PREFACE

This report documents a RAND study of the postsecondary activities of recent high school graduates and dropouts. The study brings together data from several sources to profile America's high school graduating classes during the 1980s and track their educational and vocational pursuits through the first five years after graduation. Special attention is given to college enrollment and persistence patterns as well as to the flows of young people into military service from other postsecondary activities. Projections of numbers of high school graduates by state, race, and sex to the year 2000 are provided to indicate the implications of these flows for the nation's human resources over the next decade.

This research was sponsored by the Office of the Assistant Secretary of Defense (Force Management and Personnel). The research was conducted in the Defense Manpower Research Center, part of RAND's National Defense Research Institute, a federally funded research and development center sponsored by the Office of the Secretary of Defense and the Joint Staff. The report should be of interest to policymakers, educators, and scholars as a comprehensive source of information on America's high school graduates and their postsecondary vocational and educational activities.

SUMMARY

The nation's human resources depend critically on the extent to which young people complete high school and undertake postsecondary education and training that will prepare them for productive careers. During the 1980s, 10 million school-age youth dropped out of high school before graduation; most of them face bleak employment prospects in the years ahead. Another 28 million completed high school and began to sort themselves into educational programs and career paths. Some took entry-level jobs, entered apprenticeship programs, or joined the military. Others enrolled in college or entered vocational-technical schools. Still others took summertime breaks or worked at temporary jobs, many planning to enter college full-time in the fall.

This study was undertaken to examine patterns of military service, college enrollment, and civilian labor force participation among recent high school graduates and dropouts. The main objectives of the study were to profile the high school graduating classes and determine the key factors that affect the postsecondary sorting-out process in the 1980s, paying special attention to the flows of high school graduates into and out of postsecondary educational activities and military service.

The activities that young people pursue after high school are disparate and depend on a multitude of factors. Section I provides an overview of the postsecondary sorting-out process from a human resources perspective. Despite the huge influx of young people into the educational pipeline and labor force during the 1980s, the supply of entry-level workers has not kept pace with the demand for technicians, skilled craftsmen, and college-trained workers, eroding the labor surpluses that existed in many fields in the 1970s and early 1980s. With projections pointing to a 15-percent decline in the size of the 18-year age group between 1990 and 1992, there are mounting concerns about the adequacy of America's human resources to meet the requirements for trained manpower in the 1990s.

As in the past, America looks to its youth and the educational system to fill the gap. Hence, the flows of high school graduates and dropouts into the educational pipeline and the labor force are matters of national concern. Yet, the educational and vocational activities that young people pursue after leaving high school are poorly tracked. Nationally published statistics at best provide only crude indicators of the flows into postsecondary education, military service, and civilian employment, and there is almost no information on the flows across activities as young people redirect their efforts to reflect changes in educational and career goals.

To permit a detailed examination of the postsecondary pursuits of high school graduates in the 1980s, a comprehensive data base was compiled for this study. The primary data source was High School and Beyond (HS&B), a rich longitudinal study of over 26,000 high school seniors in the Classes of 1980 and 1982 who were the subjects of follow-up surveys in 1982, 1984, and 1986. Numerous extensions to this data base were made to enhance its utility for this research and link it to other sources of information on American youth. In particular, supplemental data on the military service activities of the HS&B participants were obtained through the Defense Manpower Data Center.

Also, steps were taken to provide detailed demographic information on the sizes and compositions of high school graduation classes in the 1980s and to circumscribe the school dropout problem. It is a sorry fact that national data bases cannot provide accurate

estimates of the numbers of high school graduates and dropouts in any year, let alone the disaggregated estimates by state, race, and sex that are needed to support studies of human resources. Building on existing data from several sources and relying heavily on Census Bureau estimates and projections of age-group sizes, we derived estimates and projections of numbers of high school graduates by state, sex, race, and Hispanic origin for the years 1980–2000. See Section II.

According to estimates for 1986—the last year for which state estimates were available for both public and private schools, the high school graduation rate was 73 percent (71 percent for males, 76 for females), implying that 27 percent of the 18-year-olds in 1986 had already dropped out of school or would do so before graduation. Although high school graduation rates have moved up and down by a few percentage points over the last 25 years, the 1986 rate is almost exactly the same as it was in 1976 and 1965.

Section III examines patterns of postsecondary activities among high school graduates and dropouts during the first year after leaving school. Because many high school graduates take a break before entering college or military service, the focus of attention here is the main activity as of October in the year of graduation. For the purposes of this research, four categories of main activities were identified: full-time student, military service, civilian employment, and "other" (not enrolled full-time and not employed). The full-time student category was divided into three subcategories by type of institution: four-year college (or university), two-year college, and vocational-technical school.

Time series of college entrance and employment rates among high school graduates and dropouts indicate that activity patterns during the first year after leaving school have remained remarkably stable since the early 1970s, with some increases in both college enrollment and military enlistment rates in the early 1980s. Among graduates in the Classes of 1980 and 1982, only 40 percent were enrolled full-time in college in October following graduation, and another 7 to 8 percent were enrolled part-time. Approximately 8 percent of the graduates in these classes entered military service before 1986, but only 3 percent entered within six months after graduation. Except for the fact that military entrants were mostly male, they differed only slightly from their classmates in terms of demographic characteristics. A higher proportion of them came from lower socioeconomic status families and from minority groups, but in terms of measures of academic aptitude, they were on a par with their classmates.

More detailed analyses of HS&B data confirmed findings from previous studies indicating that academic aptitude is the primary factor affecting individual college enrollment decisions of high school graduates. However, about a third of the 1980 and 1982 graduates in the top academic aptitude quartile were not enrolled full-time in college in October following graduation, suggesting that other factors also play important roles in college enrollment decisions. Controlling for differences in academic aptitude and socioeconomic status, we find that graduates from private schools and those of Asian or Pacific Islander descent had significantly higher college entrance rates.

Section IV presents analyses of postsecondary activities during the rest of the five-year period following high school, including estimates of six-month transition rates across main activities. This examination reveals considerable turbulence in activity patterns, much of it into and out of short-term civilian jobs. For college entrants, progress toward degree completion was notably sporadic and drawn out. Among the 1980 graduates who enrolled full-time in a four-year college directly after graduation, only 46 percent had earned bachelor's degrees through February 1986.

In general, our findings indicate that a substantial proportion of high school seniors in the 1980s lacked direction when they left school, and that their subsequent activities were marked by false starts and backtracking. In October following graduation, only about half of the 1980 graduates were pursuing the activities they had planned to pursue as seniors. Their later shifts across activities indicated that many of them were having difficulty finding niches in the adult world. Only one-sixth of the graduates who entered four-year colleges after graduation enrolled continuously until they had completed bachelor's degrees. With half of the college entrants dropping out before they earned degrees, the flow of students through the educational pipeline was greatly impeded. The resulting losses of talent, on top of the huge losses represented by persistently high dropout rates in the secondary schools, point to the conclusion that America made poor use of its human resources during the 1980s and will be hard put to meet its manpower requirements in the 1990s.

ACKNOWLEDGMENTS

The authors would like to thank W. S. Sellman, Director for Accession Policy, Office of the Assistant Secretary of Defense (Force Management and Personnel), for his interest in and sponsorship of this research. We are also indebted to Zahava Doering, former Chief of the Survey and Market Analysis Division at the Defense Manpower Data Center (DMDC), for her help in getting this project under way and her active collaboration during the early stages of the work. Others at DMDC who lent their considerable talents to our work were Jerry Lehnus, John Richards, and Elaine Sellman.

At RAND, we are grateful to Glenn Gotz, who headed the Defense Manpower Research Center during the course of this study, and to Bernard Rostker, Glenn's successor in that role. Thanks also go to John Winkler, who collaborated with us in the initial phases of the study, and to Richard Buddin and Joyce Davidson, who provided formal reviews of the report. Finally, we would like to thank Robert Klitgaard and Laurel McFarland for their comments on earlier drafts of the report.

I. INTRODUCTION

As America enters the 1990s, there are mounting concerns about the adequacy of the nation's human resources. These concerns are not new. It has long been recognized that the 18–24 age group would shrink from the early 1980s through the mid-1990s, meaning fewer entry-level workers, fewer students in the educational pipeline, and more competition for high school graduates among the nation's colleges, military services, and civilian employers. With the prospect of greatly reduced numbers of high school graduates in the 1990s and with projections pointing to shortages of college-educated workers in many fields in the late 1990s, there is room to question whether enough young people will pursue the kinds of postsecondary training needed to satisfy the nation's future manpower requirements.

Eight consecutive years of economic expansion from 1982 to 1990, marked by steadily increasing employment, depleted the surplus labor supply that existed in the early 1980s. Reflecting the continual shift from labor surplus to shortage, unemployment rates fell steadily from their peak of 10.8 percent in December 1982, dipping below 5 percent in March 1989 for the first time in 15 years. After years of recruiting success in which the Armed Forces substantially upgraded their enlistment standards, the military began experiencing recruiting difficulties in late 1988. Shortages of college-trained workers—especially teachers and nurses—have been widely reported for some time, and the National Science Foundation (NSF) projects a shortfall of about 500,000 scientists and engineers by the end of the century (Holden, 1989).

Less visible is the reported increasing demand for entry-level technicians, administrative support personnel, and skilled craftsmen, who ordinarily complete high school and some postsecondary training but not a four-year college degree. According to recent projections by the Bureau of Labor Statistics, technicians and related support occupations will show the most rapid growth during the 1990s. These occupations, like most military occupational specialties, draw from the shrinking pool of high school graduates who do not enter four-year college programs after graduation but are qualified to undertake postsecondary education and on-the-job training in technical fields (Kutscher, 1989).

THE DWINDLING SUPPLY OF HIGH SCHOOL GRADUATES

As in the past, the nation will be relying on its high school graduates to fill the gaps, but there will be fewer of them in the 1990s, and there are reasons to doubt that they will sort themselves into postsecondary educational and career paths in sufficient numbers to meet future employment demands. School dropout rates remain high, and many high school graduates have deficiencies in basic skills that severely limit their employment prospects. Only a small proportion of them have the aptitude and resources to complete college programs requisite to filling the nation's most pressing needs for professional and technical workers.

In considering how the nation's manpower requirements will be met in the 1990s, it is natural to look first at the numbers of young people who will be completing school and entering the workforce. Of immediate concern to college and military recruiters is the outlook for greatly reduced numbers of 18-year-olds and high school graduates over the next few years. Census Bureau projections indicate that the 18-year-old age group will shrink by 15 percent

between 1989 and 1992. With minorities constituting an increasing proportion of the school age population and with school dropout rates remaining persistently high, especially among Hispanics, the near-term prospect of an upward surge in high school graduation rates appears dim. The clear implication is that the nation's colleges, military services, and civilian employers will be competing for substantially fewer graduates over the next few years.

How many fewer? Which states will be most affected? How will the racial/ethnic mix of the graduating classes change? How will college enrollments and military recruitment be affected? There are serious gaps in the federal data base that make it impossible to answer these questions precisely, but the questions are too important to gloss over. To a certain extent, partial answers can be provided by piecing together existing information on the numbers, characteristics, and activities of recent high school graduates.

In Section II, we take a hard look at the demographics pertaining to high school graduates and dropouts. Drawing on data from several sources and Census Bureau estimates of age group sizes, we provide detailed estimates and projections of numbers of high school graduates by state, sex, and race for the years 1980–2000. These projections point to overall declines of 8, 5, and 2 percent in 1990, 1991, and 1992, followed by gradual increases averaging 2 percent per year from 1993 to 2000. If these projections hold, the total number of graduates from 1990 to 1994 will be 10 percent less than the five-year total for 1985–1989, which would imply a considerable diminution in the educational pipeline for college-trained personnel.

LABOR MARKET UNCERTAINTIES

The main uncertainties underlying assessments of the adequacy of our human resources over the next decade stem from two factors. First, the future growth of the economy cannot be predicted accurately. A deep recession, such as the one in 1981–82, would cut the demand for entry-level workers in most occupations and could send unemployment rates back above 10 percent. Second, even if the future state of the economy were known, scholars could only guess at the timing and extent of shortages in most fields, because the pipeline into and mobility within the labor force are poorly tracked.

Despite the attention given to shortages of college-trained workers in many fields, the national data base for gauging the size and characteristics of the nation's college-trained workforce is in a sorry state. In particular, the extent of the "crisis" in education due to the shortage of qualified teachers cannot be ascertained because of the lack of basic data on the numbers, qualifications, and characteristics of teachers (Haggstrom, Darling-Hammond, and Grissmer, 1988).

The term "crisis" is also being used to describe the outlook for scientists, engineers, and technicians, but reliable statistics on the numbers and employment patterns of workers in these fields do not exist (Panel to Study the NSF Scientific and Technical Personnel Data System, 1989). To underscore the uncertainties that have confounded attempts to use survey data to assess the demand for college-trained workers in technical fields, NSF estimates that the number of employed scientists and engineers grew by over 8 percent per year between 1980 and 1986, reaching 4.6 million in 1986. That figure is half again as large as the Bureau of Labor Statistics estimate of 3.1 million, which is consistent with a much slower 1980–86 growth rate of about 5 percent per year.

On the supply side, the educational pipeline for new entrants into the labor force is also poorly tracked. Between decennial censuses, the primary continuing source of information

on the educational and vocational activities of recent high school graduates and dropouts is the Current Population Survey (CPS). This monthly survey fielded by the Census Bureau relies on samples of nearly 56,000 household units each month to gather the raw data supporting the "official" statistics on employment, unemployment, income, educational attainment, enrollment, and living arrangements that appear in *Current Population Reports*, *Employment and Earnings*, and *Monthly Labor Review*.

Although the CPS is conducted and evaluated using state-of-the-art methods, statistics drawn from the CPS are subject to the same errors that beset all population surveys. Because of the sparseness of the CPS sample for gathering information on, say, Hispanic male high school graduates in the Class of 1986, disaggregated estimates of employment, educational attainment, and enrollment derived from the CPS are subject to large sampling errors (U.S. Bureau of the Census, 1988b). Moreover, the CPS is plagued by nonsampling errors due to incomplete population coverage, nonresponse errors, and response errors (Shapiro and Kostanich, 1988). As Sections II and III show, time series on educational attainment and college enrollment derived from the CPS conflict with statistics drawn from other sources.

The National Center for Education Statistics (NCES) gathers data from schools and colleges that provide additional information about the educational pursuits of high school graduates. The earned degrees data compiled annually by NCES provide the counts of college graduates by sex, race, and field of study that appear in the *Digest of Education Statistics*. Comparable counts of high school graduates do not exist, because NCES has no systematic means for gathering data from private schools. At best, existing national statistics provide crude indicators on how many high school graduates enter college, join the military, and enter the labor force each year, but detailed information is missing on who goes where, who persists, and for how long.

TRACKING HIGH SCHOOL GRADUATES AND DROPOUTS

To better understand the implications of demographic trends on the pipeline into the workforce and to guide youth policies bearing on student aid, military recruitment, and national service, we need far more comprehensive information on which students enter the various postsecondary tracks and how, when, and why young people change courses in pursuing their educational and vocational objectives. In short, we need a much better understanding of the *sorting-out process*—the process by which young people with widely differing talents and ambitions choose among competing alternatives such as military service, higher education, civilian employment, or homemaking as they make the transition from youth to adulthood.

One of the difficulties in tracking the activities of young people is that, in essence, there is not a single sorting-out process but myriad processes depending on a variety of factors and individual circumstances that affect student outcomes. Only in the abstract is the sorting-out process for high school graduates the same as it is for dropouts. Although the differences in outcomes may not be as stark for other categories, we clearly need to distinguish the patterns of males vs. females, public school graduates vs. private, rural vs. urban, minority vs. majority, high-achieving students vs. low, rich vs. poor, college-planners vs. others. Many of these categories have several subclasses that merit attention, and there are other categories of students, such as handicapped students, unmarried mothers, and drug addicts, whose postsecondary activities are matters of public concern.

Because there is no such thing as a "typical" high school senior and many young people change paths numerous times before they find their niches, it is not surprising that there is no dominant pattern of postsecondary behavior. The closest approximation is the traditional "lockstep" pattern leading to a college degree: enrollment as a full-time student in a four-year college in the fall after high school graduation, followed by continuous enrollment (except perhaps for summer terms) until graduation four years later. However, as will be seen in Section IV, only about one in six graduates in the Class of 1980 followed that path.

PHASES IN THE SORTING-OUT PROCESS

For the most part, the postsecondary paths are far less direct and marked with flux. This is not to say that they are unpatterned. To characterize the patterns, it is convenient to divide the sorting-out process for a given age cohort into three phases. The first phase is the period before high school graduation, when a substantial proportion of the age cohort make a crucial decision—to drop out of school. As our examination of the "school dropout problem" in Section II will show, the overall proportion of high school dropouts has been around one in four for the last 20 years—a colossal, persistent wastage of talent. That this wastage of talent is not uniform across the nation is evident from the substantial variability in dropout rates across states, sexes, and race/ethnic categories.

The period before graduation is also important to the graduating seniors who make their plans and take steps toward realizing them by applying for admission to college, preparing to enter other training programs, or seeking employment. For some graduates, their plans as seniors constitute blueprints to their future actions at branch points in the sorting-out process; for others, plans are at best vague and dependent on contingencies. Whether the seniors' plans are realized or not, they reflect the seniors' best guesses about their future actions as they approach a critical juncture in their lives.

The second and perhaps most important phase in the sorting-out process occurs right after graduation when the young adults enter their initial postsecondary "tracks" in keeping with their long-term plans. Many graduates take a break of from one to four months after graduation, often for temporary work activity, before they pursue full-time educational or vocational activities consonant with their career goals. The June graduates who plan to complete a four-year degree in the traditional lockstep manner typically defer college entrance until September. Military enlistees also often delay their entry into the service for several months. To allow for these delays, we shall identify each graduate's initial postsecondary track as the main activity pursued in October in the year of graduation. In Section III, we present a detailed examination of the main activities of the Classes of 1980 and 1982 to profile the track memberships and assess the relevance of sex, ability, socioeconomic status, race/ethnicity, and senior plans to college entrance and military enlistment.

The third phase of the sorting-out process is the remainder of the five-year period following high school graduation. Although some high school graduates have definite plans leading to well-defined career objectives and they take direct routes to fulfill them, they may be in the minority. For a substantial portion of graduates, postsecondary activities appear to be less ordered and more dependent on evolving circumstances, such as moving away from home, encountering untoward work or student experiences, or starting a family. For them, sorting out is a process marked by flux, false steps, and changes of plans. Because their day-to-day activities are less tied to specific career goals, they may be more amenable to moving into new endeavors, perhaps to include military service.

CONCEPTUAL FRAMEWORK

To describe the entrants into the postsecondary sorting-out process during the 1980s and to track their subsequent transitions into and out of postsecondary education, military service, and civilian employment, we shall implicitly adopt a "cohort analysis" perspective. The cohorts of primary interest in this study are the successive high school graduating classes and the annual cohorts of school dropouts. For the present discussion, the term "Class of 1985" will refer to the combined cohort consisting of the graduating seniors in 1985 and the dropouts who last attended school in 1985.

Except for the Classes of 1980 and 1982, suitable data do not exist to profile the classes in terms of their sizes, race/ethnic composition, and dispersion across states and school types. To fill this gap, we treat the 17-year age group as of July 1 in the year preceding the graduation year as a synthetic cohort for the purpose of prescribing the sizes and race/ethnic compositions of the senior classes in each state. That is, we treat Census Bureau estimates and projections of sizes of age groups by state, sex, race, and Hispanic origin as proxies for the corresponding numbers of persons of school-leaving age. To estimate high school graduation rates within cohorts of school-leavers, we divide the number of graduates in any year by the number of 17-year-olds in the preceding year.

The Classes of 1980 and 1982 receive special attention in this study, because they are the classes for which there exist detailed longitudinal micro-level data on the activities of large numbers of graduates and dropouts. These data will be used to provide an in-depth examination of the sorting-out process of these two cohorts. We also draw on time series from several sources to examine trends in college entrance rates, military enlistment rates, and rates of employment over the last 20 years. This examination shows that the sorting-out process has been remarkably stable over time, except for the gradual closing of the gap between the sexes in college entrance rates and a trend toward higher enlistment rates in the early 1980s. This stability in the overall rates over time supports the hypothesis that the transition rates for the Classes of 1980 and 1982 have persisted without material change through the 1980s.

The micro-level data on the Classes of 1980 and 1982 come from High School and Beyond (HS&B), a rich longitudinal data base on over 26,000 high school sophomores and seniors in 1980 who were the subjects of follow-up surveys in 1982, 1984, and 1986. On the follow-ups, the HS&B participants were asked to provide information about each episode of employment and educational activity that they had experienced, including the time spans of the activities. Using these data on the students' educational and vocational activities from 1980 through February 1986 and additional data on military service provided by the Defense Manpower Data Center, we have classified each HS&B participant's main activity into one of four categories each month: (1) full-time student, (2) military service, (3) civilian employment, and (4) other (not enrolled full-time and not employed). To characterize these activities more fully, we also encoded subcategories of special interest. For example, the full-time student category has four subcategories corresponding to institutional levels: high school, four-year college, two-year college, and vocational-technical school. See App. B for further details.

