no aspect (flat)

Category and color table files are also generated for the aspect map layer.

**SLOPE RASTER MAP**

The resulting raster slope map layer will contain slope values, stated in degrees of inclination from the horizontal. Category 0 will be reserved for no data. Category 1 will represent areas with 0 degrees slope, category 2 will represent areas with 1 degree of slope, etc. The slope map layer could contain, in theory, up to 91 categories. The category file, but not the color table, is generated by `r.slope.aspect` for the raster slope map layer.

Often slope is represented in percent rise. The following table shows conversion values from degrees to percent rise:
However, for most applications, the user will wish to use a reclassified map layer of slope that groups slope values into ranges of slope. This can be done using `r.reclass`. An example of a useful reclassification is given below:

<table>
<thead>
<tr>
<th>category</th>
<th>range (in degrees)</th>
<th>category labels (in percent)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0-1</td>
<td>0-2%</td>
</tr>
<tr>
<td>2</td>
<td>2-3</td>
<td>3-5%</td>
</tr>
<tr>
<td>3</td>
<td>4-5</td>
<td>6-10%</td>
</tr>
<tr>
<td>4</td>
<td>6-8</td>
<td>11-15%</td>
</tr>
<tr>
<td>5</td>
<td>9-11</td>
<td>16-20%</td>
</tr>
<tr>
<td>6</td>
<td>12-14</td>
<td>21-25%</td>
</tr>
<tr>
<td>7</td>
<td>15-90</td>
<td>26% and higher</td>
</tr>
</tbody>
</table>

The following color table works well with the above reclassification.

<table>
<thead>
<tr>
<th>category</th>
<th>red</th>
<th>green</th>
<th>blue</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>179</td>
<td>179</td>
<td>179</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>102</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>153</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>128</td>
<td>153</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>204</td>
<td>179</td>
<td>0</td>
</tr>
<tr>
<td>5</td>
<td>128</td>
<td>51</td>
<td>51</td>
</tr>
<tr>
<td>6</td>
<td>255</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>7</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

**NOTES**

To ensure that the raster elevation map layer is not inappropriately resampled, the settings for the current region are modified slightly (for the execution of the program only): the resolution is set to match the resolution of the elevation map and the edges of the region (i.e., the north, south, east and west) are shifted, if necessary, to line up along edges of the nearest cells in the elevation map. If the user really wants the elevation map resampled to the current region resolution, the `-a` flag should be specified.
The current mask, if set, is ignored.

The algorithm used to determine slope and aspect uses a 3x3 neighborhood around each cell in the elevation file. Thus, it is not possible to determine slope and aspect for the cells adjacent to the edges in the elevation map layer. These cells are assigned a "no data" value (category zero) in both the slope and aspect raster map layers.

**WARNING**

Elevations of zero (as well as below sea level elevations) are valid. This means that areas assigned category value zero may have one of two possible meanings: they may either be areas of "no data" or areas having zero elevation. If the user wishes `r.slope.aspect` to assume that cells assigned category value zero in the elevation map layer represent true elevation values, not areas of "no data", the user should set the `-z` flag when running this program.

If the `-z` flag is not set and the raster map layer of true elevation contains areas of "no data" that are assigned to category zero, either at its edges or in its interior, incorrect (and usually quite large) slopes will result.

NAME

r.stats - Generates area statistics for raster map layers.

(Grass Raster Program)

SYNOPSIS

r.stats
r.stats help
r.stats [-laemqzgx] input=name[name,...] [fs=character | space] [output=name]

DESCRIPTION

r.stats calculates the area present in each of the categories of user-selected raster map layer(s). Area statistics can be given in units of acres, hectares, square miles, and cell counts. This analysis uses the current geographic region and mask settings. Output can be sent to a file in the user's current working directory.

The program will be run non-interactively if the user specifies the program arguments and desired options on the command line, using the form

r.stats [-laemqzgx] input=name[name,...] [fs=character | space] [output=name]

where each input name is the name of a raster map layer on which area/cell statistics are to be generated, the (optional) output name is the name of a file to contain program output (sent to the user's current working directory), the fs character or space is the field separator to be used to separate data fields in the output file (default is a space if unspecified), and the (optional) flags -l, -a, -c, -m, -q, -z, -g, and -x have the meanings described in the OPTIONS section.

Alternatively, the user can simply type r.stats on the command line, without program arguments. In this case, the user will be prompted for needed inputs and option choices using the standard GRASS parser interface described in the manual entry for parser.

OPTIONS

Flags:

-1 The data for each cell in the current geographic region will be output, one cell per line, rather than the totals for each distinct combination. Also prints the geographic coordinates (eastings and northings) associated with each cell.

Print area totals.

c Print total cell counts.

-m Report zero values, because a mask is present and the user is interested in zero data values falling within the mask.

-q Run quietly, and suppress printing of percent complete messages to standard output.

-z Report only non-zero data values. Zero data will not be output. For multiple map layers this means that zero category values in every map layer will not be output; non-zero category values in any map layer will be output.

-g Print the grid coordinates (eastings and northings), for each cell. This option works only if the -1 option is also specified.

-x Print the x and y (column and row) values, for each cell. This option works only if the -1 option is also specified.

input=name The name(s) of one or more existing raster map layer(s) whose cell counts or area statistics are to be calculated.
fs=character or fs=space
The field separator (fs) to be used to separate data fields in the output file.
Options: a character or space
Default: a space

output =name
The name to be assigned to the ASCII output file.

NON-INTERACTIVE PROGRAM USE
If users invoke program options on the command line, r.stats will print out area statistics for the user-specified raster map layers in a columnar format suitable for input to UNIX programs like awk and sed. Output can be saved by specifying the name of an output file on the command line.

If a single map layer is specified on the command line, a list of areas in square meters (assuming the map’s coordinate system is in meters) for each category in the raster map layer will be printed. (If the -c option is chosen, areas will be stated in number of cells.) If multiple raster map layers are specified on the command line, a cross-tabulation table of areas for each combination of categories in the map layers will be printed.

For example, if one raster map layer were specified, the output would look like:

```
1:1350000.00
2:4940000.00
3:8870000.00
```

If three raster map layers a, b, and c, were specified, the output would look like:

```
0:0:8027500.00
1:0:164227500.00
2:0:31277500.00
3:0:17140000.00
1:0:12177500.00
2:1:2490000.00
0:1:1152500.00
1:1:0:140092500.00
2:1:0:24207500.00
3:1:0:11270000.00
1:1:1:3355000.00
2:1:1:1752500.00
3:1:1:2500.00
```

Within each grouping, the first field represents the category value of map layer a, the second represents the category values associated with map layer b, the third represents category values for map layer c, and the last field gives the area in square meters for the particular combination of these three map layers’ categories. For example, above, combination 3,1,1 covered 2500 square meters. Fields are separated by colons.

NOTES
r.stats works in the current geographic region with the current mask.

If a nicely formatted output is desired, pipe the output into a command which can create columnar output. For example, the command:

```
r.stats input=a,b,c | pr -3 | cat -s
```

will create a three-column output
Also, the output in the examples given happen to be in sorted order, but the output from \texttt{r.stats} on more than one map layer is not guaranteed to be in any particular order. If the user desires sorted output, use the UNIX \texttt{sort} command. For example:

\verbatim
r.stats input=a,b,c | sort -t: -0n
\endverbatim

Note that the user has only the option of printing out cell statistics in terms of cell counts and/or area totals. Users wishing to use different units than are available here should use the GRASS program \texttt{r.report}.

NAME

r.support - Allows the user to create and/or modify raster map layer support files.

(GRASS Raster Program)

SYNOPSIS

r.support

DESCRIPTION

The GRASS program r.support allows the user to create and/or modify raster map layer support files. It may be run only on raster map layers in the user's current mapset.

No non-interactive version of this program currently exists; the user runs the program by typing r.support, and will be queried for inputs.

Various GRASS programs depend on one or more of the following GRASS support files:

- **cellhd**: The cell header file contains information on a map's projection, zone, regional boundaries, row and column totals, cell resolution, storage format, and compression. It describes where and how this map's raster (cell) data fits in with reference to other raster map layers' data. Without it, the raster map layer could not be displayed or analyzed properly. Using r.support, the user can change the #of columns, #of bytes per cell, and default geographic region settings. Generally, users would not change this information. Cell header files are stored under the cellhd directory under the user's current mapset.

- **stats**: Raster map layer statistics are saved in the form of a histogram and range of the category values that occur in the map layer. Statistics files are stored in subdirectories of the cell_risc directory under the user's current mapset.

- **cats**: A category file associates each category value in the raster map layer with a category description (label). The user may add or edit the category descriptions, alter the number of categories, and add or alter the map's title. Category files associated with raster map layers are stored under the cats directory in the user's current mapset.

- **colr**: A color file associates each category value in the raster map layer with a color. Using r.support, the user may assign one of eight color table types to the raster map layer. Map color table files are stored under the colr and colr2 directories under the user's current mapset.

- **hist**: Historical information about the raster map layer is stored in a history file. The user may add or edit the raster map's title, data type, data source, data description, and include comments. (Note that the specification of map data type here is somewhat archaic, and should always be set to raster.) Map history files are stored under the hist directory under the user's current mapset.

NOTES

The r.support program attempts to verify that the information in the cell header is reasonable. The data format specified in the header is verified against the raster map layer itself. This includes checking that files that the header indicates are compressed are really compressed, and that the number of rows and columns specified in the header correspond to the actual file size.

The r.support program can also be used to determine the number of columns and rows of data in a raster map layer, in the event that no cell header is available. This is useful, for example, for importing raster map layers created by software other than GRASS.

If the file is not compressed, the file size should be the product of the number of rows and columns. If the file is compressed, this test cannot be performed since the file size will bear no relation to the product. The number of rows can still be verified, but the number of columns cannot.
To compute or correct the `stats`, the cell header must be correct, since the raster map layer is read to determine the stats.

If a new `cats` or `colr` (or `colr2`) file is required, the `stats` must be correct.

The user is allowed to change the number of categories specified in the category file. This should only be done if the user knows that the maximum category value in the raster map layer is different than that which is recorded in the category file. Changing the category value in the `cats` file allows the user to add more category labels, or to remove labels. It does NOT change the category values in the raster map layer itself.

The color file is unique among GRASS support files. While it is necessary to protect a user's original data from being modified by users working under other mapsets, these users need to be able to create color tables for maps that are stored under mapsets other than their own. Color table files meet both these objectives.

Color table files get stored in one of two directories, both under the user's current mapset. The color files created by a user for raster maps stored under that user's current mapset get stored in the directory `$LOCATION/colr` and cannot be modified or removed by other users. The color table files that the user modifies/creates for raster map layers not stored under the user's current mapset get stored in a secondary color file under the user's mapset. This secondary color table is stored under `$LOCATION/colr2/<mapset>` where `<mapset>` is the name of the mapset under which the raster map data are stored. In versions of GRASS prior to 3.0, this was also the case for color tables in the user's own mapset. Now, however, if a user modifies a color table associated with a raster map layer in his own current mapset, these changes will be made to the user's original color file (i.e., the user's color changes will overwrite whatever previous color table file existed for this map under the user's `$LOCATION/colr` directory). No secondary color files are created for raster map layers stored in the user's own mapset.

**WARNING**

In order to modify the `cell header`, the raster (cell) map layer under consideration must not be a `reclass` file. This is because the `reclass` file's header does not contain positional information, but rather a reference to another raster map layer. Thus it shares a cell header with the referenced raster map layer. In order to change the cell header, `r.support` must be run on the true raster file referenced.

**SEE ALSO**

For more information regarding the location and function of GRASS support files, consult the GRASS Programmer's Manual chapter on "GRASS Database Structure."

NAME

\textit{r.surf.contour} - Surface generation program.

(GRASS Raster Program)

SYNOPSIS

\begin{verbatim}
r.surf.contour
r.surf.contour help
r.surf.contour [-f] input=name output=name
\end{verbatim}

DESCRIPTION

\textit{r.surf.contour} creates a raster elevation map from a rasterized contour map. Elevation values are determined using procedures similar to manual methods. To determine the elevation of a point on a contour map, an individual might interpolate its value from those of the two nearest contour lines (uphill and downhill).

\textit{r.surf.contour} works in a similar way. Initially, a vector map of the contour lines is made with the elevation of each line as its label (see \textit{v.digit}). When the program \textit{v.to.rast} is run on the vector map, continuous "lines" of rasters containing the contour line values will be the input for \textit{r.surf.contour}. For each cell in the input map, either the cell is a contour line cell (which is given that value), or a flood fill is generated from that spot until the fill comes to two unique values. The flood fill is not allowed to cross over the rasterized contour lines, thus ensuring that an uphill and downhill contour value will be the two values chosen. \textit{r.surf.contour} interpolates from the uphill and downhill values by the true distance.

The program will be run non-interactively if the user specifies the program parameter values and desired flag settings on the command line, using the form:

\begin{verbatim}
r.surf.contour [-f] input=name output=name
\end{verbatim}

Alternately, the user can simply type \textit{r.surf.contour} on the command line, without program arguments. In this case, the user will be prompted for needed inputs and option choices using the standard GRASS user interface described in the manual entry for \textit{parser}.

Flag:

\begin{itemize}
  \item [-f] \hspace{1cm} Invoke fast, but memory-intensive program operation.
\end{itemize}

Parameters:

\begin{itemize}
  \item \textit{input=name}\hspace{1cm} Name of an existing raster map layer that contains a set of initial category values (i.e., some cells contain known category values (denoting contours) while the rest contain zeros (0)).
  \item \textit{output=name}\hspace{1cm} Name to be assigned to new output raster map layer that represents a smooth (e.g., elevation) surface generated from the known category values in the input raster map layer.
\end{itemize}

NOTES

\textit{r.surf.contour} works well under the following circumstances: 1) the contour lines extend to the edge of the current region, 2) the program is run at the same resolution as that of the input map, 3) there are no disjointed contour lines, and 4) no spot elevation data BETWEEN contour lines exist. Spot elevations at the tops of hills and the bottoms of depressions, on the other hand, improve the output greatly. Violating these constraints will cause non-intuitive anomalies to appear in the output map. Run \textit{r.slope.aspect} on \textit{r.surf.contour} results to locate potential anomalies.

The running of \textit{r.surf.contour} is very sensitive to the resolution of rasterized vector map. If multiple contour lines go through the same raster, slight anomalies may occur. The speed of \textit{r.surf.contour} is dependent on how far "apart" the contour lines are from each other (as measured in rasters). Since a flood fill algorithm is used, the program's running time will grow exponentially with the distance between contour lines.

AUTHOR
   Chuck Ehlschlaeger, U.S. Army Construction Engineering Research Laboratory
r.surf.idw

NAME

r.surf.idw - Surface interpolation utility for raster map layers.

SYNOPSIS

r.surf.idw [-e] input=name output=name [npoints=value]

DESCRIPTION

r.surf.idw fills a grid cell (raster) matrix with interpolated values generated from a set of input layer data points. It uses a numerical approximation technique based on distance squared weighting of the values of nearest data points. The number of nearest data points used to determine the interpolated value of a cell can be specified by the user (default: 12 nearest data points).

If there is a current working mask, it applies to the output raster file. Only those cells falling within the mask will be assigned interpolated values. The search procedure for the selection of nearest neighboring points will consider all input data, without regard to the mask.

The command line input is as follows:

Flag:

-e Error analysis option that interpolates values only for those cells of the input raster map which have non-zero values and outputs the difference (see NOTES below).

Parameters:

input=name Name of an input raster map layer containing an incomplete set of data values. (i.e., some grid cells contain known data values while the rest contain zero [0]).

output=name Name to be assigned to new output raster map that represents the surface generated from the known data values in the input layer.

npoints=value Number of nearest data points used to determine the interpolated value of an output raster cell.

Default: 12

NOTES

r.surf.idw is a surface generation utility which uses inverse distance squared weighting (as described in Applied Geostatistics by E. H Isaaks and R. M. Srivastava, Oxford University Press, 1989) to assign interpolated values. The implementation includes a customized data structure somewhat akin to a sparse matrix which enhances the efficiency with which nearest data points are selected. For latitude/longitude projections, distances are calculated from point to point along a geodesic.

Unlike r.surf.idw2, which processes all input data points in each interpolation cycle, r.surf.idw attempts to minimize the number of input data for which distances must be calculated. Execution speed is therefore a function of the search effort, and does not increase appreciably with the number of input data points.

r.surf.idw will generally outperform r.surf.idw2 except when the input data layer contains few non-zero data, i.e., when the cost of the search exceeds the cost of the additional distance calculations performed by r.surf.idw2. The relative performance of these utilities will depend on the comparative speed of boolean, integer, and floating point operations on a particular platform.

Worst case search performance by r.surf.idw occurs when the interpolated cell is located outside of the region in which input data are distributed. It therefore behooves the user to employ a mask when geographic region boundaries include large areas outside the general extent of the input data.
The degree of smoothing produced by the interpolation will increase relative to the number of nearest data points considered. The utility may be used with regularly or irregularly spaced input data. However, the output result for the former may include unacceptable nonconformities in the surface pattern.

The \(-e\) flag option provides a standard surface-generation error analysis facility. It produces an output raster map of the difference of interpolated values minus input values for those cells whose input data are non-zero. For each interpolation cycle, the known value of the cell under consideration is ignored, and the remaining input values are used to interpolate a result. The output raster map may be compared to the input raster map to analyze the distribution of interpolation error. This procedure may be helpful in choosing the number of nearest neighbors considered for surface generation.

NAME

r.surf.idw2 - Surface generation program.
(GRASS Raster Program)

SYNOPSIS

r.surf.idw2 input=name output=name [npoints=count]

DESCRIPTION

r.surf.idw2 fills a raster matrix with interpolated values generated from a set of irregularly spaced data points using numerical approximation (weighted averaging) techniques. The interpolated value of a cell is determined by values of nearby data points and the distance of the cell from those input points. In comparison with other methods, numerical approximation allows representation of more complex surfaces (particularly those with anomalous features), restricts the spatial influence of any errors, and generates the interpolated surface from the data points. It is the most appropriate method to apply to most spatial data.

The program will be run non-interactively if the user specifies the values of needed program parameters and any desired optional parameter values on the command line, using the form:

r.surf.idw2 input=name output=name [npoints=count]

Alternately, the user can simply type r.surf.idw2 on the command line, without program arguments. In this case, the user will be prompted for parameter values using the standard GRASS user interface described in the manual entry for parser.

Parameters:

input=name Name of an input raster map layer that contains a set of irregularly spaced data values; i.e., some cells contain known data values while the rest contain zero (0).

output=name Name to be assigned to the new output raster map layer containing a smooth surface generated from the known data values in the input map layer.

npoints=count The number of points to use for interpolation. The default is to use the 12 nearest points when interpolating the value for a particular cell. Default: 12

NOTES

The amount of memory used by this program is related to the number of non-zero data values in the input map layer. If the input raster map layer is very dense (i.e., contains many non-zero data points), the program may not be able to get all the memory it needs from the system. The time required to execute increases with the number of input data points.

If the user has a mask set, then interpolation is only done for those cells that fall within the mask. However, all non-zero data points in the input layer are used even if they fall outside the mask.

This program does not work with latitude/longitude data bases. Another surface generation program, named r.surf.idw, should be used with latitude/longitude data bases.

The user should refer to the manual entries for r.surf.idw, r.surf.contour, and s.surf.idw to compare this surface generation program with others available in GRASS.

NAME

r.thin - Thins non-zero cells that denote linear features in a raster map layer.

SYNOPSIS

r.thin
r.thin help
r.thin input=name output=name

DESCRIPTION

r.thin scans the named input raster map layer and thins non-zero cells that denote linear features into linear features having a single cell width.

r.thin will thin only the non-zero cells of the named input raster map layer within the current geographic region settings. The cell width of the thinned output raster map layer will be equal to the cell resolution of the currently set geographic region. All of the thinned linear features will have the width of a single cell.

r.thin will create a new output raster data file containing the thinned linear features. r.thin assumes that linear features are encoded with positive values on a background of 0's in the input raster data file.

Parameters:

input=name Name of a raster map layer containing data to be thinned.
output=name Name of the new raster map layer to hold thinned program output.

The user can run this program either non-interactively or interactively. The program will be run non-interactively if "-r specifies program arguments on the command line, using the form:

```
r.thin input= blas output=name
```

Alternatively, the user can simply type:

```
r.thin
```
at the command line, without program arguments. In this case, the user will be prompted for needed parameter values using the standard GRASS parser interface described in the manual entry for parser.

NOTES

r.thin only creates raster map layers. You will need to run r.line on the resultant raster file to create a vector (v.digit) map layer.

r.thin may create small spurs or "dangling lines" during the thinning process. These spurs may be removed (after creating a vector map layer) by v.trim.

r.thin creates a 0/1 output map.

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

NAME
    r.traj - Ballistic trajectory modeling program.
    (GRASS Raster Program)

SYNOPSIS
    r.traj
    r.traj help
    r.traj input=name output=name weapon=name coordinate=x,y
        elevation=value ammunition=name left.azimuth=name right.azimuth=name

DESCRIPTION
    r.traj generates a raster map layer showing cells that can be hit from a firing point by shells from a
    user-specified weapon. Cells are marked with integer values that represent the muzzle firing angles
    required to hit them.

COMMAND LINE OPTIONS
    Parameters:
        input=name        Name of the elevation raster map.
        output=name       Name of new raster map containing results.
        weapon=name       Type of weapon used for firing. A list of weapon types and their
                          associated attributes are kept in the file $GISBASE/weapon.data/weapons.
        coordinate=x,y    The coordinates of the firing point (east, north).
        elevation=value   Maximum weapon muzzle elevation.
        ammunition=name  Type of ammunition. A list of ammunition types and their associated
                          attributes are kept in the file $GISBASE/weapon.data/ammunition.
        left.azimuth=name Far left edge of allowable firing azimuth. The angle will be in the form of:
                          [NS]0-90[EW]
                          For example, S60E indicates the angle is 60 degrees East of true South.
        right.azimuth=name Far right edge of allowable firing azimuth, stated in same form as
                          left.azimuth.

    Category values in the output raster map layer will program results. Category values between -89 and
    89 indicate the gun elevation angle in degrees needed to hit that cell. A category value of 90 is
    assigned to the weapon's firing point. A category value of -90 is assigned to those points unhittable by
    the weapon.

EXAMPLE
    r.traj input=elevation output=name weapon=M1 coordinate=600000.0,4920000.0
        elevation=2.5 ammunition=M392 left.azimuth=S30E right.azimuth=S25W

WEAPON AND AMMUNITION TYPES
    Weapon types and their attribute types are listed below. These can be listed by running the program
    r.traj.data.

       Weapon Type | 19 | -9
       ----------- |----|---
        M48       | 20 | -9
        M101      | 75 | -5
        M102      | 75 | -5

    Ammunition types and their attributes are listed below. These can be displayed by running the program
    r.traj.data.

NAME

`r.transect` - Outputs raster map layer values lying along user-defined transect line(s).

(Grass Raster Program)

SYNOPSIS

```
r.transect
r.transect help
r.transect map=name [result=type] [width=value]
    line=east,north,azimuth,distance[,east,north,azimuth,distance,...]
```

DESCRIPTION

This program outputs, in ASCII, the values in a raster map that lie along one or more user-defined transect lines. The transects are described by their starting coordinates, azimuth, and distance. The transects may be single-cell wide lines, or multiple-cell wide lines. The output, for each transect, may be the values at each of the cells, or a single aggregate value (e.g., average or median value).

COMMAND LINE OPTIONS

Parameters:

- `map=name` Name of an existing raster map layer to be queried.
- `result=type` Type of results to be output.
  - Options: raw, median, average
  - Default: raw

If raw results are output, each of the category values assigned to cells falling along the transect are output. Median and average results output a single value per transect: average outputs the average category value of all cells along the transect; median outputs the median category value of these cells.

- `line=east,north,azimuth,distance[,east,north,azimuth,distance,...]`
  - A definition of (each) transect line, specified by the geographic coordinates of its starting point (easting, northing), the angle and direction of its travel (azimuth), and its distance (distance).

  The azimuth is an angle, in degrees, measured to the east of north. The distance is in map units (meters for a metered database, like UTM).

- `width=value` Profile width, in cells (odd number).
  - Default: 1

Wider transects can be specified by setting the width to 3, 5, 7, etc. The transects are then formed as rectangles 3, 5, 7, etc., cells wide.

OUTPUT FORMAT

The output from this command is printed to standard output in ASCII. The format of the output varies slightly depending on the type of result requested. The first number printed is the number of cells associated with the transect. For raw output, this number is followed by the individual cell values. For average and median output, this number is followed by a single value (i.e., the average or the median value).

The following examples use the `elevation.dem` raster map layer in the `spearfish` sample data set distributed with GRASS 4.0. To reproduce these examples, first set the geographic region as shown:

```
g.region rast=elevation.dem
```
Single-cell transect:
```
\texttt{r.transect map=\textit{elevation.dem} line=593655,4917280,45,100}
```

4 1540 1551 1557 1550

3-cell wide transect:
```
\texttt{r.transect map=\textit{elevation.dem} line=593655,4917280,45,100 width=3}
```

22 1556 1538 1525 1555 1540 1528 1578 1565 1551 1536 1523 1569 1557 1546 1533 1559 1550 1542 1552 1543 1548

(Output appears as multiple lines here, but is really one line)

3-cell wide transect average:
```
\texttt{r.transect map=\textit{elevation.dem} line=593655,4917280,45,100 width=3 result=average}
```

22 1548.363636

3-cell wide transect median:
```
\texttt{r.transect map=\textit{elevation.dem} line=593655,4917280,45,100 width=3 result=median}
```

22 1549.000000

\textbf{NOTES}

This program is a front-end to the \texttt{r.profile} program. It simply converts the azimuth and distance to an ending coordinate and then runs \texttt{r.profile}.

\textbf{SEE ALSO}

\texttt{r.profile} and \texttt{parser}

NAME

r.volume - Calculates the volume of data "clumps," and (optionally) produces a GRASS site_lists file containing the calculated centroids of these clumps.

(GRASS Raster Program)

SYNOPSIS

r.volume
r.volwme help
r.volume [-fq] data=name [clump=name] [site_list=name]

DESCRIPTION

This program computes the cubic volume of data contained in user-defined clumps. r.volume outputs:

1. The category value assigned to each clump formed by the clump map layer. This value is stored under the "Cat Number" column (field 1) in the output table.

2. The average category value of the cells found in a data map that fall within the boundaries of each clump in a clump map. The table stores this value under the "Average in Clump" column (field 2).

3. The summed total value of the category values assigned to the cells falling within each of these clumps. This value is output under the "Data Total" column (field 3).

4. The number of cells from the data map that fall within the boundaries of each clump formed by the clump map layer. This cell count is stored under the "#Cells in Clump" column (field 4) in the output table.

5,6 The centroid (easting and northing) of each clump. These values are output under the "Centroid Easting" and "Centroid Northing" columns (fields 5 and 6) in the output.

7. The total "volume" of each clump. For each clump, the volume is calculated by multiplying the area of each cell by its category value, and taking the sum of this value for all cells within the clump. Since, in GRASS, each cell in the data map will have the same cell dimensions (i.e., the same area), this is equivalent to multiplying the area of one cell by the "Data Total" column (field 3).

(The area of each cell is equal to the product of its east-west resolution by its north-south resolution. See g.region.)

Results are sent to standard output in the form of a table. If the user sets the -f flag, this table will be output in a form suitable for input to UNIX programs as awk and sed; the table's columns are stored as colon-separated fields. The user can also (optionally) elect to store clump centroids in a GRASS site_lists file. A sample output report is shown below.

r.volume works with the current geographic region definitions and respects the current MASK.

The user can run r.volume non-interactively by specifying parameter values on the command line. If the user omits parameter values from the command line, the program will prompt the user for input using the standard interface described in the manual entry for parser.

COMMAND LINE OPTIONS

Flags:

-f Generate unformatted output. Output is in a form suitable for input to UNIX programs like awk; each column in the output is separated by a colon. Results are sent to standard output.

-q Run quietly, suppressing the printing of debugging messages to standard output.

Parameters:

data Name of an existing raster map layer containing the category values to be summed. The cell resolution (area) of the data map will also be used.

clump Name of an existing raster map layer that defines the boundaries of each clump. Preferably, this map should be the output of r.clump. If the user has imposed a mask, the program uses this mask as the clump map layer if no other clump layer
is specified by the user.

*site_list* The name to be assigned to a new GRASS *site_lists* file, in which clump centroids can be stored.

**EXAN. LE OF REPORT**
The following report might be generated by the command:

```
r.volume d=elevation c=fields.only s=field.centers
```

</tbody>
</table>

For ease of example, it is assumed that each clump in the *fields.only* map layer is a field, that cell category values in the *elevation* map layer represent actual elevation values in meters, and that the data base is a UTM data base (in meters). This means that field A1 (clump #1) contains 64 cells; the average elevation in field A1 is 1181.09 meters. The sum of all of the elevation values assigned to cells within field A1 is 75590 meters. The volume (x*y*z) of space in field A1 is equal to 755900000 cubic meters.

The "Data Total" column is the sum of the cell category values appearing in the *elevation* map layer, within each field of the *fields.only* map layer. The Total Volume is the sum multiplied by the e-w resolution times the n-s resolution.

**CENTROIDS**
The coordinates of the clump centroids are the same as those stored in the GRASS *site_lists* file (if one was requested). They are guaranteed to fall on a cell of the appropriate category; thus, they are not always the true, mathematical centroids. However, they will always fall at a cell center.

**FORMAT OF SITE LIST**
For each line of above table the GRASS *site_lists* file reads:

```
easting northing #cat v=volume a=average t=sum n=count
```

This can be converted directly to a raster map layer in which each point is assigned to a separate category.

**APPLICATIONS**
By preprocessing the *elevation* map layer with *r.mapcalc* and using suitable masking or clump maps, very interesting applications can be done with *r.volume*. For instance, one can calculate: the volume of rock in a potential quarry; cut/fill volumes for roads; and, water volumes in potential reservoirs. Data layers of other measures of real values can also be used.

**NOTES**
The output is sent to the terminal screen. The user can capture the output in a file using the UNIX redirection mechanism, as in the following example:

```
r.volume d=data_map c=clump_map s=site_list > table.out
```
Output can also be sent directly to the printer, as shown below:

```
r.volume d=data_map c=clump_map s=site_list | lpr
```

The user should be aware of what units of measurement the cell e-w and n-s resolution are in, and in what units the data map's cell category values are stated (since these three values will be multiplied together to produce the volume).

This program respects the current mask, and uses this mask as the clump map layer if none is specified by the user.

- **r.watershed help**
  - `r.watershed [-m4] elevation=name [depression=name] [flow=name]`  
  - `[disturbed.land=name] [blocking=name] [threshold=value] [max.slope.length=value]`  
  - `[accumulation=name] [drainage=name] [basin=name] [stream=name]`  
  - `[half.basin=name] [visual=name] [length.slope=name] [slope.steepness=name] [rmsed=name]`

## DESCRIPTION

*r.watershed* generates a set of maps indicating: 1) the location of watershed basins, 2) information to interface with ARMSED, a storm-water runoff and sedimentation yield model, and 3) the LS and S factors of the Revised Universal Soil Loss Equation (RUSLE).

*r.watershed* can be run either interactively or non-interactively. If the user types `r.watershed` on the command line without program arguments, the program will prompt the user with a verbose description of the input maps. The interactive version of *r.watershed* can prepare inputs to lumped-parameter hydrologic models. After a verbose interactive session, *r.watershed* will query the user for a number of map layers. Each map layer's values will be tabulated by watershed basin and sent to an output file. This output file is organized to ease data entry into a lumped-parameter hydrologic model program. The non-interactive version of *r.watershed* cannot create this file.

The user can run the program non-interactively, by specifying input map names on the command line. Parameter names may be specified by their full names, or by any initial string that distinguishes them from other parameter names. In *r.watershed*'s case, the first two letters of each name sufficiently distinguishes parameter names. For example, the two expressions below are equivalent inputs to *r.watershed*:

- `r.watershed el=elev.map th=100 st=stream.map ba=basin.map`
- `r.watershed elevation=elev.map threshold=100 stream=stream.map basin=basin.map`

## OPTIONS

- **-m** Without this flag set, the entire analysis is run in memory maintained by the operating system. This can be limiting, but is relatively fast. Setting the flag causes the program to manage memory on disk which allows larger maps to be processed but is considerably slower.

- **-4** Allow only horizontal and vertical flow of water. Stream and slope lengths are approximately the same as outputs from default surface flow (allows horizontal, vertical, and diagonal flow of water). This flag will also make the drainage basins look more homogeneous.

**elevation**

Input map: Elevation on which entire analysis is based.

**depression**

Input map: Map layer of actual depressions in the landscape that are large enough to slow and store surface runoff from a storm event. Any non-zero values indicate depressions.

**flow**

Input map: Amount of overland flow per cell. This map indicates the amount of overland flow units that each cell will contribute to the watershed basin model. Overland flow units represent the amount of overland flow each cell contributes to surface flow. If omitted, a value of one (1) is assumed.

**disturbed.land**

Raster map input layer or value containing the percent of disturbed land (i.e., croplands, and...
construction sites) where the raster or input value of 17 equals 17%. If no map or value is given, r.watershed assumes no disturbed land. This input is used for the RUSLE calculations.

blocking
Input map: terrain that will block overland surface flow. Terrain that will block overland surface flow and restart the slope length for the RUSLE. Any non-zero values indicate blocking terrain.

threshold
The minimum size of an exterior watershed basin in cells, or overland flow units.

max.slope.length
Input value indicating the maximum length of overland surface flow in meters. If overland flow travels greater than the maximum length, the program assumes the maximum length (it assumes that landscape characteristics not discernable in the digital elevation model exist that maximize the slope length). This input is used for the RUSLE calculations and is a sensitive parameter.

accumulation
Output map: number of cells that drain through each cell. The absolute value of each cell in this output map layer is the amount of overland flow that traverses the cell. This value will be the number of upland cells plus one if no overland flow map is given. If the overland flow map is given, the value will be in overland flow units. Negative numbers indicate that those cells possibly have surface runoff from outside of the current geographic region. Thus, any cells with negative values cannot have their surface runoff and sedimentation yields calculated accurately.

drainage
Output map: drainage direction. Provides the "aspect" for each cell. Multiplying positive values by 45 will give the direction in degrees that the surface runoff will travel from that cell. The value -1 indicates that the cell is a depression area (defined by the depression input map). Other negative values indicate that surface runoff is leaving the boundaries of the current geographic region. The absolute value of these negative cells indicates the direction of flow.

basin
Output map: Unique label for each watershed basin. Each basin will be given a unique positive even integer. Areas along edges may not be large enough to create an exterior watershed basin. 0 values indicate that the cell is not part of a complete watershed basin in the current geographic region.

stream
Output map: stream segments. Values correspond to the watershed basin values.

half.basin
Output map: each half-basin is given a unique value. Watershed basins are divided into left and right sides. The right-hand side cells of the watershed basin (looking upstream) are given even values corresponding to the watershed basin values. The left-hand side cells of the watershed basin are given odd values which are one less than the value of the watershed basin.

visual
Output map: useful for visual display of results. Surface runoff accumulation with the values modified to provide for easy display. All negative accumulation values are changed to zero. All positive values above the basin threshold are given the value of the basin threshold.

length.slope
Output map: slope length and steepness (LS) factor. Contains the LS factor for the Revised Universal Soil Loss Equation. Equations taken from Revised Universal Soil Loss Equation for Western Rangelands (see SEIE ALSO section). Since the LS factor is a small number, it is multiplied by 100 for the GRASS output map.

slope.steepness
Output map: slope steepness (S) factor for RUSLE. Contains the revised S factor for the Universal Soil Loss Equation. Equations taken from article entitled Revised Slope Steepness
Factor for the Universal Soil Loss Equation (see SEE ALSO section). Since the S factor is a small number (usually less than one), it is multiplied by 100 for the GRASS output map layer.

armsed Output file: Useful as input to r.grass.armsed. ASCII file output that can be fed into the r.grass.armsed program to help calculate sedimentation yields and unit hydrographs. As of 01/17/91, this option had not yet been fully tested.

NOTES

There are two versions of this program: ram and seg. Which is run by r.watershed depends on whether the -m flag is set. ram uses virtual memory managed by the operating system to store all the data structures and is faster than seg; seg uses the GRASS segment library which manages data in disk files. seg allows other processes to operate on the same CPU, even when the current geographic region is huge. Due to memory requirements of both programs, it will be quite easy to run out of memory. If ram runs out of memory and the resolution size of the current geographic region cannot be increased, either more memory needs to be added to the computer, or the swap space size needs to be increased. If seg runs out of memory, additional disk space needs to be freed up for the program to run.

seg uses the $A^T$ least-cost search algorithm to determine the flow of water over the landscape (see SEE ALSO section). The algorithm produces results similar to those obtained when running r.cost and r.drain on every cell on the map.

