This paper examines the performance of a proposed truncation and acceptance rule for the Wald Sequential Probability Ratio test for Bernoulli parameters and the rules influence on errors of the first and second kind as well as the average number of items sampled for inspection. The proposed truncation and acceptance rule suggest that there exists a natural truncation point for every Sequential Probability Ratio test such that the desired error probabilities are not exceeded or that one of the true errors is smaller then desired and the other will be exceeded by an insignificant amount. A computer program is used to simulate the sampling process and provide estimates of the true values of a plan's Operating Characteristic curve, its average sample number , as well as the probability of implementing the truncation and acceptance rule. Results suggest that truncation and rejection of a lot at the natural truncation point will maintain a plan's desired Operating Characteristic curve. The cases examined also suggest that any modifications to the natural truncation point truncation and acceptance rule may cause an unacceptable deviation from the desired Operating Characteristic curve. Finally, a linear equation was developed which provides an estimate of the upper limit on the probability of implementing a truncation and acceptance rule and that in most cases, this upper limit is less than 0.15.

ABSTRACT

This paper examines the performance of a proposed truncation and acceptance rule for the Wald Sequential Probability Ratio test for Bernoulli parameters, and the rule's influence on errors of the first and second kind as well as the average number of items sampled for inspection. The proposed truncation and acceptance rule suggests that there exists a natural truncation point for every sequential probability ratio test such that the desired error probabilities are not exceeded or that one of the true errors is smaller then desired and the other will be exceeded by an insignificant amount. A computer program is used to simulate the sampling process and provide estimates of the true values of a plan's Operating Characteristic curve, its average sample number, as well as the probability of implementing the truncation and acceptance rule. Results suggest that truncation and rejection of a lot at the natural truncation point will maintain a plan's desired Operating Characteristic curve. The cases examined also suggest that any modification to the natural truncation point truncation and acceptance rule may cause an unacceptable deviation from the desired Operating Characteristic curve. Finally , a linear equation was developed which provides an estimate of the upper limit on the probability of implementing a truncation and acceptance rule, and that in most cases, this upper limit is less than 0.15.

TABLE OF CONTENTS

I. INTRODUCTION

Quality control has been a part of every industry for as long as there has been industry. Statistical quality control, on the other hand, is a relatively new thing with its greatest developments occurring in just the past 80 or so years [Ref. 1]. During those 80 years, the military played a major role in forcing industry to adopt statistical quality controls as a way of assuring that the quality of products they were buying met their specific requirements. A number of procedures were developed for sample inspection, most of which required inspectors to randomly draw a fixed number of sample items from a lot and inspect each one. If from these drawn items the number of defective or nonconforming items exceeded a specified critical value the lot was rejected , otherwise it was accepted.

During the late 1940's , Abraham Wald indicated that there could be a fairly large economy in the average number of items inspected , or the Average Sample Number (ASN) , sometimes as much as 50%, through the use of sequential statistics [Ref. 1]. However there is one shortfall of this sequential method and that is that the number of items sampled typically has a large variance and the maximum number of items that may need to be inspected before a decision can be made is unbounded. Wald suggested a way of truncating the process but warned that this could change the probabilities of the errors of the first and second kind [Ref. 6]. In recent years there have been a number of papers written about this problem , suggesting decision rules and methods for truncation. One of these papers , by Jurgen Petersen , suggests that there is a natural truncation point (NTP) for every

Sequential Probability Ratio (SPR) test at which a decision can be such that the desired errors will not be exceeded or that one of the true errors will be smaller then required and the other will be exceeded by an insignificant amount [Ref. 5].

This paper shall examine and evaluate the effects of using the NTP and decision rule on the Operating Characteristic (OC) and ASN of given SPR plans. It will also attempt to find the probability that in any given lot of items the truncation and acceptance rule may need to be implemented , that is , that decision to accept or reject will not have been made prior to the truncation point.

In order to evaluate the proposed truncation and acceptance rules, a computer program was written to simulate a SPR sampling process using these rules. This program provides estimates of the probability of acceptance , the ASN , and the probability that the rule will be implemented for a number of specified sampling plans. These computed values will then be compared to Wald's theoretical values for the same SPR plans when no truncation rule is used.