Figure 1 provides a schematic representation of the flows of the senior classes into postsecondary tracks and the subsequent transitions across main activities that this classification scheme attempts to capture. Although our data base permits examining month-to-month tran-

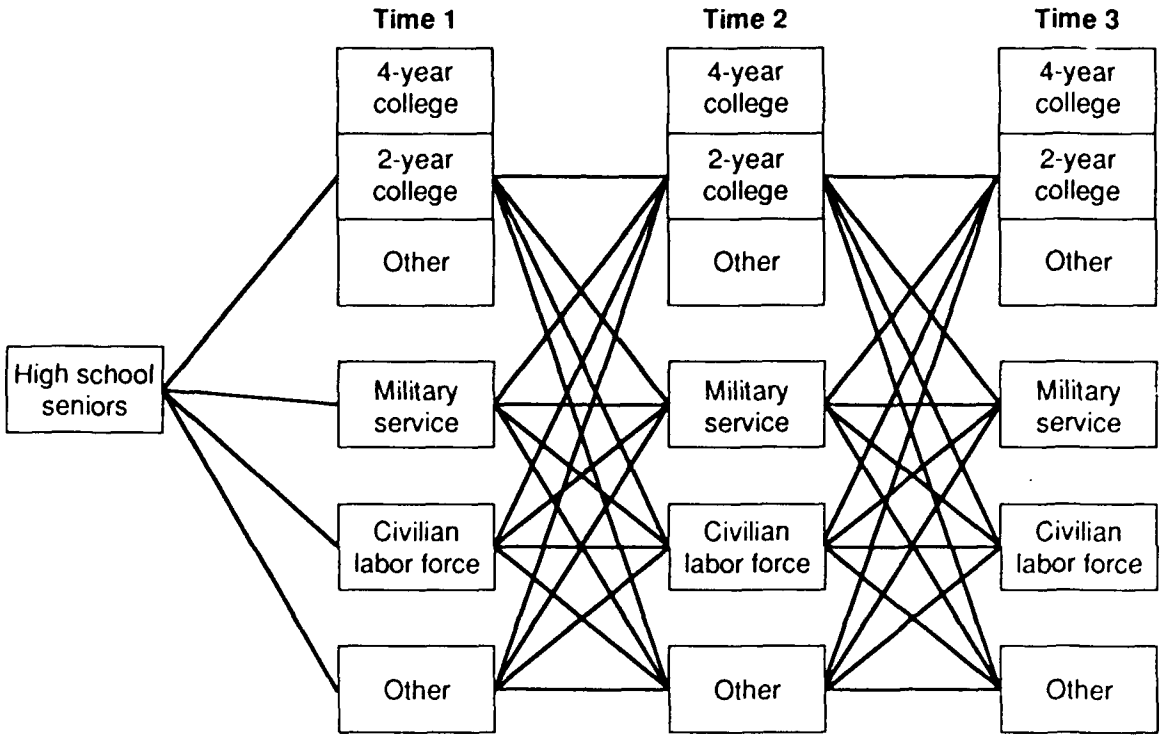

Fig. 1—Main activities after high school

sitions, we only report six-month transition rates in this study, identifying "TIME 1" with October in the year of graduation, "TIME 2" with the following April, and so forth.

In addition to providing the episodic data on employment and education needed to classify the participants' main activities each month, HS&B also provides key background information on the participants and their schools, including individual measures of cognitive ability, socioeconomic status, and postsecondary plans. These data permit examining the extent to which background factors affect young people's educational and vocational decisions at branch points in the sorting-out process.

PATHWAYS TO MILITARY SERVICE

Of special interest to this study are the high school graduates in the 1980s who enlisted in the Armed Forces. The services maintain comprehensive personnel files on their enlistees after they enter the service, but the military has only limited information on the enlistment decision process, i.e., the sequence of events that have led one of every ten graduates (and one of every six males) to enter the service during the 1980s. One of the principal purposes of this study is to gain a better understanding of the pathways to military service among recent high school graduates.

Since 1983, over 90 percent of nonprior service enlistees have been high school graduates. Only a small percentage of the recruits had completed more than a year of college

before enlisting, but many had enrolled in college or vocational-technical schools for shorter periods of time. Although the proportion of female recruits has been increasing over time, male recruits continued to outnumber females by about seven to one in 1987. As will be seen in Section IV, the military enlistees from the Classes of 1980 and 1982 were on a par with their classmates in terms of academic ability, but the enlistees had lower socioeconomic status on average, and they were more likely to come from minority groups.

From a human resources perspective, the military plays several roles in the sorting-out process. It not only serves as an employer of about 300,000 new recruits per year but as a huge vocational training institution, providing classroom instruction and on-the-job training for a wide array of occupational specialties. Through the G.I. Bill and the Army College Fund, the military also provides young people opportunities to finance college educations that might otherwise be beyond their means. Here, the fact that a disproportionate number of enlistees come from low-income and minority groups is significant, because these groups are underrepresented in the professional and technical occupations that are expected to evidence shortages in the 1990s.

Because the services are currently seeking to reduce overall force sizes, the services' requirements for new recruits may be somewhat lower in the next few years than in the recent past. However, the military faces a greatly reduced supply of potential recruits and increasing competition with the nation's colleges and civilian employers. If the services continue to restrict their recruiting to high school graduates, their target population will continue to shrink through 1992.

In part, the Armed Forces' demand for high school graduates with high aptitude stems from the need for personnel to undertake technical training in a wide spectrum of occupational specialties and to operate and maintain high-technology weapons systems. Competition with the civilian labor force for youth with aptitudes for such technical areas as electronics, computers, and communications may be increasingly severe over the next few years.

The impending decline in the supply of high school graduates also means that the military will face increasing competition with colleges and universities for high school graduates with college aspirations. In the 1970s, this competition was minimal. The Armed Forces and the colleges were recruiting from two dissimilar subpopulations. From the advent of the All-Volunteer Force in 1972 through 1980, over a third of the recruits were high school dropouts, and few young people enlisted who had college training or planned to complete college. Earlier studies of the potential for military recruiting from two-year colleges and postsecondary vocational schools bore this out, indicating that the military was having little success in recruiting college students (Shavelson, Haggstrom, and Blaschke, 1984).

But during the 1980s, the disjunction between military service and college enrollment became less clear-cut. Aided by rising military pay, better educational incentives, an enhanced public image, and a depressed youth labor market during the 1981–1982 recession, the military made considerable inroads in recruiting high school graduates with college aspirations. Thanks to the Army College Fund and other postservice educational benefits, military service came to be viewed as a viable means to finance a college education. With the enactment of the Montgomery G.I. Bill in 1984, the role of military service as a stepping stone to postservice college and vocational training was expanded, solidified, and given national prominence. On the horizon are other proposals, such as the Citizenship and National Service Act introduced last year by Senator Sam Nunn, that would curtail existing federal student aid programs and substitute educational vouchers similar to the G.I. Bill for one- or two-year stints of military or community service.

As experience with earlier G.I. Bills has shown, sweeping changes like these can result in marked changes in the sorting-out process, including some unplanned side effects. The Army College Fund and the new G.I. Bill undoubtedly help attract recruits, but they also provide strong incentives for enlistees to leave the service to reap the benefits. The person-years gained by bringing additional recruits into the service may be more than offset by later losses of experienced personnel (Haggstrom et al., 1981; Fernandez, 1982). Since the inception of the Montgomery G.I. Bill on July 1, 1985, over 60 percent of eligible recruits (and 80 percent of Army recruits) have signed up for the program, affirming their intent to use the benefits through *nonrefundable* contributions of $1,200. As a consequence, in the 1990s, the services will be facing a double dilemma. They will be losing unusually large numbers of experienced personnel at the same time that their recruiting missions become more difficult due to shrinking applicant pools.

If there is a bright spot in this scenario, it is that the military's losses will be the civilian sector's gain. Just as earlier G.I. Bills contributed to the nation's supply of college-trained personnel, the new G.I. Bill is having the same effect. The numbers of veterans completing college in the next few years will probably not be large enough to forestall anticipated shortages of college-trained personnel, especially in teaching, nursing, science, and engineering. Nonetheless, the shortages will be less than they would otherwise have been, and these programs provide pathways to professional careers for high school graduates from low-income families.

Military personnel also add to college rolls through their educational pursuits while still in service through voluntary off-duty study or in military-sponsored training programs. In a study of the military impact on college enrollments, Hexter and El-Khawas (1988) report that, in 1987, service personnel enrolled in at least 778,000 courses at the postsecondary level. Thus, with the changes that have taken place in the 1980s, the military has become a significant source of college enrollments and, thanks mainly to the new G.I. Bill, a substantial source of student aid for youth from low- and middle-income families.

II. SIZING UP AMERICA'S HIGH SCHOOL GRADUATES AND DROPOUTS

This section profiles recent entrants into the postsecondary sorting-out process in terms of their numbers, demographic characteristics, and dispersion across states. Trends in cohort sizes and graduation rates are central to examining the flows of high school seniors into postsecondary activities over time, because there is considerable evidence that the transition rates for both high school graduates and dropouts have remained relatively stable over the last 20 years. Therefore, the number of cohort members in a prescribed track at any time following graduation depends mainly on the initial cohort size.

In addition to describing how entire cohorts of high school graduates and dropouts sort themselves into postsecondary tracks, we examine how choices of activities vary across groups of individuals categorized by sex, race, Hispanic origin, ability level, socioeconomic status, and region. To envisage the process, one can think of having a separate flow chart like Fig. 1 for each group. Alternatively, one can partition each of the main activity boxes into smaller boxes corresponding to subpopulations of interest. In either case, tracking student flows over time entails estimating the subpopulation sizes at the outset and then monitoring their subsequent transitions across activities.

Unfortunately, providing detailed profiles of recent entrants into the sorting-out process necessitates a certain amount of guesswork, because the national data base on high school graduates and dropouts is in a sorry state. The National Center for Education Statistics (NCES), for example, cannot provide reasonably accurate estimates of the numbers of high school graduates or dropouts for any year, let alone the kinds of disaggregated data by state, sex, race, and school affiliation that are needed to profile the nation's youth, track their educational progress, and examine their potential for meeting the nation's future manpower needs.

To help fill the information gap, we have pieced together data from several sources, relying heavily on Census Bureau estimates and projections of age group sizes by state, age, and race to provide data on the cohorts of young people of school-leaving age in each state. The products of this effort include estimates of high school graduation rates by state, and estimates and projections of numbers of high school graduates by state, sex, race, and control (public or private) for the years 1980 to 2000.

Several government publications, including the *Digest of Education Statistics* (NCES, 1989) and the *Statistical Abstract of the United States* (U.S. Bureau of the Census, 1989), provide tables pertaining to numbers of high school graduates, dropout rates, and educational attainment. However, the published data are inadequate for assessing the magnitude and dimensions of the school dropout problem or for providing basic data on the sizes and compositions of the graduating classes. They are even less adequate for monitoring the postsecondary sorting-out process to examine the extent to which today's graduates are acquiring the skills to become tomorrow's managers, technicians, and teachers. In the absence of detailed, reliable information on the numbers of high school graduates and dropouts each year, the flows of students through the nation's schools and colleges are essentially unknown, making it difficult to measure the extent and severity of the dropout problem, assess the implications of the shrinking college age group, or analyze policies bearing on youth problems, such as student aid, military recruiting, and national service.

THE SCHOOL DROPOUT PROBLEM

High dropout rates have long been a matter of national concern, in part because dropping out has been linked with other high-profile youth problems—illiteracy, lack of basic skills, teenage pregnancy, drug abuse, and crime. The prevalent concern is that dropouts are ill equipped to make their way in American society and thus apt to become part of a self-perpetuating underclass, locked in poverty and prone to lifelong patterns of unemployment, welfare dependency, and criminal activity (Carnegie Council on Policy Studies in Higher Education, 1979).

While these concerns may be exaggerated, there is little doubt that the postsecondary activities of dropouts differ considerably from those of graduates in the same age group. High school graduation is a prerequisite for entrance into most postsecondary educational programs, and many employers, including the military services, use high school completion as a criterion in screening applicants for entry-level jobs and training programs. Hence, the educational and career opportunities open to dropouts may be severely limited.

It is not surprising that, as a group, high school dropouts fare poorly in the labor market. Among persons of age 16 to 24 who were not enrolled in school in October 1989, only two-thirds of the dropouts were in the civilian labor force (i.e., currently employed or seeking work), as compared with 87 percent of the high school graduates in the same category. Among those in the labor force, the unemployment rate was 20.5 percent for the dropouts, more than double the 8.5 percent rate for the high school graduates in the same category (Bureau of Labor Statistics, 1989b).

However, the causes and consequences of dropping out are by no means well understood, partly because of definitional and data problems that confound analyses of the dropout problem (Pallas, 1986). Despite the absence of uniform definitions of dropouts and the lack of hard data that permit comparisons of graduation and dropout rates across states, races, and genders, there is a continual stream of irreconcilable statistics on dropouts that add to what Chester Finn, former Assistant Secretary for Educational Research and Development, characterized as the "high school dropout puzzle" (Finn, 1987).

In part, the puzzle persists because two seemingly well-grounded methods for gauging the magnitude of the dropout problem yield radically different estimates. One method relies on the educational attainments reported by participants in the Current Population Survey. In 1987, 85 percent of all persons of age 20 to 24 reported having completed four years of high school, as did 88 percent of those of age 25 to 29 (U.S. Bureau of the Census, 1988a). These figures suggest that only about one of every eight Americans fails to complete high school.

By contrast, graduation rates derived from state data on numbers of high school graduates indicate that the above figures misrepresent the magnitude of the dropout problem by a factor of two. Our analysis of the state data in Appendix A supports the contention that, roughly speaking, one of every four 17-year-olds in the 1980s dropped out of school before graduating, a figure that has remained essentially unchanged for the last 20 years.

Although part of the disparity between the two sets of dropout rate estimates can be ascribed to definitional problems (e.g., recipients of "high school equivalency" certificates may classify themselves as graduates), the numbers still do not add up. At least part of the difference seems to be due to the nonresponse and response errors that plague population surveys, i.e., nonrespondents to the CPS are more likely to be high school dropouts, and the dropouts who respond are more likely to be misclassified (or to misclassify themselves) on educational

attainment. Overreporting of educational attainment is not new; it was documented on the post-enumeration studies of both the 1950 and 1960 censuses (Folger and Nam, 1967).

Adding to the confusion about dropout statistics, the Department of Education reports high school dropout rates by state that "cover public schools only, and are calculated by dividing the number of high school graduates by the ninth-grade enrollment four years earlier" (*Chronicle of Higher Education*, September 6, 1989, pp. 6, 96). These estimates have dubious validity, because they exclude private school students, dropouts before grade nine, and returnees who take more than four years to complete grades 9–12. Moreover, the disparities in the reported rates across neighboring states are too wide to be credible, perhaps because the states use different criteria in reporting ninth-grade enrollments. In 1987, when the reported national rate was 29 percent, Michigan's rate was listed at 38 percent, whereas the rates reported by its three neighboring states—Wisconsin, Indiana, and Ohio—were just 15, 26, and 17 percent respectively. South Dakota's 20 percent rate exceeded that of its six neighbors by from 6 to 11 percentage points.

The definitional difficulties will be skirted in this study by treating dropout rates as complements of high school graduation rates, i.e., if the graduation rate in a given state is 75 percent, the dropout rate is defined to be 25 percent. The graduation rates are defined by dividing the number of high school graduates from regular day schools by the size of an age group that serves as a proxy for the number of young people who graduate from or drop out of school each year. At the national level, the number of 18-year-olds as of July 1 serves that purpose. However, at the state level, because there is substantial interstate migration among 18-year-olds, the number of 17-year-olds as of July 1 in the previous year serves the purpose better.

NUMBERS OF ENTRANTS INTO THE SORTING-OUT PROCESS

Table 1 shows Census Bureau estimates and projections of the numbers of 17- and 18-year-olds in the resident population as of July 1 each year from 1970 to 2000. The near term projections for 1990–1992 indicate that the number of 18-year-olds fell by 8 percent in 1990 and will continue to fall by 5 and 2 percent in 1991 and 1992, followed by a pattern of gradual increases from 1993 through the rest of the 1990s. See Fig. 2.

It is well known that the sizes of college age groups have declined over the 1980s. What seems to have been overlooked is that the decline has been far from uniform. In fact, the number of 18-year-olds rose steadily from 1986 to 1989. As Fig. 2 shows, the three-year decline in the numbers of 18-year-olds beginning in 1990 will be much steeper than the decline during the early 1980s. Despite the gradual increases projected for the late 1990s, the average size of the 18-year-old cohorts during the 1990s will be 11 percent smaller than the average for the 1980s.

Since high school graduation rates as well as postsecondary enrollment, employment, and enlistment rates vary considerably across regions and races, disaggregated estimates corresponding to the national estimates in Table 1 are needed to infer the ramifications of these trends on college enrollments and the youth labor market. Hence, we have compiled disaggregated estimates of age group sizes by state, race, and sex for 1980–2000. These estimates depend primarily on revised Census Bureau estimates of the resident population as of the 1980 census and are linked to their estimates and projections for the years 1986–2010 by state, race, and sex (U.S. Bureau of the Census, 1988c). See Appendix A.

Our interest in these disaggregated estimates is driven by the need for analogous estimates of numbers of high school graduates in the same categories to support our analyses of

Table 1

SOURCES: U.S. Bureau of the Census (1982, 1988b, 1988c, and unpublished estimates).

High School and Beyond. To that end, we have modified the Census Bureau estimates to provide estimated age group sizes for the same five race/ethnicity categories that are reported in HS&B—one for persons of Hispanic origin of all races and four others for non-Hispanics in the main census race categories: white, black, Asian and Pacific Islander, and native American (American Indians, Eskimos, and Aleuts). For the sake of brevity, the term "non-Hispanic" will be suppressed henceforth, and these four categories will be referred to as "White," "Black," "Asian," and "Indian" in the tables below.

While the size of the 18-year age group serves as a satisfactory base for calculating national high school graduation rates, it does not serve nearly as well in defining state graduation rates. The reason is that the states are differentially affected by the migration that occurs among 18-year-olds as they leave high school and move to attend college, seek

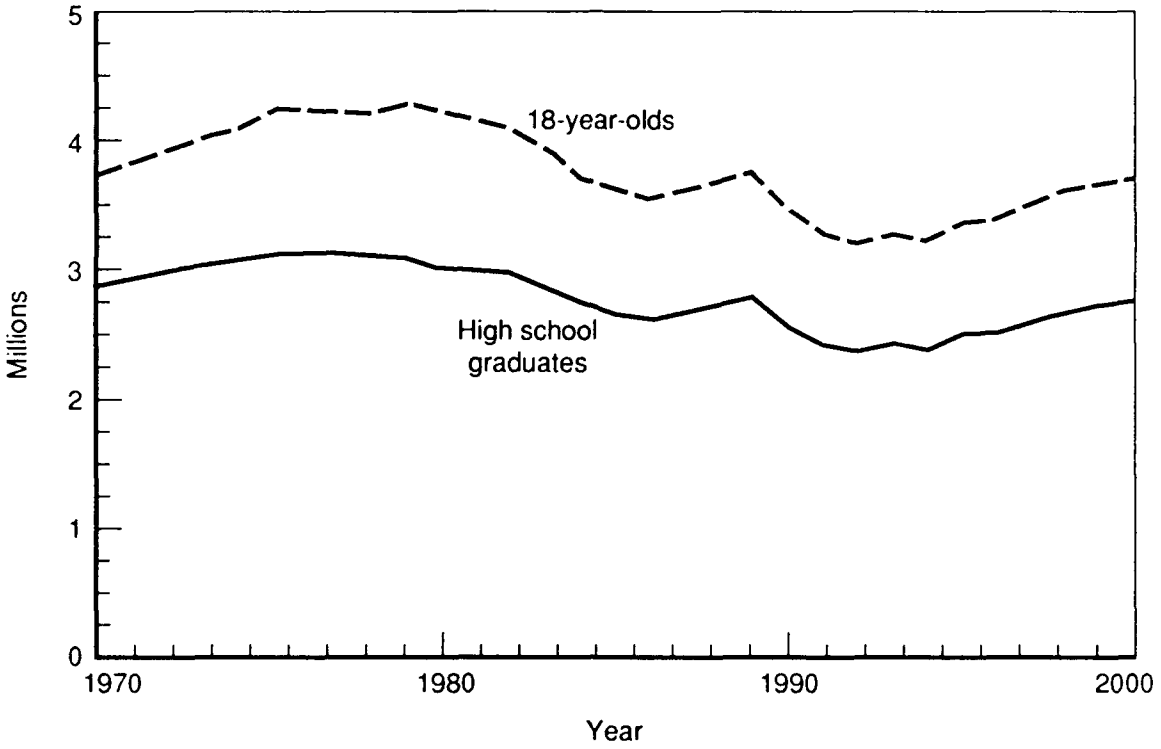

Fig. 2—Numbers of 18-year-olds and high school graduates, 1970–2000

employment, or enter the military. In particular, the District of Columbia experiences considerable immigration of 18-year-olds each year, so that the size and racial mix of the District's 18-year age group do not mirror the 17-year age group, which better reflects the size and racial composition of the District's high school population. Hence, in lieu of using the 18-year age group size as a base for calculating state high school graduation and dropout rates, we have substituted the number of 17-year-olds as of July 1 in the previous year, except for 1980, where we use the census data for the 17-year age group as of April 1.

Table A.3 in Appendix A provides estimates of the numbers of 17-year-olds by state for the years 1980–1989. The corresponding projections for 1990–2000 are listed in Table A.4. Breakdowns by sex and race/Hispanic category are provided for all years. Table 2 lists the disaggregated estimates for 1980.

During the 1980s, there was a continual shift toward increased minority representation in the school age population; this trend will continue into the 1990s. In 1980, the percentages of 17-year-olds in the five race/Hispanic categories were: White, 76.2; Black, 14.0; Asian/Pacific Islander, 1.4; Native American, 0.7; Hispanic, 7.7. The corresponding estimated percentages for 1990 are 70.1, 15.8, 2.7, 1.2, and 10.2. By the year 2000, they will become 67.5, 15.7, 3.5, 1.5, and 11.8. Thus, although minority representation has increased and will continue to increase through 2000, the changes in the race/Hispanic mix of the high school age population have been gradual.

NUMBERS OF HIGH SCHOOL GRADUATES

Table 3 lists estimates of the numbers of high school graduates for 1960–1989 by control of school and sex. The estimates for the years before 1980 are taken from NCES (1989a, 1989b) and earlier publications in the same series; the sources of the more recent estimates are listed in Appendix A. The graduation rates in the last two columns are calculated by expressing the number of graduates as a percentage of the number of 17-year-olds as of July 1 in the previous year.

High school graduation rates have changed by only a few percentage points in the last 20 years, but there was a continual decline for both sexes during the 1970s followed by steady increases in the early 1980s. Graduation rates for females have typically dominated the male rates by 4–6 percentage points.

The most reliable recent data on numbers of high school graduates by state are for 1986, when the overall graduation rate was 73.4 percent (70.8 percent for males, 76.2 percent for

Table 3

NUMBERS OF HIGH SCHOOL GRADUATES BY CONTROL OF SCHOOL AND SEX, 50 STATES AND D.C.: 1960–1989
(In thousands)

Year	High School Graduates	Control		Sex		Graduation Rate	
		Public	Private	Male	Female	Male	Female
1960	1858	1627	231	895	963	63.4	70.9

1989	2807	2533	275	1390	1418	70.5	76.0

females). Given that the estimated numbers of graduates have consistently run less than three-fourths the numbers of 17-year-olds since the mid-1970s, we can only conclude that one of every four 17-year-olds dropped out of school before graduation. The fact that the youth population contains such a high proportion of high school dropouts implies a colossal wastage of human resources, but this reality has been blurred by national statistics on educational attainment indicating that the dropout problem is far less serious. As was noted earlier, in 1987, 85 percent of the population of age 20 to 24 reported having completed four years of high school, as did 88 percent of those of age 25 to 29.