In many situations, the elevation data will be too finely detailed for the amount of time or memory available. Running r.watershed will require use of a coarser resolution. To make the results more closely resemble the finer terrain data, create a map layer containing the lowest elevation values at the coarser resolution. This is done by: 1) Setting the current geographic region equal to the elevation map layer, and 2) Using the neighborhood command to find the lowest value for an area equal in size to the desired resolution. For example, if the resolution of the elevation data is 30 meters and the resolution of the geographic region for r.watershed will be 90 meters: use the minimum function for a 3 by 3 neighborhood. After going to the resolution at which r.watershed will be run, r.watershed will be taking values from the neighborhood output map layer that represents the minimum elevation within the region of the coarser cell.

The minimum size of drainage basins is only relevant for those basins that have no basins draining into them (they are called exterior basins). An interior drainage basin has the area that flows into an interior stream segment. Thus, interior drainage basins can be of any size.

The r.watershed program does not require the user to have the current geographic region filled with elevation values. Areas without elevation data MUST be masked out using the r.mask command. Areas masked out will be treated as if they are off the edge of the region. Masks will reduce the memory necessary to run the program. Masking out unimportant areas can significantly reduce processing time if the watersheds of interest occupies a small percentage of the overall area.

Zero data values will be treated as elevation data (not no-data). If there are zero data along the edges of the current region, that edge will not be able to propagate negative accumulation data to the rest of the map. This might give users a false sense of security about the quality of their data. If there are incomplete data in the elevation map layer, users should mask out those areas.

SEE ALSO

Length slope and steepness (length.slope) factor equations were taken from "Revised Universal Soil Loss Equation for Western Rangelands," presented at the U.S.A./Mexico Symposium of Strategies for Classification and Management of Native Vegetation for Food Production In Arid Zones (Tucson, AZ, 12-16 Oct 1987), by M. A. Weltz, K. G. Renard, and J. R. Simanton.

The slope steepness (slope.steepness) factor contains the revised slope steepness factor for the Universal Soil Loss Equation. Equations were taken from article entitled "Revised Slope Steepness Factor for the Universal Soil Loss Equation," in Transactions of the ASAE (Vol 30(5), Sept-Oct 1987), by McCool et al.

NAME
r.weight — Raster map overlay program.
(GRASS Raster Program)

SYNOPSIS
r.weight
r.weight help
r.weight output=name [action=name] [color=name] [title="name"]

COMMAND LINE OPTIONS
Parameters:
output=name Name of the output raster map layer created.
action=name Specifies which mathematical operation (addition or multiplication) is to be used to calculate weights.
Options: add, mult
Default: add
color=name Type of color table to be assigned to the output raster map layer created.
Options: grey, wave, ramp
Default: grey
title="name" A title to be assigned to the output map layer created. If this title contains more than one word, it should be quoted.
Default: (none)

DESCRIPTION
r.weight is a language driven raster map overlay program. It provides a means for performing geographical analyses using several raster maps. r.weight asks the user to weight (assign numeric values to) the raster map categories of interest. The assignment of weighted values requires that the user intimately understand the analysis being undertaken. How important is the slope of the land in comparison with the current land use, or the depth to bedrock? The assignment of values to the land’s characteristics allows r.weight to mix and compare apples and oranges, such as slopes and land uses, and soil types and vegetation.

r.weight is a language-driven analysis tool. It responds to worded commands typed at the terminal. Help is always available via the one word command: help. Commands available in r.weight are listed below.

Note that raster map names appear in parentheses. The use of parentheses is now optional in r.weight.

list maps List available raster maps
list categories (name) List categories for raster map (name)
list save List saved analyses
list analysis Display current analysis request
print analysis Send current analysis request to printer
choose (name) Choose raster map (name) for analysis
assign (name) Interactive way to assign weights for raster map (name)
assign (name) (cat) (val) Assign weight (val) to category (cat) for raster map (name)
assign (name) (cat) (cat) (val) Assign weight (val) to categories (cat) (cat) for raster map (name)
save Save the current analysis
recover
add
mult
execute
erase
color grey
color wave
color ramp
quit

Recover old analysis
Request that weights be added (this is the default)
Request that weights be multiplied
Run analysis
Erase the screen
Set the graphics monitor colors to a grey scale (this is the default)
Set the graphics monitor colors to a color wave.
Set the graphics monitor colors to a color ramp.
Leave r.weight

A more detailed explanation of a command can be obtained by typing:

help (command)

SUGGESTED APPROACH

In order for r.weight to generate raster maps useful for analysis, the user must make a reasonable and defensible request. While much more powerful than r.combine, r.weight is also more dangerous. The user provides the necessary value judgements, which are registered as weights. Only well-conceived value judgements will result in defensible results. We suggest the following approach to a weighted overlay analysis:

STEP 1: BEFORE RUNNING WEIGHT
   a) Define the question to be answered. e.g., "Locate sites suitable for building apartments."
   b) Determine what mapped information is useful for answering the question. e.g., geology, soils, land_use, flood_potential.
   c) Based on professional judgement, statistical inference, and engineering principals, assign weights to the categories in the chosen raster maps.

STEP 2: CHOOSE CELL MAPS
   In r.weight, use the command choose to identify up to six raster maps of interest.

STEP 3: ASSIGN WEIGHTS
   Using the r.weight command assign, assign specific weights to raster map categories.

STEP 4: SAVE ANALYSIS
   Use the save command to save a copy of the analysis requested for later use.

STEP 5: RUN ANALYSIS
   Use execute to run the analysis.

STEP 6: EVALUATE RESULTS
   To modify an existing analysis request, use the recover command to retrieve the analysis and then go to STEP 3.

NAME

r.weight.new - Weighted overlay raster map layer analysis program.

(Grass Raster Program)

SYNOPSIS

r.weight.new [output] [action] [color]
r.weight.new [output=option] [action=option] [color=option]

DESCRIPTION

r.weight.new is the non-interactive version of r.weight. Both programs allow the user to assign numeric values (i.e., "weights") to individual category values within raster map layers. These weights are then distributed locationally throughout a raster map layer based on the distribution of the categories with which they are associated. The user can weight the categories of several raster map layers in a database. Such weighted raster map layers can then be overlaid. r.weight.new will combine weights in the overlaid map layers by cell location.

A resulting output raster map layer depicts the combination of map layer weights across a landscape. These values represent a hierarchy of suitability for some user-defined purpose. To obtain a more detailed description, see the manual entry for r.weight.

Output raster map must be specified (no default)
Action must be either (add or mult) (default: add)
Color table for the new raster map (grey | wave | ramp) (default: grey)

Once the r.weight.new command line is entered, the user will need to enter a raster map layer name and assign numeric values to its categories. Values can be assigned to the categories of up to six raster map layers within r.weight.new in a single analysis. Help is available to the user by typing r.weight.new help.

EXAMPLE

The following is the format in which data should be entered to r.weight.new:

Raster-layer1
[Reclass rule 1a]
[Reclass rule 1b]
Raster-layer2
[Reclass rule 2a]
etc.
end

Raster_layer: raster_map OR "raster_map in mapset"
Reclass rule: (example) 1 = 5 OR 20 thru 50 = 10 (must leave spaces between the category, =, and value entries)

Example: (the prompts are shown in bold)

> r.weight.new sites add wave
> soils

soils> 1 thru 20 = 5
soils> 21 thru 30 = 10
soils> landcover

landcover> 1 = 2
landcover> 2 = 4
landcover> 3 thru 8 = 6
landcover> end
NOTES
The user must be knowledgeable about r.weight to run r.weight.new. r.weight.new does not provide
the user with a listing of raster map layers or map layer categories. Users unsure about raster map
layer names should run the GRASS program g.list. To obtain a listing of the categories for a raster
map layer run r.report.

The user can create an input file containing the data needed to run r.weight.new. This file must list the
raster map layer and reclass rules in the format shown in the above example. The prompts must not be
included in the file. This file can be directed into r.weight.new at the command line by typing
r.weight.new output action color < input_file

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled
separately by the user.

BUGS
When entering data for the reclass rules, if the user does not include spaces between the category, =,
and value, the program will assume that the entry is a raster map layer.

NAME
r.what - Queries raster map layers on their category values and category labels.
(Grass Raster Program)

SYNOPSIS
r.what
r.what help
r.what [-f] input=name[name, ...]

DESCRIPTION
r.what outputs the category values and (optionally) the category labels associated with user-specified
locations on raster input map(s). Locations are specified as geographic x,y coordinate pairs (i.e., pair of
eastings and northings); the user can also (optionally) associate a label with each location.

The program will be run non-interactively if the user specifies the program parameter values and
(optionally) the flag setting on the command line, using the form:

r.what [-f] input=name[name, ...]

where each input name is the name of a raster map layer whose category values are to be queried, and
the (optional) flag -f directs r.what to also output category labels. The user can also redirect a user-
created ASCII input file containing a list of geographic coordinate pairs and (optionally) user-named
labels, into r.what using the form:

r.what [-f] input=name[name, ...] [<inputfile]

If the user does not redirect an input file containing these coordinates into the program, the program
will query the user for point locations and labels.

Alternately, the user can simply type:

r.what

on the command line, without program arguments. In this case, the user will be prompted for the flag
setting and parameter values using the standard GRASS parser interface described in the manual entry
for parser.

Flag:
-f
Also output the category label(s) associated with the cell(s) at the user-specified
location(s).

Parameters:
input=name[name, name, ...]
The name(s) of one or more existing raster map layers to be queried.

EXAMPLES
The contents of the ASCII input file to r.what can be typed in at the keyboard, redirected from a file,
or piped from another program (like d.where). Each line of the input consists of an easting, a northing,
and an optional label, which are separated by spaces. The word end is typed to end input of
coordinates to r.what. For example:

635342.21 7654321.09 site 1
653324.88 7563412.42 site 2
end

r.what output consists of the input geographic location and label, and, for each user-named raster map
layer, the category value, and (if -f is specified) the category label associated with the cell(s) at this
geographic location. Sample input (in bold) to and output (in plain text) from r.what are given below.

---

r.what Reference Manual

r.what
r.what

r.what input = soils, aspect
635342.21 7654321.09 site 1
653324.88 7563412.42 site 2
end
635342.21 | 7654321.09 | site 1 | 45 | 21
653324.88 | 7563412.42 | site 2 | 44 | 20

r.what -f input = soils, aspect
635342.21 7654321.09 site 1
653324.88 7563412.42 site 2
end
635342.21 | 7654321.09 | site 1 | 45 | NaC | 21 | 30 degrees NW
653324.88 | 7563412.42 | site 2 | 44 | NdC | 20 | 15 degrees NW

NOTES
The maximum number of raster map layers that can be queried at one time is 14.

NAME
s.db.rim - RIM database management/query interface for GRASS sites data.
(GRASS Sites Management Program)

SYNOPSIS
s.db.rim
s.db.rim data_base

db.db.rim allows users to create, manage and query information about site locations (sites) across the
landscape. Required inputs can be entered interactively, or from the command line. Command line
input may be entered through a prepared text file or from the keyboard (standard input). The s.db.rim
command language is defined in section one. The menu-driven interactive version is described in
section two.

These programs are actually a marriage of the GRASS environment and the programmer's interface
library of the relational database management program RIM, distributed publically by the University of
Washington Academic Computing Services as FORTRAN 77 code. Your system must have a
FORTRAN 77 compiler to use s.db.rim.

SECTION ONE -- THE COMMAND VERSION
The command-line driven version of s.db.rim is run by typing the below command, where data_base
is the name of an existing RIM sites data base:

s.db.rim data_base

The sites data bases are stored in a subdirectory named 'rim/sites' in the user's current mapset. Data
bases in other mapsets, selectable through the GRASS g.mapsets command, can be accessed for 'read-
only' retrieval of records. Each mapset may have many data bases. Each data base within a mapset
must have a different name; user-supplied names for data bases are limited to seven (7) characters in
order to maintain compatibility with the standard version of RIM. As with other GRASS commands,
mapsets are searched in the mapset SEARCH_PATH order when a data base needs to be opened.

Each site data base is composed of multi-field records (rows or tuples, in DBMS jargon). Each field
and its position in the site form is defined via input to the .make command when a data base is
originally defined. It is possible to add new fields or change the length of existing fields after data has
been loaded; however, this is not straightforward and is not described here; deleting of fields is also
possible, but requires ever more experience and knowledge. The user needs to carefully design the
data base fields and form (layout) and check the operation with a few pieces of test data before loading
data for a large number of sites.

COMMANDS
(Note: For each of the "dot commands," e.g., .make, described below there is a menu choice to select
when running the interactive version. The interactive menus are described in section two of this
document. Some display capabilities exist in the interactive version which are not directly implemented
in the command version.)

The commands are given alphabetically here for easy reference. The .make command is required to
create a data base and, therefore, will be the first to be entered by a new user. Abbreviations down to
the string shown in ( ) are accepted; this is primarily for those giving s.db.rim commands from a
terminal, but abbreviations may also be used in batch files.

Each command is introduced with an input record (line) which starts with a period and is followed by
one of the words shown below; for some commands the command line also contains one or more
required or optional parameters. Additional or optional input instructions/data for a command are
supplied on successive lines; a .end line is needed by some commands to signify the end of these input
lines.
Alphabetical Command Summary

/.conumrnd
This is the only .db.rim command not starting with a period. "command" is a single shell command line which is executed by a "G_system()" call (see GRASS gis library). Many UNIX utilities (e.g., vi, Is, print) and most GRASS commands (e.g., d.rast, d.points, g.list, g.region, d.zoom, r.mask) may be executed. It is permitted, and often useful, to change "region" and "MASK" within .db.rim. Multiple commands may be separated by ";" in the standard UNIX way. Note that a "!cd directory; Is" will change to the specified directory and list files, but the effective working directory for .db.rim will not be changed when the command terminates.

/add (a)
Add a new site record (row) to the open data base. Each line following contains a field name followed by spaces and/or tabs, then the value or character string to store for that field. Field information lines end with .end. Some fields may be absent and fields may appear in any order. Checks are made for the input of data for the one required field (site number), for string length for string type fields, and for duplicate site numbers. If split fields are used in the data base layout (see .make), text data for each split field must be added as a separate line. If there are any problems, the record will not be stored and a message will be output. This format makes it relatively easy to import data from most other DBMS. The ".print -a" command, see below, outputs data in this list format.

Example:
/add
site_id 204
north 4690673.30
east 601410.00
reference Jones (1987)
/end

.backup (.b) file_name
The .backup command is used to dump the entire data base from the RIM binary files to a text file format (see UNLOAD in the RIM User's Manual). The file_name can be a relative path name or full path name. The file will contain the data base definition, screen layout information, and tabular data. This text file is transportable to RIM or .db.rim running on any other computer; it may also be reloaded to recreate the .db.rim data base. A message will be output if there is any problem writing the .backup file. Backup can only be done on data bases in the user's current mapset.

To reload your data base from the backup file (normally not necessary):

```
GRASS 4> cd $LOCATION/rim/sites  # right directory
GRASS 4> rm db_name.rimdb1      # remove data base (or mv to somewhere)
GRASS 4> rm db_name.rimdb2      # remove data base (or mv to somewhere)
GRASS 4> rm db_name.rimdb3      # remove data base (or mv to somewhere)
GRASS 4> rim                    # run RIM manually
RIM> input "path/file"          # RIM rebuilds data base from data
written by .backup
RIM> exit
```

/change (.c) [-l ]
Without the -l flag, each line following .change is in the same format as for the .add command. The site number field is required and the site number must match an existing site in the data base. Only those fields for which lines are provided are changed in the record. After the .end the changed record is stored, if all is ok; otherwise, a message is output.
If the "-l" flag (for "list") is given, the site number field is omitted and the specified field values are changed for all sites currently selected by .find and/or .query.

.delete (.d)
This command is used to delete data records for sites. Deletion of sites is permanent. A backup of the data base, or copies of the data base files, are the ways to protect your valuable data.

The lines following the .delete command should contain only the site numbers, with a .end line being last.

The following command sequence will delete all the sites currently on the internal site list (the result of the last .query or .find command) after asking for approval.

.delete
.end

.end (.e)
Ends multi-line input for several other commands.

.exit (.ex)
Use .exit to end operation of s.db.rim cleanly. In general, do not use CTRL-C to exit unless absolutely necessary. When .exit is encountered in a batch file, input will revert back to the previous file, or the terminal, if any, that called the batch file.

.find (.f) [.a | .d] [.m] [.w]
The .find command is used to find the site(s) closest to a given point (the target). The target can be defined in one of several ways. The found sites are stored on an internal sites list for output by other commands; however, see note 2, below. The found sites are stored on the internal sites list in order of proximity to the target location.

The optional .find command line parameter specifies the current MASK (-m), if any, or the current region (-w), as a filter on the retrieved sites. -m automatically implies -w, as the MASK is not defined outside the current region. If the -a flag is given, the retrieved sites will be appended to those previously retrieved with a .query or .find; duplicates will be automatically discarded. The -d flag causes the retrieved sites to be deleted from the internal site list, if present there. Very complex selections can be done by interspersing appsends and deletes to arrive at a final list of sites. For instance, selecting those sites within 2000 meters of a target and then deleting those within 1500 meters of the target will give a final list of those from 1500 to 2000 meters.

The single required line following the .find line gives the program the necessary target information. The following examples show the possibilities.

.find> 602793.90 4379010.00
will find the one site nearest these coordinates and store it on the internal site list.

.find> 619840 4599000 10
will find the 10 sites (or fewer, if there are not that many) closest to the given location.

.find> site 132 10
will find the 10 sites closest to the location of site 132 in the data base (including site 132). If site 132 does not exist, no action is taken.
find> distance from 472910.06 5732001.0 5000

will find all sites within 5000 (meters, in UTM coordinates) of the target location.

find> distance from site 16 -2500

will find all sites greater than 2500 (meters) from the location of site 16.

Notes for .find:
1. All sites found are stored on the site list in order of proximity to the target location (sorted by distance from target).
2. The number of sites found is automatically printed to the active output device/file.
3. If mask is specified, the effective region is automatically set to the current region (because the GRASS mask is only defined for the current region).
4. Region and mask filtering uses the current resolution for the region to test if a point falls within a cell in the masking map.
5. In the last two examples the string "distance from" must be exactly matched. Also, the word "site" must be exactly matched.
6. If the "distance from" radius is given as a negative value, points outside the target circle are selected; whereas, if a positive value is given, points inside the circle are selected.
7. The current region may be changed with !g.region or !d.zoom prior to doing a .find, and the mask may be set or removed with a variety of GRASS commands.
8. The "find>" prompt is given only when input is from a terminal.

.help (.h)
Prints a help screen to the output device or file. Useful to have when using s.db.rim from a terminal, or when writing a script file of commands.

.input (.i) [file]
The lines in the file given are read and processed as commands or data until an end of file is reached or until a .exit command is found. Input files may call other input files to a nesting depth of eight. Without a file name, stdin is used as the input file.

.list (.l)
Lists the available data bases in the current mapset search path.

.make Using the .make command you create a new data base in the current mapset by specifying the following items which define the screen (page) layout for displaying and printing the site records, as well as the information fields:
1) The fixed text part of the screen layout.
2) The positions, types, and lengths of data fields.

Three fields must always exist in a data base; each of these field types may only occur once in a data base layout:
1) Type 's' Site identification number field (an integer).
2) Type 'x' Easting coordinate of the site (a double float).
3) Type 'y' Northing coordinate of the site (a double float).
The other field types, which may occur in any combination and order, are:

4) type 'i' An integer field.

5) type 'f' A double precision float field.
(always 2 decimal places used for output)

6) type 't' A text field.

Each of the fields can be positioned anywhere within the screen layout, which has a limit of 19 lines by 80 columns. A maximum of 70 fields may be defined within this space. A field is specified in the screen layout by a tilde ("), a field type character, a field name and enough trailing tildes to fill out the desired field length.

Each line following the .make command is taken to define a line of the screen layout until a .end is reached. If a mistake is made on any of the input lines, the .make will fail. The .make information may be prepared in advance as a text file (this facilitates fixing mistakes) and the .input command can be used to read in this file. An example text file for a data base screen layout follows, with some explanatory notes and restrictions.

```
.make

Archaeological Sites Database

Site #: "sSite" Entered By: "tEnter_by"
Description: "tDescrip.1"
             "tDescrip.2"
             "tDescrip.3"
Date: "tEnter_Date"
Type: "tType" (Should be Arch. or Hist.)
North: "yNorth" East: "xEast"

.end

Notes:

1) Any text not preceded by a tilde (" character is taken to be part of the constant or fixed text portion of the form.

2) A field definition begins with a tilde (" character immediately followed by a single character which indicates the data type of the field (s,x,y,i,f or t). Immediately following the data type character is the field name of 1 to 16 characters. Field names can be composed of any characters from the following set: [A-Z,a-z,0-9]; the RIM program and library do not distinguish upper and lower case in field names, so you should avoid making names which differ only in case. Field names may not begin with a numeral [0-9]. The rest of the field length is padded with tilde (" characters to the required maximum length.

3) The minimum field width is three characters; e.g., " tA". Be sure field widths for all fields are wide enough for the values and strings you expect to store there; e.g., UTM northings require at least 11 spaces.

4) For text fields it is possible to continue a field across more than one line. This is done by appending a .1 to the field name forming first portion of this "split field", a .2 for the second portion,
etc. This text field splitting affects how information is organized for input and output; the composite text string is concatenated (unused portions of fields are retained as spaces) and treated as a unit for storage and queries to the data base.

.output (.o) [file or | process]
Causes all output (except some error messages) from s.db.rim, including that from the .print command, to go to the named path/file (may be a full or relative path name), or to be used as standard input by the process (a pipe). If no parameter is given, output returns to stdout, usually the user's terminal. An example of the pipe usage would be

.output | grep "easting" | wc -l > Amp/my_count

A pipe is closed whenever the .output command is given again, or on a .exit command.

.pack (.pa)
This should be used when numerous data records have been deleted to recover disk space in the RIM binary data base files. It works by doing a .backup to a temporary file; moving the data base files to new names (*.bakdb*); running RIM to rebuild the data base; and, if the rebuilt data base can be opened and read, the temporary files are deleted. The user is informed if this process fails. Packing can only be done on an open data base located in the user's current mapset.

.print (.p) [-a | -l]
This command outputs the full site records for the sites currently stored on the internal sites list (result of last .query or .find). Without the flag, the screen layout format is used. With the -l flag, for list format, the field name followed by the contents are output one field per line. The -a flag also outputs in the list format but with a .add line and a .end line surrounding each site record printed; data files in this form can be read with .input, thus they form one kind of backup mechanism and can be used to transfer data (not the data base layout) from one GRASS system to another. The destination for the output is set by a previous .output command (default is stdout).

.query (.q) [-a | -d | -m | -w]
The .query command is used to retrieve sites via an SQL-like request to RIM, including a user specified "where clause." All fields for each site meeting the selection criteria are retrieved. The optional .query command line parameters cause points not in the region (-w) and/or mask (-m) to be rejected, so these conditions need not be tested in the "where clause." The -a flag causes the retrieved sites to be appended to those previously retrieved by .query or .find; duplicate entries are automatically discarded. The -d flag causes selected sites to be deleted from the current list, if present.

After the query command line, any number of lines may be entered to define the SQL "where" clause. A .end line is required to finish the request and begin data retrieval. See examples below.

The "distance from" clause may also be used as additional selection criteria exactly as described in the examples and notes for .find. It must be entered as a separate line to the query prompt.

The retrieved records may be printed at time of retrieval, rather than after the completion of the query command by including a .print (.p) line with the same options for print format as in the .print command (see above); e.g., .p -a to output in the "list add" format. The .print clause must be entered as a separate line to the query prompt. This feature is most useful when working with very large data bases where retrieval time is significant. See example 2 below.

Example 1:

query> where density < 20 and (date = "10/14/89")
query> or county eq "San Marcos")
query> .end
Example 2:

```
query > where east < 600000 and name like "%Jones%"
query > distance from site 12 3000
query > print -a
query > .end
```

Example 3:

```
query > end
```

The where and distance from clauses are each optional. If both are omitted, only the mask and region on the .query command line restrict the search; if mask and region are also omitted, all sites will be retrieved (Example 3). When querying for sites the where clause is processed first, the current region and mask tested next (if requested), then the distance from clause is applied; a site must pass all tests to be put on the internal site list for output by other commands.

Notes: (Also see Notes for .find)

1. The retrieved sites are stored on the internal site list in the order returned from the data base by RIM, not necessarily in site number order or the order the data was loaded. A "distance from" clause results in a final sorting by proximity to target.

2. See the RIM User's Manual for additional information on the "where" clause in the "select" command, especially the quotes required for matching character string fields, and the allowed comparison operators.

3. In the where clauses of the examples, "density", "date", "county", "east", and "name" are field names (column names in RIM) defined when the user initially makes the data base.

4. Each .query or .find resets the internal site list (even unsuccessful ones), unless the -a or -d flags are used.

```
.readsite (re) site_list [comment_field]
```

This command reads an existing GRASS site list and creates a data base record for each site. If the comment or description field of all entries in the site list begin with # and a number, the number becomes the site number in the data base. If some of the sites in the GRASS site list do not have a # at the beginning of the comment field, the sites are numbered sequentially starting with 1. (These options are similar to the way the GRASS sites-to-raster [in s.menu] works.)

If a data base field name "comment_field" is entered on the command line, the comment will be stored in that field for each site. If an integer or float field is specified, an attempt is made to interpret the comment as that type of number; if this interpretation fails, 0 or 0.0 is stored.

If the site number duplicates one already in the data base or found earlier in the site list, it is not added.

Once the sites have been loaded by .readsite, use .change (or the interactive version) to add data to other fields for those sites.

```
.remove
```

This command, which requires a "y" as confirmation on the next line, entirely removes the three binary files which constitute your RIM data base. Use with care. Backup files must be removed individually by the user, if desired, from the $LOCATION/rim/sites directory.
.show (.sh)
This command is used to output the screen or page layout as defined for the current data base. It serves as documentation of the data base definition and as a reminder for field names, types and lengths. By using an editor to surround the output of .show with .make and .end lines, it can be used to reload the data base definition with .input.

.site_list (.si) file_name [field_name]
This command writes the site locations and the site numbers to the specified file in the site_list directory in the current mapset. If the file exists, the sites are appended to the current list, otherwise, a new site list file is created. A "field_name" may be optionally specified; if so, the contents of that field (retrieved from the appropriate site record) are inserted as the comment (following a '#' in the site list). The site number is used if no field name is supplied.

A comment line is inserted in the site_list file with the current date and time and the name of the data base producing the site locations. The format used for each site is:

easting | northing | #comment

.tables (.t)
Prints the table structure of the currently opened RIM data base. This is the same output generated by a "list *" command when running RIM manually. The information for the table named "data" is useful for review of the user's field definitions. The information for the two other tables is for internal use by s.db.rim.
SECTION TWO -- THE INTERACTIVE VERSION

SYNOPSIS

s.db.rim

DESCRIPTION

The interactive version of s.db.rim allows you to create, manage and query information about site locations (sites) across the landscape. Operations are done on a database through a series of menus explained below. Most of the menus use VASK screens; the user should become familiar with keys that move the cursor among the fields to be entered (RETURN, ENTER, CTRL-L, CTRL-K, etc.).

THE MAIN MENU

Below is the main menu. Option 1 is the default. Note the status line at the top of the menu, and the fact that 8 records have been selected by the latest find or query operation (between items 2 and 3). Note, also, that CTRL-C can be used to exit from this menu (and most other menus in the program) back to the GRASS prompt. The specifics of each menu choice are described below.

```
s.db.rim MAIN MENU Version 1.4
Data base <water> in mapset <rono> open. 25 records.
1 Open a data base
2 List available data bases
------- Retrieve/Output Site Records (8 currently) --
3 Find sites in proximity to a Target point
4 Query to select site records (SQL)
5 Show selected site records on Terminal
6 Display maps/selected sites on graphics terminal
7 Output selected site records to Printer or File
8 Create a site list from selected records
------- Add/Edit Site Records -------
9 View a single site record
10 Add a site record
11 Change a site record
12 Delete a single record or all selected records
------- Other functions -- Shell Command -- Exit -------
13 Make a new data base & Management Functions
14 Execute a shell command
0 Done -- Exit from s.db.rim
```

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO EXIT THIS PROGRAM)

1. Open a data base. If a data base is already open, it is closed before the requested one is opened. Only data bases in the user's current mapset may be modified; others are opened in read-only mode; this will be indicated on line 2.

2. List available data bases. For each mapset in the current GRASS mapset search path, the names of the existing data bases are listed.

3. "Find" sites in the database relative to a specified target location. This is used to select sites based on proximity to the target and, optionally, sites within the current region and, optionally, sites falling in active cells within the current GRASS mask. Two modes of targeting are provided: the N sites closest to the target, and all sites within (or outside) a circle of specified radius from the target. The FIND/QUERY TARGET MENU discussed below accepts region/mask/target specifications from the user. The selected sites are then displayed one at a time until CTRL-C is entered; then other operations, choices 5-8, can be done with these sites. The line on the menu between 2 and 3 shows the number of sites currently selected by choices 3 or 4.
4. "Query" sites in the data base using an SQL-like "where clause," including specifications for region/mask/target (circle only) as in 3, above; see FIND/QUERY TARGET MENU section below. The where clause can test for ranges or matches for numeric data base fields, or matches on full strings or substrings for text fields. The selected sites are then displayed one at a time until CTRL-C is entered; then other operations, choices 5-8, can be done with these sites. This clause is entered on a menu described below; see QUERY COMMAND MENU section, below.

The where clause may use parentheses ( ) to control the order of comparisons. Field names are not case sensitive within where clauses. The following comparison operators are valid for all types of fields:

```
eq or =  ne or <>
ge or >=  le or <=
gt or >   lt or <
```

String comparisons are case sensitive and are done character by character. Substrings comparisons may be done with the "like" operator as in:

```
where name like "*Jones*"
```

Note that the string being tested against the name field for each record is in quotes (single or double) and that wild card comparisons can be done in the standard way with 'Y' and '?' characters.

Logical comparisons may also be combined with those operators above. The permitted logical operators are:

```
and or not
```

The following complex example should be examined. The line breaks can occur between any tokens (words, values, operators), except within quoted strings.

```
where (name like "*Jones*" or name = "Smith")
and ((site < 300 and not (site = 251 or site eq 15))
   or east < 601000)
```

5. This choice will display the site records resulting from the last find/query one at a time on the terminal. Use ESC or enter a number to display another record and CTRL-C to end the display.

6. If a graphics monitor is active, the locations of the selected sites will be displayed. The user may choose to erase the screen; display raster, vector, and/or site maps; or display the selected sites from the data base. These maps are requested through the following interactive screen. Just enter ESC to skip this step. If no data base sites are currently selected, that section of the menu will not appear; but the menu can still be used to display the other types of maps. This display function is a major added function of the interactive version of the program; display is not so easy in the command version.
SELECTION MENU FOR ITEMS TO DISPLAY

Enter raster and/or vector map names, if desired

- Raster map to display
- Vector map to display in color:
- Site list to display
  - Display currently selected sites (enter x)
  - Erase graphics screen (enter x)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

7. This selection results in a screen prompting for the name of the file to output the selected site records to, and for optional formatting selection. If the file name is lp, the site records are sent to the printer. The optional formatting choices are for export of data in list format (see .print in the first part of this manual page for s.db.rim for information and examples).

8. Using this choice you can write (or append) the currently selected sites to a GRASS site_list file in your current mapset. A short menu prompts for the name of the site_list file, and also for the name of a field to be used for the “comment” in the site_list (the site number is the default field). The current date and time, and the names of the mapset and database in use are entered as an information line in the site_list file. Note that various kinds of raster map layers can be produced from a s.db.rim database by writing site_lists with different fields as “comments” then converting the site_lists to raster files with s.menu.

9. Choices 9-12 operate on only a single site and do not use or modify the internal list of sites selected by find/query (choices 3 or 4). Choice 9 is the way to view a single site record, selected by site number. After viewing, ESC will allow entry of another site number and CTRL-C will exit to the main menu.

10. Use this selection to add a new site record to the database. (A new site is one whose site number does not currently exist in the open database.) After making this selection, the database layout will be displayed and you should enter the available information appropriate to each field; the only required entry is the site number field. If values for numeric fields are not entered, zero values will be stored. Unused portions of text fields are stored as strings of spaces.

11. After making this selection and specifying the site number to change field information for, the data is entered as for choice 10, except that the site number cannot be changed. (The command version of the program has provision for making bulk changes after a find or query; see .change.)

12. To delete a single record, enter its site number when requested. All site records chosen by the last find/query operation may be deleted by entering “list” in place of the site number. BE CAREFUL with this, deleted records are really gone.
13. This choice starts a new menu with less commonly used functions. See MANAGEMENT MENU section below.

14. The program will prompt you for one-line Shell Commands until you enter just a <RETURN> to return to the main menu. Often useful for changing the GRASS region, setting a MASK, etc.

**FINDQUERY TARGET MENU**

This is the screen to set up the region/mask/target information for the find choice (3) and the query choice (4), except that item B is omitted for choice (4). The choice to append or delete selected records will only be given after a successful find or query has stored some records on the internal record list. See .find and .query for more information.

If a graphics monitor is not active, the "mouse" item is omitted from the screen; and, if a mask is not set, that choice is omitted. The choices entered on this example screen will result in all the sites within a 1500 (meters) radius of the target point (to be chosen with the mouse) being selected and stored on the internal site list by find or query. They are stored in order of proximity to the target. If a site is used as the target, it is always the first in the retrieved list (useful for just selecting one site by number). If a mouse is chosen to select the target point, a menu to display reference maps is presented, exactly as in choice (6), prior to actually activating the mouse.

**QUERY/FIND: REGION/MASK/TARGET SELECTION MENU**

Data base <arch>(READONLY) in mapset <FIRSTMAP>open. 113 records.

Mark requests with 'x' and enter required values.

Respect current region

Respect current MASK

(forces current region)

A. Find all sites within (or outside) a circular target

and give the radius (negative for outside) 1500.00

OR

B. Find a number of sites nearest a point

and the number of sites requested

After selecting A or B, complete one(!) of these:

1. x to select target point with mouse

2. Enter site number for target point

3. Target coordinates east 0.00

   north 0.00

Append/Delete to current FIND/QUERY site list (a | d)

Reset to default choices for this menu

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE

(OR <Ctrl-C> TO CANCEL)

**QUERY COMMAND MENU**

The following screen completes the information for a query (choice 4). It may be left blank if no "where clause" is required. After a successful query, the selected records are displayed one at a time by hitting escape; CTRL-C will quit the display and return to the main menu where several choices of operation on the retrieved sites are offered.
QUERY COMMAND CONSTRUCTION SCREEN
Data base <A> in mapset <rim test > open. 25 records.
The SQL select query will use the current region
and a target clause of 'distance from 596463.15 4919041.88'

where date = 10/16/89

(Enter .show on a line to review screen layout and field names.)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

MANAGEMENT MENU
Choice 13 from the main menu presents this menu. Each item is discussed below.

s.db.rim DATA BASE MANAGEMENT MENU
Data base <A> in mapset <rim test > open. 15025 records.

1 Make a New Data Base in Current Mapset
2 List Available Data Bases
3 Remove (PERMANENTLY) Data Base from Current Mapset
4 Recover a Data Base from a RIM ASCII File
5 Show Screen Layout of Current Data Base
6 Backup (UNLOAD) Data Base to RIM ASCII Format File
7 Pack the Current Data Base
8 Read a Site list into the Current Data Base

0 Return to Main Menu

0. Your selection

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

1. Use this choice to create a new s.db.rim data base in the current GRASS mapset. See section below on MAKE A NEW DATA BASE.

2. List available data bases. Like 2 on MAIN MENU.

3. Delete an entire data base from the current mapset. The name of the data base and additional confirmation of the action are prompted for.
4. Choice 6 allows backup of the definition and data parts of a data base to a transportable text file. To rebuild (or build for the first time) a \texttt{s.db.rim} data base from one of these text files do the following steps:

\begin{verbatim}
# see if the rim directory exists.
is $LOCATION/rim/sites
    # if the directory was not found, make it.
mkdir $LOCATION/rim/sites
    # change directory to it.
cd $LOCATION/rim/sites
    # have rim build the binary data base files.
rim
RIM> input '/path/to/your/file'
RIM> exit
\end{verbatim}

The data base is thus created in the current mapset. Several \texttt{s.db.rim} commands should be run to verify the integrity of the newly created data base.

5. This merely shows the screen layout of the currently open data base. It is a useful way to quickly see the layout and review the field names and types.

6. When backing up to a text file, the RIM UNLOAD command is run with the output directed to a file of the user's choice. See 4 above. It is wise to do this operation after extensive changes or additions of data records. The resulting text file can be written to tape for preservation, or shared with other GRASS systems, if desired.

7. After deleting a large number of site records, some "wasted" disk space will be present in the binary data base files. This procedure will perform an unload and a reload automatically to recover this unusable disk space. If there is any problem reopening the data base after packing, the user is notified and can recover in various ways depending on the backups which have been done.

8. Data may be loaded into a data base from an existing GRASS site\_list. This procedure will prompt for the site\_list name and then add the sites to the currently open data base. If all sites in the list have a comment field of the form "#value ....", the value is used as the data base site number, otherwise the sites are numbered sequentially beginning with 1. Only the site number and location coordinates are loaded for each site record by this procedure; other fields may be later added with the "change" function. See \texttt{read\_sites}.

MAKE A NEW DATA BASE

After entering the name of the new data base you wish to create (7 characters maximum), you then decide how to input the information required. This input may be from a text file, or may be entered directly using the editor of your choice; the former is recommended.

See \texttt{make} for the way to define a data base and record (form) layout.
NOTES
This program is included in the GRASS 4.0 release, but is not automatically compiled with other GRASS commands. The user must compile this program separately.

`s.db.rim` interfaces to the RIM program. Both `rim` and `s.db.rim` contain FORTRAN code. The user must have access to a FORTRAN compiler in order to compile and use `s.db.rim`. See the FILES section, below, for the location of source code.

A "date" type field should be added to future versions. This version only allows storing of dates as strings (unless the user codes them to integers), and thus only string type searches can be made for dates.

FILES
The source code for RIM is located under `$GISBASE/src.related/rim`

The source code for `s.db.rim` is located under `$GISBASE/src.garden/grass.rim/s.db.rim`

s.in.ascii

GRASS Reference Manual

NAME

s.in.ascii – Converts an ASCII listing of site locations and their descriptions into a GRASS site list file. (GRASS Sites Program)

SYNOPSIS

s.in.ascii
s.in.ascii help
s.in.ascii sites=name [input=name] [fs=character|space|tab]

DESCRIPTION

s.in.ascii converts an ASCII listing of site locations and category labels into a file in GRASS site list file format.

Input can be entered via standard input or from the file input = name. Each line of input should contain the easting, northing, and (optionally) the category label associated with a site. The fs = name option (where name is either a character, a space, or a tab) can be used to specify the use of a particular field separator between these three input fields. This is useful when input is obtained from other programs (see NOTES below). Output is stored in the file sites = name and placed in the site lists directory under the user's current mapset.

The GRASS program s.out.ascii can be used to perform the reverse function, converting a file in GRASS site list format into an ASCII listing of eastings, northings, and category labels associated with site locations.

Parameters:

sites = name Name of the new GRASS site list file to be output.
input = name Name of an existing ASCII file containing site locations and labels.
fs = character|space|tab The field separator separating the easting, northing, and category label in each line of the input file. The field separator can be a character, a space, or a tab.
    Default: space

s.in.ascii can be run either non-interactively or interactively. The program will be run non-interactively if the user specifies a name to be assigned to the sites file output, the name of an existing ASCII file containing input, and (optionally) a field separator fs appearing in the input file, using:

    s.in.ascii sites = name [input = name] [fs=character|space|tab]

Alternatively, the user can simply type s.in.ascii on the command line, without program arguments. In this case, the user will be prompted for parameter values using the standard GRASS parser interface described in the manual entry for parser. If the user does not specify the name of an input file containing site locations and (optionally) category labels, these should be entered to the program via standard input.

NOTES

Other GRASS programs can be used to produce output in a format suitable for input to s.in.ascii. For example, the user might pipe output produced by d.where into s.in.ascii to create a site list file called my.sites containing site locations pointed to with the mouse, as illustrated below. In this example it was unnecessary to specify the field separator used in the input, since d.where output separates the easting and northing values with spaces, and spaces are the default field separator assumed by s.in.ascii.

    d.where | s.in.ascii sites = my.sites

NAME

`s.menu` - Accesses and manipulates GRASS site location data.

*(GRASS Sites Program)*

SYNOPSIS

`s.menu`

OVERVIEW

The `s.menu` program provides the user with the capability of interfacing site location data with the geographic data in raster map layers. Two types of spatial analysis reports on sites can be generated, and an interface to the "S" statistical package is provided.

DESCRIPTION

The `s.menu` program is an interface to functions that allow the user to manipulate GRASS site "lists." A site list is a list of eastings and northings describing the location of some point feature. It can also contain a category value and category label for each site location. The program is interactive. After typing `s.menu` on the command line, the user selects site functions from a menu.

The main menu is shown below:

```
SITES MAIN MENU       (current list: no sites)
LOCATION: spearfish    REGION 4928000.00(N) 4914000.00(S) 100.00 (RES)
MAPSET: PERMANENT      609000.00(E) 590000.00(W) 100.00 (RES)
MASK: none

Please select one of the following

1   Read an existing site list
2   Mask current site list
3   Save the current site list in your mapset
4   Check site list for duplicate sites
5   Edit site list using a UNIX editor
6   Convert site list to raster file (0/1)
7   Convert site list to raster file (frequency of occurrence)
8   Run reports on the current site list

stop   Leave the s.menu program
```

At the top of the menu is general information about the user's current MAPSET, LOCATION, etc. Note the above message in parentheses "current list: no sites." This message will vary depending on the status of the list. For example, after the user reads the existing site list file `arch_sites`, the message would read (given the geographic region indicated): "current list: 25 sites, 24 in current region."
1. Read an existing site list
   This option will copy an existing site list file into the current site list within the sites server. Existing site lists are stored under a GRASS data base and are pulled into the *s.menu* server via this option. Other sites menu functions operate only on the current site list file in the server - you must therefore "read an existing site list" file BEFORE performing any of the other sites menu functions.
   Note: Site lists can be created and placed into a GRASS data base using *s.menu* option 5 (edit) followed by option 3 (save). However, the user can also create site lists using other methods or programs. One simple way to do this is to create a site list file in the appropriate format using any text editor (e.g., "vi"), and to put this site list file under the *site_lists* directory under the user's current GRASS mapset (i.e., under $LOCATION/site_lists). The user can do this either inside of GRASS or outside of GRASS. Alternately, the user can run other GRASS programs that format their output as a GRASS site list file (*r.random*, *s.db.rim*, *v.mkquads*, *v.to.sites*), or the user can use UNIX programs like *awk* and *sed* to format other GRASS programs' output in the form of a site list file (*d.what.rast*, *d.what.vector*).

2. Mask current site list
   The site list can be reduced to a subset that includes only sites that fall in specific categories within a specified raster map layer. The user will be asked to specify the name of a raster map layer to form the basis for the mask, and will then be allowed to specify categories from this raster map that will limit the site list. As with *r.mask*, the category values selected designate the areas of the map in which information will remain. Areas assigned category values not selected will be re-assigned to category value "0" ("no data").
   Note: This masking operation is performed only against the site list itself and not against other raster map layers. If the user wishes to analyze masked raster map layers, a mask should be created using the *r.mask* program.

3. Save the current site list in your mapset
   The current site list can be stored permanently in your current mapset with this option. You will be asked to name the saved site list and to provide a short description of it. Saved site lists can be retrieved (option 1) during later runs of *s.menu*. Once saved, these site list files can be used with other GRASS programs, like *d.sites*, *d.points*, *d.icons*, *p.icons*, *s.surf.idw*, and *s.db.rim*.
   Note: Saved lists will be removed if the GRASS mapset under which they are stored is removed.

4. Check site list for duplicate sites
   It is not desirable that a site list contain multiple references to the same site. This option attempts to recognize duplicate sites. Duplicates are displayed to the user and can be removed automatically if the user desires. Duplicates can also be removed by hand using option 5 (edit).

5. Edit site list using a UNIX editor
   The user can modify the current site list or create a new site list by hand using a UNIX editor. You will be asked to specify the text editor you prefer to use. You should exercise some care if you select this option. Lines in the site list which have invalid formats will be (silently) ignored by *s.menu*. See the GRASS manual entry *sites.format* for a description of the site list format.
   Note: This option will only modify the site list copied into the server. It does not modify the original site list stored under a GRASS mapset. If you wish to modify a stored site list *(i.e., you will have to combine options 1 (read), 5 (edit), and 3 (save)).

6. Convert site list file to raster file (0/1)
   You can create a raster data representation of the site list in your GRASS mapset.
   Once created, this raster map layer can be used with other raster map layers in further analyses. Allowing the user to create a raster map layer of sites opens up the full analysis capabilities for site data that are available for raster map layers within GRASS.
You have the option of specifying the number of cells to represent a site. The minimum is one cell per site. The alternatives are squares around the site: 3x3, 5x5, 7x7, etc.

The number of categories present in the new raster map layers will depend on the format of your site list file (see sites.format). You can create a non-binary raster map layer representation of your site list by creating the site list in the format:

```plaintext
E[N] | # label
```

where E is the Easting, N is the Northing, and # label is the description field. The description field consists of a pound sign # followed by the category value n to be associated with the site's cell location, and the category label label for n.

If the user does not include a description field starting with #
beside the Easting and Northing on every line in the sites list file, a binary raster map layer will be created instead. In the binary raster file, each site will be represented as the category value 1. Non-site cells will be coded as category value 0.

Note that only sites within the current geographic region will be considered. However, if the size of the sites is more than one cell (3x3, 5x5, etc.) and a site lies near an edge of the geographic region, some of the cells for the site may fall outside the geographic region. These cells will not appear in the raster map layer, and the site will no longer be 3x3 or 5x5 but will be clipped to fit the geographic region.

7 Convert site list file to raster file (frequency of occurrence)

You can also create a frequency of occurrence raster map layer representation of the site list file.

The raster category values will be coded as the number of sites that fall within the cell.

In this function, you do NOT have the option of specifying the number of cells to represent a site.

8 Run reports on the current site list

The current list of sites is passed to the report server after removing sites that do not fall within the geographic region of the user's current GRASS mapset (see g.region). The user then selects the names of one or more raster map layers for analysis. Data at (or near) the sites extracted from these raster map layers form the basis for all reports.

The user specifies the 'size' of a site in cells. The 'size' may be specified as a single cell, or as a 3x3 square around the site, or 5x5, or 7x7, etc (where the size is an odd integer).

The following menu of reports is then presented:

**SITES REPORT MENU**

Please select one of the following

1. Site characteristics report
2. Site occurrence report
3. Convert data to S input format
4. Produce machine-readable data file

stop return to SITES MAIN MENU
1 Site characteristics report
This report provides geographic information about each site.

Each site is identified by description and locational information. The 'description' is an identification of the site. The site location is an easting and a northing. (The location does not denote the extent of the site, since, for example, an archeologic site which takes up two hectares would be represented as a single point).

The information reported for each site is displayed by raster map layer, and, within each map layer, gives the categories (i.e., characteristics) that occurred at the site (as well as a count of the number of cells in each category).

This can easily generate a massive amount of information, which is difficult to handle or digest quickly. Therefore, option 2 produces a synopsis of the information.

2 Site occurrence report
This report provides aggregate site characteristic information organized by raster map layer. The report produces chi-square statistics for each raster map layer, measuring number of expected sites (assuming a random distribution of sites) against actual site occurrence. The site characteristic is the most frequently occurring cell category in the site (i.e., the statistical mode). See the GRASS manual entry for sites.occur for details on this report.

3 Convert data to S input format
This function converts the GRASS data extracted for the sites into a form usable by the S statistical package. The user provides a file to contain the information. Once the file is written, the user must exit s.menu, run S on an S data base, and issue the S command

\texttt{source file}

to bring the data into the S data base. (Of course, \texttt{file} would be the name of the actual file supplied by the user.) See manual entry sites.S for an explanation of the S data structures created by this interface.

4 Produce machine-readable data file
This option provides a mechanism for the user to write his/her own reports. The data is written into a user-specified file as a text file, which has a format readable by UNIX utilities (e.g., \texttt{awk}) or user-written programs. See GRASS manual entry sites.report for details on this format.

NAME

`s.out.ascii` - Converts a GRASS site list file into an ASCII listing of site locations and their
descriptions.

*(GRASS Sites Program)*

SYNOPSIS

```bash
s.out.ascii
s.out.ascii help
s.out.ascii [-ad] sites=name [fs=character|space|tab]
```

DESCRIPTION

`s.out.ascii` converts an existing site list file (`sites=name`) into an ASCII listing of site locations and
(optionally) their category labels, in a format suitable for input to other programs (e.g., `d.points`,
`m.u211`, etc.).

Each line of output consists of the easting, northing, and category label for a site listed in the named
`sites` file. The `fs=name` option (where `name` is either a character, a space, or a tab) can be used to
place a particular field separator between these three output fields. This is useful when output is to be
manipulated by other programs, like `awk` or `sed`.

The GRASS program `s.in.ascii` can be used to perform the reverse function, converting a UNIX file
containing eastings, northings, and category labels associated with site locations into GRASS site list
file format.

Flags:

- `-a` Output all sites found in the named `sites` file, rather than limiting output to sites
  falling within the current geographic region.

- `-d` Include site descriptions (category labels) in the output.

Parameters:

- `sites=name` Name of an existing site list file.
- `fs=character|space|tab` The field separator to be placed between the easting, northing, and (optionally)
  category label on each line of output. The field separator can be a character, a space, or a tab.
  Default: space

`s.out.ascii` can be run either non-interactively or interactively. The program will be run non-
interactively if the user specifies the name of an existing site list file and (optionally) a value for `fs`,
using the form

```bash
s.out.ascii [-ad] sites=name [fs=character|space|tab]
```

where `name` is the name of an existing site list file to be converted to a brief ASCII listing, and `fs` is
the field separator to be placed between output fields. The user can also specify the `-a` and `-d` options
to use all sites in the named `sites` file and to include site descriptions in the output.

Alternately, the user can simply type `s.out.ascii` on the command line, without program arguments. In
this case, the user will be prompted for parameter values using the standard GRASS parser interface
described in the manual entry for `parser`. 

GRASS 4.0 (Summer 1991)       U.S. Army CERL
NOTES

The output from s.out.ascii may be placed into a file by using the UNIX redirection mechanism; e.g.:

```
s.out.ascii sites=archsites > outfile
```

s.out.ascii output may also be redirected into other programs; e.g.:

```
s.out.ascii sites=archsites | d.points color=red size=10 type=diamond
```

NAME

s.surf.idw - Surface generation from sites data program.

(GRASS Raster Program)

SYNOPSIS

s.surf.idw input=name output=name [npoints=count]

DESCRIPTION

s.surf.idw fills a raster matrix with interpolated values generated from a set of irregularly spaced data points using numerical approximation (weighted averaging) techniques. The interpolated value of a cell is determined by values of nearby data points and the distance of the cell from those input points. In comparison with other methods, numerical approximation allows representation of more complex surfaces (particularly those with anomalous features), restricts the spatial influence of any errors, and generates the interpolated surface from the data points. It is the most appropriate method to apply to most spatial data.

This program allows the user to use a GRASS site list file, rather than a raster map layer, as input. The program will be run non-interactively if the user specifies the values of needed program parameters and any desired optional parameter values on the command line, using the form:

s.surf.idw input=name output=name [npoints=count]

Alternately, the user can simply type s.surf.idw on the command line, without program arguments. In this case, the user will be prompted for needed inputs and option choices using the standard GRASS parser interface described in the manual entry for parser.

Parameters:

- **input=name**: Name of an input site list file that contains a set of irregularly spaced data values; i.e., some cells contain known data values while the rest contain zero (0).
- **output=name**: Name to be assigned to the new output raster map layer containing a smooth surface generated from the known data values in the input site list file.
- **npoints=count**: The number of points to use for interpolation. By default, the 12 nearest points are used for interpolation.
  
  Default: 12

NOTES

The amount of memory used by this program is related to the number of non-zero data values in the input site list file. If the input site list is very dense (i.e., contains many non-zero data points), the program may not be able to get all the memory it needs from the system. The time required to execute increases with the number of input data points.

If the user has a mask set, then interpolation is only done for those cells that fall within the mask. However, all non-zero data points in the input map are used even if they fall outside the mask.

NAME

v.area - Display GRASS area and perimeter information for GRASS vector map.

(GRASS Vector Program)

SYNOPSIS

v.area
v.area help
v.area [-f] map=name [color=name]

DESCRIPTION

The GRASS program v.area first displays the selected vector file. The user then can select an area on a
map by clicking with the mouse within the desired area. The selected area will be highlighted in the
selected color on the graphics display. On a regular screen, area information will be displayed, in
square meters, hectares, acres, and square miles. Perimeter measurements also will be displayed, in
meters, feet, and miles.

The user can repeatedly select areas for analysis, one at a time.

Flag:

-f Fill selected area with selected color on graphics display, rather than simply
outlining it in the highlight color.

Parameters:

map=name Name of the vector map layer to be displayed.

color=name Color in which perimeter will be highlighted.
Default: red

If the user simply types v.area without specifying program arguments on the command line, the
program will prompt the user for the name of a map. Then the user is given the option of specifying a
highlight color, and then, whether or not the display of selected area(s) is to be filled, rather than
merely outlined, with the highlight color.

NAME

v.cadlabel - Attaches labels to (binary) vector contour lines that have been imported to GRASS from
DXF format.

(GRASS Vector Program)

SYNOPSIS

v.cadlabel
v.cadlabel help
v.cadlabel lines=name labels=name

DESCRIPTION

v.cadlabel attaches labels to index contour lines by using the index contour lines and labels files that
have been converted from DXF format to GRASS vector format by the v.in.dxf program. Users have
the option of creating either binary or ASCII output with v.in.dxf. Since v.cadlabel works only on
binary vector files, the ASCII GRASS vector (dig.ascii) files that are generated by v.in.dxf must be
converted to binary GRASS vector (dig) files using the v.in.ascii program before v.cadlabel can be
executed.

v.cadlabel searches a binary GRASS vector file of contour lines to find the contour lines that are
closest to each box (contour label) in the binary GRASS vector file containing contour labels. The two
contour lines that are closest to a box are tagged with the same label (an elevation value) as that of the
box.

OPTIONS

Program parameters are described below.

Parameters:

lines=name Name of the binary GRASS vector (dig) file, imported from DXF format, that
contains index contour lines.

labels=name Name of the binary GRASS vector (dig.out) file, imported from DXF format, that
contains index contour line labels.

NOTES

Because line data that are created in CAD format may have unsnapped nodes or gaps, v.cadlabel will
not always be able to label every index contour line. Also, intermediate contour lines that may be
contained in the index contour vector file (because they resided on the same DXF level as the index
contour lines in the DXF design file) will not be labeled. Any lines that are not labeled with
v.cadlabel can be labeled with the contour labeling program in v-digit.

If the intermediate contour lines are in a separate GRASS dig file, they can be patched to an labeled
index contour file with the GRASS program v.patch, and then labeled in v-digit.

The user does not need to v.patch the labels vector file (boxes) to the lines vector file (contour lines).
The purpose of the labels vector file is to determine which labels should be assigned to which contour
lines (in the lines vector file) during the execution of v.cadlabel.

NAME

v.clean - Cleans out dead lines in GRASS vector files.

 bek Vector Program

SYNOPSIS

v.clean
v.clean help
v.clean map=name

DESCRIPTION

When programs like digit delete lines, they do not really go away, but are simply marked as deleted. This is done primarily for speed. But a side effect is that vector files can end up carrying a lot of dead weight with them.

v.clean will go through a vector file and remove all dead lines in the file thus potentially reducing the size of the file.

You do not have to run v.support afterwards.

COMMAND LINE OPTIONS

Parameter:

map Name of the GRASS vector file to be cleaned.

BUGS

None known.

NAME

v.db.rim - RIM data base management/query interface for GRASS vector
(GRASS Vector Program)

SYNOPSIS

v.db.rim
v.db.rim data_base

OVERVIEW

v.db.rim allows users to create, manage, and query information about labeled lines and areas from a number of different vector maps in a batch mode or interactively. Operations are done on a data base through a command language defined in section one or through an interactive set of menus described in section two.

This program, like s.db.rim, is actually a marriage of the GRASS environment and the programmer's interface library of the relational data base management program RIM distributed publicly by the University of Washington Academic Computing Services. Your system must have a FORTRAN 77 compiler to use this program.

DESCRIPTION

The vector data bases are stored in a subdirectory named 'rim/vect' in the user's current mapset. Data bases in other mapsets, selectable through the GRASS g.mapsets command, can be accessed for 'read-only' retrieval of records. Each mapset may have many data bases. Each data base within a mapset must have a different name; user supplied names are limited to seven (7) characters in order to maintain compatibility with the standard version of RIM. As with other GRASS commands, mapsets are searched in the mapset SEARCHPATH order when a data base needs to be opened.

Each vector data base is composed of multi-field records (rows or tuples, in DBMS jargon). Each field and its position in the record form is defined via input to the .make command when a data base is originally defined. It is possible to add new fields or change the length of existing fields after data has been loaded, however this is not straightforward; deleting of fields is also possible, but requires even more experience and knowledge. The user needs to carefully design the data base fields and form (layout) and check the operation with a few pieces of test data before loading data for a large number of records.

One significant difference between v.db.rim and s.db.rim is that v.db.rim needs access to the original vector maps that data were imported from to successfully complete some commands. To keep track of which records were imported from which vector maps, a new "table" has been added that keeps information of the reference vector maps. This table is called "Reference maps" in the RIM data base. The v.db.rim commands .read_vec, .map and .maps allow the user to view and update this table. The .vector_map command, which creates a new GRASS binary vector file, requires that the reference vector maps for the data base be accessible. If a reference map is not accessible, any vectors represented by the data base records that were generated from that vector map will not be transferred to a new vector map. Reference vector maps may be in any mapset in the current SEARCHPATH.

SECTION ONE -- THE COMMAND VERSION

(No.: For each of the "dot commands," e.g., .make, described below there is a menu choice to select when running the interactive version. The interactive menus are described in section two of this document. Some display capabilities exist in the interactive version that are not directly implemented in the command version.)

The commands are given alphabetically here for easy reference. The .make command is required to create a data base. Abbreviations down to the string shown in ( ) are accepted; this is primarily for those giving v.db.rim commands from a terminal, but abbreviations may also be used in batch files.

Each command is introduced with an input record (line) that starts with a period and is followed by one of the words shown below; for some commands the command line also contains one or more required or optional parameters. Additional or optional input instructions/data for a command is supplied on successive lines; a .end line is needed by some commands to signify the end of these lines.
Alphabetical Command Summary

!command
This is the only \texttt{v.db.rim} command not starting with a period. "\texttt{command}" is a single shell command line (no more than 80 characters) that is executed by a \texttt{G_system()} call (see GRASS gis library). Many UNIX utilities (e.g., vi, ls, print) and most GRASS commands (e.g., d.rast, d.sites, d.list, g.region, r.mask) may be executed. It is permitted, and often useful, to change "\texttt{region}" and "\texttt{MASK}" within \texttt{v.db.rim}. Multiple commands may be separated by ";" in the standard UNIX way. Note that a "\texttt{cd directory; ls}" will change to the specified directory and list files, but the effective working directory for \texttt{v.db.rim} will not be changed when the command terminates.

.add (a)
Add a new vector record (row) to the open data base. Each line following contains a field name followed by spaces and/or tabs, then the value or character string to store for that field. Field information lines end with .end. Some fields may be absent and fields may appear in any order. The input of data is checked for one required field (sequence number), for field length for text type fields, and for duplicate sequence numbers. If split text fields are used in the data base layout (see .make), text data for each split field must be added as a separate line. If there are any problems, the record will not be stored and a message will be output. This format makes it relatively easy to import data from most other DBMS. The \texttt{.print -a} command, see below, outputs data in this list format.

Example:

\begin{verbatim}
  .add
  seq_num  204
  north  4690673.30
  east  601410.00
  map_num  1
  vect_type L
  reference Jones (1987)
  .end
\end{verbatim}

.backup (.b) file_name
The .backup command is used to dump the entire data base from the RIM binary files to a text file format (see UNLOAD in the RIM User's Manual). The file_name can be a relative path name or full path name. The file will contain the data base definition, screen layout information, and tabular data. This text file is transportable to RIM or \texttt{v.db.rim} running on any other computer; it may also be reloaded to recreate the \texttt{v.db.rim} data base. A message will be output if there is any problem writing the .backup file. Backup can only be done on data bases in the user's current mapset.

To reload your data base from the backup file (normally not necessary):

\begin{verbatim}
GRASS 4> cd $LOCATION/rim/vect #right directory
GRASS 4> rm db_name.rimdb* #remove data base
GRASS 4> rim #run RIM manually
RIM> input "path/file" #RIM rebuilds data base from data
written by .backup
RIM> exit
\end{verbatim}

.change (c) [-I ]
Without the "-I" flag, each line following .change is in the same format as for the .add command. The sequence number field is required and the sequence number must match an existing site in the data base. Only those fields for which lines are provided are changed in the record. After the .end the changed record is stored, if all is ok; otherwise, a message is output.
If the "-l" flag (for "list") is given, the sequence number field is omitted and the specified field values are changed in all records currently selected by .find and/or .query.

.delete (.d)
This command is used to delete data records. Deletion of records is permanent. Each line following the command should contain only a sequence number that you want to delete, with a .end line being last.

A backup of the database or copies of the database files are the ways to protect your valuable data. The following command sequence will delete all the records currently on v.db.rim's query list (the result of the last .query or .find command), after asking for approval.

.delete
.end

.end (.e)
Ends multi-line input for several other commands.

.exit (.ex)
Use .exit to end operation of v.db.rim cleanly. In general, do not use CTRL-C to exit unless absolutely necessary. When .exit is encountered in a batch file, input will revert back to the previous file, or the terminal, if any, that called the batch file.

.find (.f) [-m | -w] [-a | -d]
The .find command is used to find the record(s) whose location (label point) is closest to a given point (the target). The target can be defined in one of several ways. The found records are stored on an internal query list for output by other commands; however, see note 2, below. Records are stored on the query list in order of proximity to the target location. The optional .find command line parameter specifies the current MASK (-m), if any, or the current region (-w), as a filter on the retrieved records; see notes 3 and 4, below. The append (-a) or delete (-d) options allow the "found" records to be added or deleted from the currently selected ones. When adding, duplicates will be discarded.

The single required line following the .find line gives the program the necessary target information. The following examples show the possibilities.

.find>602793.90 4379010.00
will find the one record nearest these coordinates and store it, append it or delete it on the internal query list.

.find>619840 4599000 10
will find the 10 records (or fewer, if there are not that many) closest to the given location.

.find>record 132 10
will find the 10 records closest to the location (label point) for record 132 in the database (including record 132). If record 132 does not exist, no action is taken.

.find>distance from 472910.06 5732001.0 5000
will find all records within 5000 (meters in UTM coordinates) of the target location.

.find>distance from record 16 -2500
will find all records greater than 2500 (meters) from the location of record 16.
Notes for .find:

1. All records found by each .find are stored on the query list in order of proximity to the target location (sorted by distance from target).

2. The number of records found is automatically printed to the active output device/file.

3. If mask is specified, the effective region is automatically set to the current region (because the GRASS mask is only defined for the current region).

4. Region and mask filtering uses the current resolution for the region to test if a point falls within a cell.

5. In the last two examples the string "distance from" must be exactly matched. Also, the word "record" must be exactly matched.

6. If the "distance from" radius is given as a negative value, points outside the target circle are selected; whereas, if a positive value is given, points inside the circle are selected.

7. The current region may be changed with !g.region or !d.zoom prior to doing a .find, and the mask may be set or removed with a variety of GRASS commands.

8. The "find:" prompt is given only when input is from a terminal.

9. The "distance" between the target location and a record for a line or an area is actually the distance between the target location and the representative point that is stored in the data base. This can lead to unexpected results when the representative point (label point) for a line or area is not near the "center" of the feature.

.help (.h)
Prints a help screen to the output device or file. Useful to have when using v.db.rim from
terminal, or when writing a script file of commands.

.input (.i) [file]
The lines in the given file are read and processed as commands or data until an end of file is
reached or until a .exit command is found. Input files may call other input files, by using this
command, to a nesting depth of eight. Without a file name stdin is used as the input file.

.list (.l)
Lists the available data bases in the current mapset search path.

.make Using the .make command you create a new data base in the current mapset by specifying the
following items that define the screen (page) layout for displaying and printing the records, as
well as the information fields:

1) The fixed text part of the screen layout.
2) The positions, types, and lengths of data fields.

Five fields must always exist in a data base; each of these field types may only occur once in a
data base layout:

1) Type 's' Sequence number field (a unique integer for each record).
2) Type 'x' Easting coordinate of the representative point (a double float).
3) Type 'y' Northing coordinate of the representative point (a double float).
4) Type 'v' Vector type field (a text field).
5) Type 'm' Reference Map field (an integer).
The other field types, which may occur in any combination and order, are:

6) Type 'i'  An integer field.
7) Type 'f'  A double precision float field.
   (always 2 decimal places used for output)
8) Type 't'  A text field.

Each of the fields can be positioned anywhere within the screen layout, which has a limit of 19 lines by 80 columns. A maximum of 70 fields may be defined within this space. A field is specified in the screen layout by a tilde ('~'), a field type character, a field name and enough trailing tildes to fill out the desired field length.

Each line following the .make command is taken to define a line of the screen layout until a .end is reached. If a mistake is made on any of the input lines, the .make will fail. The .make information may be prepared in advance as a text file (this facilitates fixing mistakes) and the .input command can be used to read in this file. An example text file for a data base screen layout follows, with some explanatory notes and restrictions.

```
.make
Hydrology Vector Database

Record #:  `sSegnum'  Feature Name:  `tName'
Vector type:  `vVtype'  Reference Map:  `nRefMap'
North:  `yNorth'  East:  `xEast'

Updated:  `tUpdate_Date'

Comments:
  `tComments.1'
  `tComments.2'
  `tComments.3'

.end
```

Notes:
1) Any text not preceded by a tilde (~) character is taken to be part of the constant or fixed text portion of the form.
2) A field definition begins with a tilde (~) character immediately followed by a single character that indicates the data type of the field (s,x,y,v,m,i,f or t). Immediately following the data type character is the field name of 1 to 16 characters. Field names can be composed of any characters from the following set: [A-Z,a-z,0-9]; the RIM program and library do not distinguish upper and lower case in field names, so you should avoid making names which differ only in case. Field names may not begin with a numeral [0-9]. The rest of the field length is padded with tilde (~) characters to the length desired.
3) The minimum field width is three characters; e.g., "tA". Be sure field widths for all fields are wide enough for the values and strings you expect to store there; e.g., UTM northings require at least 11 spaces.
4) For text fields it is possible to continue a field across more than one line. This is done by appending a .1 to the field name forming first portion of this "split field," a .2 for the second portion, etc. This text field splitting affects how information is organized for input and output; the composite
text string is concatenated (unused portions of fields are retained as spaces) and treated as a unit for storage and queries to the database.

 `.map (.m) [map_id map_name] | [-d map_id]`

Without arguments this command outputs a list of all the reference vector maps that are stored in the reference maps table. If a map number (map_id) and a vector map name (map_name) are given the vector map is found and added to the reference maps table in the database. If the map number (id_num) is already in that table an error is issued and no action is taken.

Finally, to delete a map from the reference maps table, use the `-d` option followed by the map number (map_id). The map information for the given map number will be displayed and the user will be asked to confirm the deletion with a `y`. Enter a `n` (for no) if you do not want to delete that reference map.

Remember, that if you delete a reference map for which there are still records in the database, you cannot make a new vector map (using the .vector_map command) that includes those records unless you put that number and vector map name back in the reference map table.

`.output (.o) [file or | process]`

Causes all output (except some error messages) from `v.db.rim`, including that from the `print` command, to go to the named path/file (may be a full or relative path name), or to be used as standard input by the process (a pipe). If no parameter is given, output returns to stdout, usually the user's terminal. An example of the pipe usage would be

```
$output | grep "casting" | wc -l >/tmp/my_count
```

A pipe is closed whenever the .output command is given again, or on a .exit command.

`.pack (.pa)`

This should be used when numerous data records have been deleted or changed to recover disk space in the RIM binary database files. It works by doing a .backup to a temporary file, moving the database files to new names (.bakdb.s); running RIM to rebuild the database and, if the rebuilt database can be opened and read, the temporary files are deleted. The user is informed if this process fails. Packing can only be done on an open database located in the user's current mapset.

`.print (.p) [-a | -l]`

This command outputs the full record for the records currently stored on the internal query list (result of last .query or .find). Without the flag, the screen layout format is used. With the `-l` flag, list format, the field name followed by the contents are output one field per line. The `-a` flag also outputs the list format but with a `add line and a `end line surrounding each record printed; data files in this form can be read with .input, thus they form one kind of backup mechanism and can be used to transfer data (not the database layout) from one GRASS system to another. The destination for the output is set by a previous .output command (default is stdout).

`.query (.q) [-m | -w] [-a | -d]`

The .query command is used to retrieve records via an SQL-like request to RIM, including a user specified "where clause." All fields for each record meeting the selection criteria are retrieved.

The optional .query command line parameters cause records whose representative points are not in the region (-w) and/or mask (-m) to be rejected, so these conditions need not be tested in the "where clause." See .find for a full explanation of the command line options.

After the .query command line, any number of lines (each no more than 80 characters) may be entered to define the SQL "where" clause. A `end line is required to finish the request and
begin data retrieval. See examples below.

The "distance from" clause may also be used as an additional selection criteria exactly as described in the examples and notes for .find. It must be entered as a separate line to the query prompt.

The retrieved records may be printed at time of retrieval, rather than after the completion of the query command by including a .print (.p) line with the same options for print format as in the .print command (see above); e.g., .p-a to output in the "list add" format. The .print clause must be entered as a separate line to the query prompt. This feature is most useful when working with very large data bases where retrieval time is significant. See example 2 below.

Example 1

```
query>where density <20 and (date = "10/14/89"
query> or county eq "San Marcos")
query>.end
```

Example 2

```
query>where east <600000 and name like "*Jones*"
query>distance from record 12 3000
query>.print -a
query>.end
```

Example 3