This study will proceed in the following way: Chapter II will describe the Wald Sequential Probability Ratio Test for a Bernoulli parameter. It will include a description of planned errors of the first and second kind, the testing procedure and sequential-sampling chart , the development of OC curves, and the calculation of the theoretical ASN . The third chapter will be a description of the NTP and decision rule that will be used and a brief explanation of how the NTP was obtained. Chapter IV will describe the simulation and the SPR plans that were evaluated and in the final chapter, the results of the simulation will be discussed and conclusions drawn.

II. WALD'S SEQUENTIAL PROBABILITY RATIO TEST

The sequential method of quality control is a hypothesis test in which items are drawn from a lot sequentially and where one of three decisions can be made at any point during the test: (1) to accept the null hypothesis , (2) to reject the null hypothesis , (3) to continue the test by sampling more items. If either the first or second decision is made, the testing is terminated. If the third decision is made, the process is continued, selecting one item at a time until either the first or second decision is made. This testing method as well as definitions of the null hypothesis , Bernoulli parameters , and possible errors will be described in the following sections.

A. BERNOULLI PARAMETERS AND ERRORS OF THE FIRST AND SECOND KIND

Like most quality control plans, Wald's SPR test requires that a number of parameters be specified. The first of these parameters is the Acceptable Quality Level or AQL. The AQL is the proportion of nonconforming items that may be found in a lot and still have the lot called acceptable. This acceptable proportion is designated as the Bernoulli parameter P1. P1 is usually specified by the consumer as well as a value for α such that:

$$\Pr(\text{Rejecting a lot} \mid Pa = P1) = \alpha \quad , \qquad (1a)$$

or

$$\Pr(\text{Accepting a lot} \mid Pa = P1) = 1-\alpha \quad , \qquad (1b)$$

where Pa is the actual proportion of nonconforming items in the lot. These equations describe the Type I error associated with acceptance sampling. Stated in terms of a hypothesis test, the null hypothesis is that the actual proportion nonconforming is P1, and α is the significance level for the test.

The value of α is often known as the "producers risk" for it is the chance that the producer takes of having a lot consisting of satisfactory items rejected by the test. The consumer also has a risk associated with acceptance sampling. This consumers risk is designated as β such that the

$$\Pr(\text{Accepting a lot} \mid Pa = P2) = \beta \quad , \qquad (2)$$

where P2 is greater than P1 and is a value of the lot fraction nonconforming that the consumer is willing to take a $\beta(100)\%$ chance of accepting. The consumer's risk equation describes a value of a Type II error associated with acceptance sampling.

The hypothesis test associated with acceptance sampling is

$$Ho: Pa = P1$$
$$Ha: Pa > P1$$

with , α , β , P1 , and P2 specified as discussed above. The values of P2 and β define a point on the test's Operating Characteristic (OC) curve. Note that the hypothesis test is only a one-sided test for it would make little sense to test for Pa being less than the AQL. The typical values for α and β are 0.05 and 0.10 respectively , and when

used in Equations (1b) and (2) , define two points on the test's OC curve.

B. SEQUENTIAL PROBABILITY RATIO

In the Wald Sequential plan, items are drawn randomly from a lot one item at a time and inspected. After the n_{th} item is inspected with c nonconforming items having been found, the sequential probability ratio is computed, compared against two test values A and B, and a decision is made as follows:

$$SPR = \frac{Pr\,(\text{reaching } n\,,\, c \,/\, Pa = P2\,)}{Pr\,(\text{reaching } n\,,\, c \,/\, Pa = P1)} = \left[\frac{P2\,(1-P1)}{P1\,(1-P2)}\right]^{c} * \left[\frac{1-P2}{1-P1}\right]^{n} , \quad (3)$$

and if $SPR \geq A$ then stop sampling and reject Ho,
if $SPR \leq B$ then stop sampling and accept Ho, and
if $B \leq SPR \leq A$ then continue sampling .