Although part of the discrepancy between educational attainment statistics and graduation rates may result from survey respondents overstating their educational attainments, a more likely explanation is that many high school dropouts pursue postsecondary educational programs that are difficult to quantify in years of educational attainment. In particular, an increasing number of high school dropouts obtain General Educational Development (GED) credentials—428,000 were issued in 1986 as compared with 333,000 in 1976 (NCES, 1988). And many high school dropouts pursue postsecondary training programs in community colleges and vocational-technical schools. In responding to surveys, many of them probably classify themselves as having completed 12 years of school and perhaps one or more years of college, thereby confounding national statistics on educational attainment. Although the Armed Forces maintain the distinction between high school diploma graduates and GED recipients in setting enlistment standards, the blurring of high school graduate status in the labor market has undoubtedly become more pervasive over time.

NUMBERS OF GRADUATES FROM PRIVATE SCHOOLS

Reliable counts of high school graduates have not existed for many years. The NCES routinely gathers state data on public high school graduates and publishes them in the *Digest of Education Statistics* (NCES, 1989). But NCES has undertaken no systematic effort to collect complete data on numbers of graduates from private schools since the mid-1960s. The often cited data for 1980, which were derived from a sample survey using an out-of-date sampling frame, do not accord with state data from other sources.

To provide better information on private high school graduates and more detailed state data on the flows of students through public schools, the Western Interstate Commission for Higher Education compiled a data base on enrollments by grade level and numbers of graduates, both public and private, for the academic years 1978–79 through 1985–86. Although some states were unable to provide time series of private school graduates, WICHE published the time series that were available as well as their best estimates for 1986 (WICHE, 1988).

Our tabulations of WICHE's state estimates by census division for the states with no missing values showed small, relatively uniform increases in the private/public ratio from 1980 to 1986. Led by the consistency of this pattern both within and across regions, we estimated the missing 1980–1985 values in the WICHE time series by using their 1986 estimates and applying the assumption that the private/public ratios for 1980–1986 in the "missing states" were proportional to the overall ratios for the nonmissing states in the same region.

The resulting state estimates for both public and private schools are given in Table 4. They indicate that the numbers of private school graduates changed little from 1980 to 1986, while the public schools were producing fewer and fewer graduates. Private schools

accounted for approximately 9 percent of the nation's high school graduates in 1980 and 10 percent in 1986.

Table 5 shows the high school graduation rates by state that result from expressing each state's total number of high school graduates as a percentage of the number of 17-year-olds in the previous year. Led by the stability in the U.S. graduation rates from 1984 to 1986 and by the flatness of the public school rates through 1987 (see Appendix A), we extended the state estimates for both public and private schools through 1989 by incorporating the assumption that the estimated state graduation rates for 1987 would persist through 1989 and applying the state rates to the Census Bureau estimates of the 17-year age group sizes by state, sex, and race for 1987–1989. Since the scheme could be readily extended into the 1990s using Census Bureau projections of age group sizes, the same procedure was used to generate projections of numbers of graduates for the years 1990–2000. See Table A.2 in Appendix A.

THE CHANGING COMPOSITION OF THE GRADUATING CLASSES

To estimate the composition of graduating classes by state, sex, race, and Hispanic origin, we relied heavily on the percentages of persons of age 19 who reported having completed four years of high school in the 1980 census. Treating the 1980 regional high school completion rates by sex, race, and Hispanic origin as first approximations for high school graduation rates and applying them to each state's numbers of 17-year-olds in those categories, we derived preliminary estimates of the number of graduates in each cell. These preliminary estimates were then rescaled using iterative proportional fitting so that the numbers of graduates in the various categories summed to the state total for that year.

The procedure for estimating the number of private school graduates in each category was similar in that, as a first approximation for each state, we used regional estimates of the percentages of high school students of each race that were enrolled in private schools as of the 1980 census. These preliminary estimates were then rescaled to conform to the state totals.

Table B.1 shows the estimated composition of the 1980 graduating class by census division, control of school, sex, and race/Hispanic category. According to these estimates, the percentages of high school graduates in the five race/Hispanic categories were: White, 81.6; Black, 11.2; Asian/Pacific Islander, 1.5; Native American, 0.5; Hispanic, 5.1. The analogous estimated percentages for the Class of 1990 are 76.7, 12.9, 2.7, 0.9, and 6.8. For the Class of 2000, the projected percentages are 74.0, 13.2, 3.6, 1.1, and 8.0. Thus, the estimated percentage of graduates from minority groups increased from 18.4 percent in 1980 to 23.3 percent in 1990, and it is projected to increase to 26.0 percent in 2000.

In addition to the shift in the race/Hispanic composition of the graduating classes, another noteworthy demographic trend is the shift toward increasing numbers of graduates from southern and western states. As can be seen from Table 5, the percentages of 1980 graduates in the four census regions were: Northeast, 23.2; North Central, 28.7; South, 30.8; West, 17.3. The corresponding estimated percentages for 1990 are 20.6, 26.4, 33.9, and 19.1. In 2000, they are projected to become 19.1, 24.5, 34.2, and 22.2.

Since minority students are less likely to attend private schools and since private schools account for smaller proportions of graduates in the South and West, both of these demographic trends portend smaller proportions of private school graduates in the 1990s.

According to the projections in Table A.2, there will be a gradual reduction in the percentage of private school graduates over time—from 9.9 percent in 1986 to 9.6 in 2000.

In summary, the compositions of the high school graduating classes changed during the 1980s to reflect greater minority representation in most states and more rapid growth in the South and West. These trends will persist through the 1990s. However, the major changes that we foresee in the near term do not pertain to the compositions of the graduating classes but to their overall sizes. The high school graduating classes are projected to shrink by 15 percent between 1989 and 1992. The consequences of those changes depend critically on how the graduates sort themselves into postsecondary paths.

III. MAIN ACTIVITIES AFTER LEAVING SCHOOL

This section examines patterns of postsecondary activities followed by high school graduates and dropouts during the first year after leaving school. We begin with a summary of trends pertaining to the numbers of graduates and dropouts who enter the three main postsecondary tracks—college, military service, and civilian employment. Time series from several sources are presented to provide an overview of young people's educational and vocational pursuits, and to examine a long-standing contention that, except for disruptions for military service during times of war, postsecondary sorting-out patterns have been relatively stable for many years.

Then, drawing on a large panel study of over 26,000 seniors in the Classes of 1980 and 1982, we present analyses of the seniors' main activities in October following graduation to show how individuals from varying backgrounds sort themselves into postsecondary tracks. Primary attention is given to examining the relevance of sex, race, Hispanic origin, socioeconomic status, academic aptitude, and economic factors on decisions to enter college or enlist in the Armed Forces.

LONG-TERM TRENDS

For the most part, previous studies of the postsecondary sorting-out process were restricted to educational pursuits. Some noteworthy exceptions are Johnston and Bachman (1972), who examined enlistment behavior during the Vietnam Conflict; Ornstein (1976), who used retrospective data to study entrance into the labor force; and Hosek and Peterson (1985) and Hosek, Peterson, and Eden (1986), who studied enlistment behavior during 1979 among males of age 17–22.

Studies of college attendance patterns before 1970 pointed to ever-increasing educational attainment among college-age youth. Although consistent time series on college enrollment by level and sex were not available before World War II, the data on earned degrees indicated continual increases in college enrollment rates and degree attainments from 1900 to 1940, except during World War I.

More detailed analyses of enrollment patterns from 1940 to 1970 revealed wide fluctuations in college enrollment patterns, especially for men. During the early stages of World War II, the Korean War, and the Vietnam Conflict, college entrance rates dropped as millions of Americans postponed or interrupted their educational and career pursuits to enter the military. The most pronounced disruptions were during World War II, when most able-bodied young men either enlisted or were inducted into military service, decimating college enrollments between 1941 and 1945. After the war, more than two million veterans swamped the college campuses, many of them staying on to complete bachelor's and advanced degrees under the G.I. Bill. Whereas colleges had awarded 129,000 degrees to men in 1940 and less than half that many in 1944, the number soared to 376,000 in 1950 (Adkins, 1975).

College enrollment patterns for men were also greatly affected during the Korean War. With almost 500,000 inductions per year from 1951 to 1953, college entrance rates dropped sharply. After the war, nearly 1.2 million veterans entered college under the Korean G.I. Bill, swelling college enrollments and stimulating degree production through the early 1960s.

Despite these disruptions of normal college attendance patterns during World War II and the Korean War, there was a remarkable finding in the mid-1960s that patterns of educational attainment beyond high school and persistence through college had been very stable across age groups since the early 1900s. In a widely quoted paper based on their analysis of educational attainment data in the 1940 and 1960 censuses, Jaffe and Adams (1964) wrote:

> Roughly half of all the white men who graduate from high school go on to college. Roughly 4 in 10 white women and nonwhite students who graduate from high school go on to college. . . . One assumption is that a larger proportion of high school graduates now goes on to college. We find, on the contrary, that the proportion continues to be the same. . . . We find that slightly over half the men are receiving their degrees and about 4 in 10 women are completing four years. These proportions continue long-standing trends.

Whether this very simple characterization of college entrance and persistence patterns held for the period before 1960 is debatable, but their contention about the long-term stability of college entrance rates became untenable during the 1960s when the rates increased markedly, especially for women. Folger, Astin and Bayer, (1970), in their report for the Commission on Human Resources and Advanced Education, presented data from several sources indicating that college entrance rates rose substantially in the late 1950s and early 1960s. A subsequent study for the Carnegie Commission on Higher Education reported consistently rising college entrance rates during the 1950s and 1960s for women and parallel increases for men after allowing for the surges of veterans into college following World War II and the Korean War (Haggstrom, 1971). That study also showed that college persistence and degree completion rates for women increased during the 1960s, bringing their rates up to the male levels, which remained relatively stable during the 1950s and 1960s despite the clear-cut effects of the Korean and Vietnam Wars on college enrollment.

As the U.S. heightened its military commitment to the Vietnam Conflict in the mid-1960s, normal college attendance patterns were again disrupted. College entrance rates fell slightly in 1966 as over 500,000 enlistees and 300,000 inductees entered military service. Opposition to the draft and U.S. military policies in Vietnam mounted over the next three years. With draft calls continuing to run between 200,000 and 300,000 from 1967 to 1969, college enrollments were stimulated as many men took advantage of the draft deferments available for full-time college students. Other men sought exemption from the draft through reserve participation, leading to long waiting lists of men trying to enlist in reserve and National Guard units.

The uncertainties that beset college age males subject to the draft were lessened when the first draft lottery was implemented in December 1969. With greatly reduced numbers of draft calls in 1970 and 1971, the phasing out of student deferments, and the advent of the All-Volunteer Force in 1972, the wartime effects on college enrollment dwindled in the 1970s except for the large numbers of veterans attending college.

In addition to the Vietnam Conflict, another important factor affecting college enrollments in the late 1960s was the aftereffect of the postwar baby boom. High school graduating classes underwent very rapid growth in the middle and late 1960s (see Table 3). As the postwar baby boomers graduated from high school and entered college, enrollments soared. The number of college degrees awarded at the bachelor's level and above more than doubled between 1960 and 1970, reaching 1,071,000 in 1970. Because degree production during the late 1960s was so much higher than it had been in previous decades, the stock of persons in the U.S. holding college degrees also increased rapidly, from 1.6 million in 1960 to 2.8 million in 1970 (Adkins, 1975), leading to an oversupply of college-trained personnel in the 1970s, especially in the field of education.

There were other factors on the horizon in the late 1960s that may have affected postsecondary pursuits. The economy slipped into a minor recession in December 1969 that lasted for 11 months. Although this recession was not as severe as the later recession of 1973–1975, the fact that it occurred following a nine-year period of rapid economic expansion and at the same time that the Vietnam Conflict was winding down may have heightened its effects on young people's educational and career pursuits.

CHANGES IN THE SORTING-OUT PROCESS IN THE 1970s AND 1980s

Before the implementation of the draft lottery in December 1969, young men had been subject to the draft through age 26, with older men being called first. Various kinds of deferments were available before 1970, the most common being for college attendance. Before these deferments were phased out beginning in 1970, college age men could forestall the uncertainties of the draft by maintaining full-time student status, which led more men to complete bachelor's and advanced degrees during the late 1960s and early 1970s than there might otherwise have been.

The draft lottery of 1969 and those that followed in 1970 and 1971 for men turning 19 years of age were significant, because they permitted college age men to plan their futures with almost complete certainty that their educational and vocational pursuits would not be interrupted for military service. Only those with low random selection numbers faced imminent induction, and they could avoid being called to active duty by enlisting in one of the active reserve components. Many young men with low random selection numbers exercised that option during the first six months of 1970.

The extent to which these changes influenced postsecondary pursuits is difficult to ascertain, but the evidence points to a turning point in the sorting-out process in 1970 as the pressure exerted by the draft on enrollments at all levels lost its force. Johnston and Bachman (1972) reported that concerns about the draft were central considerations affecting high school seniors' plans in 1969. Although it seems doubtful that the draft could have had an appreciable effect on high school completion rates, high school graduation rates began their decade-long decline in 1970, dropping from a peak of 77 percent in 1969 to a low of 71 percent in 1981. See Table 3.

There was also a marked change in college enrollment patterns in the late 1960s and early 1970s. While freshman enrollment rates for women continued to increase during the 1970s, those for men went down. See Table 6. The freshman enrollment rates were determined by expressing the number of full-time freshman enrollments as a percentage of the number of high school graduates in the same year, as reported in Table 3.[1]

These differences between the male and female rates underscore the huge gender gap in college enrollment patterns that existed in 1970. Men outnumbered women in the 1970 freshman class by about four to three, and almost the same ratio held for bachelor's degree

[1]The "freshman enrollments" reported here are for first-time students, i.e., entering students who have not previously attended other institutions of higher education. We chose to use *full-time* freshman enrollments, instead of *total* enrollments, in calculating the enrollment rates to make them more comparable with college entrance rates reported later in this report. Also, the rates shown should not be interpreted as the percentages of graduates in a specific year who entered college as full-time students that year. Any fall freshman class includes many entering freshmen from previous years' graduating classes, as well as students who were not members of any graduating class (e.g., foreign students and students who did not earn high school diplomas). Also, some entering freshmen do not enroll for the first time during the fall term. The rates are given mainly to indicate college entrance trends during the 1970s and 1980s. They can, however, also be regarded as rough estimates of the percentages of the graduates in each class who entered college as full-time students at some stage following graduation.

Table 6

FULL-TIME FRESHMAN ENROLLMENTS AND FRESHMAN ENROLLMENT RATES BY SEX: FALL 1967 TO FALL 1987

	Full-Time Freshman Enrollment (in Thousands)			Freshman Enrollment Rate		
Year	Total	Male	Female	Total	Male	Female
1967	1335	761	574	50.0	57.3	42.7

1987	1627	779	848	60.3	58.5	62.2

SOURCE: NCES (1989a, Table 159).

recipients that year (NCES, 1989a). These disparities vanished during the 1970s and early 1980s as the freshman enrollment rates for women followed a relatively steady upward path and the rates for men remained relatively stable except for a dip in the late 1970s. The cross-over year for degree completions was 1982, when there were more bachelor's degrees awarded to women than men for the first time since World War II.

The large numbers of Vietnam veterans returning to college in the early 1970s inflated the male freshman enrollment rates somewhat from 1970 to 1975, exaggerating the gender gap. The 10-percent difference in 1975 shrank to nearly zero in 1980, after which time the rates remained nearly the same for both sexes through 1983. A possible explanation for the rate divergence that began in 1984 is that a larger proportion of male high school graduates postponed college entrance for a few years. It is notable that the year of divergence was the year in which the Montgomery G.I. Bill was enacted, indicating that the effects of military service on college attendance patterns did not end with the creation of the All-Volunteer Force.

ENLISTMENTS IN THE ALL-VOLUNTEER FORCE

Table 7 shows the numbers of persons who entered the service as enlisted personnel by sex and high school graduate status for the years 1972–1987. The "military enlistment rates" are calculated by expressing the number of nonprior service accessions each year as a percentage of the number of 18-year-olds as of July 1 in the same year. For the high school graduate accessions, the base for the enlistment rate was taken to be the number of high school graduates in the same year.

Table 7

NUMBERS OF NONPRIOR SERVICE ACCESSIONS BY SEX AND HIGH SCHOOL GRADUATE STATUS: 1972–1987

	All Accessions			HSG Accessions		
Year	Total	Male	Female	Total	Male	Female
	NUMBERS OF NONPRIOR SERVICE ACCESSIONS (IN THOUSANDS)					
1972	396	382	14	266	253	13

	MILITARY ENLISTMENT RATES					
1972	10.0	19.2	0.7	9.0	17.0	0.9
1973	10.6	20.1	1.0	9.4	17.5	1.2
1974	9.6	17.5	1.5	7.8	13.9	1.8
1975	9.8	17.7	1.8	9.0	15.9	2.1
1976	9.3	17.0	1.5	8.6	15.6	1.8
1977	9.0	16.4	1.4	8.6	15.8	1.8
1978	7.3	12.6	1.8	7.4	13.0	2.1
1979	7.2	12.3	1.9	7.2	12.3	2.3
1980	8.4	14.3	2.3	8.0	13.5	2.7
1981	7.7	13.3	2.0	8.7	15.1	2.5
1982	7.3	12.7	1.6	8.6	15.2	2.1
1983	7.7	13.3	1.9	9.8	17.4	2.4
1984	8.2	14.2	2.0	10.2	18.3	2.5
1985	7.9	13.6	2.1	9.9	17.4	2.6
1986	8.4	14.6	2.1	10.4	18.3	2.7
1987	8.2	14.1	2.0	10.2	18.0	2.6

Although not all enlistees enter the service at age 18 and not all high school graduates enter the service the same year they graduate, the enlistment rates serve as crude estimates of the percentages of the cohorts who enter military service. The rates in the table indicate that the proportion of 18-year-olds entering the military has remained quite stable over the 1980s, but the proportion of male high school graduates who enter military service has risen substantially—from around 12 percent in 1979 to over 18 percent in 1984.

It is noteworthy that the large increases in the enlistment rates occurred in the early 1980s when the numbers of graduates were either changing little or declining. In particular, the 34 percent increase in the number of male high school graduate accessions between 1979 and 1984 occurred during a period in which the corresponding numbers of high school graduates went down by 10 percent. While the rates do not take into account the time lags between high school graduation and service entrance (a topic that we return to in Section IV), it is clear from this table that, during the 1980s, more and more male high school graduates included military service in their postsecondary career paths. For a thorough treatment of the geographic and demographic attributes of enlistees during the 1980s, see *Population Representation in the Military Services: Fiscal Year 1987*, Office of the Assistant Secretary of Defense (Force Management and Personnel), August 1988.

OCTOBER ACTIVITIES OF GRADUATES AND DROPOUTS

To provide a more definitive examination of trends in postsecondary activities during the first few months after leaving school, we turn to national statistics on the enrollment and employment statuses of high school graduates and dropouts as of October in the year that they left school. See Table 8. These statistics, which are derived from time series published in the *Handbook of Labor Statistics* (Bureau of Labor Statistics, 1989a), refer to activities reported in the October Current Population Survey. Because the CPS is a household survey designed to provide information on the civilian noninstitutional population, the activities of graduates who entered the military before October are not included. Also, because the statistics are based on survey data, the estimates are subject to sampling and response errors.[2]

The time series of enrollment rates in Table 8 evidence many of the same patterns that were apparent in the freshman enrollment rates in Table 6, even though the numerators in these rates are quite different. Whereas the numerator for the freshman enrollment rate includes all full-time entering students regardless of when they completed high school, the numerator of the enrollment rate reported in Table 8 is restricted to freshmen who graduated from high school the same year but includes both part-time and full-time students.

Both time series indicate that college entrance rates for male graduates dropped in the aftermath of the Vietnam Conflict, rebounded in the early 1980s, and then remained stable from 1984 to 1987. The two time series for women show slightly different patterns, in that the college entrance rates in Table 8 do not show the pronounced upward trend during the 1970s that is evident in Table 6. However, both Tables 6 and 8 support the conclusion that the gender gap in college entrance rates shrank during the 1970s, leading to approximate parity in the male and female rates in the early 1980s.

---

[2]The standard errors of the enrollment rates reported in Table 8 are approximately 2.0 percent (U.S. Bureau of the Census, 1988b). The numbers of graduates reported here are estimated totals based on CPS responses. Even though these estimates exclude high school graduates in military service, they tend to run somewhat higher than the estimates in Appendix A derived from state data.

Table 8

ENROLLMENT AND EMPLOYMENT STATUSES OF RECENT HIGH SCHOOL GRADUATES IN OCTOBER, 1967–1987

The employment status rates in Table 8 show no clear-cut trends during the 20-year period, with only minor changes in the employment and unemployment percentages during recession years (1970, 1974–1975, 1980, and 1981–1982). As Fig. 3 shows, the overall proportions of graduates in the four student and employment categories changed little from 1970 through 1987, indicating that the graduates' choices of postsecondary activities were not very sensitive to labor market conditions.

The same cannot be said for the school dropouts. Table 9 shows the corresponding employment status breakdowns for "recent high school dropouts," a term that refers to persons who dropped out of school between October of the reference year and October of the previous year. There was a 13-percent decline in the male employment rate in the 1980 recession, with commensurate rises in the unemployment and out-of-labor-force percentages. With the exception of the 1986 blip (which may be a statistical artifact due to sampling errors), employment rates for male dropouts did not recover in the 1980s despite the effects of overall economic expansion in the mid and late 1980s.

Table 9 shows that female dropouts have made some gains in labor force participation over the last 20 years. Whereas 60 percent of these women were out of the labor force in 1970, the percentage dropped to 42 percent in 1987. However, a large part of the gains showed up, not in the employed column, but in the unemployed category. Unlike the male rates, the female employment rates did not undergo marked changes during recession years.