```
query>.end
```

The where and distance from clauses are each optional. If both are omitted, only the mask and region on the .query command line restrict the search; if mask and region are also omitted, all records will be retrieved (Example 3). When querying for records the where clause is processed first, the current region and mask tested (if requested), then the distance from clause is applied; a record must pass all tests to be put on the internal query list (or appended or deleted) for output by other commands.

Notes: (Also see Notes for .find)

1. The retrieved records are stored on the internal query list in the order returned from the data base by RIM, not necessarily in sequence number order or the order the data was loaded. A "distance from" clause results in a final sorting by proximity to the target.

2. See the RIM User's Manual and the s.db.rim manual page for additional information on the "where clause" in the "select" command, especially the quotes required for matching character string (text) fields, and the allowed comparison operators. (These are also described in section two of this manual entry.)

3. In the example where clauses above, "density", "date", "county", "east", and "name" are field names (column names in RIM) defined when the user initially makes the data base.

4. Each .query or .find resets the internal query list, unless the append or delete options are used. In no case is a record allowed to be duplicated on the query list.
.read_vec (re) vector_map_name [attribute_field [text_field]]

This command will read an existing GRASS vector map and create a data base record for each labelled area, line, and point. The sequence number field will automatically be generated starting from one greater than the highest current number in the data base. If the optional attribute_field is provided it must be an integer field and it will be filled with the area, line, or point attribute label. If the optional text_field is provided and a category description file (a dig_cats file) exists for the vector map, the category descriptions will be copied into the given text field.

Once the records have been loaded by .read_vec, use .change to add data to other fields for those records.

Note: Only labeled areas, lines and points are imported from the vector map.

.remove

This command, which requires a "y" as confirmation on the next line, entirely removes the three binary files which constitute your RIM data base. Use with care. Backup files must be removed individually by the user, if desired.

.show (.sh)

This command is used to output the screen or page layout as defined for the current data base. It serves as documentation of the data base definition and as a reminder for field names, types and lengths. By using an editor to surround the output of .show with .make and .end lines, it can be used to reload the data base definition with .input.

.site_list (.si) file_name [field_name]

This command writes the location coordinates (representative point) and a comment to the specified file in the site_list directory in the current mapset for each record currently selected. If the site file exists, the sites are appended to the current list, otherwise, a new site list file is created. A "field name" may be optionally specified; if so, the contents of that field (retrieved from the appropriate site record) are inserted as the comment (following a '#') in the site list; the record number is used if no field name is given. Such site lists may be used as input to s.db.rim.

A comment line is inserted in the site_list file with the current date and time and the name of the data base producing the site locations. The format used for each site is:

  easting | northing | #number or comment

.tables (.t)

Prints the table structure of the currently opened RIM data base. This is the same output generated by a "list *" command when running RIM manually. The information for the table named "data" is useful for review of the user's field definitions, and the table named "Reference maps" contains the reference map information. The information in the two other tables is for internal use by v.db.rim.

.vector_map (.v) file_name [attribute_field [text_field]]

This command creates a new binary vector map by copying the vectors associated with each record on the query list from the reference vector maps into the new vector map.

If the optional attribute_field parameter is provided, the areas and lines in the new vector map will be labeled from the given integer (i, m, or s type) field value for each record. You may supply a fixed integer value (such as 1, 908, 7, etc.) instead of a field name; each line written to the new map will be given this constant attribute label.
If the optional text_field is provided, it will be used to build a category description file (dig_cats file) for the vector map. Instead of a field name, a constant text string of up to 100 characters may be given, if enclosed in single or double quotes; this string is used as the category description for each line written to the new vector file.

The header of the new binary vector file will contain the current date and indicate that v.db.rim was used to create the vector map.

The topology information (the dig_plus file) is not automatically built for the new vector map and the user must run support.vect to do so before v.digit can be used to edit the vector map or some other programs can be used. The vector map can immediately be displayed, from within v.db.rim by issuing the following command (assuming you have a graphics monitor selected):

!d.vect file_name c=color
SECTION TWO -- THE INTERACTIVE VERSION

SYNOPSIS

v.db.rim

DESCRIPTION

When run interactively, v.db.rim allows you to create, manage and query information about vectors across the landscape on a data base through the series of menus (VASK screens) explained below.

THE MAIN MENU

Below is the main menu. Option 1 is the default. Note the status line at the top of the menu, and the fact that 8 records have been selected by the last find or query operation (between items 2 and 3). Note, also, that CTRL-C can be used to exit from this menu (and most other menus in the program) back to the GRASS prompt. The specifics of each menu choice are described below. Except for 6, and mouse options in 3 and 4, each choice has a direct counterpart in the command version.

v.db.rim

MAIN MENU

Version 1.4

Data base <rivers > in mapset <kitchen> open. 325 records.

1. Open a data base
2. List available vector data bases
------- Retrieve/Output Site Records (8 currently) --
3. Find records in proximity to a Target point
4. Query to select records (SQL)
5. Show selected records on Terminal
6. Display maps/selected vectors on graphics terminal
7. Output selected records to Printer or File
8. Create vector/site maps from selected records
------- Add/Edit Site Records -------
9. View a single record
10. Add a record
11. Change a record
12. Delete a single record or all selected records
    Other functions -- Shell Command -- Exit -------
13. Make a new data base & Management Functions
14. Execute a shell command
0. Done -- Exit from v.db.rim
AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO EXIT THIS PROGRAM)

1. Open a data base. If a data base is already open, it is closed before the requested one is opened. Only data bases in the user's current mapset may be modified; others are opened in read-only mode; this will be indicated on line 2 of the menu.

2. List available data bases. For each mapset in the current GRASS mapset search path, the names of the existing vector data bases are listed.

3. "Find" records in the data base relative to a specified target location. This is used to select records based on proximity to the target and, optionally, records within the current region and, optionally, records falling in active cells within the current GRASS mask. The label point coordinates are used for these spatial tests. Two modes of targeting are provided: the N records closest to the target, and all records within (or outside) a circle of specified radius from the target. The FIND/QUERY TARGET MENU discussed below accepts region/mask/target specifications from the user. The selected records are then displayed one at a time until CTRL-C is entered; then other operations, choices 5-8 can be done with these records. The line on the menu between 2 and 3 shows the number of records currently selected by choices 3 or 4.
4. "Query" records in the database using an SQL-like "where clause," including specifications for region/mask/target (circle only) as in 3, above; see FIND/QUERY TARGET MENU section below. The where clause can test for ranges or matches for numeric database fields, or matches on full strings or substrings for text fields. The selected records are then displayed one at a time until CTRL-C is entered; then other operations, choices 5-8, can be done with these records. This clause is entered on a QUERY COMMAND MENU described below.

The where clause may use parentheses () to control the order of comparisons. Field names are not case sensitive within where clauses. The following comparison operators are valid for all types of fields:

- eq or =
- ne or <>
- ge or >=
- le or <=
- gt or >
- lt or <

String comparisons are case sensitive and are done character by character. Substrings comparisons may be done with the "like" operator as in:

where name like "*Jones*"

Note that the string being tested against the name field for each record is in quotes (single or double) and that wild card comparisons can be done in the standard way with '
' and '?' characters.

Logical comparisons may also be combined with those operators above. The permitted logical operators are:

- and
- or
- not

The following complex example should be examined. The line breaks can occur between any tokens (words, values, operators), except within quoted strings.

where (name like "*Jones*" or name = "Smith")
and ( ( site < 300 and not (site = 251 or site eq 15) )
or east < 601000 )

5. This choice will display the records resulting from the last find/query one at a time on the terminal. Use ESC or enter a number to display another record and CTRL-C to end the display.

6. If a graphics monitor is active, the selected vectors will be displayed. The user may choose to erase the screen; display raster, vector, and/or site maps; and/or display the selected vectors from the database; these maps are requested through the following interactive screen. Just enter ESC to skip this step. If no database vectors are currently selected, that section of the menu will not appear; but the menu can still be used to display the other types of maps.
SELECTION MENU FOR ITEMS TO DISPLAY

Enter raster and/or vector map names, if desired

________ Raster file to display

________ Vector file to display in color: ________

________ Site list to display

Points with: size=3, type=box, color=white

Display currently selected vectors (enter x)

Display red

Erase graphics screen (enter x)

Erase black

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

7. This selection results in a screen prompting for the name of the file to output the selected records to, and for optional formatting selection. If the file name is lp, the site records are sent to the printer. The optional formatting choices are for export of data in list and add formats; see the .print description in section one of this manual page for information and examples.

8. Using this choice you can create a new GRASS vector map consisting of the vectors for the currently selected records, and/or a site list consisting of the representative points (label points) for the currently selected records, in your current mapset. A short menu prompts for the map names and other information.

If a vector map name is given you can choose an integer field (i, s, or m types), or a fixed value, to write as the label value for each vector in the dig_att file for the new map. You may also specify a field name (any type), or a fixed text string in single or double quotes, to write as the category description in the dig_cats file for the new map.

If you give a site list name, you can specify the name of a field (or fixed text string in quotes) to be used for the "#comment" in the site list (the record number is the default field). The current date and time, and the names of the mapset and data base in use are entered as an information line in the site_list file. Note that you can create a new site list or append to an existing site list, or both.

A variety of raster maps can be produced from a v.db.rim data base by creating new vector files, then using the v.to.rast program, and by writing site_lists with different fields as "comments," then converting the site_lists to raster maps with s.menu.

9. Choices 9-12 operate on only a single record and do not use or modify the internal list of records selected by find/query (choices 3 or 4). Choice 9 is the way to view a single record, selected by record number. After viewing, FSC will allow entry of another record number and CTRL-C will exit to the main menu.

10. Use this selection to add a new record to the data base. (A new record is one whose number does not currently exist in the open data base.) After making this selection, the data base layout will be
displayed and you should enter the available information appropriate to each field; the only required entry is the site (record) number field. If values for numeric fields are not entered, zero values will be stored. Unused portions of text fields are stored as strings of spaces.

11. After making this selection and specifying the record number to change field information for, the data is entered as for choice 10, except that the record number cannot be changed. (The command version of the program has provision for making bulk changes after a find or query; see .change.)

12. To delete a single record, enter its number when requested. All records chosen by the last find/query operation may be deleted by entering "list" in place of the record number. BE CAREFUL with this, deleted records are really gone.

13. This choice starts a new menu with less commonly used functions. See MANAGEMENT MENU section below.

14. The program will prompt you for one-line Shell Commands until you enter just a <RETURN> to return to the main menu.

FINDQUERY TARGET MENU

This is the screen to set up the region/mask/target information for the find choice (3) and the query choice (4), except that item B is omitted for choice (4). If a graphics monitor is not active, the "mouse" item is omitted from the menu; and, if a mask is not currently set, that line is omitted.

The choice to append or delete the selected records will only be given after a successful find or query has stored some records on the internal record list. When appending records, duplicates of those previously selected will be discarded—they will not be stored a second time. If neither append nor delete is selected, the find or query will begin a new internal record list and the previous contents will be lost.

The choices entered on this example screen will result in all the records within a 1500 (meters) radius of the target point (to be chosen with the mouse) being selected and stored on the internal record list by find or query. They are sorted and stored in order of proximity to the target. If a specific record is used as the target, it's representative point (label point) is the target coordinates, and it is always placed first in the retrieved list. If a mouse is chosen to select the target point, a menu to display reference maps is presented, exactly as in choice (6), prior to actually activating the mouse.
QUERY/FIND: REGION/MASK/TARGET SELECTION MENU
Data base <arch> (READONLY) in mapset <PERMANENT> open. 25 records.

Mark requests with 'x' and enter required values.

Respect current region  x
Respect current MASK  x
(forces current region)

A. Find all sites within (or outside) a circular target x
   and give the radius (negative for outside)  1500.00_____
   OR
B. Find a number of sites nearest a point
   and the number of sites requested __________

After selecting A or B, complete one(!) of these:
1. x to select target point with mouse  x
2. Enter site number for target point _________
3. Target coordinates  
   east  0.00_____
   north  0.00_____

Append(a) or Delete(d) to the current FIND/QUERY list _
Reset to default choices for this menu _

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

QUERY COMMAND MENU
The following screen completes the information for a query (choice 4). It may be left blank if n;
"where clause" is required. After a successful query, the selected records are displayed one at a time
by hitting ESC; CTRL-C will quit the display and return to the main menu where several choices of
operation on the retrieved sites are offered. The SQL "sort by" clause may also be used after the where
clause to control the order selected records are presented; however, if option A or B in the TARGET
MENU has been selected it causes sorting by proximity to the target location which will override the
order produced by the "sort by" clause.
QUERY COMMAND CONSTRUCTION SCREEN
Data base <wells> in mapset <grant> open. 25 records.
The SQL select query will use the current region
and a target clause of 'distance from 596463.15 4919041.88'

where date = 10/16/89 and ppm_Cr gt 10

(Enter .show on a line to review screen layout and field names.)

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

MANAGEMENT MENU
Choice 13 from the main menu presents this menu. Each item is discussed below.

1. Make a New Data Base in Current Mapset
2. List Available Data Bases
3. Remove (PERMANENTLY) Data Base from Current Mapset
4. Recover a Data Base from a RIM ASCII File
5. Show Screen Layout of Current Data Base
6. Backup (UNLOAD) Data Base to RIM ASCII Format File
7. Pack the Current Data Base
8. Read a vector map into the Current Data Base
9. Execute a Bourne Shell Command Line

0. Return to Main Menu

AFTER COMPLETING ALL ANSWERS, HIT <ESC> TO CONTINUE
(OR <Ctrl-C> TO CANCEL)

1. Use this choice to create a new data base in the current GRASS mapset. See section below on MAKE A NEW DATA BASE.

2. List available data bases. Like option 2 on Main Menu.

3. Delete an entire data base from the current mapset. The name of the data base and additional confirmation of the action are prompted for. Be careful!
4. Choice 6 allows backup of the definition and data parts of a data base to a transportable text file. To re-aid (or build for the first time) a *v.db.rim* data base from one of these text files do the following steps:

```bash
# see if the rim directory exists.
ls $LOCATION/rim/Vect
# if the directory was not found, make it.
mkdir $LOCATION/rim
mkdir $LOCATION/rim/Vect
# change directory to it.
cd $LOCATION/rim/Vect
# have rim build and load the binary data base files.
rim
RIM> input '/path/to/your/textfile'
RIM> exit
```

The data base is thus created in the current mapset. Several *v.db.rim* commands should be run to verify the integrity of the newly created data base.

5. This merely shows the screen layout of the currently open data base. It is a useful way to quickly see the layout and review the field names and types.

6. When backing up to a text file, the RIM UNLOAD command is run with the output directed to a file of the user's choice. See 4 above. It is wise to do this operation after extensive changes or additions of data records. The resulting text file can be written to tape for preservation, or shared with other GRASS systems, if desired. Data bases may also be backed up by copying the three binary files that comprise the data base to a different directory with the UNIX cp command.

7. After deleting and adding a large number of site records, some "wasted" disk space will be present in the binary data base files. This procedure will perform an unload and a reload automatically to recover this unusable disk space. If there is any problem reopening the data base after packing, the user is notified and can recover in various ways depending on the backups which have been done.

8. Data (records) may be loaded into a data base from an existing GRASS vector map. This procedure will prompt for the vector map name and then add a record to the currently open data base for each labeled(?) line in the vector field. The user may also enter the name of an integer field in which to store the label (from the dig_att file) for each vector, and a text field in which to store the descriptive text from the dig_cats file for each vector. The record number, vector type, map number and location coordinate fields (*s,v,m,x* and *y* types) are automatically loaded for each site record by this procedure; other fields may be later edited with the "change" function.

9. This choice is the same as choice 14 on the main menu.

**MAKE A NEW DATA BASE**

After entering the name of the new data base you wish to create (7 characters maximum), you then decide how to input the information required. This input may be from a text file, or may be entered directly using the editor of your choice: the former is recommended. See discussion in make in section one.
v.db.rim interfaces to the RIM program. Both rim and v.db.rim contain FORTRAN code. The user must have access to a FORTRAN compiler in order to compile and use v.db.rim. See the FILES section, below, for location of source code for RIM and b.rim.

A "date" type field should be added to future versions. This version only allows storing of dates as strings (unless the user codes them to integers), and thus only string type searches can be made for dates.

FILES
Source code for RIM is located under $GISBASE/./src.related/rim
Source code for v.db.rim is located under $GISBASE/./src.garden/grass/rim/v.db.rim

NAME
v.digit - A menu-driven, highly interactive map development program used for vector digitizing, editing, labeling and converting vector data to raster format.

SYNOPSIS
v.digit

DESCRIPTION
The GRASS program v.digit is a menu-driven, highly interactive map development program used for inputting analog map data into a GRASS vector format. v.digit contains programs for vector digitizing, editing, labeling, windowing, and converting vector data to GRASS raster format.

v.digit consists of two parts: an initialization procedure, and a multiple menu-driven environment.
1) The initialization procedure involves choosing a digitizer, choosing the name of a vector map layer to digitize, and, if needed, registering a map to the digitizing surface.
2) The second part of v.digit is a multiple-menu environment in which digitizing, editing, labeling, and other options are available. It is within this second portion of v.digit that all vector creation occurs.

NOTES
v.digit was written to optimize digitizing speed and performance. It has a convenient graphic display format and very convenient windowing capabilities. Features are color-coded for ease of identification and verification. Different color schemes may be user-chosen to customize a digitizing session.

Area, line, and point features may be digitized in both "stream" and "point" modes. Both a mouse and a digitizer may be used to perform windowing functions. Labeling and editing are done from within v.digit, rather than through a separate set of programs.

v.digit has capabilities that allow users to convert vector map layers to GRASS raster format, to overlay already existing vector map layers onto the feature being digitized, and set a multitude of parameters to customize a digitizing session.

v.digit may be used with or without a digitizer. Many options are available if no digitizer is used.

All options available within v.digit are contained within 10 menus. Movement from menu to menu is done by choosing the movement options specified at the bottom of each menu.

NAME

v.import - Converts ASCII Digital Line Graph (DLG) files, binary DLG files, and ASCII vector files into binary vector files and creates the needed vector support files.

(GRASS Vector Program)

SYNOPSIS

v.import

DESCRIPTION

v.import is an interactive program which runs other vector import programs. It allows you to import DLG or ASCII vector files into GRASS vector format. It also runs v.support. No arguments are required on the command line.

This program performs all of the processes that are needed to convert ASCII Digital Line Graph (DLG) files, binary DLG files, and ASCII vector files into binary vector files. It also creates two support files, the dig_plus file and the dig_att file (only created when importing DLG files). The dig_plus file contains topological information obtained by analyzing the vector file. The dig_att file contains category (attribute) information files by the labeling function of the GRASS v.digit program. All of the above files must be run through v.import before they can be used in the v.digit program of GRASS 4.0.

IMPORT FILES

After entering the command v.import, the user will be asked for the type of file that is to be imported and for which support files will be created:

Import to GRASS Vector Format and Create Needed Support Files

1 - ASCII DLG file to GRASS Vector Format
2 - Binary DLG file to GRASS Vector Format
3 - ASCII VECTOR file to GRASS Vector Format
4 - Binary VECTOR file to GRASS Vector Format

If numbers 1-3 are chosen, v.import will respond with the current data base units (in feet or meters), and ask if the new vector file is in the correct units for the data base location. If the new vector file is not in the correct units, v.import will not allow it to be placed in the current data base location. For each data base location, all map layers should have the same units. If, for some reason, a map layer uses different units than the rest of the map layers in the same data base location, a new data base location will have to be created for it.

ASCII DLG File to GRASS Vector Format:

Converts an ASCII DLG file (such as those created in GRASS 2.0) to a GRASS vector file and creates the dig_plus and dig_att support files. The user is asked two questions:

1. Determine if this map is composed of Area or Line information. Do you want to give precedence to Areas (opposed to Lines)? (y/n) [y]

NOTE: Some machine-processed DLG files do not make the distinction between lines and area edges. For example, in a roads map, where the desired information is line data, a downtown block surrounded by roads may be processed as an area. Because of this, the user is asked to choose whether to give precedence to areas or lines. If precedence is given to lines, the user should be aware that any lines that bound unlabeled areas in the DLG file will be stored as line data. Any unlabeled areas would therefore be lost (this is only a concern when areas are unlabeled, labeled area information will be retained). If precedence is given to areas, lines will be stored as boundaries to areas that are unlabeled.
2. During the building of the Vector format:
   Do you want to snap nodes to other nodes within a threshold (y/n) [n]

   **NOTE:** BE CAREFUL! This threshold is calculated using the scale of the original DLG or dig file. If the threshold is too high, excessive snapping may occur, destroying the file. In general, users seldom need to snap nodes. If snapping of nodes is desired, the user may want to run v.support separately. v.support allows the user to set the snapping threshold.

   This process is done in three phases:
   1. The ASCII DLG file is converted to a binary DLG file.
   2. The binary DLG file is converted to a binary Vector file, and the dig.att support file containing attribute (category) information is created.
   3. The dig.plus support file is created by analyzing the vector file for topological information.

**Binary DLG File to GRASS Vector Format:**

Converts binary DLG files (such as those created in GRASS 2.0) to a vector file and creates the dig.plus and dig.att support files. The user is asked whether precedence should be given to Areas or Lines and if nodes should be snapped to other nodes within a calculated threshold.

   This process is done in two phases:
   1. The binary dig file is converted to a binary vector file, and the dig.att vector support file containing attribute information is created.
   2. The dig.plus vector support file is created by analyzing the vector file for topological information.

**ASCII Vector file to GRASS Vector Format:**

Converts ASCII vector files (such as those created in GRASS 2.0) into GRASS binary vector files, and creates the dig.plus vector support file. Since a vector maintains the distinction between lines and area edges, the user is not asked to give precedence to either. However, the user will be asked if snapping from nodes to other nodes within a calculated threshold is desired.

   This process is done in two phases:
   1. The ASCII vector file is converted to a binary vector file, and the dig.plus vector support file is created.
   2. The dig.plus vector support file is created by analyzing the vector file for topological information.

**Binary Vector file to GRASS Vector Format:**

Creates the dig.plus vector support file.

   This process is done in one phase:
   1. The dig.plus vector support file is created by analyzing the vector file for topological information.

NAME
v.in.arc - Converts data in ARC/INFO format to GRASS's vector format, and stores output in the user's current GRASS mapset.

(Grass Vector Data Import Program)

SYNOPSIS
v.in.arc
v.in.arc help
v.in.arc [-n] type==name lines_in==name [points_in==name] [text_in==name]
vector_out==name [idcol==value] [cateol==value] [attcol==value]

DESCRIPTION
The user may wish to use GRASS programs on data files that were created by other GISs. To do this, the user must first convert data files in these systems' formats to GRASS's file format. Bringing data from other systems into GRASS is termed file import. Sending GRASS data files out into other systems' formats is termed file export.

A variety of GRASS programs exist to import and export data to and from GRASS. The v.in.arc program will convert vector data in ARC/INFO's "Generate" format to GRASS's vector file format, and bring it into the user's current GRASS mapset. The files to be imported to GRASS must first have been exported from ARC/INFO using the ARC/INFO Ungenerate command, and may represent either linear features ("line coverage") or areal features ("polygon coverage"). The ARC/INFO User's Guide describes how files containing linear and polygonal features can be exported from ARC/INFO, in a section detailing the use of the Ungenerate command.

Once converted with the ARC/INFO Ungenerate command, the files to be imported into GRASS must be placed in a directory named arc in the user's current mapset. If the arc directory does not exist, it must be created (e.g., with the command mkdir $LOCATION/arc) before copying the ARC/INFO files to be converted into it.

(v.in.arc can be used to convert ARC/INFO data from other mapsets as well, since the program searches for the specified input file names in the arc directories, if any exist, in the mapsets in the user's current mapset search path.)

OPTIONS
Program parameters and the flag have the following meanings.

Flag:
- n Neatline. Vectors representing a box (neatline) around the input vector data will be inserted into the output GRASS vector file.

Parameters:
type==name Coverage type. Either polygon, or line.
Options: polygon, line
lines_in==name ARC/INFO ungenerate lines file; ungenerate format input file containing line or polygon coordinates.
points_in==name ARC/INFO ungenerate label-points file; ungenerate format input file containing label-point coordinates; only applies to 'polygon' type data.
text_in==name ARC/INFO ungenerate label-text file; ungenerate format input file containing category numbers and (optionally) attribute text.
vector_out==name Resultant GRASS vector output file.
idcol==value ID Number column in label-text file. Number of label-text column containing line-ID numbers.
catcol=value GRASS category column in label-text file. Number of label-text column containing category values.

attcol=value GRASS attribute column in label-text file. Number of label-text column containing attribute text.

This program can be run either non-interactively or interactively. The program will run non-interactively if the user specifies the (optional) flag setting and needed parameter values on the command line, using the form:

```
v.in.arc [-ni] type=name lines_in=name [points_in=name] [text_in=name]
vector_out=name [idcol=value] [catcol=value] [attcol=value]
```

Alternately, the user can type:

```
v.in.arc
```

on the command line without program arguments; in this case, the program will prompt the user for the flag setting and parameter values in the manner shown below.

In ARCGIS, three files are used to store polygon data:
1) a lines file, which contains coordinates of all the area edge lines;
2) a label-point file, which contains coordinates of label-points (each of which has associated with it a unique label-point ID number). One label-point is associated with each polygon defined in the lines file;
3) a label-text file, which associates each label-point ID number with a category number and category ("attribute") text.

Linear feature data are stored in two files:
1) a lines file, which contains geographic coordinates defining lines, each with a line-ID number; and
2) a label-text file, which associates each line-ID number with a category number and attribute text.

These data files are described in further detail below, under the DATA FILE FORMATS section.

**INTERACTIVE MODE**

The program will prompt the user for the flag setting and parameter values if the user does not specify these on the command line. First, the user will be asked to assign a name to the vector file to store program output:

```
VECTOR (DIGIT) FILENAME
Enter 'list' for a list of existing binary vector files
Hit RETURN to cancel request
> 
```

Next, the user is asked to specify the COVERAGE (feature) type to be imported into GRASS. Valid coverage types are **polygon** and **line**.

```
COVERAGE TYPE
Enter "polygon" or "line"
Hit RETURN to cancel request
> 
```

**IMPORTING A POLYGON COVERAGE**

If the user chooses POLYGON coverage, he is asked if he wishes a neatline placed around his data. (The existence of neatlines in the output file can facilitate subsequent patching of data files.)
NEATLINE
Do you want a neatline?
Enter "yes" or "no"
>
If the user types yes, vectors that box the data will be inserted into the GRASS vector output file (vector_out); otherwise, no neatline will be inserted into the output file.

Next, the user is prompted for the name of an existing lines file containing the geographic coordinates of the arcs forming polygon perimeters. The lines-file is created with the ARC/INFO Ungenerate LINES option, and is in the same format at the prefix.pol file created by the v.out.arc program. The user sees the following prompt:

LINES FILENAME:
Enter name of the file created with the LINES option of the ARC/INFO Ungenerate command.
Hit RETURN to cancel request
>

The next prompt for coverage type "polygon" asks for the name of an existing label-points file. The label-points file is created with the Ungenerate POINTS option, and is in the same format as the prefix.lab file created by the v.out.arc program. The user sees the following prompt:

LABEL-POINTS FILENAME:
Enter name of file created with the POINTS option of the ARC/INFO Ungenerate command.
Hit RETURN if there is no such file
>

Finally, the program asks the user for the name of an existing label-text file. This file associates each label-point ID number with a text string. It is in the same format as the prefix.txt file created by the v.out.arc program.

LABEL-TEXT FILENAME:
Enter the name of a file that associates label-point ID numbers with text label strings
Hit RETURN if there is no such file
>

v.in.arc then scans the label-text file to find the numbers of lines and columns, the column headers (if any), and the first three lines of actual data in the file. It displays this information to standard output to help the user determine which columns will hold the ID, Category value, and Attribute text data in the new vector output file. A sample of the program’s output is shown below:

The LABEL-TEXT file has been scanned. There are 132 lines in the file and 8 columns in the file

Column headers of the LABEL-TEXT file:
rec# AREA PERIMETER SOILS# SOILS-ID SOIL-CODE DRAIN-CODE TXTUR-CODE

Here are the first three lines:
1 -2.30228E+07 19,399.848 1 0 0 0 0
2 81,079.875 1,678.826 2 1 15 3 3
3 955,952.500 10,229.637 3 2 19 8 8
The column of category values must contain only integer values. The attribute text column can contain a floating point number, an integer, or a word (text string).

Finally, the user is prompted to enter line ID, category value, and attribute text column numbers.

Enter the number of the column that should be used for line IDs (probably the column with -ID):

Enter the number of the column that is to be used for GRASS category values:

Enter the number of the column that should be used for GRASS attribute text:

Once these column numbers have been entered, `v.in.arc` will begin converting the ARC/INFO "Generate" format files into GRASS vector file format.

IMPORTING A LINE COVERAGE

The user will also be prompted for input when importing ARC/INFO files containing linear features ("line coverage") data. Like polygon data, linear feature are constructed by the series of arcs (aka, vectors) defining their perimeters. If the user selects LINE coverage, the prompts seen by the user will be different in two respects from those for POLYGON coverage. First, the user will not be asked whether or not a neatline is desired; and second, no label-points file name will be requested. In other respects, the treatment of LINE coverage is identical to that for POLYGON coverage.

The user is prompted for the name of the lines-file containing the geographic coordinates of these arcs. The lines-file must first have been created with the ARC/INFO `Ungenerate LINES` option, and is in the same format as the `prefix.lin` file created by the GRASS `v.out.arc` program.

DATA FILE FORMATS

Following are examples of the data files discussed above.

LINE: FILE, also known as `prefix.lin` or `prefix.pol` file.
This type of file can be created in ARC/INFO by using the `lines` subcommand of the `Ungenerate` command. Each line (aka, arc) is defined by a line-ID number, followed by a list of at least two easting and northing coordinate pairs, followed by a line with the word "END". The file is terminated with the word "END".

The line-ID number is important only for line coverage data. For a line coverage, the line-ID number is the number that associates each line with its attribute data.

```
3
711916.00000 4651803.00000
711351.87500 4651786.00000
END
```

```

709562.50000 4651731.00000
709617.25000 4651624.00000
709617.25000 4651567.00000
709585.00000 4651503.00000
```
### LABEL-POINTS FILE

Also known as `prefix.lab` file.

This type of file can be created in ARC/INFO using the `Points` option of the `Ungenerate` command.

The first number on each line is a label-point ID number, and the following two numbers are (respectively) the easting and northing coordinate pair representing the geographic location of the label-point.

<table>
<thead>
<tr>
<th>ID</th>
<th>Easting</th>
<th>Northing</th>
<th>Label-Point ID</th>

</tr>
</tbody>
</table>

**NOTES**

ARC/INFO data can be imported even if a label-points and/or a label-text file are missing; however, the lines and/or areas imported will not be labeled.

`v.in.arc` can handle label-text files both with and without header lines.
This program remains under alpha testing. It resides in the src.alpha directory and must be compiled separately by the user.

NAME

v.in.ascii – Converts ASCII vector map layers into binary vector map layers.
(GRASS Vector Data Import Program)

SYNOPSIS

v.in.ascii
v.in.ascii help
v.in.ascii input=name output=name

DESCRIPTION

v.in.ascii converts a vector map in ASCII format to a vector map in binary format. The user can run
this program non-interactively by specifying all program options on the command line, in the form:

v.in.ascii input=name output=name

Parameters:
input = name Name of an ASCII vector file to be converted to binary vector file.
output = name Name given to binary vector output file.

If the user runs v.in.ascii without giving program arguments on the command line, the program will
prompt the user for input and output file names.

NOTES

After running this program, GRASS support files must be built for the binary output file before the user
can use the file in v.digit. The user can run v.support to create GRASS support files for the output
file.

The GRASS program v.out.ascii performs the function of v.in.ascii in reverse; i.e., it converts vector
files in binary format to ASCII format. These two companion programs are useful both for importing
and exporting vector files between GRASS and other software, and for transferring data between
machines.

The output from v.in.ascii will be placed into $LOCATION/dig.

NAME

v.in.dlg - Converts an ASCII or binary USGS DLG-3 (bdlg) file to a binary GRASS vector (dig) file.
(GRASS Vector Data Import Program)

SYNOPSIS

v.in.dlg
v.in.dlg help
v.in.dlg [-blj input=name output=name]

DESCRIPTION

This program converts an ASCII or binary USGS DLG-3 (dlg or bdlg) file into a binary GRASS vector (dig) file.

v.in.dlg also creates a dig_att file containing the label information 'stripped' from the DLG-3 file. However, the user must run v.support (or v.import option 4) on the output file created by v.in.dlg to create a dig_plus file containing the file topology, before using the output file in v.digit.

The user can avoid this two-step process by converting the ASCII or binary DLG-3 file into binary GRASS vector format using option 1 or 2 of the GRASS program v.import.

Flags:

-b Input is a binary DLG-3 file (default is ASCII).
-l Give precedence to line information (default is area).

Parameters:

input =name Name of USGS DLG-3 Optional format input file.
output =name Name to be assigned to the binary GRASS vector files created.

If the user simply types v.in.dlg without specifying parameter values on the command line, the program will prompt the user to enter these.

NOTES

Area vs Line Precedence:

Some machine-processed DLG-3 files do not make the distinction between line edges and area edges. For example, in a roads map, where the desired information is line edge data, a downtown block surrounded by roads may be processed as an area. Because of this, the user is asked to choose whether to give precedence to areas or lines. If precedence is given to lines, the user should be aware that any lines that bound unlabeled areas in the DLG-3 file will be stored as line data. Any unlabeled areas would therefore be lost (this is only a concern when areas are unlabeled; labeled area information will be retained). If precedence is given to areas, lines will be stored as boundaries to areas that are unlabeled.

Building support files with v.support:

When you run v.support you will have the option of snapping the nodes in your vector file that fall within a certain threshold of one another. WARNING: the default threshold is calculated using the scale of the original DLG-3 file. If the threshold is too high, excessive snapping may occur, destroying the file!! With v.support, the user has the option of snapping or not snapping nodes, and further, of setting a particular snapping threshold.

NAME

v.in.dxf - Converts files in DXF format to ASCII or binary GRASS vector file format.
(GRASS Vector Data Import Program)

SYNOPSIS

v.in.dxf
v.in.dxf help
v.in.dxf [-a] dxf=name [lines=name[,name,...]] [labels=name[,name,...]] [prefix=name]

DESCRIPTION

The v.in.dxf data conversion program generates GRASS dig, dig.ascii, and dig.att files from a file in
DXF format. Each layer in the DXF input file is converted to a separate dig (or dig.ascii) layer. For
each DXF layer containing text, a dig.att file is also created. These output files are placed in the dig,
dig.ascii, and dig.att directories under the user's current GRASS mapset.

Output from this program is designed to be used as input to the program v.cadlabel.

The v.in.dxf program will only recognize points, lines, polylines, and text in the DXF format, and will translate these to GRASS vector format; other types of data are ignored.

Flag:

-a Output an ASCII GRASS vector (dig.ascii) file rather than a binary GRASS vector
(dig) file.

Parameters:

dxf=name Name of the DXF input design file to be converted to GRASS vector format.

lines=name[,name,...] or lines=in_name:out_name[,in_name:out_name,...]
Name(s) of layer(s) in the DXF input file containing line data, and (optionally) the
name(s) to be assigned to the GRASS vector data (dig or dig.ascii) files output.

Default: Convert each layer containing data in the dxf file to a GRASS vector data
(dig or dig.ascii) file.

labels=name[,name,...] or labels=in_name:out_name[,in_name:out_name,...]
Name(s) of layer(s) in the DXF input file containing text labels, and (optionally) the
name(s) to be assigned to the GRASS vector attribute (dig.att) files output.

Default: Convert each layer containing text labels in the dxf map to a GRASS vector
attribute (dig.att) file.

prefix=name Prefix assigned to the dig or dig.ascii and dig.att output file names.

The names of the GRASS vector (dig, dig.ascii, and dig.att) files output are constructed as prefix.extension, where prefix is the prefix name specified by the user and
extension is the number of the DXF layer from which the data were obtained. If the user does not specify a prefix name, the output files take their prefix from the
prefix of the input DXF map layer. For example, for the DXF file named streams.dxf containing line data on layer 15, the GRASS vector map layer output
would be named streams.15.

EXAMPLES

lines=15 Outputs line data in DXF layer 15.
lines=15,16 Outputs line data in DXF layers 15 and 16.
lines=ROADS,WATER Converts line data in DXF layers ROADS and WATER.
lines=15:16 Outputs line data in DXF layer 15, and places it in the dig (or dig.ascii) file
for DXF layer 16.
The examples below are given for a DXF design file named `cont.dxf` containing contour lines and contour line labels, in which:

- index contour lines are in DXF layer 9,
- intermediate contour lines are in DXF layer 11, and
- index labels and some intermediate contour lines are in DXF layer 12.

`v.in.dxf` can be run with default values, as shown below:

```
v.in.dxf dxf=cont.dxf
```

Here, this is equivalent to running the following command:

```
v.in.dxf dxf=cont.dxf lines=9,11,12 labels=12
```

Either of the above commands will produce three GRASS `dig` files (named `cont.9`, `cont.11`, and `cont.12`) and one `dig_att` file (named `cont.12`).

In our example, however, the `cont.12` file contains intermediate contour lines that the user would like to add to the `dig` file `cont.11`. Our user also wishes to use a different file prefix than the default prefix `cont`. The user therefore types the following command:

```
v.in.dxf dxf=cont.dxf lines=9,11,12:11 labels=12 prefix=contour
```

The above command will generate three `dig` files (named `contour.9`, `contour.11`, `contour.12`), and will create one `dig_att` file containing text labels (called `contour.12`). No contour lines will appear in the `dig_att` file.

**NOTES**

**Output Filenames:**
The output filename, `prefix.extension`, conforms with the GRASS limit of 14 characters. The entire prefix name is used, a '.' inserted, and as much of the extension name is used as the 14-character limit will permit. Excess characters are truncated. To minimize the possibility of creating output files with the same names (resulting in loss of data from the DXF file), use the prefix option to abbreviate the DXF file name. This leaves the majority of characters available for distinguishing layer names.

**Translation:**
This data translation program does not contain any of the quality control functions available in `v.digit` that will prevent data in an improper format from being input to a GRASS data base. If present, DXF entities are placed in output file(s) corresponding to the layers on which they occurred in the DXF design file input.

**Editing:**
If the user asks `v.in.dxf` to output ASCII vector (`dig_ascii`) files, they must be converted to binary vector format before they are usable by most GRASS vector commands. The user can convert GRASS vector files from ASCII to binary format by running such programs as `v.support` or `v.in.ascii`. After conversion to binary format the vector files can be displayed (e.g., with `d.vect`); however, the user must run `v.support` on the binary vector files before they can be edited in `v.digit`. The files output by `v.in.dxf` will preserve the data in whatever form they exist in the DXF file. This means that output files may contain unsnapped nodes, overshoots, gaps, and replicated lines. The data, and the file header information (including the owner's name, map's name, date, and scale, and UTM zone) for the GRASS vector files output may require editing by the user in `v.digit`.

**Attributes:**
The `v.in.dxf` program attaches attributes only to DXF text data that are converted to GRASS vector data (such as contour line labels). Attributes are not attached to converted DXF line data. For each layer of text data in the DXF design file, `v.in.dxf` generates a vector file consisting of rectangular boxes (lines) that are drawn around the DXF text data, and uses the text values to create a GRASS attribute file for the boxes. The vector and attribute files can then be used to label contour lines with the `v.cadlabel` program.

NAME
  \texttt{v.in.tiger} - Imports Census Bureau line data (TIGER files) to GRASS vector format.
  (\textit{GRASS Vector Data Import Program})

SYNOPSIS
  \texttt{v.in.tiger}
  \texttt{v.in.tiger help}
  \texttt{v.in.tiger dbname=\textit{name} in1file=\textit{name} in2file=\textit{name} zone=\textit{value}}

DESCRIPTION
  \texttt{v.in.tiger} imports Census line data (called TIGER) and creates a "master" binary vector file containing a large amount of data. Various map layers can then be created by querying information from the master vector file using \texttt{v.db.rim} or one of the \textit{Gen.} shell scripts listed in the SEE ALSO section, below. The database name (\textit{dbname}) given on the command line will be the name of the rim data base, and the master vector file in GRASS will be named "\textit{dbname}.Master". The master vector file will include all information from the type1 and type2 TIGER files given on the command line as \textit{in1file} and \textit{in2file}. If the user simply types \texttt{v.in.tiger} on the command line, all parameters will be queried using the standard GRASS parser described in the manual entry for \texttt{parser}.

COMMAND LINE OPTIONS
  Parameters:
  \begin{itemize}
    \item \texttt{dbname=\textit{name}} \hspace{1cm} Vector/rim data name (with a maximum of seven characters).
    \item \texttt{in1file=\textit{name}} \hspace{1cm} TIGER type1 input file name.
    \item \texttt{in2file=\textit{name}} \hspace{1cm} TIGER type2 input file name.
    \item \texttt{zone=\textit{value}} \hspace{1cm} Universal Transverse Mercator (UTM) zone in which these data are located.
  \end{itemize}
  Options: -60 - 60

NOTES
  TIGER data are presented in latitude/longitude format, and are converted to UTM coordinates as part of this importing routine. The spheroid used in the conversion is clark 66, as it is the most consistent with the original data.

  This command must be compiled separately, and requires the use of \texttt{rim} and \texttt{v.db.rim}, which contain FORTRAN code. The user must have access to a FORTRAN compiler in order to compile and use this command, since it calls both \texttt{rim} and \texttt{v.db.rim}. It resides under src.alpha.

  If the user does not know the UTM zone for this data input file, the command \texttt{mtiger.region} should be run first to determine the zone.

  \texttt{v.support} must be run separately on the output file if needed.

FILES
  Source code for RIM is located under $\texttt{GISBASE}/../src.related/rim
  Source code for \texttt{v.db.rim} is located under $\texttt{GISBASE}/../src.garden/grass.rim/v.db.rim
  Source code for \texttt{v.in.tiger} is located under $\texttt{GISBASE}/../src.garden/grass.tiger/v.in.tiger
  Source code for \texttt{mtiger.region} is located under $\texttt{GISBASE}/../src.garden/grass.tiger/mtiger.region

v.mkgrid - Creates a (binary) GRASS vector map of a user-defined grid.

(GRASS Vector Program)

SYNOPSIS
v.mkgrid
v.mkgrid help
v.mkgrid map=name grid=rows,columns coordinate=x,y box=length,width

DESCRIPTION
v.mkgrid will create a binary format, vector map representation of a regular coordinate grid.

Parameters:
map = name
Name to be assigned to binary vector map layer output.
grid = rows,columns
Number of ROWS and COLUMNS to appear in grid.
coordinate = x,y
Lower left EASTING and NORTING coordinates of vector map layer output.
box = length,width
LENGTH and WIDTH of boxes in grid.

If the user simply types v.mkgrid on the command line without specifying parameter values, the program will prompt the user for inputs using the standard interface described in the manual entry for parser.

NOTES
The new binary vector map output is placed under the dig directory in the user's current mapset, and can be used like any vector map layer. Run v.support to build the topology information for the vector map before using v.mkgrid map layer outputs in the v.digit program.

Since the grid is computer-generated, the corner coordinates will be exact and can be used when patching together several v.mkgrid grids.

This is NOT to be used to generate a vector map of USGS quadrangles, because USGS quads are no exact rectangles. To generate a vector map of USGS quads, use the program v.mkquads.

The program ignores the current GRASS geographic region settings. It will create the complete grid even if part of this grid falls outside the current geographic region.

NAME

v.mkquads - Creates a GRASS vector map layer and/or sites list and/or geographic region definition file for a USGS 7.5-minute quadrangle.

(GRASS Vector Program)

SYNOPSIS

v.mkquads
v.mkquads help
v.mkquads [-esrvil map=name

DESCRIPTION

There are three types of output available from the GRASS program v.mkquads:

1. a vector map of all the full USGS quadrangles that will fit within the boundaries of the current geographic region.

2. a GRASS sites list containing the corner coordinates of each of these quads.

3. GRASS geographic region definition files associated with each of the quads created.

A quad is defined as the area covered by a USGS 7.5-minute (1:24,000) map. This program is useful for managing a GRASS data base LOCATION, which contains a number of quads that are to be patched together.

Flags:

-e Encompass current geographic region with quads (rather than only creating those quads that lie inside of the geographic region). Use of this option will affect all output options.

-s Create a GRASS sites list file. The sites list will contain all the corner coordinates of all the full quads that can be built in the current geographic region. The sites list file can then be displayed using the dsites program.

-r Create region file(s): quad.1 quad.2 ... The program will generate a separate geographic region definition file for each quad; each of the geographic region files created will have the prefix quad. with some number attached to it. For example, if only one quad were created, the geographic region file quad.1 would also be created in the windows directory under the user's current mapset. To make the program-generated geographic region definition file quad.1 your current geographic region setting, run the GRASS g.region program.

-v Create vector file (default). Only full quads will be created. The binary vector map layer output is placed under the user's dig directory and can be used like any other vector map layer. Run vsupport to build the topology information for the vector map before using v.mkquads map layer outputs in the v-digit program. Since the quads are computer-generated, the corner coordinates will be exact. This simplifies digitizing if one or more quad sheets will have to be brought together for a data base, because all of the quad corner points to be joined will be guaranteed to match.

-x Create a GRASS registration (reg) file.

Parameter:

map=name The name of a file to contain program output.

If the user runs v.mkquads without including program parameter value and desired flags on the command line, the program will prompt the user for the above information using the standard GRASS interface described in the manual entry for parser.
NOTES
All output options can be used on the command line at the same time. A listing of all the quad points in latitude/longitude and UTM coordinates will be displayed each time the program is executed. The spheroid being used for the lat/lon to UTM conversions is clark66.

BUGS
Currently, this program only works for GRASS locations in a Universal Transverse Mercator (UTM) coordinate system (in meters). There are no guarantees that v.mkquads will function properly if a quadrangle crosses UTM zones. This program has not been tested outside the northwest UTM quadrant.

NAME

v.out.arc - Converts GRASS vector files to ARC/INFO's "Generate" file format.
(GRASS Vector Data Export Program)

SYNOPSIS

v.out.arc
v.out.arc help
v.out.arc type=name vect=name arc_prefix=name

DESCRIPTION

v.out.arc is a GRASS data export program that converts files in GRASS vector format to ARC/INFO's "Generate" file format. The companion program v.in.arc imports data in ARC/INFO's "Generate" format and converts them to GRASS vector format.

This program can be run either non-interactively or interactively. The program will be run non-interactively if the user specifies parameter values on the command line using the following format:

v.out.arc type=name vect=name arc_prefix=name

Alternately, the user can simply type:

v.out.arc

on the command line; in this case, the program will prompt the user for parameter values.

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type=name</td>
<td>Coverage (feature) type. Options: polygon, line</td>
</tr>
<tr>
<td>vect=name</td>
<td>The name of a GRASS vector file to be converted to ARC/INFO format.</td>
</tr>
<tr>
<td>arc_prefix=name</td>
<td>A prefix to be assigned to the ARC/INFO-format files output by v.out.arc.</td>
</tr>
</tbody>
</table>

INTERACTIVE MODE: USER PROMPTS

v.out.arc will prompt the user to enter the name of a GRASS vector file to be exported to ARC/INFO and for a filename prefix to be used in naming the files created by the program.

A GRASS vector file to be exported to ARC/INFO must either contain only linear features (i.e., have only line coverage) or contain only area edge features (i.e., have only polygon coverage). v.out.arc will begin by asking the user which type of coverage (line or polygon) is to be imported:

**COVERAGE TYPE**

Enter "polygon" or "line"
Hit RETURN to cancel request

>

The program then prompts the user for the name of the GRASS vector file to be converted to ARC/INFO format:

**VECTOR (DIGIT) FILENAME**

Enter 'list' for a list of existing binary vector files
Hit RETURN to cancel request
>

GRASS 4.0 (Summer 1991) U.S. Army CERL
Next, the user is asked for a file-name prefix to be used in naming the output ARC/INFO Generate format files:

```
ARC/INFO (GENERATE) FILENAME PREFIX
Hit RETURN to cancel request
> 
```

The filename prefix will be used to name the various files that will be created for export to ARC/INFO. When labeled polygon coverage data are exported, three such files will be created: a *lines file* with the suffix .lin, a *label-points file* with the suffix .lab, and a *label-text file* with the suffix .txt. When line coverage data are exported, two such files will be created: a *lines file* with the suffix .lin, and a *label-text file* with the suffix .txt. Export of unlabeled polygon or line coverage data will result in creation of a *lines file* (lin suffix) only. See the DATA FILE FORMATS section for more information on these files.

**EXAMPLE**

Linear features and polygon data are made up of the series of arcs (aka, vectors) outlining their perimeters. The *ARC/INFO Users' Guide*, in its discussion of the Ungenerate command, explains how line and polygon coverage data can be created from files (like prefix.lin and prefix.pol) containing the geographic coordinates of these arcs, and from files (like prefix.lab) containing the geographic coordinates of label-points. Below is an example that illustrates the creation, within ARC/INFO, of a polygon coverage data file (named *soils*) from the files *soils.pol* and *soils.lab*.

```
Arc: GENERATE SOILS
Generate: INPUT soils.pol
Generate: LINES
Generating lines ...
Generate: INPUT soils.lab
Generate: POINTS
Generating points ...
Generate: QUIT
Arc: _
```

The above example would create a polygon coverage data file named *soils* with label-points. The label-points would have ID numbers that correspond to the GRASS category values for the polygons in the coverage. The INFO portion of ARC/INFO can be used to associate these label-point ID numbers with descriptive text from the *soils.txt* file.

**DATA FILE FORMATS**

*lines file*, also know as *prefix.lin* or *prefix.pol* file:
This text file is a "Generate" format lines file. The *lines* option of the ARC/INFO Generate command can be used to read this file into ARC/INFO. Each line in the file has a unique line-ID number.

```

237862.53 187410.50
237862.53 203392.37
END

LABEL-POINTS FILE, also known as prefix.lab file:
This text file will be created by v.out.arc if the vector file being exported represents a polygon coverage. prefix.lab consists of a list of label-point (x,y) coordinates, each with a unique label-point ID number.

1 242777.81 211533.09
2 243458.37 199282.28
3 243458.37 195199.28

LABEL-TEXT FILE, also known as prefix.txt file:
In the case of polygon coverage data, this file associates an integer category value and a category label ("attribute") text string (containing no spaces) with each label-point ID number. In the case of line coverage data, this file associates an integer category value and an attribute text string with each line-ID number.

The first column is the row number (which is arbitrary), the second column contains the category value, the third column holds the line or label-point ID number, and the fourth column contains the attribute text string.

NAME
v.out.ascii - Converts a binary GRASS vector map layer into an ASCII GRASS vector map layer.
(GRASS Vector Data Export Program)

SYNOPSIS
v.out.ascii
v.out.ascii help
v.out.ascii input=name output=name

DESCRIPTION
v.out.ascii converts a GRASS vector map in binary format to a GRASS vector map in ASCII format.
The program can be run non-interactively if the user specifies all needed program arguments on the
command line, in the form

v.out.ascii input=name output=name

Parameters:
input=name Name of the binary GRASS vector input file to be converted to ASCII format.
output=name Name of the ASCII GRASS vector output file.

If the user runs v.out.ascii without giving the names of an input and output file on the command line,
the program will prompt the user for these names.

NOTES
The GRASS program v.in.ascii performs the function of v.out.ascii in reverse; i.e., it converts vector
files in ASCII format to their binary format. These two companion programs are useful both for
importing and exporting vector files between GRASS and other software, and for transferring data
between machines.

The output from v.out.ascii will be placed in the user's current mapset under the
$LOCATION/dig-ascii directory.

v.out.ascii does not copy the dig_cats file associated with the binary vector input map to the new output
file name. The user must copy the dig_cats file to the new output name if this is desired (e.g.,
using the UNIX cp command).

NAME

*v.out.dlg* - Converts binary GRASS vector data to binary DLG-3 Optional vector data format.

*(GRASS Vector Data Export Program)*

SYNOPSIS

v.out.dlg
v.out.dlg help
v.out.dlg input = name output = name

DESCRIPTION

The GRASS program *v.out.dlg* allows the user to convert GRASS vector data to DLG-3 Optional format, for export to other systems.

The user can run the program non-interactively by specifying all program arguments on the command line, in the form:

v.out.dlg input = name output = name

Parameters:

input = name Name of the binary GRASS vector data file to be converted to DLG-3 format.
output = name Name to be assigned to the DLG-3 Optional format output file created.

If the user does not give the names of an input and output file on the command line, the program will prompt the user to enter these names.

NOTES

The *v.out.dlg* program requires that the input vector map layer have full topological information associated with it. This means that the GRASS program *v.support* should have been the last program to have effected any changes upon the vector map layer before it is run through *v.out.dlg*. If this is not the case, *v.out.dlg* will terminate with a message that *v.support* needs to be run.

The output from *v.out.dlg* will be placed in $LOCATION/dlg$.

v.out.dxf - GRASS vector format to DXF format conversion program.
(GRASS Vector Data Export Program)

SYNOPSIS

v.out.dxf
v.out.dxf help
v.out.dxf input=name output=name

DESCRIPTION

The GRASS program v.out.dxf conversion program generates an ASCII DXF (AutoCad) file from a
GRASS vector ASCII file. The output file is placed in the user's current working directory unless the
user specifies a full pathname for the output.

Parameters:

input=name The name of an existing GRASS vector ASCII file.
output=name Name to be assigned to the DXF output file.

NOTE: DXF files output by AutoCad have the suffix .dxf

NOTES

This program does not currently read in binary files.

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled
separately by the user.

v.out.dxf program in April 1989.
NAME

v.out.moss - Converts GRASS site, line, or area data into MOSS import format.

SYNOPSIS

v.out.moss

DESCRIPTION

This program produces a MOSS import file containing GRASS site, line, or area features that have been converted into MOSS point, line, or polygon features, respectively. Only one type of data (site, line, or area) can be converted at a time. Site data can be extracted from GRASS site lists files or vector files, at the user's discretion. The resultant MOSS files will be created in the moss subdirectory of the current mapset.

The user will be prompted for the GRASS data type, the name of the site lists or vector file to be converted, and the name of the MOSS import file to be created. If line data is being converted, the user will be asked whether area edges should be processed as lines. If so, the line features produced from the area edges will not have attributes associated with them.

Upon successful completion of the data export, the number of items converted will be printed, and the user will be given the option of processing another GRASS file.

NOTES

Vector data cannot be exported until the necessary GRASS support files have been built.

This program is interactive and requires no command line arguments.

NAME

v.patch - Creates a new binary vector map layer by combining other binary vector map layers.
(GRASS Vector Program)

SYNOPSIS

v.patch
v.patch help
v.patch input=name[,name,...] output=name

DESCRIPTION

v.patch allows the user to combine any number of vector map layers together to create one composite vector map layer.

Parameters:

input=name[,name,...]   Name(s) of input vector map(s) to be patched together.
output=name              Name assigned to composite "patched" vector output map.

The program will be run non-interactively if the user specifies the names of the vector map(s) to be patched and the name of an output file to store the resulting composite patched vector map on the command line, in the form:

v.patch input=name[,name,...] output=name

Alternately, if the user runs v.patch without specifying input and output file names on the command line (by typing simply v.patch), the program will prompt the user for inputs using the standard GRASS interface described in the manual entry for parser.

NOTES

The vector map layers to be patched together must exist in the user's current mapset search path, and the composite vector map layer name given must not already exist in the user's current mapset.

After running v.patch, the header file will contain only information taken from the first input file name given in the string input=name[,name,...], with the exception of the geographic region's edge information, and the scale and threshold information. (The user's current geographic region settings are ignored; this information is instead extracted from the vector file headers.) In the new composite vector map layer, the boundaries of the geographic region will be expanded to encompass all of the geographic area included in the map layers being patched, and the scale will be set equal to the smallest (i.e., most gross) scale used by any of the patched map layers (this will affect default node-snapping thresholds). The map threshold is calculated automatically from the map scales given in the file headers, and (currently) is not used directly. The composite vector map layer's header will probably need to be edited; this can be done from within the GRASS program v-digit.

The GRASS programs v.mkgrid and v.mkquads can be used to ensure that the borders of the maps to be patched together align neatly.

Any vectors that are duplicated among the maps being patched together (e.g., border lines) will have to be edited or removed after v.patch is run. Such editing can be done using v-digit.

After running v.patch the user must run v.support on the composite vector map layer in order to create a dig_plus (topology) file for it. At this time, you can request that a very small snapping threshold be used, to cause the nodes that match up across vector map layers to snap together without affecting the integrity of the remainder of the vector map layer.

BUGS

The dig_cats and reg file information for the maps being patched together is not copied to the composite, patched map layer. The user should therefore run v.support on the output file produced by this program.

AUTHOR

David Gerdes, U.S. Army Construction Engineering Research Laboratory
v.prune

GRASS Reference Manual

NAME

v.prune - Prunes points from binary GRASS vector data files.

(GRASS Vector Program)

SYNOPSIS

v.prune
v.prune help
v.prune [-i] input=name output=name thresh=value

DESCRIPTION

The GRASS program v.prune allows the user to remove extra points from a vector file. This allows users to reduce disk space required by a vector file and still have data accuracy within a given tolerance.

Flag:

-i The pruning threshold value is specified in map inches, rather than in data base units on the ground.

Parameters:

input=name Name of binary GRASS vector file containing data to be pruned.
output=name Name to be assigned to new, pruned vector output file.
thresh=value Threshold value used for pruning.

The program will be run non-interactively if the user specifies all parameters and (optionally) the -i flag on the command line, using the form:

v.prune [-i] input=name output=name thresh=value

If the user simply types v.prune without specifying program arguments on the command line, the program will prompt the user to enter parameter values.

NOTES

The threshold value is the same as the v.digit pruning threshold. This is specified in data base units on the ground (e.g., in ground meters for UTM data bases). The threshold can also be specified in inches on the map, and the program will convert these to data base ground units using the scale in the vector file. If you specify the scale in map inches rather than in ground units, you must specify that inches are used by setting the -i flag. The input vector data layer will be read and the resultant pruned vector data layer will be placed into a newly created output file whose name is specified by the user, leaving the original vector map unchanged.

The pruning algorithm throws away redundant points within the specified threshold. It works on each vector separately, working from node to node. It does not change the position or number of nodes.

v.digit, v.in.ascii

AUTHOR

David Gerdes, U.S. Army Construction Engineering Research Laboratory
NAME
v.spag - Process spaghetti-digitized binary vector file.

SYNOPSIS
v.spag
v.spag help
v.spag map=name [threshold=value]

DESCRIPTION
This program will fix vector data that were not digitized in correct GRASS vector format. It will create
a node at every line crossing, and will delete all hanging lines of length less than the specified
threshold.

COMMAND LINE OPTIONS
Parameters:
map=name Name of the binary vector file to be fixed.
threshold=value Node-snapping threshold value.

NOTES
The user must run v.support after running v.spag to correct the topology (dig_plus) file.
v.spag generally deletes many lines from the input vector map layer. Because deleted lines are not
eliminated from a vector data (dig) file, but are only marked as deleted, the user will probably wish to
run v.clean on the vector file after running v.spag to eliminate any deleted lines from the dig file and
decrease its size.

This program remains under alpha testing. It resides in the src.alpha directory and must be compiled
separately by the user.

BUGS
This program contains several known bugs. It will sometimes get stuck in a loop in which it creates
the same line over and over again. It will occasionally create an incorrect line. Users are strongly
urged to back-up their vector data files before running this alpha version of v.spag.

NAME

\texttt{v.stats} – Prints information about a binary GRASS vector map layer.

(GRASS Vector Program)

SYNOPSIS

\begin{verbatim}
\texttt{v.stats}
\texttt{v.stats help}
\texttt{v.stats [-h] map=\textit{name}}
\end{verbatim}

DESCRIPTION

The program \texttt{v.stats} will print to standard output information about a user-specified binary GRASS vector map layer.

Flag:

\texttt{-h} Display header information from the vector file.

Parameter:

\texttt{map=\textit{name}} Name of the binary GRASS vector file to be queried.

The program will be run non-interactively if the user specifies the parameter value and (optionally) sets the \texttt{-h} flag on the command line, using the form:

\begin{verbatim}
\texttt{v.stats [-h] map=\textit{name}}
\end{verbatim}

If the user instead simply types \texttt{v.stats} without specifying program arguments on the command line, the program will prompt the user to enter inputs through the standard user interface described in the manual entry for \texttt{parser}.

NOTES

Sample output follows:

\begin{verbatim}
Format: Version 4.0 (Level 2 access) (Portable)
Number of Lines: 3
Number of Nodes: 2
Number of Areas: 2 (complete)
Number of Isles: 1 (complete)
Number of Arts : 2
\end{verbatim}

The GRASS version number is given. Parenthetical text following this describes the read access level available and notes whether or not the file is in GRASS version 4.0 portable data format. The access level indicates the types of data available for the named vector map layer. “Level 1” denotes a binary vector file (without any accompanying \texttt{dig.plus} file), while “Level 2” denotes the existence of a \texttt{dig.plus} (vector topology) file for the named map layer (generally created by \texttt{v.support}). If only Level 1 information is available for a vector map layer, only the number of lines and (optionally) the file header will be printed to standard output.

If all areas and islands (isles) in the vector file have been identified (usually by \texttt{v.support}), their counts will be followed by “complete.” If not, they will be followed by “incomplete.” The \texttt{dig.plus} file, which is created and updated by \texttt{v.support}, must exist for this information to be output.

NAME

v.support - Creates GRASS support files for (binary) GRASS vector data.
(GRASS Vector Program)

SYNOPSIS

v.support
v.support help
v.support [-spr] map=name [option=name] [threshold=value]

DESCRIPTION

v.support builds GRASS support files for (binary) GRASS vector data files. These support files supply topology (dig_plus) and category (dig_att) information that are needed by other GRASS programs (e.g., by v.digit, v.to.rast, etc.).

The program gives the user the options of: (1) building topological information (the dig_plus file) needed by v.digit for the vector data file, and/or (2) editing the category label (dig_cats) file associated with the vector data file.

OPTIONS

Program parameters and flags have the following meanings.

Flags:

- Snap nodes. Valid only with build option.
- Prompt user for threshold value. Valid only with build option. This flag is designed to be used only by the v.import program, and can usually be ignored.
- Reset corners of map region from range of data values.

Parameters:

map=name Name of binary GRASS vector data file for which support files are to be created or modified. This map layer must exist in the user's current GRASS mapset.

option=name Build topology information (dig_plus file), or edit categories (dig_att file) for map.

Options: build, edit
Default: edit

threshold=value Snapping threshold value to be used when building topology. Valid only with build option and -s flag.

The user can run this program non-interactively by specifying parameter values (and optionally, flag settings) on the command line.

Alternately, the user can simply type the command v.support on the command line. In this event, the program will prompt the user to enter parameter values and flag settings.

If the build option is chosen, the user may further specify the -s flag, to snap nodes in the vector file. If nodes are to be snapped, the user can either: (1) use the calculated default threshold (based on the scale of vector data); (2) enter the -p flag, causing the program to prompt the user for a snapping threshold value; or (3) enter a specific threshold value on the command line.

The spatial assignment of category values (found in the dig_att file) is also performed during building of file topology.

The edit option allows the user to edit the category labels to be associated with the category values attached to the vector data during topology building. These labels, if created, are then used for raster map layers derived from their vector counterparts. The labels are placed in the dig_cats directory.
NOTES
A dig_plus file must be created for each imported vector map before it can be used in post-GRASS 3.0 versions of digit (now referred to as v.digit).
Topological information for GRASS vector files can also be built using option 4 of the v.import program.
This program will convert pre-4.0 version GRASS vector files to 4.0 format.
v.support creates support files only for binary vector files located in the user's current mapset.

NAME

v.to.rast - Converts a binary GRASS vector map layer into a GRASS raster map layer.

(GRASS Vector Program)

SYNOPSIS

v.to.rast
v.to.rast help
v.to.rast input=name output=name

DESCRIPTION

v.to.rast transforms (binary) GRASS vector map layers into GRASS raster map layer format. Most GRASS analysis programs operate on raster data.

Parameters:

input=name    Name of the binary vector map layer to be converted.
output=name   Name to be assigned to the raster map layer output.

The user can run the program non-interactively by specifying the names of a vector input file and raster output file on the command line, using the form:

v.to.rast input=name output=name

If the user instead types simply v.to.rast on the command line, the program will prompt the user to enter these names.

NOTES

v.to.rast will only affect data in areas lying inside the boundaries of the current geographic region. Before running v.to.rast, the user should therefore ensure that the current geographic region is correctly set and that the region resolution is at the desired level; the program may otherwise create an empty raster map layer. An empty raster map layer will also be created if the vector map layer has not been assigned category/attribute labels (e.g., through use of the v.digit program).

The v.to.rast program creates two files: a raster map layer, and a history file. The GRASS program r.support must be run to create additional support files for the raster map.

Additional problems sometimes lead to the creation of empty raster map layers. Unfortunately, error messages explaining these phenomena do not yet exist.

NAME

v.to.sites - Converts point data in a binary GRASS vector map layer into a GRASS site_lists file.

(GRASS Vector Program)

SYNOPSIS

v.to.sites
v.to.sites help
v.to.sites input=name output=name

DESCRIPTION

The v.to.sites program extracts site data from a GRASS vector map layer and stores output in a new GRASS site_lists file. The resulting sites map layer can be used with such programs as d.sites. Only site (point) features in the named vector map layer are extracted and placed into the resulting site list. Lines and areas in the vector file are ignored.

The user can run the program non-interactively by specifying the names of an existing vector input map layer and a new site list file to be output on the command line. The program will be run interactively if the user types v.to.sites without arguments on the command line. In this case, the user will be prompted to enter parameter values through the standard user interface described in the manual entry for parser.

Parameters:

input = name  Name of an existing binary vector map layer from which site data are to be extracted.

output = name  Name to be assigned to the resultant site_lists file.

If any of the sites have been labeled in v.digit, then the resultant site list will contain category information. If none of the sites are labeled, a binary (0/1) site list file will be produced.

NAME
v.transform - Transforms an ASCII vector map layer from one coordinate system into another coordinate system.
(GRASS Vector Program)

SYNOPSIS
v.transform
v.transform help
v.transform [-y] input=name output=name [pointsfile=name]

DESCRIPTION
This program has been used to import vector files that were in scanner or digitizer (x,y) coordinates and to transform these into UTM coordinates.

Flag:
-y Suppress the printing of residuals or other information to standard output.

Parameters:
input=name Name of the ASCII vector map layer to be transformed.
output=name Name to be assigned to the resultant (transformed) ASCII vector map layer.
pointsfile=name Name of a file containing transformation points, whose format is given below. Give a full path name for this file or it will be assumed to be located in the user's current directory.

The user can run this program non-interactively by specifying parameter values (and optionally, the flag setting) on the command line.

If the user runs v.transform without specifying program arguments on the command line, the program will prompt the user for inputs. When the program prompts the user for two sets of transformation points, the first set of points entered by the user should be in the coordinate system of the input map, and the second set of points should represent the corresponding geographic points in the coordinate system into which the map will be transformed. A user must enter 4 to 10 of each set of points for the transformation to work correctly.

After the user has entered both sets of points, the program will show the amount of error associated with the transformation of the given points as the residual mean average (RMS). (An acceptable RMS for a 1:24,000 UTM map would be 1.2 to 2.4 (meters).) It will then ask if the transformation RMS value is acceptable. After an RMS is accepted by the user, v.transform will transform the ASCII (dig.ascii) vector map and its associated attribute (dig.atr) file into the requested coordinate system.

Remember to run v.support or v.import on the output map.

NOTES
When rectifying a map to another coordinate system using v.transform, the user should specify the coordinates of between 4 to 10 points, and state these both in the coordinate systems of the input and output maps. The two sets of coordinates can be input to v.transform interactively, or from a file specified on the command line with the pointsfile option. The pointsfile option is especially useful when several maps in the same geographic area require transformation, as it eliminates the necessity for the user to repeatedly type in the same transformation coordinates.

A pointsfile file will contain between 4 to 10 lines; each line will contain the set of coordinate transformation points for the input map and the corresponding set of coordinates for the output map. The minimum number of lines for the transformation to take place is four.
The format of the *pointsfile* file is shown below:

<table>
<thead>
<tr>
<th>Input Map</th>
<th>Output Map</th>
</tr>
</thead>
<tbody>
<tr>
<td>x  y  x  y</td>
<td></td>
</tr>
<tr>
<td>x  y  x  y</td>
<td></td>
</tr>
<tr>
<td>x  y  x  y</td>
<td></td>
</tr>
<tr>
<td>x  y  x  y</td>
<td></td>
</tr>
</tbody>
</table>

In the format shown above the x’s and y’s can be thought of as eastings and northings, depending on what coordinate systems you are transforming to and from.

An example of the *pointsfile* file:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>589000</td>
<td>4913000</td>
</tr>
<tr>
<td>1</td>
<td>17000</td>
<td>589000</td>
<td>4930000</td>
</tr>
<tr>
<td>17000</td>
<td>17000</td>
<td>610000</td>
<td>4930000</td>
</tr>
<tr>
<td>17000</td>
<td>1</td>
<td>610000</td>
<td>4913000</td>
</tr>
</tbody>
</table>

Within the *pointsfile* file, numbers on a line must be spaced apart with tabs or blanks. The example shown above was used to convert a map in digitizer coordinates (range of 1-18000) to UTM coordinates within the UTM zone for the Spearfish sample data base location.

Because this *pointsfile* file is not your usual GRASS data file, the user will have to keep track of where it is on the system. When the *pointsfile* option is used on the command line to input the transformation points, the program does not ask whether or not everything is acceptable before converting the vector file and the attribute file.

The user is advised to run this program interactively with a specific set of transformation coordinates and to examine the resulting residuals, to determine how accurate the transformation will be (i.e., pick points with known values in both coordinate systems). After the residuals are acceptable, those transformation coordinates can be used with the program run non-interactively to transform other maps in the same geographic area.

**WARNING**

This is a general-purpose program and can be fooled into giving low residuals; i.e., low residual values may not necessarily imply a better resolution of ground coordinates to digitizer coordinates. It is strongly suggested that any transformed map be checked for accuracy. The program assumes that the coordinate systems will be planimetric and has never been tested with negative values.

If this program is being used to transform maps from State Plane to UTM coordinates, and vice versa; users should be aware of the following points. This program will work better with State Plane zones that use the Transverse Mercator projection. Those are states that have their state zones splitting the state vertically, like Illinois. This program will not work as well with states that use the Lambert Conformal Conic projection. Those are states that have their state zones splitting the state horizontally, like Wisconsin. It is also best to keep the area being transformed relatively small.

NAME

v.trim - Trims small spurs, and removes excessive nodes from a binary GRASS vector (dig) file.
(GRASS Raster Program)

SYNOPSIS

v.trim
v.trim help
v.trim input=name output=name [trim=value]

DESCRIPTION

v.trim scans the user-specified GRASS vector input file and removes from it all lines having a length less than a user-specified trimming factor. Excess nodes (those unnecessary to a line's definition) between line junctions are also removed. The resulting vector output is sent to a user-named output file; the original vector input file is not modified by v.trim.

The trimming factor parameter (trim=value) gives the user control over the size of small spurs or "dangling lines" to be removed. The trimming factor is expressed in the same units (map coordinates) as the vector (dig) data within the user's current GRASS data base LOCATION (e.g., in meters for UTM locations, in pixels or cells for locations in an x,y coordinate system, etc.).

OPTIONS

The user can run this program either non-interactively or interactively. The program will be run non-interactively if the user specifies program arguments on the command line, using the form:

v.trim input=name output=name [trim=value]

If vector map input and output names are given on the command line, any other parameter values left unspecified on the command line will be set to their default values (see below). Alternately, the user can simply type v.trim on the command line, without program arguments. In this case, the user will be prompted for needed parameter values using the standard GRASS user interface described in the manual entry for parser.

Parameters:

input=name Name of an existing vector map layer in the user's current mapset search path containing lines to be "trimmed."

output=name Name of a new vector file to contain the "trimmed" output.

trim=value A user-specified trimming factor, denoting the length of trimmed lines in map units. All lines having a length less than this trimming factor will be "trimmed" (i.e., removed) from the named vector input file.

Default: 10 (in units of meters or cells)

NOTES

v.support must be run on the vector input file prior to running v.trim.

v.support must also be run on the resultant vector output file to build the needed topology information stored under the user's dig_plus directory.

r.line maintains the same format (binary or ASCII) and attribute type (linear or area edge) as those of the original vector (dig) input file.

A trimming factor of zero (0) will not remove any small spurs, but will remove all excess nodes.

Like Main Programs, UNIX shell script programs have received both alpha- and beta-testing. However, while other GRASS programs are written in the "C" programming language, shell scripts are UNIX Bourne and C-shell scripts readily developable by nonprogrammers and others unfamiliar with "C." Shell scripts are separately described for the convenience of potential system developers at GRASS user sites, who are encouraged to examine the shell scripts, located on-line in the directories indicated in this manual, and to develop their own scripts.
NAME
3d.view.sh - Displays several 3-dimensional views of a landscape on the user's graphics monitor.
(GRASS Shell Script)

SYNOPSIS
3d.view.sh
3d.view.sh help
3d.view.sh file=mapname ef=mapname vh=viewing_height sv=sink_value exag=exag
If=line_frequency back=background_color

DESCRIPTION
3d.view.sh is a Bourne shell (sh(1)) script that displays several 3-dimensional views of a landscape on
the user's graphics monitor. It erases the graphics monitor and then prepares it for the display of nine
equally-sized frames. The user-specified raster map layer (given by file=name) is displayed using
d.rast in the middle frame. The remaining frames are then used to display 3-d perspective views. The
top middle panel is a view from the north, the top right from the north-east, the right from the east, and
so on. Each is drawn with a call to the d.3d program. The viewing angles are calculated
automatically. If options are not stated on the command line, default values will be used. These values
are listed under Parameters, below.

Parameters:
file=mapname  Name of raster map layer to be displayed.
             Default: elevation
ef=mapname    Name of raster map layer whose category values will supply the elevation values
             used to generate 3-d perspective views.
             Default: elevation
vh=viewing_height Height (in meters) of the location from which scenes will be viewed.
             Default: 30000
sv=sink_value Sink factor value, causing the image to be displayed lower, or higher, on the
             graphics screen.
             Default: 0
exag=vertical_exaggeration Vertical exaggeration factor of the values in the elevation file.
             Default: 3
If=line_frequency Contour intervals at which vector grid lines will be drawn, in meters.
             Default: 20
back=background_color Color of the background of the display frames.
             Options: red, orange, yellow, green, blue, indigo, violet, magenta, brown, gray,
                      white, and black
             Default: black

NOTES
In the spearfish sample data base, the user must specify a viewing height when running 3d.view.sh.
Note also that the raster elevation map layers in the PERMANENT mapset under spearfish are named
elevation.dem and elevation.dma.

This program will not prompt the user for inputs; if the user types 3d.view.sh without program
arguments on the command line, default values will be used.

FILES
This program is simply a shell script. Users are encouraged to make their own shell scripts using
similar techniques. See $GISBASE/scripts/3d.view.sh.

NAME

Gen.Maps - Generates various vector maps from a rim/TIGER data base.

(Grass Shell Script)

SYNOPSIS

Gen.Maps help
Gen.Maps dbname tractN1 tractN2 ...

DESCRIPTION

Gen.Maps is a shell script that queries information from a rim data base using the GRASS command v.db.rim, which is an interface between GRASS and RIM. The dbname given on the command line should be the name of a rim data base created using v.in.tiger. Gen.Maps will create several new vector files. Three of these are: a county outline map, a map of tract boundaries within the county, and a map showing block group boundaries. For every tract number given on the input line, additional vector maps will be created showing: the tract outline, a block group boundary map for each block group within the tract, and a map showing block boundaries within each block group. Output files will be named dbname.county, dbname.tract and dbname.bg for the map layers showing the county outline, the tract outlines within the county, and the block group boundaries within the county. The vector file showing the boundary for an individual tract will be named TractN, where tractN is the tract number given on the command line. The vector files created to show an individual block group boundary and block boundaries within that block group will be named using the appropriate tract number and block group number as part of the name, with suffixes of .bg and .bk respectively.

Parameters:

dbname | Name of an existing rim data base.
tractN | Number of a tract located within this county.

NOTES

This command must be installed separately as part of the package of routines dealing with the import of Census (TIGER) data. It requires the use of rim and v.db.rim, which must be compiled first.

You must include at least one tract number on the command line for this command to function. Use tiger.info.sh to obtain all tract numbers for a given TIGER type1 data file.

If the master binary vector file created using v.in.tiger is modified after it is in GRASS, this program will probably not work. In that situation, the processes from this shell script may simply be run by hand, using v.db.rim directly, but searching the old vector file to find lines for the new vector files without using the binary offset field (vectoff).

Vector files showing the block boundaries within a block group may contain hydrology lines, which in fact define the edge of a census block.

NAME

`Gen.tractmap` - Generates two vector maps from a RIM/TIGER data base.

*(GRASS Shell Script)*

SYNOPSIS

```
Gen.tractmap help
Gen.tractmap dbname
```

DESCRIPTION

`Gen.tractmap` is a shell script which queries information from a RIM data base using the GRASS command `v.db.rim`, which is an interface between GRASS and RIM. The `dbname` given on the command line should be the name of a RIM database created using `v.in.tiger`. `Gen.tractmap` will create two new vector files: one showing the county outline and one showing all tract boundaries within the county. These output files will be named `dbname.county` and `dbname.tract`, respectively.

Parameters:

- `dbname` Name of an existing RIM data base.