The constants A and B are derived so that the test will meet the requirements of Equations (1) and (2) . An upper limit for the constant A is found to be the ratio of the probability of rejecting the null hypothesis Ho when the alternative hypothesis Ha is true divided by the probability of rejecting Ho when Ho is true, yielding

$$A \leq \frac{1 - \beta}{\alpha} \quad . \quad (4)$$

A lower limit for B is found to be the ratio of the probability that Ho is accepted given that Ha is true divided by the probability that Ho is accepted given that Ho is

true or written as an inequality:

$$B \geq \frac{\beta}{1 - \alpha} \quad . \qquad (5)$$

Wald showed that when the inequalities in Equations (4) and (5) are replaced by equalities, we have conservative values for A and B. [Ref. 6]

C. SEQUENTIAL SAMPLING CHART

Wald then greatly simplified the SPR test by removing the requirement of computing the SPR every time a sample is taken. He removed this requirement by developing a chart on which an inspector needed only to plot a point, where the abscissa is the total number of items inspected up to that time and the ordinate is the total number of those items which were found to be nonconforming [Ref. 1]. If the plotted point stays between the two parallel lines on the sampling chart, no decision is made about the lot and the inspection is continued. If a point is plotted and it falls on or above the upper parallel line the inspection is terminated and the lot rejected, but if a point is plotted and it falls on or below the lower of the two parallel lines, the inspection is terminated and the lot is accepted. Figure 1 shows what a typical

sequential sampling chart may look like and how the points are plotted until a decision can be made. In Figure I , the decision would be made is to reject the lot.

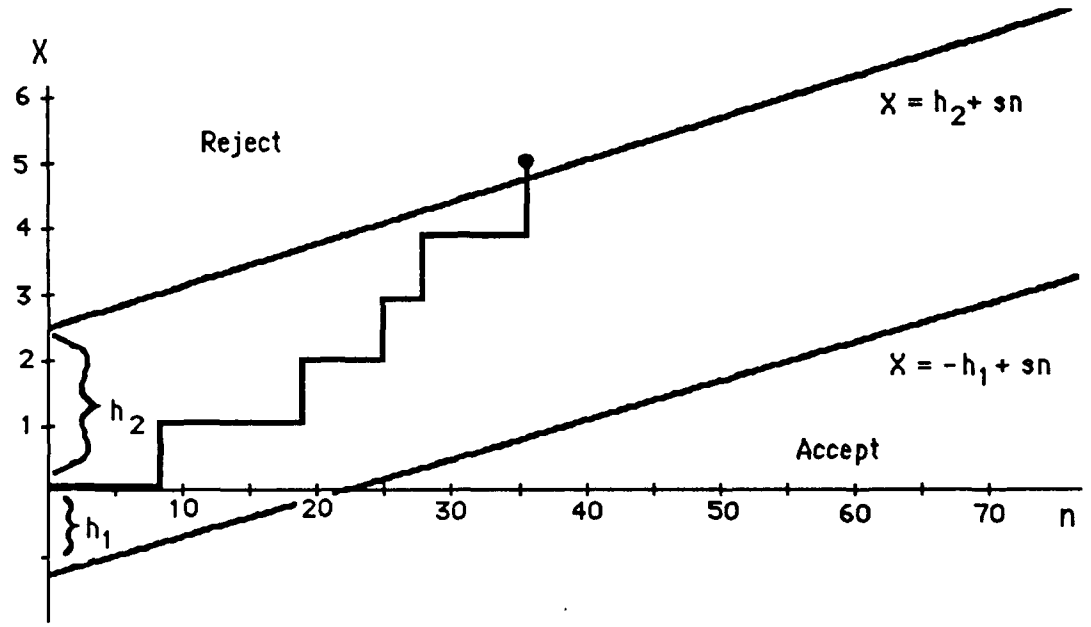

Figure 1 -AN EXAMPLE OF A SEQUENTIAL SAMPLING CHART

The values of h_1 , h_2 , and s are arbitrary labels for constants which can be derived by setting the values for A and B equal to the right hand side of Equation (3) and then solving for c. When the value for A is set equal to the right hand side of Equation (3) and c is solved for, the result takes the form of $c= -h_1+sn$. When B is set equal to the right hand side of Equation (3) and c is solved for, the result takes the form of $c=h_2+sn$ where [Ref. 1]

$$h_1 = \frac{\ln\left[\frac{1-\alpha}{\beta}\right]}{\ln\left[\frac{P2\,(1-P1)}{P1\,(1-P2)}\right]}\quad , \qquad (6)$$

$$h_2 = \frac{\ln\left[\frac{1-\beta}{\alpha}\right]}{\ln\left[\frac{P2\,(1-P1)}{P1\,(1-P2)}\right]}\quad , \qquad \text{and} \qquad (7)$$

$$s = \frac{\ln\left[\frac{(1-P1)}{(1-P2)}\right]}{\ln\left[\frac{P2\,(1-P1)}{P1\,(1-P2)}\right]}\quad . \qquad (8)$$