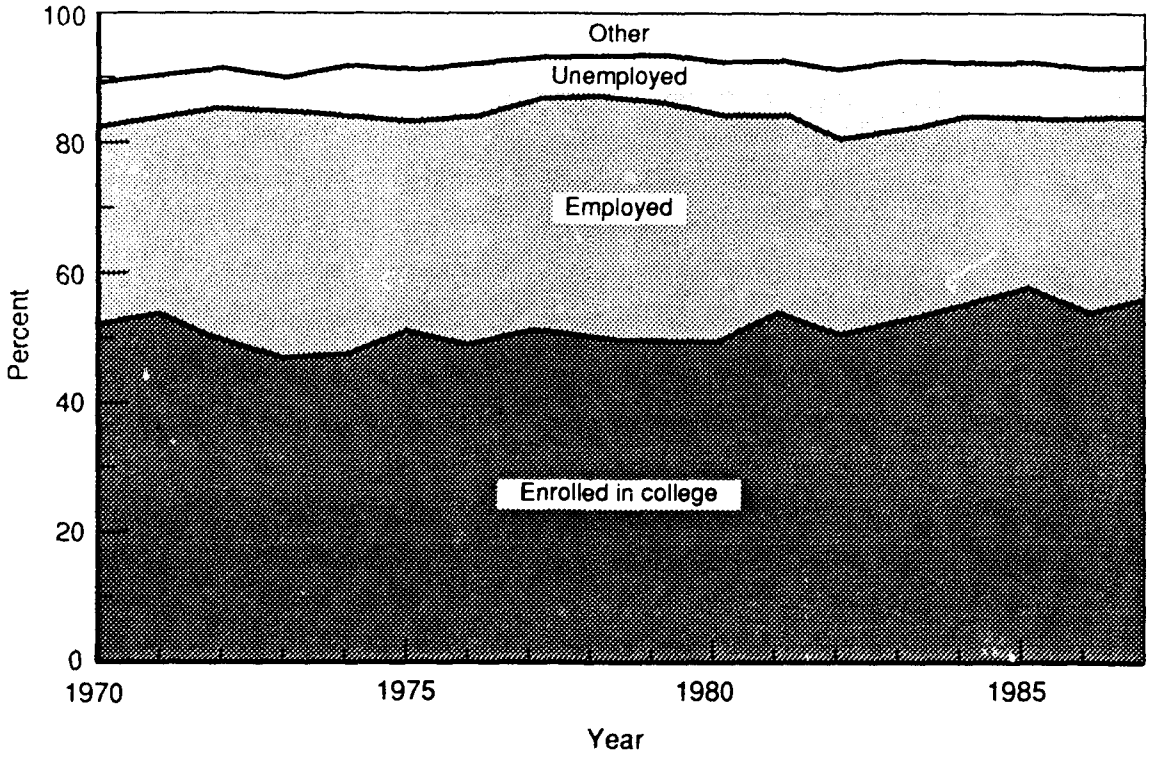

Fig. 3—Student/employment status in October by year of graduation

1987	100.	100.	45.6	36.0	28.1	21.5	26.3	42.4

A comparison of the employment statuses of recent graduates in Table 8 with those of dropouts in Table 9 makes it clear that dropouts fare poorly in the labor market relative to graduates who do not enter college. Among the dropouts, 54 percent of the men and 64 percent of the women were unemployed or out of the labor force in 1987 whereas, among recent graduates not enrolled in college, the jobless rates were 23 percent for males and 38 percent for females. These statistics underscore the concern that a large proportion of high school dropouts, who constitute one-fourth of America's college age youth, face bleak employment prospects after they leave school.

INDIVIDUAL DIFFERENCES

Except for the closing of the gender gap in college entrance rates during the 1970s and the trend toward higher enlistment rates among men in the early 1980s, the time series reported in this section indicate that the sorting-out process among high school graduates has been quite stable since the advent of the All-Volunteer Force in 1972. Although time series based on national statistics are useful for examining overall trends, they often raise more questions than they answer. When one considers the myriad opportunities, constraints, preferences, and norms that shape young people's activities after leaving high school, national statistics provide little illumination as to who does what, when, and why. In essence, the sorting-out process is individualistic in nature, with each young person facing a unique set of options depending on his or her abilities, attitudes, and circumstances.

While we cannot hope to characterize how particular individuals with specific traits make the transition from youth to adulthood, there is a middle road between examining national statistics and looking at individual behavior, namely, studying the postsecondary activities of relatively homogeneous subgroups of young people. Led by previous investigations as to what factors are most important in determining postsecondary behavior, we turn to an examination of differences in postsecondary pursuits across subgroups of individuals categorized by sex, race, Hispanic origin, academic aptitude, socioeconomic status, postsecondary plans, school control, degree of urbanization, and location. Our main data base, High School and Beyond, provides individual measures on these factors for over 28,000 seniors and 30,000 sophomores in Spring 1980, as well as comprehensive longitudinal data on the postsecondary activities of nearly 12,000 seniors and 15,000 sophomores in the same classes. See Appendix B.

There have been hundreds of studies devoted to examining the determinants of college entry and progress toward bachelor's and higher degrees. Folger, Astin and Bayer (1970) provide an excellent review of the literature before 1970, including supplemental analyses of Project TALENT, a large-scale longitudinal study of over 100,000 high school students in 1960. Manski and Wise (1983) provide a more recent review plus a thorough analysis of college attendance patterns based on the National Longitudinal Study of the High School Class of 1972 (NLS72). The main finding that runs through this literature is that academic aptitude, as measured by performance on cognitive tests or in terms of classroom performance, is of primary importance in determining who goes to college, but sex and socioeconomic status also play important roles.

Table 10 shows the extent to which college entrance rates depended on these factors in the early 1960s. Derived from the Project TALENT five-year follow-up survey, the entries in the table are the estimated percentages of seniors in the Class of 1961 who attended college within five years after leaving high school (Flanagan et al., 1971). Using the same data,

Table 10

PERCENTAGES OF CLASS OF 1961 ENTERING COLLEGE WITHIN FIVE YEARS BY SEX, SOCIOECONOMIC STATUS QUARTILE, AND ACADEMIC APTITUDE QUARTILE

Academic Aptitude Quartile	Socioeconomic Status Quartile				
	Lowest	Second	Third	Highest	Total
Lowest					
Males	14	29	35	42	25
Females	14	24	27	33	22

Females	47	65	72	95	77
Total					
Males	32	53	69	86	58
Females	18	36	51	78	43

Folger, Astin and Bayer (1970) estimated that 49 percent of the males and 35 percent of the females in the Class of 1961 entered college within a year after leaving school.

The two major successors to Project TALENT—NLS72 and HS&B—provided better data for analyzing student flows after high school and achieved much higher follow-up response rates. Like Project TALENT, NLS72 and HS&B began with large-scale base year studies of students selected at random from over 1000 high schools. In both cases, the selected students were administered a battery of cognitive tests, and considerable background information was obtained from the students themselves, their parents, and their schools. Follow-up surveys for NLS72 were conducted in 1973, 1974, 1976, 1979, and 1986; those for HS&B were fielded in 1982, 1984, and 1986. Of the two panel studies, HS&B obtained more detailed information on the participants' postsecondary activities by eliciting separate items on each episode of employment and schooling that the student had experienced since the previous follow-up. To provide reliable information on the military service and reserve participation of HS&B participants, the Defense Manpower Data Center supplemented our data files with extracts of service-related information on the enlistees, including dates of service entry and separation.

Using data from both sources, we classified each HS&B participant's main activity into one of four categories each month from January 1980 through February 1986: (1) full-time student, (2) military service, (3) civilian employment, and (4) not employed. Each of these categories was subdivided further to permit finer breakdowns of the participants' main activities. In particular, the full-time student category was divided into four subcategories corresponding to levels of schooling—high school, four-year college, two-year college, and vocational-technical school.

To prescribe "college entrance rates" for the Classes of 1980 and 1982, we combined the estimated percentages of graduates who were enrolled full-time in two- or four-year colleges

as of October in the year of graduation. Table 11 shows how these rates depend on sex, academic aptitude, and socioeconomic status.

Although the measures of academic aptitude and socioeconomic status derived from HS&B are quite different from those used in Project TALENT (see Appendix B), the dependence of the college entrance rates on those factors in Table 11 is as clear-cut as it was in Table 10 for the Class of 1961.[3] However, the levels of the rates in Tables 10 and 11 are not

Table 11

PERCENTAGES OF HIGH SCHOOL GRADUATES ENROLLED AS FULL-TIME COLLEGE STUDENTS IN OCTOBER BY SEX, SOCIOECONOMIC STATUS QUARTILE, AND ACADEMIC APTITUDE QUARTILE: CLASSES OF 1980 AND 1982

Females	21	32	45	67	41

[3]Although the overall rates were about the same for the Classes of 1980 and 1982, there are notable differences in the rates for individual cells that merit comment, especially those corresponding to the highest and lowest quartiles. These differences may be statistical artifacts stemming from the fact that the classification of HS&B participants into SES and test score quartiles was less reliable for the senior cohort (Class of 1980) than for the sophomores; SES scores or test scores (or both) were missing for 17 percent of the seniors but only 6 percent of the sophomores.

comparable, because those in Table 11 refer to full-time enrollment in a particular month following graduation, whereas those in Table 10 refer to both full-time and part-time enrollment at any time within five years after graduation.

Table 12 shows the analogous percentages of graduates in military service as of October in the year of graduation. Only 2.6 percent of the Class of 1980 and 2.3 percent of the Class of 1982 were on active duty as of that month. Because the majority of military entrants in the Classes of 1980 and 1982 delayed their entries into service for several months, these percentages do not reflect the prevalence of military duty among the Classes of 1980 and 1982. According to our estimates from the HS&B/DMDC files, 7.9 percent of the Class of 1980 and 7.6 percent of the Class of 1982 had served on active duty through February 1986. These estimates are in line with the enlistment rates reported in Table 7 (namely, 8.0 percent in 1980, 8.6 percent in 1982), which were derived by expressing the number of nonprior service accessions in any year as a percentage of the number of high school graduates in the same year.

Whereas Table 11 indicates that college entrance is more closely related to academic aptitude than to SES, Table 12 suggests that the opposite is true for military service. With military entrance rates for males in the lowest SES quartile running three or four times higher than those for males in the highest SES quartiles, it is clear from Table 12 that a disproportionate number of the enlistees who entered the military right after high school came from lower SES backgrounds.

PATTERNS OF MAIN ACTIVITIES AFTER GRADUATION

To show that postsecondary activity patterns also vary considerably across subgroups of youth categorized by sex, race, control of school, and location, we turn to an examination of October activities for other categories of students based on the weighted HS&B data. Table 13 shows the estimated percentages of high school graduates in each of the main activity categories. To facilitate interpretation, the small number of graduates who were either still in high school in October or whose HS&B records did not permit us to classify their main activities that month were allocated proportionately across activities. The numbers of cases in these two categories were small—1.6 and 5.9 percent respectively for the Class of 1980, 0.2 and 3.9 percent for the Class of 1982.

For the most part, the estimated track entrance rates for the two classes follow similar patterns. The most pronounced change between 1980 and 1982 was in the "Other" category consisting of graduates who were not full-time students and not employed. The overall increase from 14.6 percent in 1980 to 19.3 percent in 1982 is close to the increase from 15.8 to 19.5 percent in the jobless rates reported in Table 8 for recent high school graduates not enrolled in college. These increases reflect the tightening of the job market for entry-level workers during the 1981–1982 recession.

Combining the four-year and two-year college rates in Table 13, we see that the full-time college enrollment rates in October for the Classes of 1980 and 1982 were 40.5 and 39.9 percent respectively. Since the analogous part-time college enrollment rates for the two classes were 7.8 and 7.2 percent, the overall college enrollment rates in October following graduation were 48.3 and 47.1 percent.[4] These estimates accord very well with the estimates

[4]The difference between these estimates is not statistically significant. The standard errors of the estimates (and the analogous estimates for full-time enrollments) are approximately 0.7 each, and the standard error of their difference is about 1.0. In calculating these *college* enrollment rates, we excluded enrollments in vocational and technical schools to maintain comparability with enrollment statistics cited in government publications. If one

Females	0.5	0.5	0.6	0.5	0.5

in Table 8 derived from the Current Population Survey—49.4 percent in 1980, 50.6 in 1982 (with standard errors of about 1.4). While the latter rates show a slight increase between 1980 and 1982, the decrease of 1.2 percent in the estimates derived from HS&B data is consistent with the decrease in the freshman enrollment rates reported in Table 6.

It is noteworthy that the distribution of graduates across main activities in 1980 accords very closely with the analogous distribution for the Class of 1972 reported by Kanouse et al. (1980, p. 17). Their estimated percentages in the three full-time student categories were 30.0, 13.3, and 6.7 percent, and their estimates for military service, civilian employment, and

includes the graduates who were enrolled in vocational-technical schools in October (6.5 percent in 1980, 5.7 in 1982), the overall October enrollment rates for the Classes of 1980 and 1982 were 54.8 and 52.8 percent.

Table 13

ESTIMATED PERCENTAGES OF HIGH SCHOOL GRADUATES BY MAIN ACTIVITY IN OCTOBER: CLASSES OF 1980 AND 1982

Category	Number in 1000s	Main Activity in October Following Graduation					
		Student			Military Service	Civilian Employment	Other
		4-year	2-year	Voc-tech			
CLASS OF 1980

the "Other" category were 2.5, 37.6, and 9.8 percent. The concordance of the 1972 and 1980 rates underscores the stability of the overall college entrance rates during the 1970s and early 1980s. A comparison of the 1972 and 1980 rates for males and females separately confirms the closing of the gender gap during the 1970s. The 1972 female percentages reported by Kanouse et al. for the full-time student categories were 29.1, 12.6, and 8.5 percent, and those for males were 31.0, 14.0, and 4.9. Noting the reduction in the full-time vocational-technical percentage for females from 8.5 percent in 1972 to 5.6 in 1980, we see that part of the narrowing of the gender gap in college entrance rates between 1972 and 1980 reflected a shift of female enrollments from vocational-technical schools (e.g., for health services and secretarial training) into community colleges.

Although the differences in the 1980 and 1982 track entrance rates across categories of graduates are not as marked as those between the first and fourth quartiles in academic aptitude or SES, the differences are still sizable. Private school graduates were much more likely to enroll full-time in four-year colleges in October than public school graduates. Among minority groups, the full-time college enrollment rates in October ranged from a low of 30 percent for Hispanics to a high of 58 percent for Asian/Pacific Islander graduates, whereas the white non-Hispanic rates were around 42 percent in both years.

The differences in track entrance rates across census divisions show that postsecondary sorting-out patterns vary considerably across the country. In terms of full-time college enrollment rates, the Middle Atlantic states (New Jersey, New York, and Pennsylvania) had the highest rate in 1982 at 46 percent, more than ten points above the rates for the southern divisions and the Mountain states. Although the Pacific states (Alaska, California, Hawaii, Oregon, and Washington) had a relatively high rate of 45 percent in 1982, they ranked lowest in terms of four-year college enrollment rates, with only 22 percent of the Class of 1982 attending four-year colleges full-time in October. These variations in enrollment patterns across regions and race/Hispanic origin categories are important in analyzing subsequent educational attainments because of the very different persistence patterns across institutional categories.

Table 13 shows that the proportion of graduates in military service in October also varied widely across subgroups of high school graduates. In addition to the pronounced gender gap in the military service rates, there were substantial differences between public and private school graduates and between blacks and whites. As will be seen from multiple regression analyses later in this section, part of these differences are attributable to differences in socioeconomic status across categories.

PLANS VERSUS REALIZATIONS

The HS&B base year surveys for both the seniors and sophomores included the question "What is the one thing that most likely will take the largest share of your time in the year after you leave high school?" The responses to this item, when contrasted with the same students' activities following graduation, shed light on the timing and stability of plans formulated prior to graduation. Given the multitude of personal factors that affect choices of postsecondary activities and the infeasibility of assessing them accurately via population surveys, one can regard the plans reported by the seniors themselves as the most informed guesses as to how those factors will play out in the months following graduation. Hence, they provide important information about the decisionmaking processes of young people as they approach a key juncture in their lives.

However, senior plans do not provide very reliable predictors. Only about half of the senior HS&B participants' main activities in October matched the plans that they reported in the spring. While this discordance of plans and realizations can be dismissed as indicating that some seniors do not treat survey questions seriously, scholars who have studied this phenomenon explain it differently, saying that plans made in high school tend to be unreasonable and unstable (Flanagan et al., 1971). Studies of educational attainment objectives and career aspirations have consistently shown that many high school seniors have unrealistic expectations, and that others skew their responses to conform to socially acceptable norms (Kanouse et al., 1980).

One explanation for the instability of high school students' plans is that they are affected by changes in the students' circumstances and attitudes. For seniors who have found more ups than downs in their high school experiences, who have doubts about the personal benefits of further education, or who have only vague notions as to where they are going and how they will get there, it is understandable that their plans might fluctuate over time, perhaps depending on day-to-day developments in their personal relationships with friends, parents, and teachers. On the other hand, these uncertainties may not exist for some seniors who have long-standing plans supported by their families and tailored to their desires, talents, and resources.

Johnston and Bachman (1972) found that plans made in grades 10 and 11 to get a job or enter the military were poor predictors of later behavior, but that college plans made in those grades were more reliable. They concluded that the decision to go to college is made fairly early for most students who attend college, but that "the decision to get a job or enter the service is typically made very late in high school or even subsequent to graduation. . . . Military service and work often become first choices only after it is realized that continued education is an unsuitable or impossible goal to achieve" (Johnston and Bachman, 1972, p. 30).

We concur with the view that decisions regarding postsecondary activities are sequential in nature and that educational goals play an important role in determining those activities. However, we contend that decisions to enter the military or to take jobs in the civilian sector, especially those entailing lengthy periods of classroom or on-the-job training, may represent first steps in well-formulated plans to achieve concrete educational goals rather than digressions from those objectives. In particular, individuals who enter the military right after high school may not be opting away from educational pursuits but entering technical training programs consistent with their career goals or accepting temporary diversions to pave the way for subsequent college attendance funded through postservice educational benefits. If most students have well-orchestrated plans of this nature, the concordance of their plans and outcomes should demonstrate the coherence of their plans. However, as we shall now see, there is plenty of evidence to show that high school students' plans are erratic.

Tables 14 and 15 show how well seniors' plans accord with their October activities based on the weighted HS&B data for the Classes of 1980 and 1982. The top halves of these tables show the estimated numbers of graduates in each of the cells that result from crossing the plans and activity categories. The bottom halves of these tables are similar to Table 13 in that they show the track entrance rates for each plans category. The entries along the diagonal are the percentages of graduates who were pursuing the same main activity in October that they had checked in responding to the plans item. Hence, they are measures of the reliability of senior plans as predictors of October activities.

Only about two-thirds of the seniors in both classes who planned to devote most of their time to four-year college attendance were actually pursuing that activity full-time in October.

For the Class of 1980, the same two-thirds figure applied to those with "Civilian employment" plans, but the figure dropped to around three-fifths for the Class of 1982. This drop was partially offset by a rise in the "Other" category (not employed and not enrolled full-time), presumably as a result of reduced employment opportunities during the 1981–1982 recession.

The seniors in the "Military service" plans category were those who checked "Going into regular military service (or service academy)" in responding to the plans item. Only 50 percent of the 1980 graduates and 40 percent of 1982 graduates who checked this response were on active duty in October following graduation, but the percentages were higher for the males (57 and 43 percent). Allowing for the fact that some enlistees delay their service entry several months after enlistment, we have also estimated the percentages of the graduates with military plans who served on active duty at any time following graduation through February 1986, the last month for which we have follow-up data. Those estimates were 66 percent for the Class of 1980 (73 percent for males, 44 percent for females) and 64 percent for the Class of 1982 (69 for males, 39 for females).

Shifting attention to the top halves of Tables 14 and 15, we note that, of the estimated 77,800 graduates in the Class of 1980 on active duty in October, only 38,500 (49 percent) reported plans to enter the service. The analogous percentage for the Class of 1982 was somewhat higher at 56 percent, perhaps due to the decrease in civilian employment opportunities during the 1981–1982 recession. The remainder of the enlistees on active duty in October following graduation were drawn disproportionately from the other plans categories, with the largest representation coming from the seniors who planned to take jobs in the civilian sector. These figures and those for the other plans categories suggest that, for a substantial portion of the seniors, plans regarding postsecondary activities fluctuate over time as the seniors' personal circumstances change and they gain additional information, perhaps through employment and educational experiences during the summer following graduation.

The fact that about half of the seniors were not pursuing main activities in October consistent with their plans reported in the spring indicates that the time around high school graduation is a period of considerable uncertainty and flux for many seniors. In the absence of firm plans regarding postsecondary activities, they may simply treat a survey item about "plans" as one about "hopes" or "desires." As Table 14 shows, the number of 1980 seniors who reported plans to enroll full-time in four-year colleges exceeded the actual number of graduates in that category by about 30 percent.

Whether senior plans represent vague guesses, unfounded hopes, or well-conceived blueprints for future actions, they merit examination either as the students' best informed guesses about postsecondary activities or as indicators of desired activities. While some of these assessments may be unrealistic, senior plans still provide indications of future behavior that can be treated as proxies for preferences or aggregated across subgroups of seniors to examine group behavior. The marginal entries in Tables 14 and 15 indicate that the distribution of seniors across plans categories conforms quite well with the distribution of main activities in October, and the concordance of the two distributions can be improved further by allowing for exaggerated college attendance plans. Given that the HS&B base year data on senior plans are more numerous, more representative, and more complete than the follow-up data on postsecondary outcomes, we have augmented our multivariate analyses of main activities by performing similar analyses using the plans data.

MULTIVARIATE ANALYSES OF TRACK ENTRANCE RATES

To examine the factors that influence young people's choices of postsecondary activities, we turn to multiple regression analyses of track entrance rates based on the HS&B/DMDC data. There are three types of information available for this purpose: (1) school-level estimates by HS&B school adminstrators of the proportions of the 1981 graduates from their schools who entered college, vocational-technical schools, and military service; (2) plans data for the students who participated in the HS&B base year surveys in Spring 1980; and (3) individual data on the postsecondary activities of members of the Classes of 1980 and 1982 derived from the HS&B follow-up surveys.