NOTES

This command must be installed separately as part of the package of routines dealing with the import of Census (TIGER) data. It requires the use of `rim` and `v.db.rim`, which must be compiled first.

The output maps produced by this command are also included as part of the more extensive output from `Gen.Maps`.

If the master binary vector file created using `v.in.tiger` is modified after it is in GRASS, this program will probably not work. In that situation, the processes from this shell script may simply be run by hand, using `v.db.rim` directly, but searching the old vector file to find lines for the new vector files without using the binary offset field (`vectoff`).

AUTHOR

James Hinthorne and David Samnik, GIS Lab, Central Washington University, Ellensburg, WA.
NAME
blend.sh - Combines the red, green, and blue color components of two raster map layers.
(GRASS Shell Script)

SYNOPSIS
blend.sh file1 file2 perc outbase

DESCRIPTION
blend.sh is a Bourne shell (sh(1)) script that extracts the red (R), green (G), and blue (B) color components from each of two raster map layers, and creates three new raster map layers whose category values respectively represent the combined red, combined blue, and combined green color values from the two input layers. Category values in each of the output map layers will fall within the range of 0 - 255.

The R,G,B values from the two input map layers (file1 and file2) are not simply added together, but are instead combined by a user-named percentage (perc) of the R,G,B values in file1. Specifically, blend.sh executes three r.mapcalc statements that: (1) convert the R,G,B values in file1 and file2 to the range 0 - 255; (2) multiply the R, G, and B values in file1 by a user-named percentage (perc); (3) multiply the R, G, and B values in file2 by (100 - perc); (4) create three new raster map layers, whose category values represent the summed R, summed G, or summed B values resulting from (2) and (3). Resulting R, G, and B values will respectively be stored in three new raster map layers named outbase.r, outbase.g and outbase.b.

This program runs non-interactively; the user must state all parameter values on the command line.

Parameters:
file1 Name of a first raster map layer, whose R, G, and B color components will be combined with those of the second raster map layer (file2) named. The percent value (perc) given will apply to file1.

file2 Name of a second raster map layer, whose color components will be combined with those of file1. The percent value (perc) given will apply to the R,G,B values in file1. The R, G, and B values in file2 will be multiplied by (100 - perc) %.

perc Percentage or amount of the color contribution in terms of color intensity. This value is multiplied by the R,G,B values in file1.

outbase The root name assigned to each of the three output files created. A suffix is added to each file name, indicating which hold the red, green, and blue color values.

blend.sh executes three r.mapcalc statements:

r.mapcalc "outbase.r = r\$file1 * perc + (1.0 - perc) * r\$file2"
r.mapcalc "outbase.g = g\$file1 * perc + (1.0 - perc) * g\$file2"
r.mapcalc "outbase.b = b\$file1 * perc + (1.0 - perc) * b\$file2"

It uses the # operator to separately extract the red, green, and blue components in the named raster map layers, essentially allowing color separates to be made.

EXAMPLE
Typing the following at the command line:

blend.sh aspect elevation 40 elev.asp

will create three new raster map layers named elev.asp.r, elev.asp.g, and elev.asp.b, that respectively contain 40 of the red, green, and blue components of the elevation map layer and contain 60 of the red, green, and blue components of the aspect map layer.
FILES

This program is simply a shell script. Users are encouraged to make their own shell scripts using similar techniques. See $GISBASE/scripts/blend.sh.

AUTHOR

David Gerdes, U.S. Army Construction Engineering Research Laboratory
NAME

`bug.report.sh` - A mechanism for writing, storing, and e-mailing to USACERL users' bug reports on GRASS 4.0 commands.

*(GRASS Shell Script)*

SYNOPSIS

```
bug.report.sh 4.0_programname [program_arguments]
```

DESCRIPTION

`bug.report.sh` is a Bourne shell (sh(1)) script that, when given a GRASS 4.0 program name, allows the user to complete a bug report for that program. Completed bug reports can be e-mailed to the GRASS development group at USACERL, saved to a file in the user's home directory, or discarded.

This program is not interactive; the user must specify the name of a 4.0 program on the command line. Program arguments can optionally be entered by the user.

Parameters:

- `4.0_programname` The name of an existing GRASS version 4.0 program tested by the user.
- `program_argument(s)`

Program arguments (parameters and/or flags) for the `4.0_programname` tested by the user. The user should enter whatever command arguments were actually run when the program bug occurred.

EXAMPLE

For example, if the user wished to complete a bug report on `v.to.rast` after running the program, the user might then type:

```
bug.report.sh v.to.rast
```

A standard bug report form would then be displayed on the user's text terminal, containing the user's current GRASS region settings, and the machine name, GRASS data base, location, and mapset, on which the user is currently running GRASS. Program parameters and flag settings, and the command entered by the user on the command line, are also automatically entered on the bug report form. The user is put into a text editor and expected to enter additional information describing the nature of the bug found or the results of program testing.

The user is then asked whether the completed bug report is to be:

1. mailed to westerve@zorro.cecerc.army.mil
2. added to the file "grass.bugs" in the user's home directory
3. both 1 and 2
4. thrown away

NOTES

This program prints whatever region settings, GRASS data base, location, and mapset are current when the user runs `bug.report.sh`. The user is therefore advised to run `bug.report.sh` immediately after experiencing a program bug, to ensure that the settings current when the bug occurred are reported on the bug report form.

FILES

This shell script is stored under the $GISBASE/scripts directory on the user's system. The user is encouraged to examine the shell script commands stored in this directory and to produce similar scripts for their own use. Users might modify this shell script to e-mail reports of program bugs to a local systems' administrator in addition to someone at USACERL.

NAME
dcorrelate.sh — *Graphically displays the correlation* raster map layers in the active frame on the
graphics monitor.
*(GRASS Shell Script)*

SYNOPSIS
dcorrelate.sh layer1 layer2 [layer3 [layer4]]

DESCRIPTION
dcorrelate.sh is a C-shell (csh(1)) script that graphically displays the results of an r.stats run on two
raster map layers. This shell script is useful for highlighting the correlation (or lack of it) among data
layers.

The results are displayed in the active display frame on the user’s graphics monitor. decorrelate.sh
erases the active frame before displaying results.

Parameters:
layer1 layer2 [layer3 [layer4]]
The names of from two to four existing raster map layers to be included in the

correlation.

NOTES
This is a shell script that uses r.stats and the UNIX awk command to calculate the correlation among
data layers, and uses d.text and d.graph to display the results.

If three or four map layers are specified, the correlation among each combination of two data layers is
displayed.

This command is written for /bin/csh. If your system doesn’t support this shell, don’t install this script.

FILES
This program is simply a shell script. Users are encouraged to make their own shell script programs
using similar techniques. See $GISBASE/scripts/dcorrelate.sh.

grass.logo.sh – Displays a GRASS/Army Corps of Engineers logo in the active display frame on the
graphics monitor.

(Grass Shell Script)

SYNOPSIS

grass.logo.sh

DESCRIPTION

grass.logo.sh is primarily a demonstration of the GRASS d.graph program in a UNIX Bourne shell
macro that generates the U.S. Army Corps of Engineers logo. Users are encouraged to generate their
own unique logos by writing similar macro shell scripts. Examine the contents of the input file called
grass.logo.sh located in the GRASS shell script command directory ($GISBASE/Scripts) to see how
the GRASS logo was generated using d.graph graphics commands. The coordinates for this logo were
taken from a drawing done on graph paper.

To view the graphics described by this file use d.graph or d.mapgraph, making sure that a copy of this
file is either in your current directory or is given by its full path name.

NOTES

grass.logo.sh, like d.rast, will overwrite (not overlay) whatever display appears in the active graphics
frame.

This program requires no command line arguments.

d.font, d.graph, d.mapgraph, d.rast

AUTHOR

James Westervelt, U.S. Army Construction Engineering Research Laboratory
**NAME**

*hsv.rgb.sh* - Converts HSV (hue, saturation, and value) cell values to RGB (red, green, and blue) values.

*(GRASS Shell Script)*

**SYNOPSIS**

*hsv.rgb.sh* file1 file2 file3

**DESCRIPTION**

*hsv.rgb.sh* is a Bourne shell *(sh(1))* program that converts HSV to RGB using *r.mapcalc*. The Foley and Van Dam algorithm is the basis for this program. Input must be three raster files - each file supplying the HSV values. Three new raster files are created representing RGB.

**NOTES**

Do not use the same names for input and output.

**FILES**

This program is simply a shell script stored in the file *hsv.rgb.sh* under the `$GISBASE/scripts` directory. Users are encouraged to make their own shell script programs using similar techniques.

NAME
old.cmd.sh - Provides the new GRASS version 4.0 program name for any program name in GRASS version 3.2.

(GRASS Shell Script)

SYNOPSIS
old.cmd.sh 3.2_program.name

DESCRIPTION
old.cmd.sh is a Bourne shell (sh(1)) script that, when given a GRASS 3.2 program name, returns the name of the new GRASS version 4.0 program performing its functions. This program is useful as a quick on-line cross-reference between GRASS versions 3 and 4. This program is not interactive; the user must specify the name of a 3.2 program on the command line.

Parameter:
3.2_program.name The name of an old GRASS version 3.2 program.

Output will be in the form:

old 3.2 program name replaced with: new 4.0 program name

EXAMPLE
For example, to learn which GRASS 4.0 command performs the function of the GRASS 3.2 list command, the user might type:

old.cmd.sh list

The user would then see the following message displayed to standard output:

list replaced with: g.list

FILES
This shell script is stored under the SGISBASE/scripts directory on the user's system. The user is encouraged to examine the shell script commands stored in this directory and to produce similar scripts for their own use.

NAME

shade.rel.sh - Creates a shaded relief map based on current resolution settings and sun altitude and azimuth values entered by the user.

(GRASS Shell Script)

SYNOPSIS

shade.rel.sh

DESCRIPTION

shade.rel.sh is a Bourne shell (sh(1)) script that creates a raster shaded relief map based on current resolution settings and on sun altitude and azimuth values entered by the user. The new shaded relief map is named shade and stored in the user's current mapset. The map is assigned a grey-scale color table.

This program is interactive; the user enters the command:

shade.rel.sh

The program then prompts the user to enter values for:

1) the altitude of the sun in degrees above the horizon (a value between 0 and 90 degrees),
2) the azimuth of the sun in degrees to the east of north (a value between -1 and 360 degrees), and
3) the name of a raster map layer whose cell category values are to provide elevation values for the shaded relief map. Typically, this would be a map layer of elevation; however, any raster map layer can be named.

Specifically, shade.rel.sh executes the following r.mapcalc statement:

r.mapcalc <<EOF
shade = eval(\n x=(Selev[-1,1] + 2*Selev[0,1] + Selev[1,1])/8.*ewres) , \n y=(Selev[-1,1] + 2*Selev[-1,0] + Selev[-1,1])/8.*ewres) , \n slope=90.-atan(sqrt(x*x + y*y)) , \n a=round(atan(x,y)) , \n aspect=if(x<0,0,if(a>360,0,if(a<90,0,90))), \n cang = sin(Salt)*sin(slope) + cos(Salt)*cos(slope)*cos(Saz-aspect), \n if(cang <0,0,100*cang))
EOF

Refer to the manual entry for r.mapcalc for an explanation of the filtering syntax shown in the above expression. See, for example, the section on “The Neighborhood Modifier.”

shade.rel.sh then runs r.colors to assign a grey-scale color table to the new shaded relief map shade, by executing the command:

r.colors shade color=grey

FILES

This program is simply a shell script. Users are encouraged to make their own shell scripts using similar techniques. See SGISBASI/SGIS/shade.rel.sh.

show.color.sh – Displays and names available primary colors used by GRASS programs, in frames on
the graphics monitor.

(GRASS Shell Script)

SYNOPSIS

show.color.sh

DESCRIPTION

show.color.sh is a UNIX Bourne shell macro that displays and names available primary colors used by
GRASS programs in frames on the graphics monitor. Available colors are: red, orange, yellow,
green, blue, indigo, violet, white, black, gray, brown, magenta, and aqua.

No program arguments are required to run this program.

NOTES

The full monitor screen is made the active frame after this program ends.

This macro is located in $GISBASE/scripts/show.color.sh.

SEE ALSO

d.colormode, d.colors, d.colortable, d.display, d.frame, grass.logo.sh, show.fonts.sh

AUTHOR

David Gerdes, U.S. Army Construction Engineering Research Laboratory
NAME

`show.fonts.sh` - Displays and names available font types in the active display frame on the graphics monitor.

*(GRASS Shell Script)*

SYNOPSIS

`show.fonts.sh`

DESCRIPTION

`show.fonts.sh` is a UNIX Bourne shell macro that runs the `d.erase -a` command, then names and displays the font types that can be selected using `d.font`. This macro also runs the GRASS commands `d.font` and `d.text`. See the manual entry for `d.font` for instructions on choosing a font type.

No program arguments are required to run this program.

BUGS

The font is set to `romans` (Roman simplex) after running `show.fonts.sh`. There is no mechanism to query the current font, so there is no way to automatically restore the font. The user will have to reset the font type using `d.font` if `romans` is not desired.

FILES

This program is simply a shell script stored under the `$GISBASE/scripts` directory. Users are encouraged to examine the shell script programs stored here and to produce others for their own use.

James Westervelt, U.S. Army Construction Engineering Research Laboratory
NAME

slide.show.sh - Displays a series of raster map layers existing in the user's current mapset search path on the graphics monitor.

(GRASS Shell Script)

SYNOPSIS

slide.show.sh [across=value] [down=value] [mapsets=list]

DESCRIPTION

slide.show.sh is a UNIX Bourne shell macro that clears the entire screen, creates a series of display frames on the graphics monitor, and displays in slideshow format each of the raster map layers listed in the user-specified mapsets. This is a shell script example that makes extensive use of GRASS and UNIX commands. Users are encouraged to examine this macro and develop similar on-line demos using their own data files.

Parameters:

across=value The number of display frames across the graphics monitor screen to be used for map display.
Default: 4

down=value The number of display frames down the graphics monitor screen to be used for map display.
Default: 3

mapsets=list The names of the mapsets under the user's current location whose raster map layers are to be displayed, separated by commas.
Default: All mapsets listed in the user's current mapset search path.

FILES

See the file slide.show.sh under $GISBASE/scripts.

NAME
split.sh — Divides the graphics monitor into two frames and then displays two maps in these frames.
(GRASS Display Program)

SYNOPSIS
split.sh mapname mapname [cmd=GRASS_command] [cmd2=GRASS_command] [view=horiz]

DESCRIPTION
split.sh is a Bourne shell (sh(l)) script that clears the entire graphics screen and divides it into two display frames. Map layers are then displayed in each of the two frames. This command is very useful for visually comparing maps (raster, vector, and 3-d views) and can be used by other GRASS shell macros. It is also useful for creating demos. Program parameters are given below.

Parameters:
view=horiz
The graphics screen can be split either horizontally or vertically. The default view splits the screen into two frames, one on the left and one on the right (a vertical split). Some maps (3-d views) are better represented with more width than height (horizontal split). The first map name listed on the command line will be displayed in the top or left window (depending on whether the screen was split horizontally or vertically), and the second map will be displayed in the bottom or right window.

cmd=GRASS_command
The GRASS command used to display the named mapnames. If no command is specified by the user, d.rast is used by default. However, any GRASS display command (e.g., d.3d, d vect, etc...) can be entered.

cmd2=GRASS_command
This command will be used to display map data in the second frame only.

If the user fails to specify the values of both cmd and cmd2, split.sh will use the default command (d.rast) to display user specified map layer names in both frames. If the user specifies only the value of cmd on the command line, then that command will be executed for both frames. If the user specifies the values of both cmd and cmd2 on the command line, the cmd command will be executed in frame 1 and the cmd2 command will be executed in frame 2.

EXAMPLES
split.sh soils vegcover
split.sh soils cmd2=d.legend "soils red"
split.sh elevation vegcover cmd=d.3d view=horiz

NOTES
split.sh leaves the frame that the last map was drawn in as the active frame. The order in which the options (cmd, cmd2, view) are placed on the command line doesn’t matter, but the order is important for the map names.

FILES
This program is simply a shell script. Users are encouraged to make their own shell scripts using similar techniques. See SGISBASH/scripts/split.sh.

NAME

(GRASS Shell Script)

SYNOPSIS

start.man.sh 4.0_programname

DESCRIPTION

start.man.sh is a Bourne shell (sh(1)) script that, when given a GRASS 4.0 program name, creates a basic manual entry for that program in the same standard format as that used by the GRASS User's Reference Manual. The named program must already exist under a directory for GRASS main, alpha, or contributed source code.

This program is not interactive; the user must specify the name of a 4.0 program on the command line.

By default, program output will be sent to standard output (i.e., displayed to the user's text terminal). If the user wishes to save the manual entry created by start.man.sh, program output can be redirected into a file. For example, the below command will create a manual entry for the program new.program, and save output to the file new.program.man in the user's current directory.

```
start.man.sh new.program > new.program.man
```

Parameter:

4.0_programname The name of an existing GRASS program located in a source code directory for main, alpha, or contributed software.

FILES

This shell script is stored under the $GISBASE/scripts directory on the user's system. The user is encouraged to examine the shell script commands stored in this directory and to produce similar scripts for their own use.

tiger.info.sh - Provides tract number(s) and classification codes found within a given U.S. Census Bureau TIGER type1 data file.

(Grass Shell Script)

SYNOPSIS

tiger.info.sh help
tiger.info.sh infile

DESCRIPTION

tiger.info.sh is a shell script that outputs tract number(s) and classification codes found within the TIGER type1 data file infile. Output is written to standard out, and can be captured in a file by redirecting output. This information is useful when querying (using v.db.rim) from the master binary vector file created by v.in.tiger. It also provides tract number(s) that can be used as input to the command Gen.Maps.

Parameters:

infile Name of a TIGER type1 data file.

NOTES

This command must be installed separately as part of the package of routines dealing with the import of Census (TIGER) data.

4 CONTRIBUTED PROGRAMS

This chapter describes code, primarily contributed by other user sites, that has undergone only limited internal testing and has not yet been beta-tested. These programs appear in the src.contrib directory and are not compiled during general GRASS compilation; users must compile these programs separately to run them. Be advised that these programs may not work as expected.

Other software also distributed with GRASS is not documented in this volume; this includes programs contained under the src.garden and src.related directories that the user must compile separately (see the GRASS Installation Guide for compilation instructions). The src.garden directory includes program interfaces that link GRASS 4.0 with other related software (including UW-RIM and BNOISE). The src.related directory includes programs to which GRASS has been interfaced that program developers have allowed to be distributed with GRASS (such as UW-RIM and BNOISE, MAPGEN, GCTP, PBMPLUS, and XGEN). These programs are described in their original program documentation.
NAME
  \texttt{DOS.delete} – SCS DOS PC6300 display station image support.
  \textit{(SCS GRASS Graphics File Management Program)}
  \textit{(Available for PC6300 workstations, only)}

SYNOPSIS
  DOS.delete
  DOS.delete help

DESCRIPTION
  This command allows a user to interactively remove PC6300 saved images from the MS-DOS disk.
  \texttt{DOS.save} will store an image produced by \texttt{d.display}, \texttt{d.rast}, etc. on the PC6300 display from the 6300 hard disk.

d.to.sites - Allows the user to create a GRASS site_lists file by selecting points on the graphics monitor with a mouse.
(SCS GRASS Map Development Program)

SYNOPSIS

  d.to.sites
  d.to.sites help
  d.to.sites sites=name

DESCRIPTION

  This program allows a user to create a new GRASS site_lists file by selecting locations within the active display frame. The user is prompted for the label that is placed in the site_lists file with the corresponding geographic coordinates.

COMMAND LINE OPTIONS

Parameter:

  sites=name The name to be assigned to the GRASS site_list file to be created.

EXAMPLE

  For example, to create a site_lists file called SAMPLE:

        d.to.sites sites=SAMPLE

  The user is prompted as follows:

        Enter the label to place in the site file: SAMPLE

Buttons

        Left: Place Label Here
        Middle: Change the label
        Right: Quit

Note: The site_lists file must not already exist.

m.bsplit GRASS Reference Manual m.bsplit

NAME

m.bsplit - Splits a large (greater than 1,048,000 megabyte) file into smaller portions.
(SCS GRASS File Management Program)

SYNOPSIS

m.bsplit
m.bsplit help
m.bsplit input=name [size=value] [prefix=name]

DESCRIPTION

m.bsplit works much like the UNIX command csplit; however, it was developed to be used on binary, not ASCII, files.

The first parameter, size, has a default value of 500000. The user may assign larger or smaller values, as long as 1000000 is not exceeded.

The second parameter, prefix, is comparable to the UNIX csplit command use of "x" as a prefix to output files. m.bsplit uses the default of "bx" as a prefix on output.

COMMAND LINE OPTIONS

Parameters:
input=name The name of the binary input file to be split.
size=value The value, in megabytes, of one of the new, split-up files created from the input file.
prefix=name File name prefix assigned to the new (split) files.

SEE ALSO

The UNIX csplit command.

R. L. Glenn, USDA SCS, NHO-CGIS
NAME

m.eigensystem - Computes eigen values and eigen vectors for square matrices.

(GRASS Data Import/Processing Program)

SYNOPSIS

m.eigensystem <inputfile

DESCRIPTION

m.eigensystem determines the eigen values and eigen vectors for square matrices. The inputfile must have the following format: the first line contains an integer K which is the number of rows and columns in the matrix; the remainder of the file is the matrix, i.e., K lines, each containing K real numbers. For example:

3
462.876649 480.411218 281.758307
480.411218 513.015646 278.914813
281.758307 278.914813 336326645

The output will be K groups of lines; each group will have the format:

E  real part  imaginary part  relative importance
V  real part  imaginary part
... K lines ...
N  real part  imaginary part
... K lines ...
W  real part  imaginary part
... K lines ...

The E line is the eigen value. The V lines are the eigen vector associated with E. The N lines are the V vector normalized to have a magnitude of 1. The W lines are the N vector multiplied by the square root of the magnitude of the eigen value (E).

For the example input matrix, the output would be:

E  1159.7452017844  0.0000000000 88.38
V  0.6910021591  0.0000000000
V  0.7205280412  0.0000000000
V  0.4805108400  0.0000000000
N  0.6236808478  0.0000000000
N  0.650301526  0.0000000000
N  0.4336967751  0.0000000000
W  21.2394712045  0.0000000000
W  22.1470141296  0.0000000000
W  14.7695575384  0.0000000000
W  -5.9705414972  0.0000000000
W  0.7119385975  0.0000000000
W  -0.6359200627  0.0000000000
W  -0.0703936743  0.0000000000
N  0.7438340890  0.0000000000
N  0.6643053754  0.0000000000
N  -0.0703936743  0.0000000000
W  1.8175555606  0.0000000000
W  1.6232006923  0.0000000000
W  0.1737074067  0.0000000000
The relative importance of the eigen value (E) is the ratio (percentage) of the eigen value to the sum of the eigen values. Note that the output is not sorted by relative importance.

In general, the solution to the eigen system results in complex numbers (with both real and imaginary parts). However, in the example above, since the input matrix is symmetric (i.e., inverting the rows and columns gives the same matrix) the eigen system has only real values (i.e., the imaginary part is zero). This fact makes it possible to use eigen vectors to perform principle component transformation of data sets. The covariance or correlation matrix of any data set is symmetric and thus has only real eigen values and vectors.

**PRINCIPLE COMPONENTS**

To perform principle component transformation on GRASS data layers, one would use `r.covar` to get the covariance (or correlation) matrix for a set of data layers, `m.eigensystem` to extract the related eigen vectors, and `r.mapcalc` to form the desired components. For example, to get the eigen vectors for 3 layers:

```
(echo 3; r.covar map.1,map.2,map.3) | m.eigensystem
```

Note that since m.covar only outputs the matrix, we must manually prepend the matrix size (3) using the echo command.

Then, using the W vector, new maps are created:

```
r.mapcalc 'pc.1 = 21.2395*map.1 + 22.1470*map.2 + 14.7696*map.3'
r.mapcalc 'pc.2 = 2.9083*map.1 + 4.4599*map.2 - 10.8699*map.3'
r.mapcalc 'pc.3 = 1.8175*map.1 - 1.6232*map.2 - 0.1797*map.3'
```

**NOTES**

The source code for this program lives under `/src.contrib/CERL/misc/m.eigensystem` and requires a Fortran compiler.

**SEE ALSO**

`r.covar`, `r.mapcalc`, `r.pca`, `r.rescale`

**AUTHOR**

This code uses routines from the EISPACK system. The interface was coded by Michael Shapiro, U.S. Army Construction Engineering Research Laboratory.
NAME

\texttt{m.geo} - Calculates conversion coordinates for geographic positions.

(SCS GRASS Map Development Program)

SYNOPSIS

\texttt{m.geo}

\texttt{m.geo help}

DESCRIPTION

This program allows a user to interactively: convert projection coordinates Northings and Eastings to Latitude and Longitude values, or
allows a user to interactively: convert Latitude and Longitude values to projection coordinate Northings and Eastings.

It allows a user to do all of the above: reading from a file, writing to the screen, or reading from the keyboard, writing to a file, or reading from a file, writing to a file,

Note: The program does not transform GRASS files, it is designed to determine coordinate values on an individual position.

Several map projections are currently supported:

- \texttt{stp} - State Plane, for all CONUS, Alaska, Hawaii, Puerto Rico, Guam, Virgin Islands, American Samoa, Northern Mariana Islands, Palau, and U.S. Minor Outlying Islands
- \texttt{airy} - Airy-F
- \texttt{aea} - Albers Equal Area-F
- \texttt{apian} - Apian Globular-F
- \texttt{aeqd} - Azimuthal equidistant-F
- \texttt{aitoff} - Aitoff-F
- \texttt{august} - August Epicycloidal-F
- \texttt{bacon} - Bacon Globular-F
- \texttt{bipc} - Bipolar Conic-F
- \texttt{boggs} - Boggs Eumorphic-F
- \texttt{bonne} - Bonne-F

- sphere - Sphere of 6370997 m

**INPUT FILE FORMAT**

When reading from a file of LATITUDE/LONGITUDE data the file will contain three (3) columns of information:

- the first column - latitude - in degrees minutes seconds,
- the second column - longitude - in degrees minutes seconds,
- the third column - zone - zero(0) if not required.

For example:

```
+40 36 31.4563 -87 2 7.8193 16
40n 36 31.4563 87w 2 7.8193 16
```

When reading from a file of PROJECTION COORDINATES data the file will contain three (3) columns of information:

- the first column - easting - ground coordinates
- the second column - northing - ground coordinates
- the third column - zone - zero(0) if not required.

For example:

```
500000.00 4496918.64 16 < utm
424489.11 1908736.13 0 < lambert
```

Note: No column headings are required, just the numbers.

m.get.fips

NAME
m.get.fips – Finds a state and county FIPS code for the user.
(SCS GRASS Data Import/Processing)

SYNOPSIS
m.get.fips
m.get.fips help

DESCRIPTION
m.get.fips prompts the user for a State FIPS or two-letter state abbreviation code, and then for the name of a county located in that state. The program then prints the State and County FIPS code numbers to the user’s terminal screen (standard out).

EXAMPLE
m.get.fips
Enter State FIPS code or press RETURN if unknown:
Enter Two-Letter State or Territory Abbreviation: pa
Enter County Name: cambria
42 21

m.qcalc  GRASS Reference Manual  m.qcalc

NAME

m.qcalc - Creates tables, performs conversions, and performs simple math calculations.
(SCS GRASS Data Import/Processing Program)

SYNOPSIS

m.qcalc
m.qcalc help
m.qcalc [-shcm] init=value [end=value] [incr=value] [unit=name]

DESCRIPTION

This program allows the user to:
* Create a table of cell sizes, showing how many square feet, acres, and hectares each cell would represent
* Create a table of acreage sizes, showing how many square feet, hectares, and what cell size would be represented
* Create a table of hectare sizes, showing how many square feet, acres, and what cell size would be represented
* Convert values among feet, meters, miles, and kilometers
* Allows a user to use the UNIX bc simple math calculator

COMMAND LINE OPTIONS

Flags:

-s  Create a cell size table.
-a  Create an acres size table.
-h  Create a hectares size table.
-c  Convert value to user-stated units.
-m  Perform a math calculation.

Parameters:

init=value  Initial value.
end=value  Ending value.
incr=value  Increment value.
unit=name  Units of measure.

Options:  ft, mt, mi, km

EXAMPLE

The following command produces the subsequent table:

```
g.qcalc -s init=100 end=400 incr=100
```

<table>
<thead>
<tr>
<th>Cell Size</th>
<th>Sq.Ft.</th>
<th>Acres</th>
<th>Hectares</th>

NAME

*m.setproj* - Allows the user to create the PROJ_INFO and the PROJ_UNITS files to record the projection information associated with a specified mapset.

*SCS GRASS Data Import/Processing Program*

SYNOPSIS

```
m.setproj
m.setproj help
m.setproj [set=\textit{name}] proj=\textit{name}
```

DESCRIPTION

*m.setproj* allows a user to create a new PROJ_INFO file in the specified mapset. The file is used to record the projection information associated with the specified mapset.

Note:

- The "set" mapset must exist and must not contain a PROJ_INFO or PROJ_UNITS file.
- The specification of any projection other than ll and xxx will generate a request to the user for a name of a standard ellipse.
- The projections of aea, llc, merc, and tmec will generate a request to the user for the prime meridian and standard parallel for the output map.
- The projection of stp will generate a request to the user for the state abbreviation and choice of zone for the output map.
- The projection of xxx will request mapgen *proj* parameters. See the mapgen *proj* documentation for the uses of this software.

COMMAND LINE OPTIONS

**Parameters:**

- \texttt{set=\textit{name}}
  Mapset in which the projection information file is to be stored.

- \texttt{proj=\textit{name}}
  Map projection name.
  Options: utm, aea, stp, llc, merc, tmec, xxx

SEE ALSO

EXAMPLE

To create a PROJ_INFO file recording mapset SAMPLE as being a UTM projection in zone 13:

```
m.setproj set=SAMPLE proj=utm
```

The user will be prompted for the spheroid and zone of the UTM projection.

NAME

r.in.erdas – Creates raster files from ERDAS files. It creates one raster file for each band, and creates color support if an ERDAS trailer file is specified.

(SCS GRASS Raster Program)

SYNOPSIS

r.in.erdas
r.in.erdas help
r.in.erdas erdas=name [trl=name] prefix=name

DESCRIPTION

This command prompts the user twice:

First the user is asked if he wishes to select a subset of the bands available in the ERDAS file for output.
If unspecified by the user, all bands are used, by default.

Second, the user is asked if he wishes to select a subregion of the image available in the ERDAS file. If unspecified by the user, the complete image is used, by default.

Note:
GRASS raster files will be named prefix.band
Remember that it is necessary to run:
  r.support: to create the histogram or change the color table.
  i.group: to associate the individual raster files as an image group.

COMMAND LINE OPTIONS

Parameters:

  erdas=name  Input ERDAS file name.
  trl=name    Input ERDAS trailer file name.
  prefix=name Prefix of the GRASS raster files to be created.

AUTHOR

M. L. Holko, USDA SCS, NHQ-CGIS
NAME

*r.in.miads* - Converts a MIADS output ASCII text file into an GRASS raster import (*r.in.ascii*) formatted file.

(SCS GRASS Raster Program)

SYNOPSIS

```
r.in.miads
r.in.miads help
r.in.miads input=name output=name strip=value line=value cell=value
    Northing=value Easting=value size=value
```

DESCRIPTION

*r.in.miads* allows a user to create a *r.in.ascii* formatted ASCII file from a MIADS output printer format ASCII file.

The program will actively read the MIADS data file, selectively remove and process each strip, creating a individual *r.in.ascii* formatted file for each strip, and finally create one category file for all strips. The program also produces a report file summarizing all pertinent information for each strip.

The resulting *r.in.ascii* files for each strip are then used in conjunction with the GRASS commands *r.in.ascii* and *r.patch* to create a complete raster file.

COMMAND LINE OPTIONS

Parameters:

- **input=name**: MIADS input file name.
- **output=name**: GRASS raster data output file name.
- **strip=value**: MIADS strip number of reference cell.
- **line=value**: MIADS line number of reference cell.
- **cell=value**: MIADS cell number of reference cell.
- **Northing=value**: UTM Northing at the cell reference.
- **Easting=value**: UTM Easting at the cell reference.
- **size=value**: Cell size (length one side) in meters.

SCS has developed scripts *run.miads*, *getstrip*, and *strip.99s*. These scripts make the MIADS to GRASS conversion easier.

- **run.miads**: SCS macro to perform the complete conversion of a MIADS printer format data set to a GRASS raster file.
- **getstrip**: Reads each MIADS strip file and converts it to an independent GRASS data file. Support may be run on any one of these strip files; however, there is no category information available. Each strip may be viewed at this time with *d.rast* or *d.display*.
- **strip.99s**: Special pre-*run.miads* macro that removes the 99's from the MIADS data file. This effectively removes border information, replacing it with "no data" values.

SEE ALSO

*d.display*, *d.rast*, *r.in.ascii*, *r.patch*, *r.support*

GRASS 4.0 (Summer 1991) U.S. Army PIRL
NAME

\texttt{r.reclass.scs} – Create a new raster map layer based on an existing raster map.

\textit{(SCS GRASS Raster Program)}

SYNOPSIS

\texttt{r.reclass.scs}
\texttt{r.reclass.scs help}

DESCRIPTION

\texttt{r.reclass.scs} is an interface to the GRASS \texttt{r.reclass} program. The program will reclassify the category values in a raster map layer based on reclass instructions entered by the user. The user can enter map reclassification rules to \texttt{r.reclass.scs} either from standard input or from a file. The program then issues \texttt{r.reclass} commands to produce the new reclassified raster map layer.

Input to \texttt{r.reclass.scs} consists of a list of category names or category values that will be grouped into the same category in the output (reclassified) map. Only one category name should appear on each line of input. Input can be entered either interactively, or from a file.

A file containing these reclass rules can be created using a text editor, word-processor, DBMS, etc. It is no more than a list of category names which will have the same category value after the reclassification.

NAME

`s.to.vect` - Converts a GRASS site_lists file into a vector file.

(SCS GRASS Sites Program)

SYNOPSIS

```
s.to.vect
s.to.vect help
s.to.vect input=name output=name
```

DESCRIPTION

`s.to.vect` converts GRASS site_lists file into vector files. The resulting vector file can be treated as any other vector file. The requirements of the site_lists file are standard (i.e., a regular site_lists file format is required). Site_lists file values are used as `dig_cats` category values.

COMMAND LINE OPTIONS

Parameters:

- `input = name` Name of input GRASS site_lists file to be converted.
- `output = name` Name to be assigned to the vector output file.

AUTHOR

R. L. Glenn, USDA SCS, NHQ-CGIS
NAME

v.export - Converts binary vector files into formatted ASCII files for transfer to other computer systems.

(SCS GRASS Vector Program)

SYNOPSIS

   v.export
   v.export help

DESCRIPTION

This program performs all of the processes that are needed to convert binary vector files into formatted ASCII files.

It also creates support files:

- an attribute flat file, which contains information for each area in the DLG file -- i.e., the DLG area number, the GRASS area label, and the GRASS category code (only created when exporting in DLG format);
- an attribute file which contains the information from the dig.art file (only created when exporting ASCII vector format).

EXPORT FILES

After entering the command v.export, the user will be asked which type of file to export:

Exports from GRASS Vector (v.digit) Format

1 - ASCII DLG file from GRASS Vector Format
2 - ASCII DIGIT file from GRASS Vector Format
3 - ASCII SCS-GEF file from GRASS Vector Format
4 - ASCII ARC/INFO file from GRASS Vector Format
5 - ASCII DXF file from GRASS Vector Format

If numbers 1-4 are chosen, v.export will respond with a request for the vector file name. After the user enters the file name the program proceeds to create the respective output format files.

GRASS Vector to DLG File

Converts binary vector files (such as those created by v.digit) to a DLG file and creates the attribute file. Both files are placed in the dig directory under a user selected name; the attribute file has .att appended.

GRASS Vector File into ASCII Vector File

Converts a binary vector file into a readable ASCII file. Both files are placed in the dig_ascii directory under the same name as the given vector file, the attribute file has .att appended.

GRASS Vector to SCS-GEF File

Converts binary vector files to SCS-GEF files. Creates the SCS-GEF header, lines, text, and feature files. All files are created and placed in a $LOCATION/gef directory as a single UNIX file under a user selected name.

The following is the SCS-GEF file structure:

header record 1
    |   |
header record n
    -head
line record 1
    |   |
line record n
    -line
The user will be required to use standard UNIX commands to separate this file into individual files as required by SCS-GIF specifications.

**GRASS Vector to ARC/INFO(generated) File**

Converts binary vector files to a "ARC ungenerate" format. A GRASS vector file to be exported to ARC/INFO must be either a line coverage (must contain only lines) or a polygon coverage (must contain only area edges). Both "ungenerate lines and points" files are created and are placed in a SLOCATION/arc directory under a user selected name.