There are a number of items to note about the sequential sampling chart. The first item to note is that there is a minimum number of samples that need to be taken before a decision can be made. The second item worthy of being pointed out is that not all values of n represent an opportunity for accepting or rejecting Ho. Acceptance can occur only at those values of n where $-h_1+s(n-1) < X \leq -h_1+sn$, where both X and n are non-negative integers. The values of n that meet this condition will be called acceptance points. The final item worth noting is that since the acceptance and rejection lines are parallel to each other , the maximum number of items that need to be sampled before a decision can be made is unbounded. It is this difficulty with sequential sampling that led to the truncation and acceptance rule that will be discussed in the next chapter.

D. THE OC CURVE FOR A SPR SAMPLING PLAN

The Operating Characteristic (OC) curve for SPR sampling plan is a curve that shows the probability of accepting a lot of items given the actual proportion of nonconforming items in that lot (Pa). This OC curve should reflect the desired parameters such that

$$\Pr(\text{accepting Ho} \mid Pa = P1) = 1 - \alpha ,$$

and

$$\Pr(\text{accepting Ho} \mid Pa = P2) = \beta$$

are two points on the plan's curve. It also has been shown that a third point on the curve is [Ref. 1]

$$\Pr(\text{accepting Ho} / Pa = s) = \frac{h_2}{h_1 + h_2} .$$

Other points on the OC curve can be obtained from the parametric equations

$$Pa = \frac{1 - \left[\frac{1 - P2}{1 - P1}\right]^{\theta}}{\left[\frac{P2}{P1}\right]^{\theta} - \left[\frac{1 - P2}{1 - P1}\right]^{\theta}} , \qquad (9)$$

and

$$\Pr(\text{accept Ho} / Pa) = \frac{\left[\frac{1-\beta}{\alpha}\right]^{\theta} - 1}{\left[\frac{1-\beta}{\alpha}\right]^{\theta} - \left[\frac{\beta}{1-\alpha}\right]^{\theta}} , \qquad (10)$$

where θ is an arbitrary value which ranges from negative infinity to infinity such

that for $\theta = 1$, we have Pa = P1, for $\theta = -1$ we have Pa = P2 and for $\theta = 0$, Pa = s. An example of an Operating Characteristic curve is shown in Figure 2.

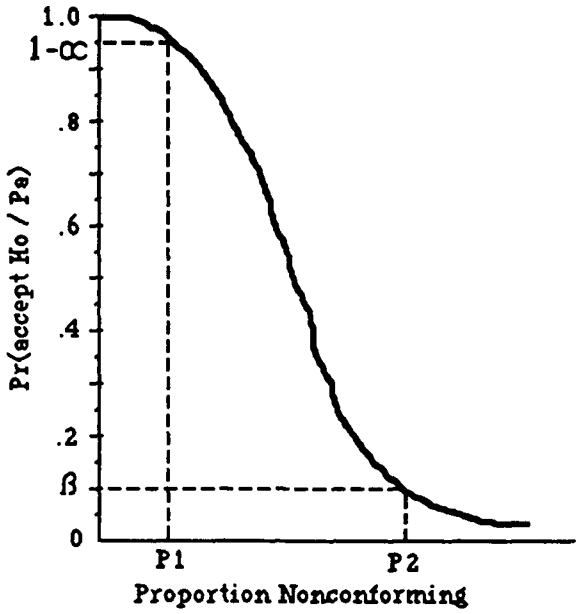

Figure 2 - AN OPERATING CHARACTERISTIC CURVE

E. THE AVERAGE SAMPLE NUMBER (ASN) CURVE

As discussed earlier in this paper, the number of items that will be required to be sampled before a decision can be made is a random variable, but Wald showed that it is possible to compute its expected value as a function of the plan's parameters and Pa. The equation for computing the ASN is as follows [Ref 1]:

$$ASN(Pa) = \frac{Pr(accept|Pa)\, h_1 - (1 - Pr(accept|Pa))\, h_2}{s - Pa} \quad . \quad (11)$$

Equation (11) can be simplified at specific values of Pa such that $ASN(Pa = 0) = h_1/s$, $ASN(Pa=1) = h_2/(1-s)$, and $ASN(Pa=s) = h_1 h_2 / s(1-s)$.