The school-level data on track entrance rates were provided by school adminstrators in responding to HS&B school survey questionnaires fielded in February 1982. The questions regarding the postsecondary activities of their graduates were Items 2–4 on the questionnaire:

2. To the best of your knowledge, about what percentage of the entire 1980–1981 graduating class is now enrolled in a regular two-year or four-year college? _____ %
3. To the best of your knowledge, about what percentage of the 1980–1981 graduating class went on to post-secondary education or training of some kind OTHER THAN A JUNIOR COLLEGE OR FOUR-YEAR COLLEGE (for example, beauty school, vocational-technical school, or business school)? Do not include military service. _____ %
4. To the best of your knowledge, about what percentage of the 1980–1981 graduating class went into military service? _____ %

The responses to Items 2 and 4 provide school-level estimates of college entrance and military enlistment rates for the Class of 1981. Although Item 2 asks for estimates of current college enrollment rates (as of February 1982), most school survey respondents would not have had up-to-date information to provide these estimates. Assuming that the school administrators attempted to provide estimates of college entrance rates for the fall term following graduation and that many of them had to rely on senior plans data to provide these estimates, we shall treat these data as rough estimates of the college entrance rates for the Class of 1981. The overall weighted college entrance rate based on the estimates is 50.3 percent, which is about 10 percent above the full-time college enrollment rate in October for the Classes of 1980 and 1982 (see Table 13) and 2–3 percent above the analogous rate that includes part-time enrollments.

If the school estimates are reasonably good proxies for the actual college entrance and military enlistment rates, they provide extensive data for examinir , how the rates vary across school types and locations. The 987 HS&B schools for which these data are available were chosen to provide representative samples of the nation's public and private high schools, and these schools accounted for over 350,000 graduates in the Class of 1981. However, the school-level data are *estimates* of the college entrance and enlistment rates for these schools, not the actual proportions. To the extent that the school estimates reflect senior plans rather than their actual activities, they are subject to the same biases that affect the plans data.

To analyze the reported college entrance rates for the Class of 1981 and the corresponding planned entrance rates derived from the base year survey of seniors and sophomores in the HS&B schools, we fitted logistic regression equations of the form

$$p = 1/[1 + \exp(-\Sigma_{j=1}^{k} \beta_j x_j)]$$

to the grouped data points (p_i, X_i), $i = 1,2,\ldots,n$, where p_i is the reported entrance rate (or plans rate) for the i-th school and X_i is a vector of independent variable values x_{ij} for the i-th school. Under this formulation, the logit of the dependent variable p defined by $\text{logit}(p) = \log[p/(1-p)]$ is assumed to be a linear function of the k independent variables x_j, $j = 1,\ldots,k$, where $x_1 = 1$.[5]

Some of the independent variables used in the school-level analyses are listed in Table 16. In selecting schools to participate in HS&B, Frankel et al. (1981) stratified by school type, identifying four types of public schools (regular, alternative, Cuban, and other Hispanic) and five types of private schools (regular Catholic, black Catholic, Hispanic Catholic, elite private, and other non-Catholic). Preliminary analyses incorporating separate indicators for the strata revealed no significant differences within the three main categories—public, Catholic, and other private. Using the public school category as the benchmark (omitted) category from which increments for the other categories would be estimated, we kept two indicator variables in the equations, one for Catholic and one for other private schools. The regional and urban/rural indicators are those reported on the HS&B school file. The North Central and urban categories serve as benchmark categories in the equations.

The student attributes included as independent variables in the school-level fitted equations are the student minority percentages and the mean values of SES (socioeconomic status), TEST (a measure of academic aptitude), and family income for the base year participants in the school. To allow for the effects of local economic conditions in the vicinity of the schools, three state-level economic characteristics were included: (1) the estimated average unemployment rate in the state in 1981; (2) estimated per capita income in thousands of dollars; and (3) average hourly earnings of production workers on manufacturing payrolls. See Appendix B for further details.

Table 16 lists the regression coefficients and t-statistics for the logistic regression equations fitted to three dependent variables. First is the estimated college entrance rate. Next is the analogous military enlistment rate, which is designated in the table by "U" for "unconditional." Like the college entrance rate, this is the school-reported proportion of 1981 graduates that entered military service (Item 4). The third rate is the military enlistment rate among the graduates who did not enter college. This (conditional) rate, denoted by "NC" for "noncollege," is relevant in treating military enlistment as a two-stage procedure in which a high school graduate first decides whether to enter college or not; if he does not enter college,

[5]The standard method for fitting a logistic regression equation to grouped data is to estimate the parameters using the minimum logit chi square estimates b_j of β_j (Cox, 1970; Haggstrom, 1983), which entails replacing the school rates p_i by their (modified) logits and applying weighted least squares with weights $w_i = N_i p_i(1-p_i)$ where N_i is the class size for the i-th school. This case is nonstandard in the sense that decisions to enter college by graduates in the same school cannot be assumed to be independent, because the decisions are arrived at jointly and depend on unobserved factors. The minimum logit chi square procedure, unlike other commonly applied methods (i.e., maximum likelihood and discriminant function techniques), affords protection against intragroup correlation and reporting errors.

he then decides whether to enlist or enter one of the other noncollegiate tracks.[6] Analysis of the noncollege enlistment rate serves to identify school and student attributes that tend to increase the likelihood of enlistment in lieu of civilian employment, vocational-technical school enrollment, apprenticeship programs, and other noncollegiate activities.

The logistic regression results in Table 16 identify control of school, location, minority percentages, and socioeconomic status as important factors affecting college entrance and enlistment rates for the Class of 1981. Both categories of private schools show higher college entrance rates and lower enlistment rates than the public schools after controlling for differences due to other factors. Since the overall college entrance rate for public schools was

[6]Under the assumption that military enlistment (M) and college entrance (C) are mutually exclusive events following graduation, the probability P(M) of enlisting is the probability of not entering college, 1 - P(C), times the conditional probability P(M | NC).

about 40 percent in 1981 (see Table 13), the regression coefficient of .494 for Catholic schools implies that the estimated "effect" of Catholic school enrollment on college entrance is a shift of .494 on the logit scale, which represents an increment of 12 percent above the public school rate. This illustrates the fact that shifts on the logit scale for probabilities between .4 and .6 are about four times as large as the corresponding increments on the probability scale.

Table 16 shows that graduates' choices of main activities after graduation are also affected by community and regional factors. The coefficients for the regional indicators imply lower college entrance rates for the South and West and lower enlistment rates in the North Central (omitted) region than in the other regions. Other things equal, students from rural schools tend to have lower college entrance rates and higher enlistment rates than those from urban and suburban schools.

The minority percentages and the mean values of SES, TEST, and family income are interrelated in ways that make it difficult to assess their separate effects using school-level data. Mean SES is the dominant predictor among these factors in accounting for differences across schools in reported college entrance rates. However, as will be seen below, academic aptitude is the dominant factor for explaining individual behavior.

When one considers the huge sample sizes represented by the school-level data, perhaps the most surprising finding to emerge from this analysis is that mean family income and the state economic factors are at best only marginally significant predictors. Collectively, they explain only a small proportion of the variability in the school rates that remains unaccounted for by the other factors listed in Table 16.[7] Although the state unemployment rate is a statistically significant predictor of school enlistment rates ($t = -3.7$), the coefficient has the "wrong" sign, indicating that, other things equal, enlistment rates are lower in states having high unemployment rates. This anomalous finding casts doubt on the validity of the school-reported estimates of the 1981 graduates' track entrance rates.

Table 17 shows the corresponding regression results when the school estimates of college entrance and enlistment rates for the Class of 1981 are replaced by the corresponding *planned* entrance rates derived from the individual plans reported by the HS&B seniors in Spring 1980. These results are similar to those in Table 16 in that they identify control of school, minority percentages, and SES as significant predictors of college entrance and enlistment plans, but there are notable differences.

First, the measure of academic aptitude, TEST, emerges as the dominant predictor of both college entrance plans and plans to enlist, especially among the graduates who did not plan to attend college. Second, wage rates in manufacturing show up as statistically significant predictors of both college entrance and enlistment plans, indicating that graduates in states having high wage rates are more likely to plan to work after leaving high school than to enter college or enlist in military service. Third, the regional indicators in Table 17, unlike those in Table 16, evidence little explanatory power, showing that the other factors account for most of the regional variations in senior plans.

The highly significant coefficients for the minority percentages (except for Native Americans) indicate that, other things equal, more minority students plan to enter college. Among minority students who do not plan to enter college, more report plans to enlist. However, as we observed earlier, matches between college plans and realizations are less frequent for minority students, so that the increases implicit in the regression coefficients may not translate into increased fall enrollment rates for minority students.

[7]The proportions of residual variance explained by the four income and economic factors are 1.1, 0.4, and 0.6 percent respectively for the three regression equations reported in Table 16.

Table 18 sheds more light on the planning process by providing the same type of analyses for the sophomores who participated in the HS&B base year survey in Spring 1980. Since the sophomore plans item was the same as the one for the seniors, the sophomore data can be contrasted with the senior data to provide information about the evolution of postsecondary plans. The percentage of sophomores planning to devote most of their time to college attendance the year after high school was 46.8 percent, which is in line with the senior figure (52.1 percent), considering that some of the sophomores will drop out of school before graduating. The proportion of sophomores planning to enlist during the year after graduation was 3.6 percent, which accords very well with the 3.4 percent figure for the seniors.

A comparison of the regression coefficients in Tables 17 and 18 shows a remarkable amount of agreement, the main exception being the rural schools coefficient for plans to enter

college. This concordance of the sophomore and senior plans data suggests that, whereas individual plans may be unstable and erratic, there is considerable stability in the distribution of planned activities over time, at least back to the sophomore year in high school.

Shifting from school-level data to individual data on the main activities of the HS&B participants in October following graduation, we fitted logistic regression equations separately by sex to the HS&B activities data to examine the effects of student and school attributes on individual decisions to enter college or military service. Tables 19 and 20 present these results for the same set of independent variables as before except that individual student attributes are used in lieu of school averages. Family income was omitted because of its

lack of explanatory power and because values of family income were unavailable for a substantial number of graduates.[8]

With a few exceptions, the patterns of the regression coefficients in Table 19 for college enrollment in October are similar for males and females, and they are consistent with the patterns for the college plans data. These results pinpoint academic aptitude as the predominant factor affecting college entrance. The TEST scores that served as measures of academic aptitude measures for this study had overall means of 510 and 521 for the Classes of 1980 and 1982, and a standard deviation of 88 in both years. See Appendix B for further details.

The dependence of the college entrance rates on sex, SES quartiles, and TEST score quartiles was displayed in Table 12. Except for certain categories of student, that table provides a convenient summary of the extent to which the likelihood of college entrance depends on student characteristics. Two exceptional categories are Asian/Pacific Islander graduates, who have substantially higher college entrance rates after controlling for other factors, and Native Americans, who have much lower college entrance rates. Other things equal, graduates from private schools had higher college entrance rates, and graduates from rural schools had lower college entrance rates than those from suburban schools.

The corresponding logistic regression results for military entrance are presented in Table 20. Only the equations for male graduates are listed, because the corresponding equations for females were based on too few enlistments and were nonrevelatory. For males, the coefficient on SES is negative and statistically significant in all four equations, indicating that low SES graduates were more likely to be on active duty in October after graduation. Table 12 provides estimates of enlistment rates by sex, SES quartile, and TEST quartile that support this finding.

Other things equal, black male graduates in the Classes of 1980 and 1982 were more likely to enlist than white non-Hispanic males. The other regression coefficients for minority groups were too erratic to support a similar conclusion for nonblack minorities.

There is some evidence in Table 20 of changes in enlistment patterns between 1980 and 1982. The South and Asian/Pacific Islander coefficients showed marked changes, and the urban/rural differences became less pronounced. Another noteworthy change was the coefficient on TEST, indicating that military enlistment became more attractive to graduates with above average academic aptitude in 1982.

---

[8]Because of the nature of the sample allocation scheme for the HS&B follow-up surveys (see Appendix B), the graduates who participated in the follow-ups were not representative samples of students from their schools. This ruled out the use of school-level averages to permit fitting logistic regression equations by minimum logit chi square. Instead, the equations reported here were fitted by maximum likelihood.

IV. FINDING NICHES IN THE ADULT WORLD

This section examines the main activities of high school graduates and dropouts during the turbulent five years after leaving school. During this period of transition from adolescent dependency to adult self-sufficiency, young people are likely to make several critical decisions that will affect the rest of their lives. Some will marry and have children. Most will leave their parents' homes, complete their initial phases of postsecondary education, enter the labor market, and gain some measure of financial independence.

In going their separate ways after leaving high school, young people undergo a sequence of social, educational, and work experiences that lead many of them to change their objectives and redirect their pursuits. The discordance between seniors' plans and their postgraduation activities demonstrates that many, if not most, high school seniors have only vague notions as to where they are headed and how they will get there. Their activities during the first few months after leaving school are tentative first steps along educational and career paths that may be mapped out ahead of time but, more likely, will be determined sequentially, depending on contingencies and unforeseen events. Lacking clear-cut objectives and being subject to myriad factors that can deflect them from their pursuits, many of them will experience numerous diversions and setbacks before they find their niches in the adult world.

MODELS AND MAVERICKS

There is no such thing as a typical high school senior or a dominant pattern of postsecondary behavior. Although some high school graduates have well-formulated courses of action leading to concrete career objectives and they follow direct routes in pursuit of those goals, the patterns followed by most high school graduates are less direct.[1] Given that 40 percent of the high school seniors in Spring 1980 expected to enter professional careers and that 46 percent expected to complete a bachelor's degree (Peng, Fetters, and Kolstad, 1981), one would think that the dominant pattern of postsecondary behavior would be the traditional "lockstep" pattern through college—enrollment in a four-year college in the summer or fall term after graduation followed by a continuous pattern of enrollments until graduation, except perhaps for summertime breaks. However, Carroll (1989) reports that only 16 percent of the 1980 graduates followed that pattern.

For most high school graduates, postsecondary activities appear to be less ordered and more dependent on evolving circumstances. Perhaps the closest thing to a "model" for postsecondary behavior is based on the premise that, as young people mature, they develop self-concepts (or self-images) based on their previous experiences, their relationships with others, and personal assessments of their interests, capabilities, and aspirations. Their notions of themselves include perceptions of what they will become. Those perceptions, in turn, imply educational, career, and lifestyle objectives that guide their decisions and lead them to

[1]Some economists hypothesize that young people's choices of postsecondary activities can be explained in terms of utility-maximizing behavior. For example, in deciding whether to take a job after high school or enter college, a high school graduate weighs the "utilities" of the two actions and chooses the action that has the higher utility. The argument is made that, although the utilities cannot be observed, the choices that individuals make reveal preferences that can be analyzed to determine how the individuals' utility functions depend on personal attributes and other factors that affect their preferences. See Manski and Wise (1983) for formulations along those lines.

undertake activities in preparation for their perceived adult roles. As their personal circumstances change and they gain additional information about themselves and the options and constraints that affect their behavior, they modify their plans and activities accordingly.

The first full-time job after high school or the first episode of postsecondary education represents an incursion into the adult world and a major step toward independence. As such, it can be a very telling experience for gauging one's talents, limitations, and ambitions, and for illuminating the promises and pitfalls associated with a particular course of action. Since few entry-level jobs and freshman experiences live up to their expectations, the first few months after high school are a time of uncertainty and reappraisal, especially for young people who have qualms about their objectives or capabilities.

As we saw in Section III, senior plans are unreliable predictors of the activities pursued in October following graduation. The matches between plans and realizations are somewhat better for the seniors who plan to enter four-year colleges, perhaps because college attendance is consonant with a wide range of career and lifestyle objectives, and because "getting a college education" is widely viewed as an integral part of the maturation and acculturation process in American society. The bachelor's degree represents the culmination of that process, which relegates the two-year colleges and vocational-technical schools to, at best, a transitory role for students who aspire to complete four or more years of college. Since many students enter two-year colleges to pursue vocational courses of study and only a small proportion of the students in academic programs complete college degrees, the distinction between two-year college attendance and enrollment in noncollegiate educational programs may be immaterial in this regard.

Except for summertime breaks, most young people remain in school or college until they have completed their initial educational objectives. Once they leave student status, most of them enter the labor force and remain there indefinitely, perhaps with intermittent episodes of unemployment. There are two main exceptions to this pattern: (1) military personnel, some of whom enter the service before they enter college to avail themselves of the G.I. Bill or other educational benefits; and (2) women with children, who may remain out of the labor force and educational activities for long periods of time to devote most of their time to homemaking.

Within this overall pattern, there are three groups of young people whose postsecondary patterns are quite distinct—high school dropouts, graduates who do not enter college in the fall following graduation, and college entrants. As we showed in Section II, about one in four young people drop out of school before graduating, a figure that has remained virtually unchanged for 25 years. College entrance rates also remained quite stable during the 1970s and early 1980s (see Table 8), and data on earned degrees indicate that college completion rates changed little during this period. About 40 percent of the graduates in the Classes of 1980 and 1982 were enrolled in college full-time in October following graduation (see Table 13). We estimate that another 20 percent entered or will enter college at other times, and half of the college entrants will eventually complete a bachelor's degree, so that about 30 percent of each class (and 22 percent of each age group) will earn college degrees.

These are rough estimates, but they are consistent with college entrance rates based on first-time freshmen enrollments (see Table 7) and college completion rates determined by dividing the number of bachelor's degrees awarded each year by the number of high school graduates five years earlier. The latter ratios remained stable at 30–32 percent from 1975 through 1985 but rose slightly during the late 1980s—from 31 percent in 1984 to 34 percent

in 1988.[2] These ratios may exaggerate college completion rates among high school graduates, because the numerators include degrees awarded to foreign students and Americans who did not earn high school diplomas, and some college graduates earn more than one bachelor's degree.

Nevertheless, the 30 and 22 percent figures are lower than college completion rates based on self-reported educational attainment data. According to estimates derived from the Current Population Survey, 25.8 percent of the persons of age 30 to 34 in March 1987 reported having completed four or more years of college, and 87.1 percent said they had completed high school (U.S. Bureau of the Census, 1988a). If we take these estimates at face value, it follows that 30 percent of the high school graduates of age 30–34 had already completed four or more years of college, and some persons in that age group will earn bachelor's degrees after reaching 35 years of age.

DISTRIBUTIONS ACROSS MAIN ACTIVITIES

The estimated 30-percent college completion rate for the Classes of 1980 and 1982 exceeds the 29-percent estimate of the proportion of the graduates from those classes who were enrolled full-time in four-year colleges in October, and it is almost twice as high as the 16-percent estimate for the proportion of graduates who followed a lockstep pattern in completing bachelor's degrees in four years or less (Carroll, 1989). The implication of these statistics is that almost half of the graduates who entered four-year colleges right after graduation either dropped out or "stopped out" (i.e., temporarily quit), and those who dropped out were replaced by others who pursued less direct routes to college completion. This indicates that there is a lot of turbulence in educational activities, even among the high school graduates who complete college degrees.

Table 21 shows the estimated proportion of graduates in the Class of 1980 in each of the main activity categories at six-month intervals after graduation, beginning with October 1980. Table 22 shows the corresponding table for the Class of 1982.[3] Not surprisingly, the two tables show very similar patterns. As we observed in Section III, the most pronounced changes between 1980 and 1982 were the increases in the "Other" category consisting of graduates who were not enrolled full-time and not employed. The increases in this category are in line with the increases in jobless rates among recent high school graduates during the 1981–1982 recession. See Table 8.

With that exception, the patterns for the two classes are very similar. During the first three years after graduation, the proportion of graduates enrolled full-time in four-year colleges remained quite stable, as the students who dropped out were replaced by entrants from

[2]Table 3 lists estimated numbers of high school graduates for the years 1960–1989. For the analogous time series on bachelor's degrees, see NCES (1989a, p. 221). Using NLS72 data, NCES estimates that 28 percent of the graduates in the Class of 1972 had completed a bachelor's degree as of June 1986 (*Ibid.*, p. 279).

[3]The entries in these tables and those displayed in later tables were obtained by first using the weighted HS&B data to estimate the total number of graduates, $N(i,j;t)$, who moved from the i-th main activity category at the beginning of the t-th time period to the j-th category at the end of the period. In estimating these totals, a separate activity category was included for those participants whose main activities were unclassified. Once those estimates were obtained for each of the time periods ($t = 1, 2, \ldots, 11$), they were combined with the analogous estimates of transitions between senior plans categories and main activities as of October 1980 (see Table 14), which served as initial estimates for $t = 0$. To allocate the estimated totals for the unclassified categories into the six main activity cells, a sequential scheme was adopted in which the estimated number of graduates whose activities were unclassified at any time t were first divided into six categories according to their classifications at time $t - 1$. Then, in each of the six categories, the cases in the unclassified category at time t were allocated across the other categories proportional to the numbers of transitions into classified activities during time t.

other tracks. As of April 1983 (almost three years after graduation), 27 percent of the Class of 1980 were enrolled full-time in four-year colleges. Over the same period, the proportion of graduates in military service almost doubled—from 2.6 percent in October 1980 to 4.8 percent in April 1983. As we shall see, there was an almost continuous flow of enlistees into military service over the course of the five-year period.

As the young adults completed their initial phases of education and military service, most of them entered the civilian labor force. In October 1985—five years after graduation, 72 percent of the Class of 1980 were employed full-time in civilian jobs, 4 percent were in the military, and 7 percent were still enrolled full-time in four-year colleges. Anticipating that most of the latter would undertake full-time employment after graduation, we see that the full-time employment rate was approaching 80 percent as the Class of 1980 entered the second five-year period after graduation.

As Table 23 shows, the pattern of activities for the dropouts from the Class of 1980 was markedly different from that of the graduates. These estimates pertain to a special subgroup of dropouts, namely, those who remained in school through part of their senior year, and who chose to participate in the HS&B follow-up surveys. Hence, this table may not present an

accurate picture of the employment patterns for the general population of school dropouts.[4] However, it is clear from a comparison of Tables 21 and 23 that the overall activity patterns

[4]As partial evidence on this score, the proportions of dropouts enrolled full-time in two-year colleges (7.9 percent in April 1981) are much higher than the corresponding proportions for dropouts from the Class of 1982, which ran less than 2 percent in all periods. With that exception, however, the overall patterns of main activities were quite similar for the two cohorts.

for dropouts are starkly different from those for graduates, not only in terms of educational activities but in terms of employment status. Among young adults not enrolled in college, there was a much higher percentage of dropouts in the "Other" category, demonstrating the prevalence of joblessness among school dropouts. Nevertheless, 80 percent of the male dropouts and 50 percent of the females had full-time jobs in October 1985.