The binary vector name will be used to name the various files that will be created for export to ARC/INFO. In the case of a labeled polygon coverage, the following three files will be created: a lines file with the suffix .lin, a label-points file with the suffix .lab, and a label-text file with the suffix .txt.

In the case of a line coverage the following two files will be created: a lines file with the suffix .lin, and a label-text file with the suffix .txt.

An unlabeled polygon or line coverage will result in a lines file (.lin suffix) only. See the DATA FILE FORMATS section of v.import for more information on these files.

**GRASS Vector to DXF file**

Converts binary vector files to a "DXF" format.

**NOTES**

Support files must be built using the GRASS program v.support before exporting any vector file.

Other ASCII formats are useful when importing/exporting data into and from GRASS. Such data files should be in ASCII format when transferred.

**AUTHOR**

R. L. Glenn, USDA SCS, NHQ CGIS
**NAME**

`v.extract` - Selects vectors from an existing vector map and creates a new map containing only the selected vectors.

*(SCS GRASS Vector Program)*

**SYNOPSIS**

```
v.extract
v.extract help
v.extractFR [-dln] type =name input =name output =name new =value
[list=range] [file =name]
```

**DESCRIPTION**

`v.extract` allows a user to create a new vector map layer from an existing vector map layer. User provides the program with category numbers or option (n) names, input vector file name, an output vector name, and the type of input map. There is an option (d) to dissolve common boundaries between adjoining map areas in the same category list. The user may specify a file containing category values or names.

**Note:**

The dissolve option will work on only those areas which are in the given category list. If a map area is inside (island) a listed category area and is NOT in the given category list, its boundaries are output to the resultant map.

**COMMAND LINE OPTIONS**

Flags:

- `-d` Dissolve common boundaries (default is no).
- `-n` Use category names NOT category values.

Parameters:

- `type =name` Select area, line, or site.
  Options: area, line, site
- `input =name` Input vector map name.
- `output =name` Output vector map name.
- `new =value` Enter 0 or a desired NEW category value.
- `list=range` Category ranges.
  For example: 1, 3-8, 13
  For example: Abc, Def2, Xyz
- `file =name` Text file name for category range list.

**EXAMPLE**

```
$GISBASE/etc/v.extract -d list=1,2,3,4 &
input=soils output=soil_groupa type=area new=1
```

Produces a new vector area file `soil_groupa` containing 'area' boundaries from `soils` with area category values of 1 thru 4; any common boundaries are dissolved, and all areas of the new map will be assigned category value 1.

```
$GISBASE/etc/v.extract -dn list=Abc,Def1,12A,WWd &
input=soils output=soil_groupa type=area new=0
```

Produces a new vector area file `soil_groupa` containing 'area' boundaries from `soils` with area category names of Abc, Def1, 12A, WWd; these names correspond to values 1 thru 4 of `soils`. Any common boundaries are dissolved, all areas of the new map will retain their original category values 1 thru 4, in this case, since new was set to 0.
$GISBASE/etc/v.extract -a input=soils output=soil_groups &\type=area new=1 file=sample

Produces a new vector area file soil_groups containing 'area' boundaries from soils. No common boundaries are dissolved, all areas of the new map will be assigned category value 1. The "names" (-n option) can be found in the file sample of the current directory.

The format for "sample" is:
Abc
Def1
12A
WWd

AUTHOR
R. L. Glenn, USDA SCS, NHQ-CGIS
NAME
    \texttt{v.import} - SCS user interface to GRASS import programs.
    (SCS GRASS Vector Program)

SYNOPSIS
    \texttt{v.import}
    \texttt{v.import help}

DESCRIPTION
    This program performs all of the processes that are needed to convert ASCII DLG files, binary DLG files, ASCII SCS-GEF files, ASCII ARC Unigenerate files, ASCII DXF files, and ASCII vector files into binary vector files. It also creates support files, the dig_plus file and the dig_att file (only created when importing DLG, SCS-GEF, or ARC files). The dig_plus file contains topological information obtained by analyzing the vector file. The dig_att file contains attribute information 'stripped' from the DLG file or SCS-GEF text data. This dig_att file is created for vector files by the labeling function of the GRASS \texttt{v.digit} program.

IMPORT FILES
    After entering the command \texttt{v.import}, the user will be asked which type of file to import and create support files for:

    Import to GRASS Vector Format and Creates Needed Support Files
    1 - ASCII DLG file to GRASS Vector Format
    2 - Binary DLG file to GRASS Vector Format
    3 - ASCII DIGIT file to GRASS Vector Format
    4 - Binary DIGIT file to GRASS Vector Format
    5 - ASCII SCS-GEF file to GRASS Vector Format
    6 - ASCII ARCINFO file to GRASS Vector Format
    7 - ASCII DXF file to GRASS Vector Format
    8 - ASCII TIGER file to GRASS Vector Format

    If numbers 1-3 or 5-8 are chosen, \texttt{v.import} will respond with the current data base units (in feet or meters), and ask if the new vector file is in the correct units for the data base location. If the new vector file is not in the correct units, \texttt{v.import} will not allow it to be placed in the current data base location. For each data base location, all data layers should have the same units. If, for some reason, a data layer has different units than the rest of the data layers in the same data base, a new data base location will have to be created for it.

ASCII DLG File to GRASS Vector
    Converts ASCII DLG files (such as those created in GRASS) to a vector file and creates the dig_plus and dig_att support files. The user is asked several questions:
    1. The name of the DLG data file.
        NOTE: It should be available in the $LOCATION/dlg directory. If the DLG data has an attribute flat file, it should also be in $LOCATION/dlg.
    2. Determine if this map is composed of Area or Line information.
        NOTE: Some machine-processed DLG files do not make the distinction between lines and area edges. For example, in a roads map, where the desired information is line data, a downtown block surrounded by roads may be processed as an area. Because of this, the user is asked to choose whether to give precedence to areas or lines. If precedence is given to lines, the user should be aware that any lines that bound unlabeled areas in the DLG file will be stored as line data. Any unlabeled areas would therefore be lost (this is only a concern when areas are unlabeled, labeled area information will be retained). If precedence is given to areas, lines will be stored as boundaries to areas that are unlabeled.
    3. Determine if you want to snap nodes to other nodes within a threshold.
        NOTE: BE CAREFUL!!! This threshold is calculated using the scale of the original DLG or
v.import file. If the threshold is too high, excessive snapping may occur, destroying the file. In general, users seldom need to snap nodes. If snapping of nodes is desired, the user may want to run v.support separately. v.support allows the user to set the snapping threshold.

4. Does the DLG data contain GRASS category codes?

NOTE: Most non-GRASS computer systems will not be able to provide the necessary codes. The flat attribute file serves this purpose. If the answer to this question is NO:

1) Enter a SUBJECT MATTER file name.
A subject file will be used to assign GRASS category codes to the DLG data. It is structured the same as a dig.cats category file. It is suggested that a SUBJ directory be created in the GRASS location and a file containing all DLG attribute text labels by category be created. This will be required to provide consistency across several maps (quads) within one location. The user may use the vi text editor or the SCS macro make_subject to create it.

2) Enter an ATTRIBUTE file name.
This is the name of the flat file which will accompany a DLG from a non-GRASS system. This file contains all of the DLG area numbers with a corresponding text label.

3) Is the DLG data from an ARC/INFO system?
ARC/INFO DLG data is handled in a slightly different manner.

4) Does the DLG contain a Universe Polygon?
Some DLG files may or may NOT have this and processing will be required to handle each case differently.

This process is done in three phases:

1. If the DLG does NOT contain category codes, then a category file from the attribute file is created. Then the ASCII dlg file is converted to a binary dig file.
   - OR -
   If the DLG does contain category codes, then the ASCII DLG file is converted to a binary DLG file.

2. The binary dig file is converted to a binary vector file, and the dig.att support file containing attribute information is created.

3. The dig_plus support file is created by analyzing the vector file for topological information.

**Binary DLG File to GRASS Vector**

Converts binary DLG files (which should be in the bd1g directory) to a vector file and creates the dig_plus and dig_att support files. The user is asked whether precedence should be given to Areas or Lines and if nodes should be snapped to other nodes within a calculated threshold.

This process is done in two phases:

1. The binary DLG (bd1g) file is converted to a binary vector file, and the dig.att support file containing attribute information is created.

2. The dig_plus support file is created by analyzing the vector file for topological information.

**ASCII Vector File into GRASS Vector**

Converts ASCII v_digit files (which are located in dig_ascii directory) into binary vector files and creates the dig_plus support file. Since a vector file keeps the distinction between lines and area edges, the user is asked to give precedence to either. However, the user will be asked if the user wants to snap from nodes to other nodes within a calculated threshold.

This process is done in two phases:

1. The ASCII vector file is converted to a binary vector file, and the dig_plus support file is created.

2. The dig_plus support file is created by analyzing the vector file for topological information.
Binary Vector File to GRASS Vector
Creates the `dig_plus` support file.

This process is done in one phase:
1. The `dig_plus` support file is created by analyzing the vector file for topological information.

ASCII SCS-GEF File to GRASS Vector
Creates the `dig_plus`, `dig_att`, and `dig_cats` support files. Creates a registration coordinates file.

Allows a user to create a GRASS vector file from a SCS-GEF format ASCII file.

1. The program will first request the name of the SCS-GEF file to be read in; it expects to find the data in the `$LOCATION/gef` directory.
2. The program will then request the name of a GRASS vector file.
3. The program will then request the name of a SUBJECT file. A subject file will be used to assign GRASS category codes to the SCS-GEF data. It is structured the same as a `dig_cats` category file. It is suggested that a SUBJ directory be created in the GRASS location and a file containing all SCS-GEF text labels by category be created. This will be required to provide consistency across several mapsets (quads) within one location. The user may use the `vi` text editor or the SCS macro `makel_gef` to create it.
4. The program will then read the SCS-GEF header information, interactively present information that was available, and request additional data of the user. These questions are:
   - Name of their organization. (from SCS-GEF)
   - Digitized Date. (from SCS-GEF)
   - Map Name. (from SCS-GEF)
   - Map Location. (from SCS-GEF)
   - Other Information. (from SCS-GEF)
   - State FIPS code.
   - County FIPS code.
   - Present GEF Coord. System (table, stplane, II, utmn).
   - Coord. System Desired (utm, stplane, ll, albers).

   The program will then actively read the SCS-GEF data file and process it.

Note: scripts contains SCS macro `makel_gef`. This macro makes one file out of the three (3) files found in SCS-GEF (see SCS-GEF technical specifications for more information). The macro must be run on each data set BEFORE `v.import`.

ASCII ARC/INFO Ungenerate Format Files to GRASS Vector Format
Creates the `dig_plus`, `dig_att`, and `dig_cats` support files.

The program will prompt you to enter the names of ARC/INFO files to be imported to GRASS. ARC/INFO vector files to be imported into GRASS must be exported from ARC/INFO using the ARC/INFO Ungenerate command. ARC/INFO vector files which are to be imported to GRASS, must be either line or polygon coverages. They must also be placed in a $LOCATION/arc directory. The section of the ARC/INFO manual that covers the Ungenerate command describes how to export line and polygon coverages.

A polygon coverage is represented by three files:
1) a lines file, which contains coordinates of all the area edge lines;
2) label-point file, which contains coordinates of label-points each with a unique label-point ID number. There is one label-point for each polygon defined in the lines file; and
3) a label-text file, which associates label-point ID number with a category value and attribute text.
A line coverage is represented by two files:
1) a lines file, which contains coordinates of the lines, each with a line-ID number; and
2) a label-text file, which associates each line-ID number with a category value and attribute text.

The program will start out by asking you which type of coverage is to be imported, as follows:

**IMPORTING A POLYGON COVERAGE**

The prompts that will be presented for coverage type "polygon."

**COVERAGE TYPE**
Enter "polygon" or "line"
Hit RETURN to cancel request

**Answer "polygon"**

**NEATLINE**
Do you want a neatline? 
Enter "yes" or "no"

If you answer yes then vectors representing a box around the data will be inserted into the resulting GRASS vector file, otherwise no neatline will be created.

Next the program will prompt for the name of the lines-file containing the arc coordinates of the polygons. The lines-file is created with the *Ungenerate LINES* option and is the same format as the `map_name.pol` file created by the program. The following is the prompt:

**LINES FILENAME**
Enter name of the file created with the LINES option of the ARC/INFO Ungenerate command.
Hit RETURN to cancel request

The next prompt for coverage type "polygon" asks for the name of the label-points file. The label-points files is created with the *Ungenerate POINTS* option and is the same format as the `mapname.lab` file created by the `export.vect` ARC program. The following is the prompt:

**LABEL-POINTS FILENAME**
Enter name of file created with the POINTS option of the ARC/INFO Ungenerate command.
Hit RETURN if there is no such file

The last prompt for coverage type "polygon" asks for the name of the label-text file. This file associates each label-point ID number with a text string and is the same format as the `mapname.txt` file created by the `export.vect` ARC program. The following is the prompt:

**LABEL-TEXT FILENAME**
Enter the name of a file that associates label-point ID numbers with text label strings.
Hit RETURN if there is no such file

The program will then scan the label-text file to determine how many columns are in the file and to determine which column should be used as the label-point ID number column. The program will then tell you how many lines and columns are in the label-text file. Next you will be prompted to enter the number of the column to be used for GRASS category values. The category number column MUST contain only integers.
Enter the number of the column that is to be used for GRASS category values:

and the number the column to be used for GRASS attribute text. The attribute text column can contain a floating point number, an integer, or a word.

Enter the number of the column that should be used for GRASS attribute text:

Once you enter the category and attribute column numbers, the program will begin conversion of the ARC/INFO Ungenerate files into GRASS vector format.

IMPORTING A LINE COVERAGE

First, you are prompted for the name of the lines-file containing the arc coordinates of the lines. The lines-file is created with the Ungenerate LINES option and is the same format as the mapname.lin file created by the export.vect ARC program.

LINES FILENAME
Enter name of the file created with the lines option of the ARC/INFO Ungenerate command.
Hit RETURN to cancel request

The last prompt for coverage type "line" asks for the name of the label-text file. This file associates each line-ID number with a text string and is the same format as the mapname.txt file created by the export.vect ARC program.

LABEL-TEXT FILENAMES
Enter name of file associating line ID numbers with label text.
Hit RETURN if there is no such file

The program will scan the label-text file to determine how many columns are in the file and will then tell you how many columns are in the label-text. Next you will be prompted to enter the number of the column to be used for line-ID numbers.

Enter the number of the column that is to be used for line-ID numbers:

Next you will be prompted to enter the number of the column to be used for GRASS category values. The category number column MUST contain only integers.

Enter the number of the column that is to be used for GRASS category values:

and the number of the column to be used for GRASS attribute text. The attribute text column can contain a floating point number, an integer, or a word.

Enter the number of the column that should be used for GRASS attribute text:

Once you enter the column numbers, the program will begin conversion of the ARC/INFO Ungenerate files into GRASS vector format.

DATA FILE FORMATS

Following are examples of the data files discussed in the section above.

LINES FILE, also known as xxx.lin or xxx.pol file. This type of file can be created in ARC/INFO by using the lines subcommand of the Ungenerate command. Each line, or arc, is defined by a line-ID number, followed by a list of at least two easting and northing coordinate pairs, followed by a line with the word "END’. The file is terminated with the word "END’.
The line-ID number is only important for line coverages. For a line coverage, the line-ID number is the number that associates each line with its attribute data.

```plaintext
3
711916.000000 4651803.000000
711351.875000 4651786.000000
END
3
709562.500000 4651731.000000
709617.250000 4651624.000000
709617.250000 4651567.000000
709585.000000 4651503.000000
709601.125000 4651470.000000
709696.875000 4651503.000000
709720.500000 4651574.000000
709823.750000 4651575.000000
709893.125000 4651741.000000
END
3
710296.875000 4651491.000000
710295.125000 4651470.000000
710223.000000 4651454.000000
710154.500000 4651463.000000
END
```

**LABEL-POINTS FILE**, also known as *.xxx.lab* file. This type of file can be created in ARC/INFO by using the `Points` subcommand of the `Ungenerate` command. The first number on each line is a label-point ID number, the following two are easting northing coordinates for the label-point.

```plaintext
1 711539.875000 4651743.000000
2 711429.000000 4650632.000000
3 711027.625000 4651736.000000
4 711022.625000 4651519.000000
5 710482.750000 4651494.000000
6 710474.500000 4651667.000000
7 709269.750000 4651018.000000
8 709726.500000 4651604.000000
9 708926.375000 4651195.000000
10 708567.500000 4651644.000000
END
```

**LABEL-TEXT FILE**, also known as *xxx.txt* file. This type of file can be created in ARC/INFO by using the `Display` command.

```plaintext
1 -2.30228E+07 19.399.848 1 0 0 0
2 81,079.875 1,678.826 2 1 15 3
3 955,952.500 10,229.637 3 2 19 8
4 41,530.875 926.887 4 3 17 3
5 87,900.188 1,900.909 5 4 13 3
6 166,125.125 3,512.950 6 5 15 3
7 29,460.563 824.968 7 6 17 3
8 1022769.875 9,105.707 8 7 20 9
9 51,385.500 1,075.638 9 8 17 3
10 376,834,875 4,470.027 10 9 9 2
```
NOTES
When importing a polygon coverage, the program finds the label-point ID in a label-text file by looking for the second column in the file that contains a "1" on line 1, and a "2" on line 2.
If you are missing a label-points or a label-text file you can still import ARC/INFO data (but none of your lines or areas will be labeled).

ASCII DXF Format Files to GRASS Vector
Creates the dig_plus, dig_att, and dig_cats support files.

ASCII TIGER Format Files to GRASS Vector
This program imports Census line features from TIGER records type1 and type2 into GRASS vector format. Both pre-Census and post-Census data formats can be used. Specific Census Feature Class Codes (CFCs) can be extracted completely or in various combinations. These codes are described in the TIGER/line Census Files 1990 documentation available from the Bureau of the Census. An additional feature code consisting of the three letters "BOU" may also be specified to extract a county boundary. Condensed Record 1 files may be imported with the -c flag. These files should be identified with a trailing "x" character on the filename.
The TIGER files must be in sorted order before being used. This can be done by using the following command:

```bash
sort TGR12113.F21 -o t12113.1
sort TGR12113.F22 -o t12113.2
```
For consistency, the sorted file should be written as above. It should consist of a 't' followed by the State and County FIPS code, then a '.' and then a value to identify the record number.

v.in.dlg.scs

GRASS Reference Manual

NAME

v.in.dlg.scs - Developed to handle DLG-3 ASCII import of data, specifically a DLG WITHOUT category/attribute codes. DLG files with this affliction will require a flat ASCII file having a 1 to 1 correspondence between DLG area number and a text label.

(SCS GRASS Vector Program)

SYNOPSIS

v.in.dlg.scs
v.in.dlg.scs help
v.in.dlg.scs [-uf] [dlg=name] [bdlg=name] [att=name]

DESCRIPTION

Under normal circumstances, the v.in.dlg program will handle the requirements of reading DLG data and creating vector maps from it. However, v.in.dlg assumes that the DLG-s file will contain major/minor category numbers; this is NOT always the case. In some instances, the user may want label names with the DLG data; the current DLG-3 specification does not provide that. SCS has developed this program to meet that need.

Notes:

This program is normally NOT called from the command line. v.import will create the command string, then execute it.

This program converts an ASCII DLG file to a binary DLG file with attribute codes in the major minor fields, and creates a dig_cats file with the correct code/label correspondence. The program v.a.b.dlg must be run after this program to create the GRASS vector files.

It is assumed that the DLG data file contains only one set of geographic information; i.e., areas, or lines, or points. This program WILL FAIL if mixed data is encountered.

Degenerate lines are accepted in this program as point data.

DLGatt File format

The DLGatt attribute file format is simple:

field 1 - DLG [area|line|point] number
field 2 - Label

COMMAND LINE OPTIONS

Flags:

-u 
DLG file contains universe area.

-f 
An attribute file is included.

Parameters:

dlg =name 
ASCII DLG (dlg) file name.

bdlg =name 
Binary DLG (bdlg) file name.

att =name 
DLG attribute (dlg.att) file name.

NAME
v.in.scsgef - Converts SCS Geographic Exchange Format (SCS-GEF) ASCII data into a GRASS vector file.
(SCS GRASS Vector Program)

SYNOPSIS
v.in.scsgef
v.in.scsgef help
v.in.scsgef [-o] [gef=name] [output=name] [cat=name]

DESCRIPTION
v.in.scsgef allows a user to create a GRASS vector file from a SCS-GEF format ASCII file.

1. The program will first request the name of the SCS-GEF file to be read in; it expects to find the data in the current directory. It is suggested to create a gef directory and put all SCS-GEF data there.

2. The program will then request the name of a GRASS vector file.

3. The program will then request the name of a SUBJECT file. A subject file will be used to assign GRASS category codes to the SCS-GEF data. It is structured the same as a dig_cats category file. It is suggested that a SUBJ directory be created in the GRASS location and a file containing all SCS-GEF text labels by category be created. This will be required to provide consistency across several maps (quads) within one location. The user may use the vi text editor or the SCS macro make_subject to create it.

4. The program will then read the SCSGEF header information, interactively present information that was available, and request additional data of the user. These questions are:
   Name of their organization. (from SCS-GEF)
   Digitized Date. (from SCS-GEF)
   Map Name. (from SCS-GEF)
   Map Location. (from SCS-GEF)
   Other Information. (from SCS-GEF)
   State FIPS code.
   County FIPS code.
   Present GEF Coord. System (table, stplane, ll, utm).
   Coordinate System Desired (utm, stplane, ll, albers).

The program will then actively read the SCS-GEF data file and process it.

scripts contains SCS macro make_1_gef. This macro makes one file out of the three (3) files found in SCS-GEF (see SCS-GEF technical specifications for more information). The macro must be run on each data set BEFORE v.in.scsgef.

COMMAND LINE OPTIONS
Flag:
-o The SCS-GEF is in the OLD format (24 char).

Parameters:
gef=name ASCII SCS-GEF file name.
output=name Vector file name.
cat=name Category file name.

NAME
v.in.tiger.scs - Converts ASCII TIGER data files from the U.S. Dept. of Commerce Bureau of the
Census.
(SCS GRASS Vector Program)

SYNOPSIS
v.in.tiger.scs
v.in.tiger.scs help
v.in.tiger.scs [-cv] tig1=name tig2=name out=name cfc=name[name,...]

DESCRIPTION
This program imports Census line features from TIGER records type1 and type2 into GRASS vector
format. Both pre-Census and post-Census data formats can be used. Specific Census Feature Class
Codes (CFCC) can be extracted completely or in various combinations. These codes are described in
the TIGERline Census Files 1990 documentation available from the Bureau of the Census. An
additional feature code consisting of the three letters "BOU" may also be specified to extract a county
boundary. Condensed Record 1 files may be imported with the -c flag. These files should be identified
with a trailing "x" character on the filename.

COMMAND LINE OPTIONS
Flags:
-c Condensed TIGER file.
-v Verbose output.
Parameters:
tig1=name TIGER file 1.
tig2=name TIGER file 2.
out=name New vector file name.
cfc=name,name,... Specific Census Feature Class (CFCC) codes.

EXAMPLE
To extract all Primary (Al) and Secondary (A2) roads from a county's TIGER files the following
command would be used:
   v.in.tiger.scs tig1=12113.1 tig2=12113.2 out=roads cfc=A1,A2
To extract all the Hydrographic features in a county's TIGER files with verbose output:
   v.in.tiger.scs -v tig1=12113.1 tig2=12113.2 out=hydro cfc=H
To extract the county boundary the command would be:
    v.in.tiger.scs tig1=12113.1 tig2=12113.2 out=bou cfc=BOU

NOTES
The TIGER files must be in sorted order before being used. This can be done by using the following
command:
   sort TGR12113.F21 -o 12113.1 sort TGR12113.F22 -o 12113.2
For consistency the sorted file should be written as above. It should consist of a 't' followed by the
State and County FIPS code, then a ',' and then a value to identify the record number.
The CFCC code 'BOU' used to extract the County Boundary should be used alone as it will result in a
polygon AREA being created.
Currently output is in UTM only.

NAME

v.makesubj - Create a "subject" file from all category labels found in a set of listed vector maps.

(SCS GRASS Vector Program)

SYNOPSIS

v.makesubj
v.makesubj help
v.makesubj map=name[,name,...] subj=name

DESCRIPTION

Program to read the dig_cats file for each listed map. The program then creates (or appends to, if the SUBJ file exists) a "subject" file of all of the labels, giving a unique category value to each.

This program was designed to create a common category file from maps of areas that have the same category labels, but different category values; and that must be joined/merged together.

COMMAND LINE OPTIONS

Parameters:

map=name Vector map--source for composite.
subj=name New SUBJ file name.

SEE ALSO

v.merge

AUTHOR

R. L. Glenn, USDA SCS, NHQ-OGIS
NAME

\texttt{v.merge} - Merges vector map files.

(\textit{SCS GRASS Vector Program})

SYNOPSIS

\texttt{v.merge}
\texttt{v.Merge}
\texttt{v.merge help}
\texttt{v.merge [-m] map=name[,name,...] output=name subj=name}

DESCRIPTION

Program to read the \texttt{dig.cats} file for each named map. The program then compares the category label (NOT the value) to the labels in the named subject file. If the label is found in the subject file, the corresponding attribute values of the map are changed to the subject file category value. When all maps are completed a patch operation is performed.

This program was designed to merge maps for areas that have the same category labels, but different category values associated with those labels.

There are two flags for \texttt{v.merge}:

Flags:

\texttt{-m} Use RAM to hold subject file category values. This may be faster than the default (use of disc files); however, memory may not be large enough for all of the subject file.

\texttt{-v} By default, only the name of the mapset processing is sent to standard output. In verbose mode, the user is given additional information on program operations.

Parameters:

\texttt{map=name,name,...} Vector map--source for composite.

\texttt{output=name} New name assigned to vector composite map.

\texttt{subj=name} SUBJ file name.

NOTES

The program \texttt{v.make subj} can be run prior to using \texttt{v.merge}. \texttt{v.make subj} will read the category labels of each map in its list and create a subject file of labels and values. Users may opt to create the subject file by other means if they wish.

\texttt{v.rmerge} must be run on any mapsets in the \texttt{v.merge} list prior to issuing the \texttt{v.merge} command. Common edges will need to be removed prior to the \texttt{v.merge} operation.

NAME

v.out.dlg.scs - Converts binary GRASS vector data to binary DLG-3 Optional vector data format.
(SCS GRASS Vector Data Export Program)

SYNOPSIS

v.out.dlg.scs
v.out.dlg.scs help
v.out.dlg.scs input=name output=name

DESCRIPTION

The GRASS program v.out.dlg.scs allows the user to convert GRASS vector data to DLG-3 Optional format, for export to other systems, just as v.out.dlg does. However, a flat ASCII file of labels and their corresponding dlg record numbers is created. This flat file is used to provide the label information to other systems, since most do NOT support text attributes in a DLG import.

The user can run the program non-interactively by specifying all program arguments on the command line, in the form:

v.out.dlg.scs input=name output=name

Parameters:

input=name Name of the binary GRASS vector data file to be converted to DLG-3 format.
output=name Name to be assigned to the DLG-3 Optional format output file created.

If the user does not give the names of an input and output file on the command line, the program will prompt the user to enter these names.

NOTES

The v.out.dlg.scs program requires that the input vector map layer have full topological information associated with it. This means that the GRASS program v.support should have been the last program to have effected any changes upon the vector map layer before it is run through v.out.dlg.scs. If this is not the case, v.out.dlg.scs will terminate with a message that v.support needs to be run.

The output from v.out.dlg.scs will be placed in $LOCATION/dlg. The output flat file from v.out.dlg.scs will also be placed in $LOCATION/dlg, with the extension "att" attached to the same output name.

AUTHOR

R. L. Glenn, USDA SCS, NHO-CGIS
NAME

*v.out.scsgef* – Converts binary GRASS vector data to ASCII SCS-GEF vector data format.

*(SCS GRASS Vector Data Export Program)*

SYNOPSIS

```
v.out.scsgef
v.out.scsgef help
v.out.scsgef input=name output=name
```

DESCRIPTION

The GRASS program *v.out.scsgef* allows the user to convert GRASS vector data to SCS-GEF format, for export to other systems.

*v.out.scsgef* creates the SCS-GEF header, lines, text, and feature files. All files are created and placed in a `$LOCATION/gef` directory as a single UNIX file under the output name.

The following is the SCS-GEF file structure:

```
header record 1
  | | header record n
  -head
line record 1
  | | line record n
  -line
text record 1
  | | text record n
  -text
feature record 1
  | | feature record n
  -feat
```

The user will be required to use standard UNIX commands to separate this file into individual files as required by SCS-GEF specifications.

The user can run the program non-interactively by specifying all program arguments on the command line, in the form:

```
v.out.scsgef input=name output=name
```

Parameters:

- `input=name` Name of the binary GRASS vector data file to be converted to SCS-GEF format.
- `output=name` Name to be assigned to the SCS-GEF output file created.

If the user does not give the names of an input and output file on the command line, the program will prompt the user to enter these names.

NOTES

The *v.out.scsgef* program requires that the `input` vector map layer have full topological information associated with it. This means that the GRASS program *v.support* should have been the last program to have effected any changes upon the vector map layer before it is run through *v.out.scsgef*. If this is not the case, *v.out.scsgef* will terminate with a message that *v.support* needs to be run.

NAME
v.proj - Allows projection conversion of vector files.
(SCS GRASS Vector Program)

SYNOPSIS
v.proj
v.proj help

DESCRIPTION
v.proj allows a user to create a new vector map in another mapset with a different projection, from an
existing vector map in the current or some other user-specified mapset.

Note: If the "outset" mapset is not available, v.proj will create it in the current location. If the
"outset" mapset exists, v.proj reads its projection information, and uses it to convert to the output
projection.

If the "outset" projection information is not available, v.proj runs the program m.setproj to create it.

EXAMPLE
The current mapset (Map_utm14) has a utm projection, the coordinates are for zone14 meters, and
contains the map sample. The user wants to create a new map of scample in the mapset lambert
(which is a Lambert Conformal Conic projection mapset).

The command:

    v.proj map=sample outset=lambert

will create a new map sample in the mapset lambert, changing the utm coordinates of sample into
lambert coordinates. If the mapset lambert did not exist, v.proj would have created it.

v.proj will create dig, dig_att, and dig_cats directories in the output mapset, if they do NOT exist.
Map files for dig, dig_att, and dig_cats are also created for the new map layer.

v.psu - Program to build PSU polygon and PSU sites from single labeled line segment.
(SCS GRASS Vector Program)

SYNOPSIS
v.psu
v.psu help
v.psu input=name output=name psu=name subj=name [xdist=name]
[ydist=name]

DESCRIPTION
This program builds a complete PSU polygon and PSU points from a single labeled line segment
identifying the west edge of the PSU. The resultant polygon and points will be automatically labeled
based on the original line segment label.

Parameters:
input=name Vector input file name.
output=name Vector output file name.
psu=name psu_data file name.
subj=name Subject file name.
xdist=value x distance.
ydist=value y distance.

EXAMPLE
psu.vect in=spr out=spr.psu psu=SD009.PNT subj=bonhomme.psu

NOTES
Refer to SCS PSU Digitizing Manual for examples and further instruction.

NAME

\texttt{v.random} - Creates a GRASS site_lists file of randomly placed symbols (sites) within a GRASS vector area. 

(SCS GRASS Vector Program)

SYNOPSIS

\begin{verbatim}
v.random
v.random help
v.random [-nsv] map=name [site=name] dot=name
\end{verbatim}

DESCRIPTION

\texttt{v.random} allows a user to create a GRASS site_lists file containing sites randomly placed within an area. This program is designed for demographic map areas, and may NOT perform well for resource maps (very irregularly shaped polygons). The user provides the program with: a file (dot=) containing area category names [default] (the -n option allows the use of the area category number) and a count of dots for that name; input vector file name (map=), and a site_lists file name (site=). All sites in the site_lists file will have the same category code (1). \texttt{v.random} is made to work with the \texttt{mapgen} mapping package to create special symbols at the site locations.

Flags:

- \texttt{n} Use category numbers NOT names.
- \texttt{s} Determine optimum dot size.
- \texttt{v} Verbose mode.

Parameters:

- \texttt{map=name} Input vector file name.
- \texttt{site=name} Output site_lists file name.
- \texttt{dot=name} File name containing labels and dot counts.

FORMATS

The dot file format is:

- Using Names-
  area name_1:3 category_num_1:3
  area name_2:15 category_num_1:15
  area name_3:5 category_num_1:5
  area name_n:54 category_num_1:54

NAME
v.reclass - Changes vector category values for an existing vector map.
(SCS GRASS Vector Program)

SYNOPSIS
v.reclass
v.reclass help
v.reclass [-d] type=name input=name output=name file=name

DESCRIPTION
v.reclass allows a user to create a new vector map based on the reclassification of an existing vector map. The user provides the program with a category conversion file, input vector map name, an output vector map name, and the type of input map. There is an option (d) to dissolve common boundaries between adjoining map areas of the same re-classed category value.

Note: The dissolve option will work on only those areas that are of the same conversion category value. If a map area is inside (island) a converted area and is NOT converted to the same value, its boundaries are output to the resultant map.

COMMAND LINE OPTIONS
Flag:
-d Dissolve common boundaries (default is no).

Parameters:
type=name Select area, line, or site.
Options: area, line, site
input=name Vector input map name.
output=name Vector output map name.
file=name Text file name for category conversion.

EXAMPLE
$GISBASE/etc/v.reclass -d input=soils output=soil_groupa type=area
file=convert1,convert2,convert3

The input map soils contains 15 map area categories, the conversion files contain:

<table>
<thead>
<tr>
<th>convert1</th>
<th>convert2</th>
<th>convert3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1:1</td>
<td>3:2</td>
<td>2:3</td>
</tr>
<tr>
<td>10:1</td>
<td>4:2</td>
<td>7:3</td>
</tr>
<tr>
<td>12:1</td>
<td>5:2</td>
<td>8:3</td>
</tr>
<tr>
<td>15:1</td>
<td>6:2</td>
<td>9:3</td>
</tr>
<tr>
<td>11:2</td>
<td>13:3</td>
<td>14:3</td>
</tr>
</tbody>
</table>

Produces a new vector area file soil_groupa containing 'area' boundaries from soils with area category values of 1,10,12,15 changed to category 1; values of 3-6,11 changed to 2; and values 2,7,9,13-14 changed to 3. Any common boundaries are dissolved.

NOTE:
The format for "category label" is:

if NO SPACES in the labels if SPACES in the labels
Abc area name 1:
Def1 area name 2:
12A ...
WWD area name n:
The format for "category value" is:

1
10
12
15

INTERACTIVE MODE

v.reclass

- The first question asked is the map type:
  Enter the type of map (area, line, site) [area] :
  The default is for areas.

- The next question is if common boundaries are dissolved:
  Do you want common boundaries dissolved ?(y/n) [n]
  The default is no, meaning all exiting boundaries will be retained.

- The next question is an option for using category labels:
  Do you want to use category names ?(y/n) [n]
  The default is no, meaning the user will be using category values.

- The next question asks for the name of the input map:
  Enter vector map
  Enter 'list' for a list of exiting vector files
  Hit RETURN to cancel request
  >
  Any map in the user's search list is available.

- The next question asks for the name of the output map:
  Enter name for resultant vector map
  Enter 'list' for a list of exiting vector files
  Hit RETURN to cancel request
  >
  If the name is for an existing map, the user will be asked if the map can be over-written.

- The next question asks if a file of labels/categories is to be used:
  If names was selected previously:
    Do you want to use a file of labels? (y/n) [n]
  If names was NOT selected previously:
    Do you want to use a file of categories?(y/n) [n]

- At this time the user will be asked for category 1 information:
  1. be asked to enter a file name - if file input was selected, or
  2. be asked to enter the information manually.

Then the user will be asked for category 2 information:
Then the user will be asked for category 3 information:

Then the user will be asked for category n information:

- When no entry is provided the program will begin.

NAME
v.report - Generates statistics for vector files.
(SCS GRASS Vector Program)

SYNOPSIS
v.report
v.report help
v.report [-h|f] map=name type=name [units=name[name,...]] [pl=value] [pw=value]

DESCRIPTION
v.report generates a table showing the area present in each of the categories of a user-selected data layer. Area is given in hectares, square meters, and square kilometers. If the units option is used, area is given in acres, square feet, and square miles. v.report works on the map data; therefore, the current region and mask are ignored.

Flags:
-h Suppress page headers.
-f Use formfeeds between pages.
-q Run quietly.

Parameters:
map=name vector map to report on.
type=name Type of vector map.
Options: area, line, site
units=name[name,...] m(les), f(eet), m(e ters), k( ilometers), a(cres), h(ectacres), c(ounts).
pl=value Page length, in text lines.
Default: 0
pw=value Page width, in characters.
Default: 79

EXAMPLE
Following is a sample table generated by v.report where type=area.

v.report -hfq map=soils type=area units=c,me

NAME

v.medge - Selects edge vectors from an existing vector map, removes them, and creates a new vector map.
(SCS GRASS Vector Program)

SYNOPSIS

v.medge
v.medge help
v.medge input=name output=name

DESCRIPTION

v.medge allows a user to create a new vector map from an existing vector map, however **ALL OUTER** boundaries will be gone. Any outer edge that needs to be retained will require adding another outside boundary; v.digit can be used to provide this additional boundary.