There are several items that should be noted about the ASN for any given SPR plan. The first of these is that the maximum ASN for any given plan will occur around the point where Pa = s and it is possible that this ASN will be larger than the sample numbers for some other types of sampling plans [Ref. 1]. Second is that the larger the difference between P1 and P2, the smaller the ASN. A final observation is that the greater the values of α and β, the smaller the ASN. Figure 3 shows what a typical ASN curve might look like.

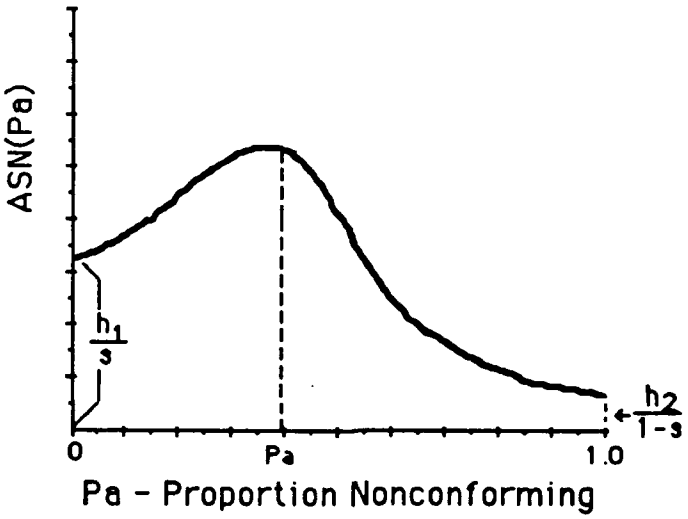

Figure 3 - AN ASN CURVE

III. THE NATURAL TRUNCATION POINT AND ACCEPTANCE RULE

It has been shown that the probability that a sequential test will eventually terminate is 1.0, but we have also seen that the maximum value for n at which this termination will occur is unbounded [Ref. 6 , p. 157-158]. It is because this maximum value is unbounded that we may find it necessary to set a definite upper limit , n_o , for the number of items to be inspected. It is at this truncation point that the test will be terminated and a decision on whether to accept or reject Ho will be made. Wald warns that if we truncated the sequential process at the n_oth trial, we will be changing the probabilities of errors of the first and second kind by some unknown amount, but as n_o becomes larger, the effect of this change will be smaller [Ref. 6].

In his paper, Petersen suggested that for every SPR plan there exists a natural truncation point (NTP) at which the test may be stopped and neither of the two error probabilities will be exceeded, or that the error of the second kind will be insignificantly greater then ß [Ref. 5 , p 22]. In the following sections we will give a brief description of the NTP and the decision rules that will be used when it is reached.

A. THE NATURAL TRUNCATION POINT

We have seen that not every point on the sequential sampling chart represents an opportunity to accept the null hypothesis. The only points at which the null hypothesis can be accepted are the values of n at which the equation $(-h_1 + sn)$ is

equal to or has just become greater than a value of X, which is the number of nonconforming items that have been found in the sample of size n. These special values of sample number n are called acceptance points and are designated as A_0 , A_1 , A_2 , ... , where at each sample number A_i there is an unconditional probability that the test will be terminated given that the null hypothesis is true [Ref. 5].

A similar observation can be made about the opportunity to reject the null hypothesis. There are a number of points at which the number of nonconforming items needed to reject the null hypothesis increases by one. Analogous to above, these special values of sample number n are called rejection points. While these rejection points are interesting to note, we will see that they do not play a role in identifying the natural truncation points. Figure 4 shows the location of some acceptance and rejection points on a typical SPR chart.