CHANGING COURSES

The preceding tables mask the turbulence in activities that young people experience as they wend their ways along career and educational paths. To capture that turbulence, we shift to an examination of the six-month transition rates between main activities during the five-year period following graduation. Table 24 lists the transition rates separately by sex for the Class of 1980. Table 25 presents analogous rates for the Class of 1982.

The entries in these tables are the percentages of graduates who made the transition from one activity (the "Start" state) to a second activity (the "End" state) during each of the six-month intervals from October following graduation through October 1985. Here, the main activities are designated by "S4," "S2," etc., with the same ordering as before, so that "CE" refers to "Civilian Employment." For the Class of 1980, the first time period (t = 1) is from October 1980 to April 1981; the last period (t = 10) is from April to October 1985. For example, the first two entries 92.8 and 0.7 in Table 24 for t = 1 indicate that 92.8 percent of the males enrolled full-time in a four-year college in October 1980 were also enrolled in a four-year college in April 1981, and 0.7 percent were enrolled in two-year colleges as of that date.

Restricting attention to the block of entries for transitions from four-year college attendance (S4), we see that most transitions occurred 3-1/2 years or more after leaving school, which would ordinarily signify the completion of requirements for a bachelor's degree. The exits were mainly into civilian employment and the "Other" category, marking the completion of the initial phase of college attendance and entry into the civilian labor force.

Looking at the other blocks of transition rates in Tables 24, we note that military service (M) consistently had the highest six-month persistence (or continuation) rates for males at about 95 percent, with lower rates beyond the three-year point as early entrants completed their initial tours of duty and left the service. In both classes, the female transition rates differed little from those for males, except for lower continuation rates for women in the military during the first three years and higher rates thereafter.

STUDENT PERSISTENCE

The high transition rates out of full-time student status indicate that college entrants experience considerable flux in pursuing their educational goals. As Tables 24 and 25 show, students in two-year colleges and vocational-technical schools have low persistence rates, reflecting the fact that vocational-technical courses of study are usually of limited duration, and two-year colleges have high attrition among students pursuing academic programs. The higher transition rates into four-year colleges at the end of the second and third year after high school show that some two-year college students make the transition to continue working toward their bachelor's degrees. But, for both sexes, the transition rates into four-year colleges are lower than the rates into the civilian employment and "Other" categories.

The fact that student persistence rates are very low in two-year colleges and vocational-technical schools is not new. Relying on follow-up data for the Class of 1972, Kanouse et al. (1980) reported that, among the freshmen enrolled full-time in four-year colleges in October 1972, 80 percent were still enrolled full-time in October 1973, whereas the corresponding percentages for the two-year colleges and vocational-technical schools were only 60 and 36 percent respectively. Carroll (1989) reported that less than a tenth of the 1980 graduates who entered two-year colleges and vocational-technical schools subsequently attained bachelor's degrees.

Four-year college entrants have substantially higher persistence rates, but their progress toward degree completion is often sporadic and drawn out, and almost half of the four-year college entrants drop out of college before they complete their degrees. Analyzing the progress of 1980 graduates who enrolled full-time in a four-year college directly after graduation, Porter (1989) found that only 55 percent had enrolled continuously for four years, and only 46 percent had earned bachelor's degrees by February 1986. Degree completion rates were somewhat higher in private four-year colleges at 54 percent, as compared with 43 percent in public colleges. And they were higher still for graduates in the highest academic aptitude quartile—55 percent in the public colleges, 63 percent in the independent colleges. But even these higher rates indicate that the pipeline for college graduates suffers from excessive leakage.

The overall 46 percent degree completion rate for four-year college entrants as of *six* years after graduation is well below the *five*-year rates of 60–65 percent reported for four-

year college entrants in the early 1960s (Folger, Astin, and Bayer, 1970), but it is in line with estimates derived by taking the ratio of the number of bachelor's degrees earned in any year to the number of entering freshmen four years earlier. No matter which estimates are used, it is clear from the overall pattern of student persistence and degree completion rates in the early 1980s that student flows through higher education are impeded by lengthy delays and high dropout rates.

SOURCES OF NEW ENTRANTS

While transition rates provide a convenient means for quantifying the flows *out* of main activities, for some purposes it is of greater interest to examine the flows *into* activities to see where the track entrants are coming from. This is especially true for military service. Although the postservice activities of veterans merit special attention because of the importance of their educational and vocational pursuits to the nation's human resources, the preservice activities of enlistees are of more direct interest for examining the enlistment process among college-age youth. Information about enlistees' main activities between high school graduation and service entry illuminates the pathways into military service and helps guide youth policies bearing on postsecondary education, student aid, military recruitment, and national service.

The precollege activities of late entrants into four-year colleges are also of considerable interest, because this group and the college entrants who "stop out" of college for a year or

more before completing their degrees constitute a sizable proportion, if not the majority, of college graduates, and there is some evidence that time lags between high school graduation and college completion are getting longer. Among the members of the Class of 1972 who received bachelor's degrees before 1986, almost half took more than four years to complete their degrees, and 15 percent took more than six years (NCES, 1989a). Among college seniors of age 16–34 in October 1986, 70 percent graduated from high school more than four years earlier, and 45 percent graduated more than five years earlier (U.S. Bureau of the Census, 1988b). As more and more veterans return to college under the Montgomery G.I. Bill, they will add to the growing numbers of students who either delay college entrance or stop out for long periods of time.

To provide a closer look at transition rates *into* military service and other main activities, Tables 26 and 27 present "backward transition rates" analogous to the (forward) transition rates in Tables 24 and 25. Considering the first block of entries for transitions into four-year colleges, we see that, throughout the five-year period covered by Table 26, most of the late four-year college entrants of both sexes came from civilian employment. Since civilian employment is the most common main activity among recent high school graduates, this finding might be dismissed as a natural consequence of the large numbers of graduates pursuing this activity.

However, that is only part of the story. As Tables 24 and 25 show, the transition rates *out* of civilian employment ran about 20 percent per period over the first two years after graduation. Considering that the transitions included in these rates are changes from civilian employment to some other main activity (as distinguished from job-switching from one employer to another), one sees that these transitions represent only a small part of the turbulence in the youth labor market in the five years following high school graduation. The fact that transition rates out of civilian employment run much higher than the rates for military service and four-year college attendance indicates that episodes of employment are of shorter duration than periods of schooling or tours of military duty. Moreover, most transitions out of civilian employment are into the "Other" category and *vice versa*, signifying movements of *nonstudents* into and out of employment. Hence, much of the turbulence in postsecondary activities among recent high school graduates is linked to stints of employment and unemployment rather than to movements in and out of full-time student status or military service.

PRESERVICE ACTIVITIES OF ENLISTEES

It is clear from the backward transition rates in Tables 26 and 27 that most of the late entrants into military service from the Classes of 1980 and 1982 did not come out of full-time student status but from civilian employment and the "Other" (not employed) category. There was a minor departure from this pattern for 1980 male graduates at the four-year point (t = 8) due to the increased flow from the four-year colleges as newly graduated ROTC officers entered the service after completing their bachelor's degrees.

With that exception, the transition rates into military service indicate that few enlistees enter the military directly from full-time student status. Most enlistees who attended colleges or vocational-technical schools after graduation had a break between student status and service entrance in which they either remained unemployed or held one or more jobs in the civilian sector. The overall pattern of the rates, in conjunction with our earlier finding that only two percent of the seniors in 1980 planned to enter the military following

graduation, is consistent with the view that military service was a second or third choice for many enlistees until they had pursued other educational and vocational activities first.

According to our estimates reported in Tables 14 and 15, only 77,800 (2.6 percent) of the 1980 graduates and 69,800 (2.3 percent) of the 1982 graduates had entered military service by October following graduation. These "early entrants" constituted about a third of the graduates from these classes who entered military service before February 1986. Based on the weighted HS&B data for the military entrants, we estimate that 239,000 members of the Class of 1980 and 226,000 of the Class of 1982 served some time on active duty before February 1986.[5]

Tables 28 and 29 show the distribution of main activities for the military entrants in the Classes of 1980 and 1982 at six-month intervals beginning with October in the year of graduation. A comparison of these tables with Tables 21 and 22 for the Classes of 1980 and 1982 shows that the pattern of preservice activities for the enlistees was similar to the pattern of the entire class, except for the fact that the military entrants were less likely to be enrolled as full-time students. In particular, the percentages of military entrants in the "Other" category ran about the same or lower than the percentages for the entire class, contradicting the view that military entrants experience high rates of joblessness before they enlist.

A surprising finding for the Class of 1980 is that over 25 percent of the military entrants were enrolled as full-time students in October 1980, and over 20 percent were

[5]These estimates are in line with the reported annual numbers of accessions with high school diplomas during 1980–1985, which ranged from 242,000 in 1980 to 284,000 in 1984. See Table 7.

enrolled full-time in October 1981. These percentages are substantially higher than the October 1982 and October 1983 rates for the Class of 1982—17 and 14 percent. A partial explanation for the difference between classes is that both sets of figures pertain to military service prior to February 1986, which is more than five years beyond the normal graduation date for the Class of 1980 but less than four years for the Class of 1982. Hence, officers from the Class of 1982 who completed four years of college before entering the service were excluded by virtue of the February 1986 cutoff date, whereas those from the Class of 1980 were included.

TIMING OF SERVICE ENTRY

Our data on the preservice activities of enlistees from the Classes of 1980 and 1982 come from the HS&B/DMDC records for 1,025 members of the senior cohort and 1,042 members of the sophomore cohort who were identified as having served some time on active duty through February 1986. Both samples included a small number of enlistees who did not graduate from high school—24 seniors and 163 sophomores. There were 42 officers in the senior sample, none in the sophomore sample.

In addition to having the data on military service that the HS&B participants reported on the follow-up surveys, we had access to more detailed and more reliable information for a subset of 752 seniors and 761 sophomores whose military service was verified by matches of social security numbers and dates of birth on DMDC military personnel files. See Appendix

B. Although we found good agreement between the service-related items on the HS&B files and those on DMDC records, we relied on the "official" DMDC data for key service information, including the date of entry into active duty.

Figure 4 shows how many of the 752 seniors with DMDC-validated service dates entered the service as of the end of each month through September 1985. Less than half

(355) went on active duty before April 1981—nine months after the normal graduation date for most members of the Class of 1980. And one of every four of these seniors entered the service after January 1983, more than 2-1/2 years after graduation. As the figure shows, the pattern of service entrances was relatively steady over the five-year period after graduation, with a continual flow into the military even after the three-year point following graduation, when most entrants would be 20–22 years of age.

Figure 5 shows the breakdowns into student and employment activities of the same 752 seniors as a function of months before enlistment. With the inverted time scale used here, the last bar on the right depicts the activity breakdown during the month before service entry. It confirms that few enlistees entered the service directly from full-time student status, but the pattern for earlier months indicates that many of the later entrants had attended college and vocational-technical schools previously. Although almost half of the enlistees were in the "Not employed" category during the month preceding service entry, the pattern for earlier months suggests that many of the enlistees took a one- or two-month break from full-time student and employment activities before they entered the service.

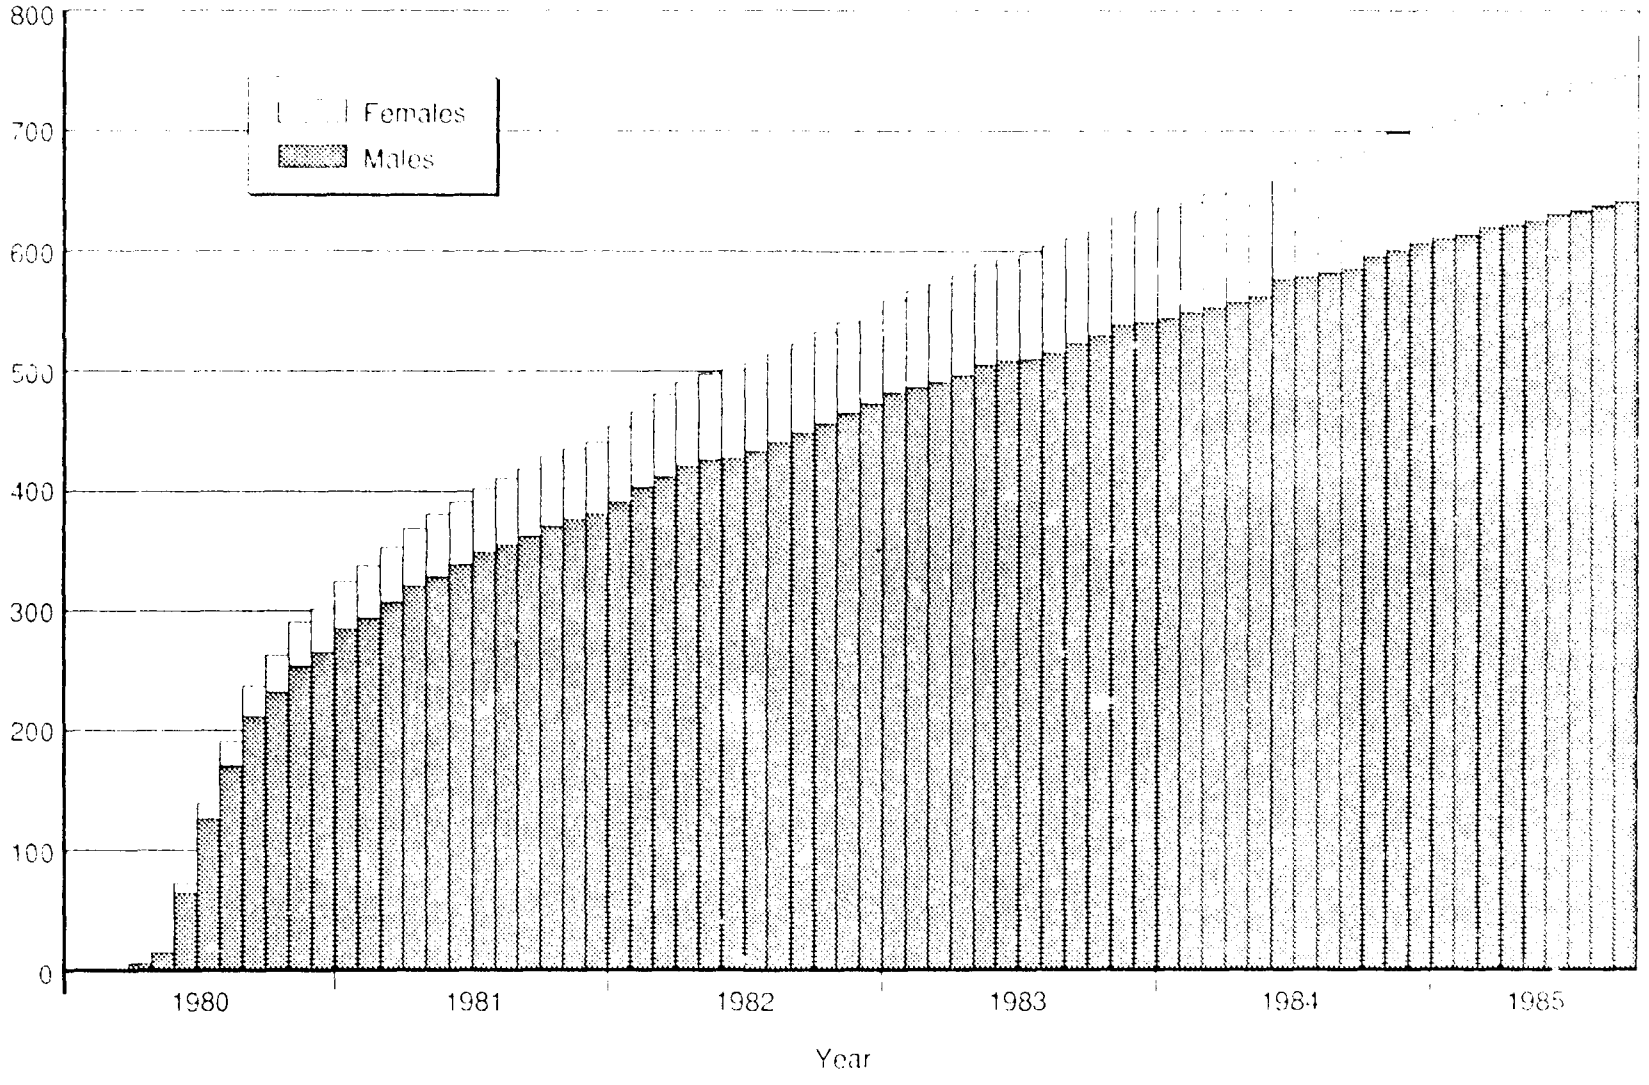

Fig. 4—Timing of service entry for HS&B participants in Class of 1980

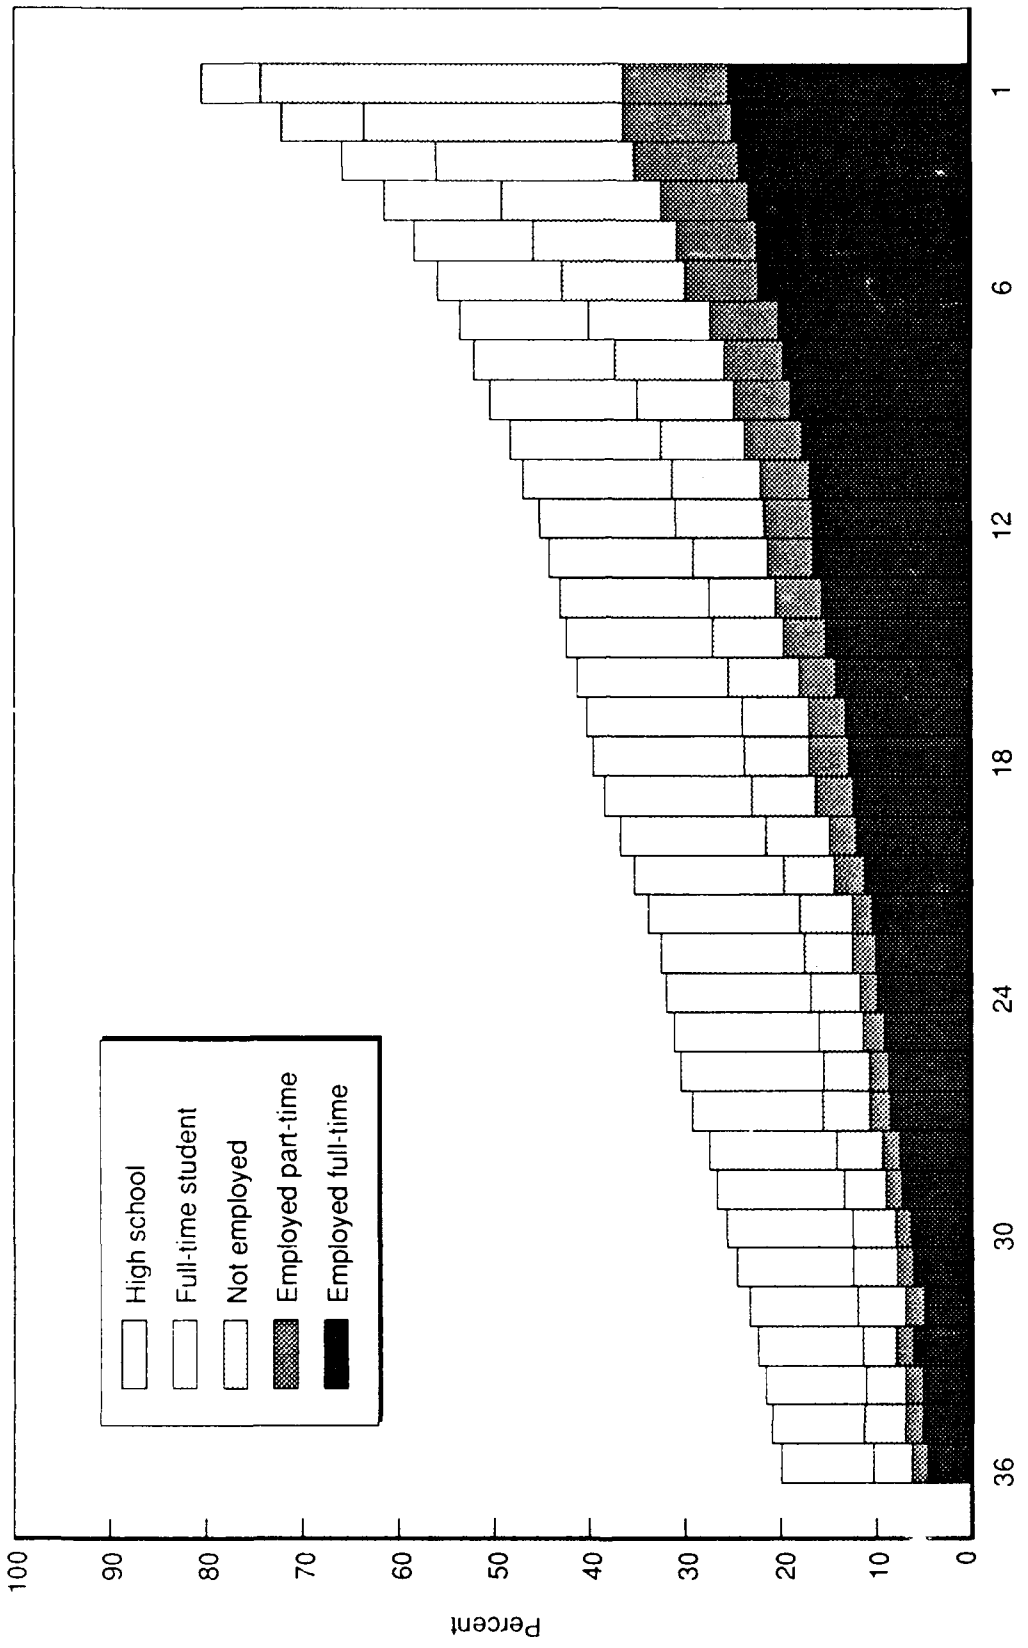

Fig. 5—Preservice main activities among military entrants in Class of 1980

The pattern of service entry dates for the military entrants from the sophomore cohort was similar but somewhat more variable, partly because the sophomore cohort included large numbers of school dropouts, early graduates, and students who graduated a year or more behind schedule, leading to a wider range of graduation and school-leaving dates. To provide comparable distributions of service entry times for both cohorts and to permit comparisons with analogous data for the Class of 1972, we rescaled the individual service entry dates of the graduates relative to their graduation dates, so that all dates would be expressed in terms of months since graduation.