Parameters:

input=name Name of vector input file.
output=name Name of vector output file.

NOTES

When using v.digit to add an additional boundary to a map, it may be necessary to break the boundary of an existing area. The user *** MUST REMEMBER *** that breaking the boundary of a named area *** REMOVES THE LABEL ***, and the area *** MUST BE RE-LABELED *** prior to leaving v.digit;
-OR-
*** v.medge will REMOVE that area boundary ALSO ***
This will result in MISSING data in a patching operation.

v.scale.random – Creates a site_lists file of randomly placed symbols within a GRASS vector area. 
(SCS GRASS Vector Program)

SYNOPSIS
v.scale.random
v.scale.random help
v.scale.random [-n] map=name site=name dot=name [outdot=name]
   scale=value [cover=value] [size=value]

DESCRIPTION
v.scale.random allows a user to create a GRASS site_lists file containing sites randomly placed within an area. This program is designed as an interface to v.random to aid the user in determining the number of dots to locate. This program uses the same type of file listing the category and counts. This file is then modified to try to produce a pleasing dot count for a map of a specified scale.

COMMAND LINE OPTIONS
Flag:
-n Use category values, NOT category names.

Parameters:
map=name Input vector file name.
site=name Output site_lists file name.
dot=name Name of file containing labels and counts.
outdot=name Name of new file to contain scaled counts.
scale=value The denominator of the map scale.
   Options: 1 - 999999999999
cover=value The fraction of the most dense area to cover with dots.
   Options: 0 - 1
size=value The size of each dot, in centimeters.
   Options: 0 - 100

SEE ALSO

AUTHOR
M. L. Holko, USDA SCS, NHQ-CGIS
This chapter contains descriptions of file formats and drivers used by some GRASS programs.

Other software also distributed with GRASS is not documented in this volume; this includes programs contained under the src.garden and src.related directories that the user must compile separately (see the GRASS Installation Guide for compilation instructions). The src.garden directory includes program interfaces that link GRASS 4.0 with other related software (including UW-RIM and BNOISE). The src.related directory includes programs to which GRASS has been interfaced that program developers have allowed to be distributed with GRASS (such as UW-RIM and BNOISE, MAPGEN, GCTP, PBMPPLUS, and XGEN). These programs are described in their original program documentation.
NAME

imagery - Description of GRASS image processing functions.

IMAGE PROCESSING IN GRASS

The following discussion is intended to provide a quick overview of image processing in GRASS. Some concepts and some hints are provided. For a more complete discussion and description of image processing in GRASS see GRASS Tutorial: Image Processing.

EXTRACTING IMAGERY DATA INTO A GRASS DATABASE

Remotely sensed images are captured for computer processing by filtering radiation emanating from the image into various electromagnetic wavelength bands, converting the overall intensity for each band to digital format, and storing the values on computer compatible media such as magnetic tape.

The GRASS programs that extract image data from magnetic tape can read LANDSAT multi-spectral scanner (MSS) data (i.tape.mss), LANDSAT thematic mapper (TM) data, (i.tape.tm), and other formats, such as scanned aerial photography or SPOT satellite data (i.tape.other). They extract the band data into raster files in a GRASS data base. Each band becomes a separate raster file, with standard GRASS map layer support, and can be displayed and analyzed just like any other raster file.

UNREGISTERED DATA

The band data extracted from tapes are assumed to be unregistered data. This means that the GRASS software does not know the earth coordinates for pixels in the image. The only coordinates known at the time of extraction are the columns and the rows relative to the way the data were stored on the tape.

Data can only be extracted into a data base that has an x,y coordinate system, and not into a projected data base (e.g., a UTM data base). This is to prevent users from mixing the unregistered data with registered data in the same data base. The GRASS system comes with the data base imagery, which is an x,y data base. New data bases can be created by users during GRASS startup. See the g.help section on "Setting Up a GRASS Database" for instructions on creating a new data base.

CELL HEADERS

The cell headers for the band files in these x,y data bases are set to reflect the rows and columns of the extracted data. The north-south values represent the rows, and the east-west values represent the columns. The resolution of the unregistered data is set to 1.

Note, however, that while the row numbers increase from 1 to n from north to south, GRASS requires that the values of the user's current geographic region decrease from north to south. The solution adopted was to represent the rows with negative values (i.e., -1 to -n). This allows them to decrease from north to south and, if the minus sign is ignored, to reflect the row numbers.

The cell headers for the layers in x,y data bases are set so that the coordinates at the center of each pixel exactly reflect the row and column for that pixel. The northern edge is set to 0.5 less than the first row, the southern edge 0.5 larger than the last row, the west to 0.5 less than the first column, and the east to 0.5 larger than the last column. When the image is displayed on the graphics monitor, the d.where command can be used to report row and column values.
For example, suppose rows 100-500 and columns 200-800 are extracted. Then the cell headers for the extracted data will be given the following values:

- north: -99.5
- south: -500.5
- west: 199.5
- east: 800.5
- ns res: 1.0
- ew res: 1.0

REGION AND MASK
Since the data layers are given essentially contrived cell headers, users must exercise extra care when analyzing or displaying unregistered images. It is very easy for the user's GRASS region to have absolutely no relationship to the data the user is attempting to display. This could happen when the region is set for data extracted from one tape, but the analysis is attempted on data extracted from another tape. A good habit to develop is to set the region to exactly match one of the band files. This can be done using the GRASS `g.region` command.

Another pitfall is to have a mask set to a band file from one data set while trying to read another. Even if the region is set properly, the data will appear to be all no-data since the mask will effectively knock out any data. Be sure that the mask is either set to a related data layer or not set at all. See `r.mask` for information on setting and unsetting the mask.

Please note that the tape extraction routines set your data base region to match the rows and columns of the data that is extracted.

GROUPS
Since the band files are individual raster files, it is necessary to have a mechanism to maintain a relationship between band files from the same image as well as raster files derived from the band files. The GRASS `group` data structure accomplishes this goal. The group is essentially a list of names of raster files that belong in the group. For user convenience, groups are also created (and updated) by the tape extraction routines. The tape extraction programs ask the user to supply a group name as well as to specify the bands to be extracted. Suppose that the user extracts bands 1, 2, and 3 into a group called `nhap`. Then the band files will become the raster files `nhap.1`, `nhap.2`, and `nhap.3` and the group `nhap` will list these 3 raster files as members of the group.

Groups can also be created and modified by the user using the GRASS command `i.group`.

IMAGE REGISTRATION AND RECTIFICATION
Image registration and image rectification is the process of associating earth coordinates with pixels on the image and then converting the unregistered raster files to raster files in a projected data base.

Image registration (`i.points`) is applied to a group, rather than to individual raster files. The control points are stored in the group, allowing all related band files to be registered in one step rather than individually.

Image rectification (`i.rectify`) is applied to individual raster files, with the control points for the group used to control the rectification and the group target (`i.target`) used to specify the data base where the rectified layer will live.

IMAGE CLASSIFICATION
Image classification methods process all or a subset of the band files as a unit. Spectral signatures for the image are generated (`i.cluster`) and then used to produce a landcover map (`i.maxlik`).
The signatures must be associated only with the raster files actually used in the analysis. This means that with a group subgroups must be created (i.group) that list the band files to be grouped for classification purposes. The signatures are stored with the subgroup.

Note that multiple subroups can be created within a group. This allows different classifications to be run with different combinations of band files.

Also note that raster files produced by the classification process (i.maxlik) are automatically listed as part of the group.

RECTIFIED VS. UNRECTIFIED ANALYSIS

There are two possible routes for processing image data. The first is to register the group (i.points), perform the analyses on the unrectified band data (i.maxlik), and then rectify the results (i.rectify). The second is to register the group (i.points), rectify the band data (i.rectify), then run analyses on the rectified band data in the target location (i.rectify). Both routes are permissible in GRASS. Users will most likely prefer the first. The second route requires leaving GRASS and re-running GRASS under the target location. It also will require that a group be created to hold the rectified band files since i.rectify does not create or modify groups. Also, spatial filtering may not be as effective on rectified data since the rectification of the data requires resampling the original data.

NAME

monitorcap – Description of device-driver data base file format.

DESCRIPTION

The d.mon command and all graphics commands access a device-driver data base stored in the file $GISBASE/etc/monitorcap. This file contains a line for each graphics monitor on the system. Each line contains six fields separated by colons:

- **name**: The name by which the user identifies the driver
- **program**: The full pathname of the executable driver or a pathname relative to $GISBASE
- **description**: A short four- or five-word description of the driver.
- **fifos**: Full pathnames to the input and output fifos over which the driver communicates with the libraries
- **tty**: The name of the tty from which the driver must be started, or empty if there is no such restriction
- **msg**: A message to print to the user if an attempt is made to start the driver from the wrong tty.

EXAMPLE

The following is an example of a single-monitor system. The driver may be started from any terminal and uses /dev/fifo.a and /dev/fifo.b for communication with application programs:

```
x:driver/X:graphics monitor:/dev/fifo.a /dev/fifo.b::any terminal
```

This example has 2 monitors on the system, using the same device driver. Note that each has a different name field and uses a different pair of fifos. Also, each must be started on a specific terminal:

```
1:driver/X:monitor 1:/dev/fifo.1a /dev/fifo.1b:/dev/tty8:tty8
2:driver/X:monitor 2:/dev/fifo.2a /dev/fifo.2b:/dev/tty10:tty10
```

NOTES

Each line in this file must refer to a valid driver. No comment lines are supported. Also, no blank lines are allowed.

NAME
paint – Description of hardcopy color output system for GRASS.

INTRODUCTION
The paint system allows the user to produce color hardcopy maps of vector, raster, and sites file data at any scale. For a discussion of the GRASS paint functions, see the manual entries for p.chart, p.colors, p.icons, p.labels, p.map, p.screen, and p.select.

PAINT DEVICES
The GRASS paint system supports multiple color printers using a device driver concept. The paint (p.) functions listed above send graphics requests to device-dependent paint drivers. These drivers translate the application requests into device-dependent requests to produce hardcopy maps.

INSTALLING A PAINT DRIVER
A number of paint drivers have been distributed with GRASS. The installation of a driver is a two-step process. The first involves identifying the driver(s) which correspond to printer(s) connected to your system and compiling those drivers. The second involves telling each driver which I/O port it is to use.

1. The source code for the drivers lives in $GISBASE/src/paint/Drivers (The variable GISBASE refers to the directory in which GRASS is installed on your system.)

   The selection and compilation of the drivers is done when GRASS is compiled as a whole.

2. Each driver expects to send its output to /dev/driver. For example, the tek4695 driver expects to find a tektronix 4695 (or 4696) printer on /dev/tek4695.

   Suppose the printer is actually on /dev/tty10. Then, a link named /dev/tek4695 is made to /dev/tty10:
   
   In /dev/tty10 /dev/tek4695

NOTES
There are 2 drivers which do not use I/O ports. One is the preview driver, which sends its output to the graphics screen instead of a hardcopy printer. This driver is very handy and should definitely be compiled on your system.

   The other is the null driver, which is used for debugging purposes and probably should not be compiled on your system.

   If you compile either of these drivers, you shouldn’t create a /dev file for them.

AUTHOR
Michael Shapiro, U.S. Army Construction Engineering Research Laboratory
NAME
sites.S  - Description of the GRASS s.menu "S" interface option.

DESCRIPTION
This describes the GRASS s.menu "S" statistical package interface option. See also the manual entry for s.menu.

SPECIAL ADJUSTMENT
Due to the fact that "S" references all subscripts beginning with 1, and the GIS data begins with 0, it was necessary to add 1 to the category numbers. Therefore, category value 0 ("no data") becomes category value 1, category 1 becomes category 2, etc.

S DATA STRUCTURES
Below are descriptions of the data structures created by the interface. As a general comment, within "S", simply typing the data structure name will display the values contained in the structure. You may also find it interesting to display the data structures using the "S" function dpltO.

cat.histo, (cat.#histo)
This structure contains the histogram for the categories in each map layer. The histogram contains the number of cells of each category that occur in the user's geographic region (see wind.n, et al., below). It is a 2-dimensional integer array (matrix). The first subscript references the map layer. The second subscript references the category value.

Examples:
   cat.histo[2,5] is the cell count for layer 2, category 5.
   cat.histo[2,] is the full histogram for layer 2.

Note: since more than one layer may occur in the data, and the number of categories in each layer varies, it was necessary to create this structure with sufficient dimension to hold the largest category value for all layers. Histogram data for categories which do not occur are set to NA ("S" notation for "no data"). However, there is also an individual histogram structure for each layer: cat.1.histo, cat.2.histo, etc. These are simple vectors.

cat.name
This structure contains the names for the categories in each map layer. It is a 2-dimensional character array (matrix). The first subscript references the map layer. The second subscript references the category.

Examples:
   cat.name[2,5] is the name of category 5 for layer 2.
   cat.name[2,] are all category names for layer 2.

Note: since more than one layer may occur in the data, and the number of categories in each layer varies, it was necessary to create this structure with sufficient dimension to hold the largest category value for all layers. Names for categories which do not occur are set to ". However, there is also an individual category name structure for each layer: cat.1.name, cat.2.name, etc. These are simple vectors.

site.data
This structure contains the data for each site. It is a 3-dimensional integer array. The first subscript references the categories which occurred at the site. The second subscript references the site. The third subscript references the layer.
Examples:

site.data[5,3] is the data for site 5 in layer 3.
site.data[2,1] is the data for site 2 in all layers.
site.data[.,1] is all site data for layer 1.

Note: the size of the first dimension will be the number of cells in a site, the size of the second dimension will be the number of sites, the size of the third dimension will be the number of layers.

site.mode

Since "S" does not provide a statistical mode function, this structure contains the most frequently occurring category for each site in each layer. It is a 2-dimensional integer array (matrix). The first subscript references the site. The second subscript references the layer.

Examples:

site.mode[5,3] is the mode for site 5 in layer 3.
site.mode[2,1] are the modes for site 2 in all layers.
site.mode[.,1] are all site modes for layer 1.

Note: this 'mode' is not the strict definition of the mode. Since category 0 (which in "S" is category 1) represents "no data" in the GIS database, it was excluded from the mode calculations (essentially as if it had been NA). For example, if the data for a site are 1 1 1 2 2 3 2 3 1 1, the mode will be 2.

layer.name

This structure contains the raster map layer names. It is a 2-dimensional array (i.e., a matrix). The first subscript references the map layer. The second subscript selects either the map layer name, or the map layer title.

Examples:

layer.name[3,1] is the name of layer 3.
layer.name[3] is also the name of layer 3.
layer.name[2] is the name of layer 2.
layer.name[3,2] is the title for layer 3.

location

This is a simple character vector giving the GRASS location from which the data was extracted.

mapset

This is a simple character vector giving the GRASS mapset.

nlayes

This is a simple integer giving the number of map layers.

nsites

This is a simple integer giving the number of sites.

site.x

This is a simple integer vector giving the geographic easting for each site.

site.n

This is a simple integer vector giving the geographic northing for each site.
site.name
This is a simple character vector giving the description for each site.

sitelist
This is a simple character vector giving the name and description of the site lists file from which the sites were taken.

wind.n, wind.s, wind.w, wind.e
These are simple real numbers giving the north, south, west, east of the mapset's current geographic region.

wind.res
This is a simple real number giving the GRASS data base resolution (in meters).

S MACROS
You may find the following "S" macros helpful when referencing the 'site.data' and 'site.mode' structures, since they allow you to specify parameters:

MACRO site.data(site, layer)
{{
   site.data[ , site, layer]
}}
END

MACRO site.mode(site, layer)
{{
   site.mode[ site, layer]
}}
END

MACRO USAGE
To select the site.data for all sites for layer 2:

?site.data(layer=2)

to select the site.data for site 4 in all layers:

?site.data(site=4)

to select the site.mode for site 10 in layer 1:

?site.mode(layer=1,site=10)

SORRY, BUT ...
These macros are not provided by the interface. To use these macros, you will have to type them into a text file and then, from "S", issue the command:

define("<file>")

SEE ALSO
s.db, s.in.ascii, s.menu, s.out.ascii, s.surf.idw, sites.format, sites.occurs, sites.report
NAME

sites.format - Description of GRASS site list file format.

DESCRIPTION

This is a description of the site list files found in the GRASS data base. The files are kept in the site_lists directory under the current mapset.

SAMPLE SITES LIST

Here is a sample site list:

name: sample
desc: sample site list
728220 5182440 P27
727060 5181710 P28
725500 5184000 P29
719800 5187200 P30

EXPLANATION

Each record of data begins with a named field describing the record type, followed by fields of information. The fields are separated by the pipe character |

name

This field contains the name of the site list file, and is printed on all the reports.

It is permissible for this field to be missing, since the sites software will force this field to agree with the name of the site list file itself.

desc

This field contains a description of the site list file, and is printed on all the reports.

It is permissible for this field to be missing, in which case the site list will have no description.

point

Each site is described by a 'point' record. The fields for this record are:

<east> <north> <description>

<east> easting for the site
<north> northing for the site
<description> site description

The east and north fields, which are integers, must be present and valid or the record itself will be skipped by the sites software. The description field is optional, but recommended.

BUGS?

Invalid records will be (silently) ignored by the sites software. Other record types may be added in the future.

EXPLANATION

The "Site Occurrence Report" provides aggregate site information organized by raster map layers.

The report header contains the following information:

Location
GRASS data base location (e.g., yakima),

Mapset
GRASS mapset (e.g., sample)

Analysis Region
The rectangular area in which the analysis was run, reflecting the current geographic settings of the user’s mapset.

Site List
Name and description of the site list used for the report and the number of sites in the list. See manual entry for s.menu for more discussion about these site lists.

The rest of the report is divided into reports for each raster map layer specified by the user. In this SAMPLE OUTPUT, only one map layer (arch_survey) was specified.

Certain information heads up each of these reports:

layer
Identifies the raster map layer along with the map layer title.

cells in analysis region
The size of the analysis region (in cells).

sites in analysis region
The number of sites in the analysis region.
For each map layer category that occurs in a cell falling within the boundaries of the analysis region, as well as totals for the map layer as a whole, various statistics are presented:

**Site Characteristics**
These are the numbers (i.e., values) and names (i.e., descriptions) for each category (i.e., characteristic) that occurs in the map layer.

**cells cover**
The number of cells in the analysis region having the category value (i.e., site characteristic).

**% cover**
The predominance of the category within the analysis region.

**expected sites**
The number of sites in the analysis region that would be expected to be observed having the category value if all sites were evenly distributed in the region.

**actual sites**
The number of sites in the analysis region that occurred in cells having the category value.

**chi square**
Gives the user a statistical test of the hypothesis that 'site distribution is dependent on environmental factors.' For this hypothesis to be true, the chi-square test must fail since we are calculating expected sites according to the hypothesis that 'sites are randomly distributed.'

**degrees of freedom**
Number of degrees of freedom for the chi-square test. Each category value will have 1 degree of freedom, and can be tested alone. The entire map layer will have 1 less degree of freedom than the number of categories.
NOTE
Category zero (0) throughout GRASS represents "no data." Therefore, it is reported, but not included in the totals or in the computation of the chi-square statistics.

EXPLANATION

The machine readable report file consist of lines of text, with fields that are separated by the pipe character |. The first field on a line defines the record type, and the remaining fields are defined according to the record type.

location
This record gives the GRASS data base location.

location <name> <full name>

<name> Data base location
<full name> Long name for the location

mapset
This record gives the GRASS mapset.

mapset <mapset>

<mapset> Mapset under which the report was run

region
The region records give the mapset region coordinates.

region north <N>
region south <S>
region west <W>
region east <E>

<N> North for current region (float)
<S> South for current region (float)
<W> West for current region (float)
<E> East for current region (float)

resolution
This record gives the GRASS data base resolution in meters.

resolution <res>

<res> Resolution of the data base, in meters (float)

point
These records describe the sites that were used in the report. There is one 'point' record for each site.

point <site_ref> <E> <N> <desc>

<site_ref> A reference number, used by other lines in the report to reference this site
<E> Site easting
<N>' Site northing
<desc> A description of the site (usually an site number)

layer
These records describe the map layers that were used in the report. There is one 'layer' record for each layer.

layer <layer_ref> <name> <full_name>

<layer_ref> A reference number, used by other lines in the report to reference this layer
<name> Name of the map layer (raster file name)
<full_name> Full name (title of raster file)

cat
These records give information about each category in each layer.

cat <layer_ref> <cat> <count> <name>

<layer_ref> Reference number of the layer
<cat> Category number
<count> Number of times this category occurred
<name> Full name of the category

matrix size
This record gives the number of cells in each site.

matrix size <matrix size>

<matrix size> Number of cells per site.

matrix
These records describe the locations of each cell in the site relative to the center of the site.

matrix <ew_disp> <ns_disp> ...

<ew_disp> east-west displacement from the site
<ns_disp> north-south displacement from the site

The displacements are in units of 1 cell, which is equal to the resolution of the data base. They are paired, and there will be <matrix size> pairs. To compute the coordinates for the cell:

north = site_north + <ns_disp> * resolution
east = site_east + <ew_disp> * resolution

data
This is the site data. There is one 'data' record for each site for each layer. The <cat> field is repeated <matrix size> times.
data <layer_ref> <site_ref> <cat> ...

<layer_ref> Reference number of the layer
<site_ref> Reference number of the site
<cat> Category which occurred

APPENDIX: GRASS VECTOR DATA FILE FORMATS

David Gerdes, Michael Higgins, and James Westervelt
U.S. Army Corps of Engineers Construction Engineering Research Laboratory
P.O. Box 9005, Champaign, IL 61826-9005

1. INTRODUCTION

To be used by GRASS programs, data must be digitally stored in a GRASS database. Data can be entered into a GRASS database in one of several ways:

1. Hardcopy data (like paper maps) may be either digitized or scanned into GRASS's vector file format;
2. Data already available in another digital format (like ARC/INFO data) may be converted into one of GRASS's digital data file formats, and stored in a GRASS database;
3. GRASS analysis programs can be used to create new GRASS data from data already stored in a GRASS digital data file format.

GRASS commands operate on three basic forms of digital data: vector data, raster data, and sites data. In whichever of these forms data are represented, supporting information is needed to describe the geographic location and nature of the data stored.

For data stored in GRASS vector format, information on the location of vectors, the vector topology, vector category values, and category labels are stored in separate files. For data stored in GRASS raster format, additional files are also stored to hold information on category colors, the map's development history, etc. Information on site (point) data locations and categories are stored in a single file.

The programs v.support and r.support help the user build necessary GRASS support files for vector and raster data. GRASS commands automatically generate necessary support files. Refer to specific GRASS User's Reference Manual (Westervelt, Shapiro, et al.) program manual entries to learn when the user must explicitly create support files.

This paper describes the formats of files containing information on data stored in GRASS vector format. GRASS vector format is also referred to as digit format; the GRASS vector digitizing program is named v-digit.

USACERL first released this GRASS vector file format with version 3.0, to store vector data without all the topological information and data structures that are necessarily contained by files in USGS' Digital Line Graph (dlg) format. The new digit file format makes it easier to update and edit files being digitized, while maintaining the accuracy of vector data.

2. GRASS VECTOR DATA FILE FORMATS

Four basic files are used to represent the geographic location and nature of data in GRASS vector file format. These files contain information on the location of vectors, the vector topology, vector category values, and category labels. GRASS vector locations may be stored in ASCII or binary format. If the map is digitized in GRASS, another file containing the coordinates of points used to register the map to the digitizing tablet is also stored.

Each file is assigned the same name (a user-assigned map layer name), but is stored in a separate subdirectory of the user's current GRASS mapset (i.e., different subdirectories of $LOCATION). Relevant subdirectories are shown in the table below.

---

1 Program prefixes indicate whether command create support files for raster ('r.') or for vector ('v.') data.
GRASS VECTOR DATA DIRECTORIES:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dig_ascii</td>
<td>Contains ASCII files in GRASS vector (dig) format.</td>
</tr>
<tr>
<td>dig</td>
<td>Contains binary files in GRASS vector (dig) format.</td>
</tr>
<tr>
<td>dig_plus</td>
<td>Contains topology information for files in GRASS vector (dig) format.</td>
</tr>
<tr>
<td>dig_att</td>
<td>Contains the locations at which category labels will be placed for files in GRASS vector (dig) format.</td>
</tr>
<tr>
<td>dig_cats</td>
<td>Contains the category text labels used for files in GRASS vector (dig) format.</td>
</tr>
<tr>
<td>reg</td>
<td>Contains the geographic coordinates of points used to register to a known coordinate system a (vector) map layer digitized with the GRASS v_digit program.</td>
</tr>
</tbody>
</table>

3. HELPFUL TIPS

To import a map layer into GRASS 4.0, at least two files are needed. They are a dig_ascii file (or a dig file, its binary representation) describing the geographic locations of vectors, and a dig_att file describing map feature attributes. The dig_ascii contains some brief header information to describe the map region, etc., as well as line segment information. The attribute file contains information as to what type of feature the attribute describes, the x,y map coordinates of the label placement, and an integer number representing the attribute. It is also recommended that a separate ASCII file be provided with which to cross-reference these attributes with textual information.

There are a few important restrictions on the import files:

- Area attribute coordinates MUST be located within the area.
- Line attribute coordinates MUST be closer to the line they describe than any other. This implies that they must NOT be located on a node where two or more lines meet.
- Vectors (as separated by A, L, and P in the dig_ascii file) must NOT cross one another. Instead, each should be broken into separate traces all ending at the same point. This point is then defined as a node. These lines should be snapped, (i.e., the common x and y values are exactly the same value for each vector).
- There should be one and only one vector defining a given border or line (i.e., if two areas share a common border, that border should only be specified once). As another example, if a road (Line information) and an area boundary (Area Edge information) share a common line within the same map overlay, this line should be digitized once as an Area Edge so that the area may be resolved, but the line may also then be given an attribute to identify it as a road. The user is advised to NOT mix data types like this in a single file, but it may be done in this manner.
- If there are vectors that are identified as Area Edges, this implies that it is possible to complete each area by following one or more Area Edges that are connected by common nodes, and that all such line traces can each be resolved into closed areas.
4. DIG.ASCII AND DIG FILES DESCRIBING GEOGRAPHIC LOCATIONS OF VECTORS

Like their pre-3.0 counterparts, the new dig_ascii files have two components: a header, and the series of vectors digitized.² The header contains historical information, a description of the map, and its location in the universe. It consists of fourteen lines. Each line has two parts. The first part of each line is a description of the data on that line, while the second part of the line contains the data. A sample dig_ascii file header is shown below:

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>DIGIT DATE:</td>
<td>03/18/91</td>
</tr>
<tr>
<td>DIGIT NAME:</td>
<td>michael higgins</td>
</tr>
<tr>
<td>MAP NAME:</td>
<td>v.digit example</td>
</tr>
<tr>
<td>MAP DATE:</td>
<td>12/25/90</td>
</tr>
<tr>
<td>MAP SCALE:</td>
<td>24000</td>
</tr>
<tr>
<td>OTHER INFO:</td>
<td></td>
</tr>
<tr>
<td>ZONE:</td>
<td>5</td>
</tr>
<tr>
<td>WEST EDGE:</td>
<td>608000.00</td>
</tr>
<tr>
<td>EAST EDGE:</td>
<td>630000.00</td>
</tr>
<tr>
<td>SOUTH EDGE:</td>
<td>3720000.00</td>
</tr>
<tr>
<td>NORTH EDGE:</td>
<td>3739000.00</td>
</tr>
<tr>
<td>MAP THRESH:</td>
<td>0.0</td>
</tr>
<tr>
<td>VERTI:</td>
<td>unused</td>
</tr>
</tbody>
</table>

The description of the data starts in column 1 and continues through column 14. The description is left-justified and it MUST be padded with blanks up to and including column 14. Data begins in column 15 of the header. The size limits of the header data lines follow below.

<table>
<thead>
<tr>
<th>ORGANIZATION:</th>
<th>Limited to 30 characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIGIT DATE:</td>
<td>Limited to 20 characters</td>
</tr>
<tr>
<td>DIGIT NAME:</td>
<td>Limited to 20 characters</td>
</tr>
<tr>
<td>MAP NAME:</td>
<td>Limited to 40 characters</td>
</tr>
<tr>
<td>MAP DATE:</td>
<td>Limited to 11 characters. Prefer mm/dd/yy</td>
</tr>
<tr>
<td>MAP SCALE:</td>
<td>Integer</td>
</tr>
<tr>
<td>OTHER INFO:</td>
<td>Limited to 73 characters</td>
</tr>
<tr>
<td>ZONE:</td>
<td>Integer</td>
</tr>
<tr>
<td>WEST EDGE:</td>
<td>Real number (double)</td>
</tr>
<tr>
<td>EAST EDGE:</td>
<td>Real number (double)</td>
</tr>
<tr>
<td>SOUTH EDGE:</td>
<td>Real number (double)</td>
</tr>
<tr>
<td>NORTH EDGE:</td>
<td>Real number (double)</td>
</tr>
<tr>
<td>MAP THRESH:</td>
<td>Real number (double)</td>
</tr>
<tr>
<td>VERTI:</td>
<td>Unused</td>
</tr>
</tbody>
</table>

The first five lines of the header contain historical information. Remaining lines contain information about the map and its location that are used by v.digit. The map edges (defined by the eastings and northings) must describe a region large enough to encompass the entire map. If the MAP THRESH is unknown or irrelevant, set it to 0.0.

Vectors appear in the second portion of the dig_ascii file, beneath the header information. Three vector types exist: Area Edges, Lines, and Points. The type of vector appearing in the dig_ascii file will depend on the way in which the map features were digitized. In general, a soils map, consisting of a series of polygons, would have been digitized as an Area Edge; a feature like roads or railroads would

² Note: The dig file is a binary machine-readable representation of the dig_ascii file. Here, we examine the dig_ascii file because it is readable by the user.
have been digitized as a Line Edge; a map depicting features without area, like one of sewage outfalls, would have been digitized as a Point.

Although possible, users are discouraged from placing both vector types in the same file. A vector that is used both as an Area Edge and a Line (e.g., a road also serving as a boundary) should be digitized as an Area Edge. Do not double-digitize. An example of vector data as they appear in a dig ascii file are shown below. Vectors digitized as Area Edges are preceded with an A, while vectors digitized as Lines are preceded with an L, and vectors digitized as points are preceded with a P.

A 3
3724747.38  616579.60
3724722.69  613539.73
3724703.68  610786.90
L 3
3734862.31  612043.33
3734872.42  614662.14
3734871.44  618094.75
A 2
3734871.44  618094.75
3734456.04  618142.16
A 5
3734456.04  618142.16
3734446.65  618202.64
3734407.49  620524.38
3734107.06  620523.59
3733326.51  620526.48
L 6
3732811.36  624620.86
3732888.15  624627.01
3731714.29  624641.11
3729790.89  624635.87
3729631.08  624640.55
3729497.65  624631.16
P 2
3724928.00  624625.46
3732800.25  624625.46

Each vector definition consists of two parts: a description line, followed by a series of coordinate pairs. The line describing the vector will specify both the type of vector it is (Area Edge, Line, or Point), and the number of points (coordinate pairs) that were used to construct the vector. For example, in the below vector definition, the description line contains the letter A (specifying that the vector is an Area Edge), followed by the number 3 (notifying us that this vector consists of 3 points).

A 3
3724747.38  616579.60
3724722.69  613539.73
3724703.68  610786.90

For each vector definition the description line then consists of: (1) a letter A, L, or P defining vector type (as Area Edges, Lines, or Points, respectively), (2) followed by one or more spaces, (3) followed by a number stating the number of points used to define the vector. This line can be written using the Fortran format: A1,IX13. Following the data line that describes the vector will be the actual coordinates of which the vector consists. Note that the coordinates are stated as pairs of Northings and Eastings (y,x), in this order. This differs from the format of the dig files used by pre-3.0 versions of GRASS, in which this order was reversed. These lines can be written with the Fortran format: 2(1X,F12.2).
5. GRASS VECTOR ATTRIBUTE FILE FORMAT

GRASS attribute files will be used to store attribute information associated with GRASS vector files. The attribute file will contain category numbers that will be used when generating a raster (cell) file, and may also be needed when converting GRASS files to other systems' data formats. Attribute files will be stored in ASCII in their own data directory and can be used by v.digit or any other GRASS program. The words attribute and category are used interchangeably in this paper.

There is one type of data line in the attribute file. The data line will specify the type of map feature (Area, Line, or Point), category location point \((x, y)\), and a category number. This category number should be cross-referenced to a textual description in a separate ASCII file. An example follows:

\[ \text{A 628368.51 3727988.27 7} \]

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Either an A or L which specifies the type of map feature. (Other codes may and will be allowable in the future.)</td>
</tr>
<tr>
<td>2-3</td>
<td>Spaces.</td>
</tr>
<tr>
<td>4-15</td>
<td>Easting ((x)) of category location point. Right-justified.</td>
</tr>
<tr>
<td>16-17</td>
<td>Spaces.</td>
</tr>
<tr>
<td>18-29</td>
<td>Northing ((y)) of category location point. Right-justified.</td>
</tr>
<tr>
<td>30-31</td>
<td>Spaces.</td>
</tr>
<tr>
<td>32-39</td>
<td>Category number. Right-justified.</td>
</tr>
</tbody>
</table>

The category location point for an Area map feature must be inside the area. A category location point for a Line feature must be a point somewhere on the line, preferably towards the middle of the line and not at a node. A category located at the nodes of lines would make it difficult to determine the line with which the attribute is meant to be associated. The category location point for lines with only two points (which are nodes) will be the midpoint of the line, which will have to be calculated. The midpoint formula is as follows:

\[ x = \frac{(x_1 + x_2)}{2}, \quad y = \frac{(y_1 + y_2)}{2} \]

The category location point for a Point map feature will be the same as that of the Point.

If no attribute is associated with a particular map feature then no line will exist for it in the map's dig_att file.

Attributes are attached to their corresponding features by running the GRASS command v.support or v.import. Currently, if more than one attribute is associated with a feature, all but the first will be ignored, and a warning message given to that effect. The GRASS User's Reference Manual (Westervelt, Shapiro, et al.) details the use of these commands.

A brief example of an attribute file is shown below:

| L   | 386073.72 | 3903017.14 | 101 |
| L   | 405139.94 | 3896838.27 | 102 |
| L   | 403345.13 | 3894572.69 | 102 |
| A   | 383186.04 | 3903117.52 | 524 |
| L   | 386023.05 | 3901056.16 | 104 |
| L   | 388980.59 | 3901737.43 | 105 |
| A   | 388554.45 | 3899862.40 | 533 |
| A   | 392332.92 | 3900345.36 | 533 |
| A   | 405541.79 | 3899489.16 | 563 |
| L   | 385997.59 | 3900572.64 | 101 |
| A   | 381782.42 | 3905945.17 | 501 |
| A   | 397110.53 | 3898251.52 | 999 |
6. CONVERTING DATA AMONG VECTOR, RASTER, AND SITES DATA FORMATS

If you need to convert data into a specific file format, GRASS contains programs that will convert data to and from GRASS raster, vector, and sites file formats. For example, `v.to.rast` converts vector data to raster data, and `v.to.sites` converts vector data to sites data. The following GRASS programs are used to convert data among GRASS raster, vector, and sites formats:

<table>
<thead>
<tr>
<th>Raster Data</th>
<th>Sites Data</th>
<th>Vector Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>r.line</td>
<td>s.in.ascii</td>
<td>v.to.rast</td>
</tr>
<tr>
<td>r.poly</td>
<td>s.out.ascii</td>
<td>v.to.sites</td>
</tr>
<tr>
<td>r.thin</td>
<td>v.in.ascii</td>
<td>v.to.sites</td>
</tr>
<tr>
<td>r.in.ascii</td>
<td></td>
<td>v.out.ascii</td>
</tr>
<tr>
<td>r.out.ascii</td>
<td></td>
<td></td>
</tr>
<tr>
<td>r.in.sumrast</td>
<td></td>
<td></td>
</tr>
<tr>
<td>r.in.ll</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Other GRASS programs exist to convert data files in GRASS raster, vector, or sites formats to other systems' data file formats, and to bring data files in other systems' formats into GRASS' data formats. For example, `v.in.arc` can be used to import ARC/INFO data into GRASS vector format, and `v.out.arc` can be used to export GRASS vector data to ARC/INFO's data file format.

7. GLOSSARY

**Area:** A closed polygon, built with one or more Area Edges.

**Area Edge:** A vector that defines a portion of an area boundary or polygon.

**Attribute:** An integer number that identifies a specific type of map feature. This can be thought of as being equivalent to the category value in the raster side of GRASS.

**Line:** A vector that defines a linear feature (e.g., roads).

**Line Segment:** A straight line with two discrete end points.

**Map Feature:** A line or area on a map.

**Node:** A discrete point where one or more vectors end.

**Vector:** An element within the `dig.asci` or `digfile` that is defined as Point, Line, or Area Edge information and consists of a number of coordinate pairs, which define the number of line segments.