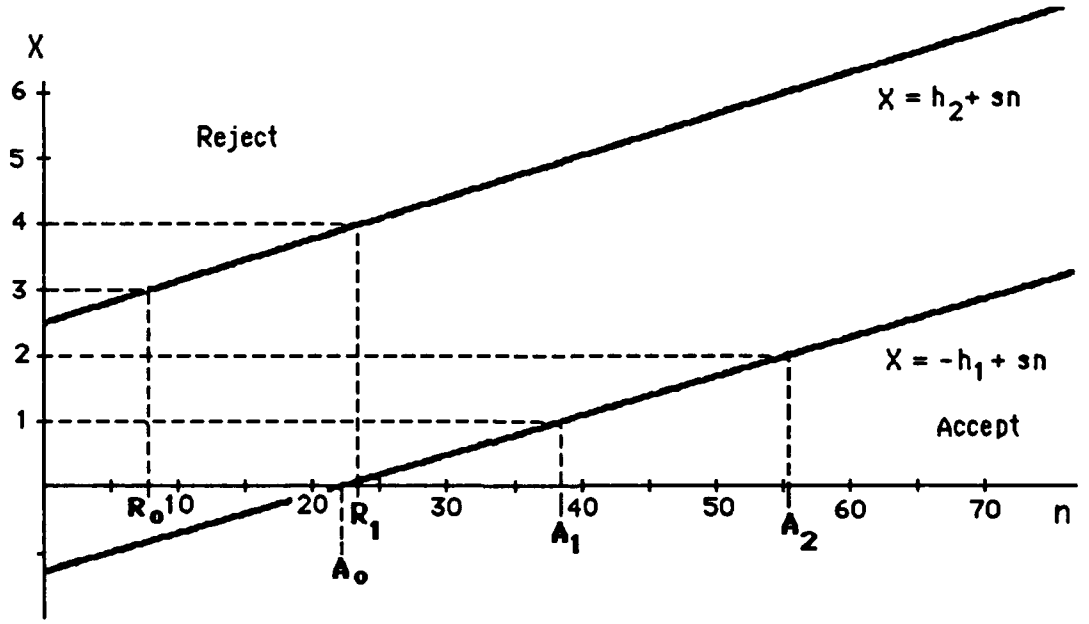

Figure 4 - SEQUENTIAL PROBABILITY RATION CHART WITH ACCEPTANCE AND REJECTION POINTS HIGHLIGHTED

If there is no truncation, the sum of the acceptance probabilities for all the values of A_i up to and including n is the probability that Ho will be accepted when

at most n samples are drawn. Given that $n<A_{i+1}$, the following statements can be made about the acceptance probability when at most n samples have been drawn [Ref. 5 , p 16]:

(i) Since $-h_1 < 0$, the Pr (accept Ho | n = 0) = 0.

(ii) As n increases in size, the Pr (accept Ho | n) never decreases , and only increases at acceptance points.

(iii) For all sample numbers between A_i and A_{i+1} , the Pr(accept Ho | n) is a constant and is equal to the Pr(accept Ho | $n = A_i$).

Figure 4 shows how the acceptance probability accumulates for an arbitrary sampling plan when the null hypothesis is true , that is Pa = P1 [Ref. 5].