Table 30 shows the distribution of these "lag times" between high school graduation and service entry based on the weighted HS&B data for the high school graduates who entered active duty between June 1980 and December 1985. For most enlistees in the two samples (who graduated in June 1980 or June 1982), the first time interval spanning 0–6 months after graduation corresponds to the period June–December in the year of graduation, so that the later 12-month periods correspond to subsequent calendar years. The bases for the percentages in Table 30 are the total numbers of high school graduates in 1980 and 1982, namely, 3,021,000 and 2,984,000.

Except for the fact that the estimated rates of service entry ran about 10 percent higher for the Class of 1982, the distributions of lag times for the two classes were remarkably similar through 3-1/2 years after graduation, by which time 6.8 percent of the Class of 1980 and 7.6 percent of the Class of 1982 had entered active duty. Among those who entered within 3-1/2 years after graduation, the estimated percentages in each of the first four time intervals were 44, 25, 18, and 13 percent respectively for the Class of 1980, and 43, 29, 19, and 8 percent for the Class of 1982.

Although the recruitment climate in the early 1980s differed greatly from that in the early 1970s during the transition to an All-Volunteer Force, it is interesting to compare the percentages in these time intervals with estimates for the Class of 1972 reported by Black and Fraker (1984). Of the members of that class who entered active duty before 1976, the

31–42	18.6	0.6	225.8	7.6

percentages who enlisted in 1972, 1973, 1974, and 1975 were 53, 24, 12, and 11 percent respectively. Hence, except for a tighter clustering of entrances during the first six months after graduation (perhaps linked to inductions and draft-induced enlistments in the latter half of 1972), the pattern of service entry rates for the Class of 1972 was similar to the patterns for the Classes of 1982 and 1984.

CHARACTERISTICS OF MILITARY ENTRANTS

Our regression analyses of enlistment status as of October in the year of graduation identified socioeconomic status (SES) and minority group membership as factors that tended to distinguish military entrants from their classmates. The SES scores of the HS&B participants who entered the military before February 1986 averaged about one-fourth of a standard deviation below the class averages. See Table B.3.

In terms of their academic aptitude (TEST) scores, the military entrants differed little from their classmates, except that the dropouts from the sophomore cohort who entered the military had TEST scores that averaged 37 points above the mean for all sophomore dropouts and 33 points above the mean for senior dropouts who entered the military. The apparent reason for this change is that, effective October 1, 1981, the services curtailed enlistments among high school dropouts whose Armed Forces Qualification Test (AFQT) scores fell below the 31st percentile.[6]

Just as there is no such thing as a typical high school graduate, there is no such thing as a typical enlistee or a characteristic pattern of preservice activities. As the preceding discussion has shown, there was a remarkable lack of uniformity in the service entry times of the military entrants. Except for the graduates who went on active duty within a month or two after leaving school, the preservice activities of military enlistees appear to be more variable than their classmates, but they were similar in other respects. Although late military entrants were less likely to enter college, about a fourth of the enlistees from the Class of 1980 were full-time students in colleges and vocational-technical schools in October 1980. Like many of their classmates, the late military entrants evidenced considerable mobility into and out of the civilian work force before they enlisted.

Table 31 presents summary statistics that permit contrasting the characteristics of early and late military entrants. There are notable differences between the two cohorts. The enlistees from the Class of 1980 who entered within six months of graduation averaged about 25 points lower on TEST and 10 points lower on SES than those who entered later, and a higher proportion of the early entrants came from minority groups. While the latter was also true for the early entrants from the Class of 1982, the mean TEST and SES scores were almost exactly the same across service entry time categories.

There were two factors affecting enlistment behavior in the early 1980s that would explain the differences between the cohorts. One was the 1981–1982 recession. It seems plausible that many of the 1980 graduates with above average TEST and SES scores, especially those who entered college or vocational-technical training after graduation, experienced greater difficulties when they tried to shift into civilian employment from other main activities in 1981 and 1982. Because their mobility into civilian jobs was restricted, military service became a more attractive option.

---

[6]AFQT scores are reported as percentiles. Enlistees with AFQT scores between 10 and 30 are classified as belonging to AFQT Category IV. In addition to proscribing enlistments of high school dropouts in Category IV, the services also limited the total number of Category IV enlistments among high school graduates to not more than 20 percent of the total number of accessions in any one fiscal year (Office of the Assistant Secretary of Defense, 1988).

Table 31

SUMMARY STATISTICS FOR MILITARY ENTRANTS BY TIMING OF SERVICE ENTRY: CLASSES OF 1980 AND 1982

Months from Graduation to Service Entry	Number of Enlistees (in 1000s)	Mean TEST	Mean SES	Percent Minority		Percent Female
				Black	Other	
CLASS OF 1980						
0–6	90.3	489	470	20.8	10.0	15.2
7–18	51.8	510	471	13.7	7.9	16.7
19–30	38.2	514	485	10.6	6.0	16.4
31–42	26.7	499	484	17.7	5.0	19.3
43–66	32.4	553	508	14.2	6.5	17.3
Total	239.4	507	479	16.4	7.8	15.7
CLASS OF 1982						
0–6	98.0	517	475	14.6	9.5	13.5
7–18	65.5	518	479	10.5	11.0	11.8
19–30	43.7	518	480	10.4	7.3	14.9
31–42	18.6	507	476	12.5	9.9	19.7
Total	225.8	517	478	12.4	9.5	13.8

Another explanation is that the military services tightened their enlistment standards considerably between 1980 and 1982. Whereas only 65 percent of the nonprior service enlistees in Fiscal Year 1980 had AFQT scores above the 30th percentile (AFQT Categories I–III), the analogous percentages for 1981 and 1982 were 79 and 85 percent, and the percentage continued to rise, reaching 96 percent in FY 1986 (Office of the Assistant Secretary of Defense, 1988, p. II-21). While restricting enlistments among applicants with low AFQT scores would only seem to affect the mean TEST scores, not the SES scores, the two scores are positively correlated. The sample correlation coefficients were .32 for the senior cohort, .38 for the sophmores.

The sharp drop in the percentage of minorities between 1980 and 1982 is consistent with national recruitment data. Whereas 36 percent of the nonprior service accessions in FY 1980 were from minority groups, the percentage dropped to 25 in FY 1982 (*Ibid.*, p. II-33). These percentages are much higher than the figures listed in Table 31, because the latter pertain to high school graduates. But both sets of figures indicate that minority groups—especially blacks—were overrepresented among military entrants. According to our estimates (see Tables B.1 and B.2), blacks accounted for 11.3 percent of the graduates in the Class of 1980 and 11.5 percent in 1982, and other minorities accounted for 7.1 and 7.3 percent of the graduates in those classes. Hence, the extent to which minorities were overrepresented among recruits with high school diplomas dropped considerably between 1980 and 1982.

The marked changes in the characteristics of recruits between 1980 and 1982 indicate that recruitment policies play an important role in the sorting-out process. Because so many young people move into and out of educational activities and short-term employment during the first few years after leaving school, they constitute a highly mobile population that would

seem to be especially amenable to changes in economic policies and youth policies, such as the implementation of the Montgomery G.I. Bill in 1985. Nevertheless, summary statistics on the characteristics of nonprior service accessions have remained surprisingly stable since 1982. It is noteworthy that the median age of military entrants in FY 1987 was 19.9 years (*Ibid.*, p. II-37), which is about two years above the median age of high school graduates. This suggests that, like the enlistees from the Classes of 1980 and 1982, a substantial proportion of the military entrants from the Classes of 1983 to 1987 spent a year or more in other activities before they entered the service.

V. CONCLUSIONS

During the 1980s, 28 million American youth completed high school and embarked on career paths, some taking entry-level civilian jobs or entering military service, others continuing in the educational pipeline to become tomorrow's professional and technical workers. Despite this huge influx of high school graduates into the educational pipeline and the labor market during the 1980s, the demand for college-trained workers, technicians, skilled craftsmen, and administrative personnel outpaced the supply of entry-level workers in these areas, eroding the labor surpluses that existed in the late 1970s and early 1980s. As a consequence, there are mounting concerns about the adequacy of America's human resources to satisfy manpower requirements in the 1990s.

It has become a cliche to say that America's future depends on its youth. The educational and vocational activities that young people enter in the first few years after leaving high school are critical in assessing the extent to which they will contribute to the nation's human resources. Yet, the postsecondary pursuits of young people have been poorly tracked. Nationally published statistics provide at best only crude indicators of the flows of young people into postsecondary education, military service, and civilian employment activities. To augment the existing data and thus provide the needed information, we examined patterns of college enrollment, military service, and civilian labor force participation among recent high school graduates and dropouts.

In carrying out this work, we relied extensively on data from HS&B, a panel study of 26,000 high school sophomores and seniors in 1980 who participated in follow-up surveys in 1982, 1984, and 1986, and on supplemental data for a subset of HS&B participants who entered military service before 1986. These data are well-suited for examining the postsecondary sorting-out process among members of the Classes of 1980 and 1982. However, being restricted to two classes in the early 1980s, these data could not provide a complete picture of activity patterns in the 1980s that would take into account demographic trends, changes in economic conditions, and other developments that have affected young people's activities since 1982, such as the Montgomery G.I. Bill. For those purposes, it was necessary to link HS&B to other national data sources.

In particular, we needed more detailed information about the demographics of high school graduation classes in the 1980s. Building on existing data from several sources and relying heavily on Census Bureau estimates and projections of age group sizes, we derived the estimates and projections of numbers of high school graduates by state, sex, race, and Hispanic origin for the years 1980–2000 that are reported in Appendix A. The near-term projections point to a 15 percent decline in the number of graduates between 1989 and 1992. Although the decline will be followed by steady increases over the remainder of the 1990s, the projected total number of graduates during the 1990s will be 10 percent below the total for the 1980s.

While reductions in the numbers of high school graduates do not imply commensurate reductions in the educational pipeline or in the numbers of new entrants into the labor force, our study of the postsecondary activities of recent high school graduates and dropouts led us to conclude that the postsecondary sorting-out process has remained remarkably stable during the last 20 years. High school graduation rates, college entrance rates, and student persistence rates have changed little during that period, except for the closing of the gender gap in student flows through higher education.

According to our estimates, in 1986, the last year for which state estimates were available for both public and private schools, the high school graduation rate was 73 percent (71 percent for males, 76 for females), implying that 27 percent of the 18-year-olds in 1986 had either already dropped out of school or would do so before graduation. The dropout rates were substantially higher for blacks and Hispanics at 40 and 48 percent respectively. Although dropout rates have moved up and down by a few percentage points over the last 25 years, the dropout rate in 1986 was almost exactly the same as it was in 1976 and 1965. During the 1980s, 10 million young people dropped out of school before graduation, a fact that points to a large waste of human resources in the secondary schools.

The statistics measuring educational progress beyond high school indicate that postsecondary educational institutions have not performed much better. Only 40 percent of the graduates in the Classes of 1980 and 1982 were enrolled full-time in college as of October in the year of graduation. Adding part-time college enrollments (8 percent in 1980, 7 percent in 1982) brings the rates nearer to 50 percent. Assuming that other members of those classes will enter college later, we estimate that the (cumulative) college entrance rate among high school graduates in the early 1980s was about 60 percent. Based on earned degrees data and student persistence patterns for the Classes of 1980 and 1982, we estimate that about half of the college entrants from these classes will eventually complete a college degree, a figure that has apparently prevailed since the early 1900s except during wartime periods.

Our analyses indicate that academic aptitude is the main factor affecting individual college enrollment decisions after high school. However, only 63 percent of the 1980 graduates in the top academic aptitude quartile were enrolled full-time in college in October following graduation. Although the analogous figure for the Class of 1982 was somewhat higher at 70 percent, both figures are surprisingly low for a nation that, in the past, has prided itself on the way that it develops its human resources.

Among the 30 percent of high school graduates who eventually complete college, progress toward degree completion is often sporadic and drawn out. Only about one of every ten two-year college students eventually earns a bachelor's degree. Among the 1980 graduates who enrolled full-time in a four-year college directly after graduation, only 46 percent had earned bachelor's degrees through February 1986. The obvious conclusion is that student flows through higher education are impeded by lengthy delays and high dropout rates, signaling more talent loss.

College students are not the only ones whose postsecondary activities are prone to false steps and backtracking. Our examination of six-month transition rates across main activities indicates a substantial amount of activity switching, both among students and nonstudents. Most of these transitions are either into or out of civilian employment, indicating that a large part of the turbulence in postsecondary activities is linked to brief episodes of employment and unemployment.

For the most part, the graduates in the Classes of 1980 and 1982 who joined the military also spent considerable time in other activities before they entered the service. According to our estimates, only 3.0 percent of the Class of 1980 and 3.3 percent of the Class of 1982 entered the service within six months after graduation, whereas the cumulative percentages of military entrants through 1985 were 7.9 and 7.6 percent for the two classes.

Patterns of preservice activities among late military entrants were similar to those of their classmates, although the enlistees were less likely to enter college after graduation. Except for the fact that the military entrants were mostly male, they differed only slightly from their classmates in terms of demographic characteristics. A somewhat higher

proportion of them came from lower socioeconomic status families and from minority groups. In terms of academic aptitude, the military entrants were on a par with their classmates.

Our finding that about half of the high school graduates were not pursuing the same activities in October following graduation that they planned to follow in the spring indicates that many, if not most, high school seniors do not know where they are headed or how they will get there. Our examination of postsecondary activities indicates that this lack of direction persists beyond high school. A substantial proportion of the military enlistees enter the service only after having tried other alternatives, and only one-sixth of the graduates who enter four-year colleges after graduation enroll continuously until they complete bachelor's degrees. The prevalence of lengthy delays in completing degree programs and high college dropout rates, even among four-year college students, show that most high school graduates follow indirect courses in pursuing their educational objectives, and a surprisingly large proportion of them fail to achieve their objectives. As a result, the nation's supply of college-trained personnel will be severely tested over the next decade.

Appendix A

ESTIMATING NUMBERS OF HIGH SCHOOL GRADUATES

This study relies heavily on the High School and Beyond surveys of the Classes of 1980 and 1982 for the purposes of examining how high school graduates and dropouts sort themselves into postsecondary paths. The longitudinal data base derived from HS&B raises numerous analytic problems for reasons that are outlined in Appendix B. To profile the Classes of 1980 and 1982 accurately and to derive the case weights needed to compensate for the nonrepresentativeness of the HS&B school and student samples, counts of the numbers of high school graduates by state, sex, race, and school affiliation are required. Given the nonexistence of these counts, we sought ways to provide estimates that would accord with the more reliable published estimates.

Because counts of *public* high school graduates by state are regularly published in the *Digest of Education Statistics* (NCES, 1988), the main problem in deriving the estimates for 1980 and 1982 was to devise a means for estimating numbers of *private* (nonpublic) school graduates. For that purpose, we made use of state-level data for the years 1980–1986 compiled by the Western Interstate Commission on Higher Education (WICHE, 1988). Although the WICHE state data are incomplete except for 1986, they provide complete time series on most states that have large numbers of private school graduates. Exploiting patterns in the private/public ratios in the states having no missing values, we extended WICHE's estimates to provide a complete set of state estimates for 1980–1986. To provide further breakdowns of the state totals by sex, race, and Hispanic origin, we derived a second set of state estimates by applying high school completion rates by sex and race to Census Bureau estimates of age group sizes; the resulting detailed estimates were then adjusted to agree with the state totals.

The state high school graduation rates derived from the 1980–1986 estimates were listed in Table 5. The rates are defined by dividing the estimated number of high school graduates in any year by the number of 17-year-olds as of July 1 in the previous year. The analogous census division and regional rates for 1980–1986 evidence the same overall pattern as the U.S. rates in Table 5, including the stable pattern over the years 1984–1986. This apparent leveling off of the graduation rates was confirmed by the 1987 state data for public high school graduates, which showed a very slight decrease of 0.1 percent in the public high school graduation rate.

Adopting the assumption that the state graduation rates remained stable through the 1980s and applying the estimated 1987 graduation rates to Census Bureau age group sizes by state, sex, and race, we extended our state estimates through 1989. Since the scheme could be readily extended to future years by applying the estimated graduation rates to the Census Bureau projections of age group sizes, we have also provided "projections" of high school graduates by state, sex, race, and control (public or private) for the years 1990–2000. The remainder of this appendix is devoted to presenting the estimates and projections, and documenting the estimation process that led to them.

THE ESTIMATES AND PROJECTIONS

Table A.1 summarizes the state estimates by sex, control of school, and race/Hispanic category for the years 1980–1989. Table A.2 provides the corresponding projections for 1990–2000. Although all estimates and projections are listed to the nearest unit for the convenience of potential users, this belies the precision of the estimates, not only for the years after 1987 but for most of the entries before 1987. The only estimates in the tables that accord with published state-level counts are the 1980–1987 entries for public high school graduates and a subset of the 1980–1986 entries for private high school graduates.

The 1980–1987 state data on public high school graduates are taken from the *Digest of Education Statistics* (NCES, 1988, p. 100). These data, which pertain to graduates from regular public day schools and exclude persons receiving high school equivalency certificates, come from NCES's Common Core of Data. In theory, the NCES counts result from annual censuses of the public school systems in all states, but the published counts may not be totally reliable, and we have filled in a few missing values.

There is no analogous source of counts of private high school graduates, because NCES has no systematic means for gathering complete data from the private schools. In the past, NCES has published tables displaying state-by-state estimates for the private schools, but those estimates were derived from school surveys that relied on incomplete, out-of-date sampling frames and were not designed to provide accurate state estimates.

THE WICHE DATA

In a notable effort to fill the information gap on private high school graduates, WICHE elicited the cooperation of state educational agencies in compiling a data base on school enrollments by grade level and numbers of graduates, both public and private, for the academic years 1978–79 through 1985–86. Although some states were unable to provide time series of counts of private school graduates, WICHE published the time series that were available as well as their best estimates for 1986. Using their more complete data on enrollments by grade level in both public and private schools, they applied a cohort survival method to generate projections of numbers of high school graduates for the years 1987–2004. The accordance of the WICHE projections with those generated in this study will be examined at the end of this appendix.

WICHE provides no 1980–1985 estimates of private high school graduates for 20 states and the District of Columbia, and a few other states have isolated missing values. However, the WICHE data are complete for most states with large numbers of private high school graduates, including California where their estimates agree with those reported by the California State Department of Education. In fact, the states with complete time series accounted for 70 percent of the nation's private high school graduates in 1986.

Restricting attention to the WICHE state estimates for the states with no missing values, we found that there were small, relatively uniform increases in the private/public ratios in all census divisions from 1980 to 1986. For the states having no missing values, the overall private/public ratio rose steadily from .109 in 1980 to .124 in 1985 and then dipped slightly to .122 in 1986. Led by the consistency of this pattern both within and across regions, we estimated the missing values in the WICHE time series for 1980–1985 by using their 1986 private school estimates and imposing the assumption that the private/public ratios for 1980–1986 in the "missing states" were proportional to the overall ratios for the

nonmissing states in the same region, with the constant of proportionality determined from the observed 1986 ratios.

For 1987, we used the state counts of public school graduates to estimate the numbers of private school graduates by applying the assumption that each state's private/public ratio remained the same as it was in 1986 (except for California, where the actual 1987 counts were used). This reflects the finding from the WICHE data that there was almost no change in the private/public ratio between 1985 and 1986.

The resulting state estimates in Table A.1 indicate that the number of private school graduates changed little from 1980 to 1987, at a time when the 17–18 year age group was shrinking and the public schools were producing fewer and fewer graduates. Private schools accounted for approximately 9 percent of the nation's high school graduates in 1980 and 10 percent in 1986.

ESTIMATES OF AGE GROUP SIZES

To augment the data on high school graduates, detailed estimates and projections of age group sizes by state, sex, race, and Hispanic origin were compiled for each of the years 1980–2000. Table A.3 lists the estimates of the numbers of 17-year-olds for the years 1980–1989. All estimates are for July 1 in the reference years, except for 1980, where the census estimates as of April 1980 are listed. Table A.4 provides the analogous projections for 1990–2000.

For the most part, the entries in these tables are taken directly from Census Bureau estimates and projections listed on public use tapes. The age group estimates for 1980 come from a tape that provides revised county population estimates by age, sex, race, and Hispanic origin derived from the 1980 census (U.S. Bureau of the Census, 1983). The estimates for later years are taken from a tape listing estimates and projections for the years 1986–2010 by state, race, and sex (U.S. Bureau of the Census, 1988c).

Minor adjustments have been made to the Bureau's estimates to fill in disaggregated estimates by race/Hispanic category for 1981–1985 and to reconcile the estimates with more recent estimates for the U.S. and Hispanic populations. In brief, the state estimates by age, sex, and race for 1981–1985 were obtained by first interpolating between the relevant cell sizes in 1980 and 1986 (e.g., the number of 17-year-olds in 1982 is estimated by interpolating between the number of 15-year-olds in 1980 and the number of 21-year-olds in 1986). To provide age group breakdowns by Hispanic origin, the estimated Hispanic age group total for the U.S. was first allocated across states proportional to the 1980 state estimates for the corresponding age groups, and then the state's Hispanic total was allocated across race categories assuming that the proportions of Hispanics in the white, black, and other categories were the same as they were for that age group in 1980.

The Census Bureau estimates for 1980 reported in Table A.3 are the "OMB-consistent modified race" estimates, which means that the "Other Non-Hispanics" category corresponds to the union of two race categories—Native American (American Indians, Eskimos, and Aleuts) and Asian/Pacific Islander. State estimates for those categories were derived by dividing the "Other Non-Hispanics" estimate into two categories proportional to their relative population sizes in 1980.

Thus, although some changes were made to provide more detailed estimates of age group sizes for the purpose of generating detailed estimates of numbers of high school graduates by state, sex, race, and Hispanic origin, all estimates are tied to Census Bureau age

group estimates for the resident population. None of the age group estimates were adjusted for "census undercount," because those adjustments are small except for blacks of ages 1–9 and 21 and up (U.S. Bureau of the Census, 1988d).

SELF-REPORTED EDUCATIONAL ATTAINMENT BY REGION AND RACE

The U.S. high school graduation rate in 1980 was 71.5 percent—69.3 for males, 73.6 for females. The 71.5 percent figure is close to the percentage of 19-year-olds who reported having completed four years of high school on the 1980 census, which was 75.9 percent (72.3 for males, 79.5 percent for females).

Table A.5 shows how the reported school completion rates varied across regions and race/Hispanic categories in 1980. The race-specific percentages are remarkably uniform across regions. The main exceptions are the black and Asian/Pacific Islander percentages in the West, which are much higher than in other regions. As one might expect, the pattern of school completion rates across regions is similar to the pattern of high school graduation rates: Northeast, 77.3; North Central, 77.2; South, 65.9; West, 66.9. This suggests that the educational attainment rates can be used as proxies for the analogous high school graduation rates, provided that the former are scaled down to agree with the observed graduation rates in each region.

Table A.5

PERCENTAGES OF 19-YEAR-OLDS WHO REPORTED HAVING COMPLETED FOUR YEARS OF HIGH SCHOOL BY SEX, REGION, RACE, AND HISPANIC ORIGIN: APRIL 1980

	Total	White	Black	Asian	Native American	Hispanic Origin
Both sexes						
Northeast	80.0	83.4	62.5	77.0	62.6	52.5
North Central	78.7	81.3	61.2	74.5	55.7	55.0
South	71.8	75.1	63.0	72.2	59.3	55.0
West	74.8	77.6	74.0	81.4	53.2	54.4
U.S.	75.9	79.1	63.6	78.8	55.8	54.3
Males						
Northeast	76.3	80.1	55.5	75.1	58.1	47.9
North Central	75.7	78.6	54.5	72.1	52.4	51.2
South	67.6	71.5	55.9	72.0	55.4	51.3
West	71.8	74.9	70.5	79.2	48.2	50.4
U.S.	72.3	76.0	57.0	76.9	51.4	50.3
Females						
Northeast	83.5	86.6	69.1	79.0	67.0	56.9
North Central	81.7	84.0	67.4	77.1	58.9	58.9
South	76.1	78.7	69.9	72.5	63.6	59.1
West	77.9	80.5	78.1	83.6	58.1	58.7
U.S.	79.5	82.3	69.9	80.8	60.1	58.5

SOURCES: U.S. Bureau of the Census, *1980 Census of Population*, Detailed Population Characteristics, United States Summary, Section B: Regions, PC80-1-D1-B, March 1984. The U.S. figures are from Section A: United States, PC80-1-D1-A, April 1983, Table 262.

To spell out the rescaling procedure for a given region, consider filling the entries of a 2x10 contingency table with two rows (for "Graduates" and "Nongraduates") and ten columns (corresponding to the cells that result from crossing sex with five race/Hispanic categories) by multiplying the number of 17-year-olds in each category by the appropriate regional rate in Table A.5. Then the column entries of the contingency table will add up to the numbers of 17-year-olds in the ten categories, but the row sums will differ from the numbers of graduates and nongraduates in the region. Since the latter can be determined from state totals, the problem reduces to adjusting the entries in the contingency table to accord with prescribed marginal totals.

There is a standard method for carrying out this adjustment called "iterative proportional fitting" or "raking" (U.S. Bureau of the Census, 1971, p. 707). The method entails finding row and column multipliers such that, when the table entries are rescaled using those multipliers, the resulting entries will sum correctly along both rows and columns. The iterative procedure to accomplish the rescaling is equivalent to shifting the logits of the graduation rates (i.e., the logarithms of the odds ratios) for the race/Hispanic categories by the same constant so that the weighted average of the category graduation rates will conform to the overall graduation rate. Hence, from a logistic regression perspective, iterative proportional fitting amounts to shifting the constant term in the regression equation so that the fitted proportions are consistent with the population proportion.

DISAGGREGATED ESTIMATES OF NUMBERS OF GRADUATES

To provide state high school graduation rates by sex, race, and Hispanic origin that are consistent with the overall state rates for each of the years 1980–1987, we applied iterative proportional fitting using the regional rates in Table A.5 as first approximations for the state rates in the ten sex/race/Hispanic categories. That is, in each state, the numbers of 17-year-olds in the ten categories were multiplied by the appropriate regional rates to generate preliminary estimates of the numbers of graduates and nongraduates in each category. These estimates were then "raked" to make them conform with the actual (or estimated) number of high school graduates in that state and year.

To a certain extent, this method relies on an implicit assumption that the pattern of graduation rates across sex/race cells has remained relatively stable over time. As partial evidence on that score, we can compare the reported school completion rates in Table A.5 derived from the 1980 census with analogous rates for 1987 derived from the Current Population Survey (U.S. Bureau of the Census, 1988a). Whereas 75.9 percent of the persons of age 19 reported having completed four years of high school in 1980, the 1987 figure was 77.6 percent, an increase that is commensurate with the change in graduation rates reported in this study. The 1980 and 1987 rates for males were 72.3 and 73.4; for females, 79.5 and 81.7; whites, 79.1 and 80.4; blacks, 63.6 and 62.8; and Hispanics, 54.3 and 57.6. Taking into account the sampling errors associated with the 1987 estimates, we see little evidence of changes in the overall pattern of school completion rates in terms of differences across sex and race/Hispanic categories.

EXTENDING THE ESTIMATES BEYOND 1987

The estimated numbers of high school graduates for 1988–1989 and the projections for 1990–2000 result from applying the assumption that the observed stability in the overall graduation rates from 1983 to 1987 will persist through 2000. Partly because of uncertainties about the numbers of private high school graduates in 1985 and 1987 but also because of questions about some of the 1987 public school estimates, the projected graduation rate for each state was taken to be the average of the observed rates for 1985 through 1987. Applying the projected rate to the 17-year age group estimates for the years after 1987 yields projections of total numbers of graduates for each state, which are then disaggregated by sex and race using the same raking procedure that was used for the 1980–1987 estimates.

The assumption that the states' graduation rates will remain stable as the composition of the school age population changes to include higher percentages of minority students (with lower graduation rates) implies that the race-specific rates will rise. To assure that the state projections would reflect this condition of nondecreasing race-specific rates, a slight modification of the above scheme was used. For each state, the scheme was implemented sequentially, storing each year's rates by sex and race as they were generated. In those cases where the race-specific rates would drop under the uniform rate assumption, the state projections were modified to keep the sex/race rates at the same level that they were the previous year, thereby leading to a slight increase in the state's overall rate.

Given that the U.S. population is projected to shift to the South and West during the 1990s and that the states in those regions tend to have lower than average graduation rates, a scheme that keeps the state rates completely fixed at the 1987 rates would imply steadily decreasing U.S. rates. With the modification indicated above, the U.S. graduation rates remain almost flat at around 73 percent between 1987 and 2000 (73.3 in 1987, 73.2 in 2000). The overall Hispanic rates rise from 51.7 percent in 1987 to 53.6 in 2000, the black rates go from 60.4 to 61.4, and the white (non-Hispanic) rates increase from 78.6 to 79.1.

PROJECTIONS OF GRADUATES FROM PRIVATE SCHOOLS

Motivated by the apparent stability in the regional private/public ratios between 1985 and 1986, we projected overall numbers of private school graduates in each state by applying the most recently observed private proportion to the state's projected total numbers of high school graduates. To provide breakdowns of the state estimates by sex, race, and Hispanic origin, we used the percentages of high school students enrolled in private schools in Table A.6. Applying these estimates to the estimated state totals in each of the ten sex/race/Hispanic cells in any year leads to preliminary estimates of the numbers of private school graduates in those cells. Those estimates and the corresponding estimated numbers of public school graduates were then raked to match the prescribed private and public totals in those years.

The assumption that the state private proportions will remain stable over time implies a gradual reduction in the U.S. proportion of private school graduates—from 9.9 percent in 1986 to 9.6 in 2000. The main reason for this decline is the population shift into southern and western states where the private schools account for smaller proportions of high school graduates.

Table A.6

PERCENTAGES OF HIGH SCHOOL STUDENTS ENROLLED IN PRIVATE SCHOOLS BY REGION, RACE, AND HISPANIC ORIGIN: APRIL 1980

	Total	White	Black	Asian	Native American	Hispanic Origin
Northeast	12.68	13.53	7.73	9.92	14.25	11.70
North Central	9.17	9.50	6.26	7.67	12.72	12.75
South	7.18	8.63	2.96	6.00	8.81	7.65
West	6.91	6.92	6.40	6.89	9.15	7.00
U.S.	8.90	9.73	5.07	6.99	10.18	8.57

SOURCES: U.S. Bureau of the Census, *1980 Census of Population*, Vol. I: Characteristics of the Population, Chapter C: General Social and Economic Characteristics, PC80-1-C1, December 1983, pp. 71, 97–99, and 223–224.

ACCORDANCE WITH WICHE PROJECTIONS

The WICHE cohort survival method for projecting numbers of high school graduates by state depends mainly on the state estimates of enrollment by grade levels, whereas the projections reported here are tied to Census Bureau estimates of age group sizes. The two sets of projections for the years 1990–2000 agree closely in terms of projected U.S. totals, but the two sets of projections imply quite different growth rates for certain states and for the private schools.

WICHE's projected U.S. total for 2000 is 2,823,928, which is only 1.5 percent above our projection of 2,782,284, but their projection for California (355,087) is 8.2 percent above ours (328,120). WICHE's projection of 218,176 private school graduates in 2000 portends a steep deline in the proportion of private school graduates—from 9.9 percent in 1986 to 7.7 percent in 2000.

As an indication that WICHE's long-term public/private projections lack coherence, they project that the number of private school graduates in California will fall from 24,548 in 1987 to 12,916 in 2000, while the number of public school graduates will increase from 224,896 to 342,171. If there are forces at play in California that would lead to such a rapid decline in the private schools, we are not aware of them. Our projections indicate that the number of private high school graduates in California will increase from 25,507 in 1987 to 30,087 in 2000, and the number of public school graduates will increase from 237,414 to 298,033.

Appendix B

THE HS&B/DMDC DATA BASE

In addition to compiling a micro-level data base that provides detailed information on the postsecondary activities of over 26,000 young adults from the Classes of 1980 and 1982, we have brought together several supplemental data sources that permitted us to extend the scope of the study and link our research findings to national and state statistics bearing on the postsecondary activities of recent high school graduates and dropouts. This appendix describes the main features of the data base and provides summary statistics profiling the student populations of special interest in this study.

HIGH SCHOOL AND BEYOND

The main source of micro-level data on postsecondary activities is HS&B, a large-scale longitudinal study of the Classes of 1980 and 1982 that was conducted by NCES. The base year survey for HS&B was fielded in Spring 1980 to gather comprehensive information on 28,240 seniors and 30,030 sophomores from 1015 high schools. The survey was conducted using a two-stage cluster sample in which the first-stage sampling units were secondary schools stratified by school type, census division, and degree of urbanization (with three levels—urban, suburban, and rural). Within strata, schools were chosen with probabilities proportional to total sophomore and senior enrollment (Frankel et al., 1981).

In each selected school, completely random samples of up to 36 sophomores and 36 seniors were chosen to participate in the study. The participants were administered a battery of cognitive tests and asked to fill in questionnaires eliciting personal information. Additional data were gathered from the students' teachers, school administrators, and a subsample of the students' parents. The resulting student files provide a rich array of demographic and background measures on the students, including cognitive test scores, measures of socioeconomic status, rank in class, high school curriculum, and attitudinal information. They also contain data on the students' postsecondary plans, educational and career aspirations, and plans regarding family formation.

The First Follow-Up Survey of 11,995 seniors and 29,737 sophomores was conducted in February 1982. The sophomores who were still enrolled in their base year schools were administered a second battery of tests and resurveyed using questionnaires similar to those administered to the seniors in 1980. The other sophomores—dropouts, early graduates, and transfers to other schools—were mailed questionnaires to ascertain their current student and employment statuses.

The Second and Third Follow-Ups were fielded in February 1984 and February 1986 using the same 11,995 senior participants and a subsample of 14,825 sophomores. The mailed questionnaires for these follow-ups asked the participants to fill in several items about each episode of employment and educational activity that they had experienced between surveys, including the dates that the activity began and ended, thereby providing key information for tracking the participants' activities through February 1986. For full documentation of the longitudinal files, including further information on the survey design

and a complete listing of data elements, see the HS&B user's manuals (National Opinion Research Center, 1987a, b).

The base year survey was well designed to profile the Classes of 1980 and 1982, providing extensive baseline data derived from large samples of schools and students stratified by census division, school type, and degree of urbanization. The sampling allocation scheme for the follow-up surveys was tailored to provide longitudinal data on sufficiently large samples of participants to support detailed analyses for special categories of students. The follow-up participants were chosen using a highly nonrepresentative sample allocation scheme in which most minority base year participants were selected to participate, as were most students whose parents participated in the base year parents' survey.

In theory, this lack of representativeness can be handled in analyses by incorporating case weights that are inversely proportional to the sampling inclusion probabilities, with appropriate adjustments for nonresponse so that the case weight totals in each cell match the cell population sizes. However, the specification of case weights for HS&B was confounded by the incompleteness of the school sampling frame, the lack of reliable population counts to specify stratum sizes, and other complications associated with selecting and enlisting schools to participate in the study.[1] The case weights on the follow-up files (but not the base year file) appear to have been calculated incorrectly, with widely varying weights for students in the same school having similar demographic characteristics. Hence, the use of HS&B follow-up data to estimate population means (such as the proportions of the Class of 1980 attending college at various times after graduation) entails special handling to allow for the nonrepresentativeness of the student samples.

With four public school types, five private school types, and a total school sample size of about 1000, the survey designers could not choose representative samples of schools in all cells defined by census division, school type, and degree of urbanization. Given the way the base year cluster samples were chosen and the nonrepresentativeness of the follow-up samples, we found it necessary to reconstruct the high school graduate populations for 1980 and 1982 to provide a basis (and stratum weights) for analyzing the follow-ups as a stratified two-stage probability sample within cells defined by school control (public or private), census division, sex, and race/Hispanic category.

The estimated numbers of high school graduates in these cells for the Classes of 1980 and 1982 are listed in Tables B.1 and B.2. These estimates are derived from the corresponding state estimates reported in Appendix A. So that the total case weights in each cell for majority (white non-Hispanic) and minority students would agree with the stratum sizes and would reflect the unequal school selection probabilities, the base year weights for all students in each cell were first summed and then rescaled to agree with the corresponding stratum cell sizes. In essence, adopting this reweighting procedure in analyses amounts to adjusting the base year weights to make them agree with known population sizes and treating the unsampled students at follow-up in each cell as missing observations.

---

[1]As an indication of the operational and statistical problems inherent in fielding and analyzing a large-scale panel study of this type, of the 1122 schools selected in the initial HS&B school sample, 104 were ineligible to participate for various reasons, and 298 others refused to participate (Frankel et al., 1981).

INFORMATION ON MILITARY SERVICE

To provide more detailed and reliable data on the military service of the HS&B participants, the social security numbers (SSNs) of the 10,925 senior and 13,682 sophomore respondents to the Second Follow-Up Survey were passed through DMDC's accession, master, and loss files for Fiscal Years 1979–1985 to extract records of military personnel having the same SSNs as those reported by the HS&B participants.

This search turned up matches on SSNs for 857 seniors and 950 sophomores, of which 833 seniors and 913 sophomores also matched on dates of birth. A closer examination of the matched records indicated that some of the matches on SSN but not on date on birth did not match on demographic characteristics (e.g., sex, race, and age), so that only matches on both criteria were deemed valid. Of the 833 senior matches, 752 had served on active duty, the others only in the reserves. Of the 913 sophomore matches, 761 served on active duty.

A comparison of the military service items reported on HS&B with analogous items on the DMDC file for matched cases revealed that the HS&B data on military service are quite reliable, including the reported dates of service entry and separation.[2] However, a few participants (46 seniors and 73 sophomores) whose HS&B records showed some active duty served only in the reserves, according to DMDC records. Moreover, 19 seniors and 39 sophomores whose HS&B records indicated no active duty showed up on the DMDC file as having entered the military.

In addition to the 752 seniors and 761 sophomores whose service statuses were verified on the DMDC file through matches on SSN and date of birth, there were 273 other seniors and 281 sophomores who reported having some active duty but whose SSNs did not turn up on the DMDC file, perhaps because their SSNs were erroneously recorded or missing on their HS&B records. Altogether, 1025 (8.5 percent) of the senior participants and 1042 (7.0 percent) of the sophomores were identified as having spent some time on active duty.

INFORMATION ON OTHER ACTIVITIES

Using the individual HS&B episodic data on employment, student activities, and military service (and substituting DMDC data when available), we constructed vectors of educational, employment, and military service measures indicating each HS&B participant's status on these dimensions for each month between January 1980 and February 1986. In particular, the components of the education vector included separate codes to reflect four levels of schooling (high school, four-year college, two-year college, and vocational-technical school) and student status (full-time or part-time).

Creating these vectors of activity measures from longitudinal data is a major undertaking due to myriad problems presented by missing and sometimes conflicting data elements, which necessitate leaving some individuals' activities unclassified. In brief, we began by using the reported school-leaving date to fill in the components for the months when the participant was still in high school. Then, proceeding sequentially across episodes of educational activities reported on the follow-ups, we first used the data on each episode to encode the participant's student status. Then we determined the months (components) in that status

[2]The reliability of military service data reported on mailed questionnaires was documented earlier by Kolstad (1986), who used SSN matches on NLS72 participants to create a linked NLS72/DMDC file analogous to our HS&B/DMDC file. In examining the concordance of data elements derived from NLS72 data by Kanouse et al. (1980) with items drawn from DMDC records, Kolstad found very close agreement. In particular, he reported a correlation of .97 between the service entry dates reported on the two files.

using the reported beginning and ending dates for the episode, except in cases where the students reported being "still enrolled" as of the follow-up date, in which case the later date was used as the episode ending date. In cases of overlapping sojourns of student activity, we opted for full-time student data over part-time data. And we opted for the data on earlier surveys over later surveys, but we substituted the latter when the former were not available. Insofar as possible, we tried to use the same coding scheme for classifying employment and educational activities that was used in an earlier study based on NLS72 (Kanouse et al., 1980, Appendix B).

By combining these activity vectors with information available in other items, we then constructed a "track" vector for each participant with monthly components indicating his or her main activity each month from January 1980 to February 1986. To reconcile cases in which two full-time activities were reported (e.g., military service and full-time student status), we adopted a priority scheme, beginning with a determination of military status. For those on active duty during a given month, the main activity was classified as "military service." Otherwise, student status was checked to determine whether a "full-time student" assignment was appropriate. If not, employment status was checked next, leading to a "not employed" assignment if the participant was jobless, or to "civilian employment" if the participant was employed full-time or if he or she worked part-time and was not enrolled part-time. The remaining cases were assigned to the "unclassified" category, including the part-time students who held part-time jobs and the participants whose student statuses were unclassified.

One of the implications of this scheme is that the main activities of nonrespondents to a particular follow-up were typically not classified during the months spanned by the follow-up unless, for example, they entered military service and their dates of service included some of the months in question. Fortunately, HS&B maintained very high response rates throughout (94 percent on the First Follow-Up Survey), and a substantial portion of the nonrespondents were high school dropouts. Since this study focuses almost entirely on the post-secondary behavior of the graduates in the Classes of 1980 and 1982, nonresponse is not a major concern in this study.

SOCIOECONOMIC STATUS AND ACADEMIC APTITUDE

Earlier studies have pinpointed socioeconomic status and academic aptitude as important determinants of college entrance among high school graduates. The HS&B student files provide measures of these attributes that we shall refer to as SES and TEST. Except for changes of scale, these measures coincide with the base year composite measures BYSES and BYTEST for members of the senior cohort, and the First Follow-Up composites FUSES and FUTEST for the sophomores. In cases where FUSES or FUTEST were missing and the quartile codes SESQ and TESTQ derived from the sophomores' base year scores were available, we used the latter to estimate missing values of SES and TEST.

The SES composite score is based on student-reported information on five components: (1) father's occupation, (2) father's education, (3) mother's education, (4) family income, and (5) material possessions in the household. To calculate SES, the students' responses were first scored on each component using standardized scales having mean 0 and variance 1. Then each student's composite score was calculated using the unweighted average of the student's nonmissing standardized scores on the five components. To provide a more convenient scale for SES, we multiplied the resulting composite score by 100 and added 500.

The academic aptitude TEST score was derived using an unweighted average of the nonmissing standardized scores on three cognitive tests of vocabulary, reading, and mathematics. A similar rescaling like that used for SES was adopted to provide TEST scores that have an overall mean close to 500.

Table B.3 provides summary statistics on the SES and TEST scores with breakdowns by graduate status for all participants and for the military entrants in the two classes. As the table shows, TEST scores were available for 10,259 of the 11,995 members of the senior cohort and for 14,392 of the 14,825 members of the sophomore cohort. For the enlistees whose records were available from DMDC files, we also had AFQT scores. Our examination of the complete pairs of TEST and AFQT scores showed that the correlation coefficients between TEST and the normalized score corresponding to the AFQT percentile were .54 for the senior cohort and .56 for the sophomores.

LINKAGES TO OTHER DATA BASES

Other extensions of the HS&B/DMDC data base have enhanced its utility for studying the sorting-out process in the 1980s. To permit examining how seniors' postsecondary plans and activities are affected by regional variations in labor market conditions and educational opportunities, an effort was undertaken to pinpoint the locations of the high schools and colleges attended by the HS&B participants. HS&B provides institutional codes for the colleges that the participants planned to attend as seniors and those that they actually attended after graduation. By linking these items to a Department of Education file on institutional characteristics (including state and county codes) and making use of other information on the HS&B file, we have identified the locations of all HS&B schools by state and urban/rural category.

To incorporate information on local economic conditions into our analyses, we used the derived state codes for the HS&B schools to link the student files to state-level data on four factors: (1) unemployment rate among high school graduates of age 16–19 not enrolled in school, April 1980; (2) unemployment rates, 1980–1984; (3) per capita personal income, 1980–1984; and (4) average hourly earnings of production workers on manufacturing payrolls, 1980–1983.[3] While the availability of the state codes permits appending other state-level economic and population characteristics to the file, our findings in Section III indicate that neither the seniors' postsecondary plans nor their activities after graduation appear to be sensitive to these characteristics once one controls for individual and school attributes.

HS&B's principal shortcoming for the purposes of this study is that its coverage is limited to two high school classes in the early 1980s. To offset that disadvantage and to permit linking the findings of this study to national time series that provide continual updates on youth employment, college enrollment, and educational attainment, we have linked our estimation procedures throughout to population estimates of high school graduates by state, race, and sex for the Classes of 1980 and 1982. The comparable estimates and projections for the years 1980–2000 in Appendix A provide a basis for estimating changes in the demographics of high school graduating classes since 1982. Insofar as changes over time in the postsecondary flows of graduates and dropouts are concerned, we have presented numerous time