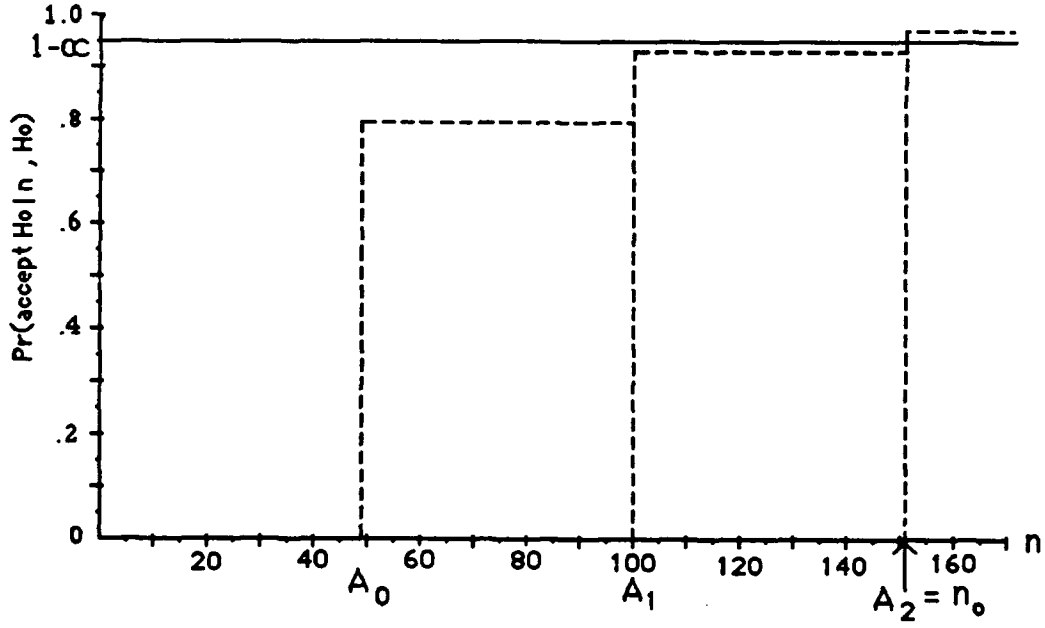

Figure 4 - ACCUMULATED ACCEPTANCE PROBABILITY

In the above example, the acceptance point A_2 is the first point where the probability of acceptance exceeds the (1- α) requirement. It is this point that is designated as

this plan's natural truncation point , n_o.

At n_o , α can an be considered as an upper bound for the probability of a Type I error. It is also possible to compute an upper bound for the probability of an error of the second kind as n approaches n_o. It has been shown that as n increases , the upper limit for the probability of a Type II error decreases , approaching ß from above [Ref. 6, p 62-64].

It is also possible to show that the sum of the acceptance probabilities, when the alternate hypothesis is true , approaches ß as n increases . In addition, it has been suggested that the true probability of a Type II error will be at most, insignificantly greater than the planned error when n is equal to the natural truncation point [Ref. 5]. Figure 5 shows how the acceptance probability may accumulate for an arbitrary sampling plan when the alternate hypothesis is true , that is Pa = P2 .

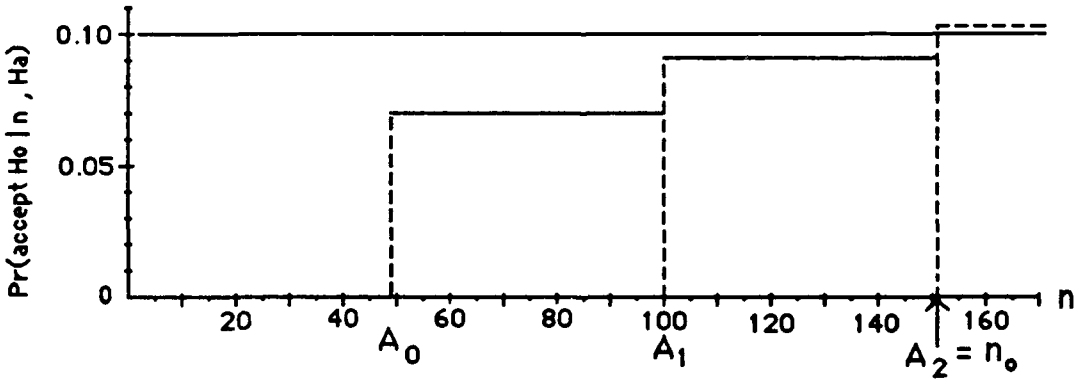

Figure 5 - ACCUMULATED ACCEPTANCE PROBABILITY WHEN THE ALTERNATE HYPOTHESIS IS TRUE

If the true probability of a Type II error does not significantly exceed ß for any sample number n, it is then not necessary to specify a special truncation point to control it.

B. ACCEPTANCE RULES

Once the natural truncation point is reached , a decision must be made as whether to accept or reject the null hypothesis. We will examine three related rules starting with the simplest and working toward slightly more complicated ones. The simplest and most conservative rule is that if no decision has been made after the last item has been sampled the null hypothesis should be rejected. By rejecting Ho, we insure that the true probability of errors of the first and second kind are as close to the desired values as possible [Ref. 6].

The second decision rule is known as the (h_1-m) rule. This rule divides the region between the upper rejection and lower acceptance lines into two parts. The line which makes this division is the line $-(h_1-m)+sn$ where m is a positive integer such that $0 \leq m \leq (h_2 - (-h_1))$. Figure 6 shows how the region is divided when m=2.

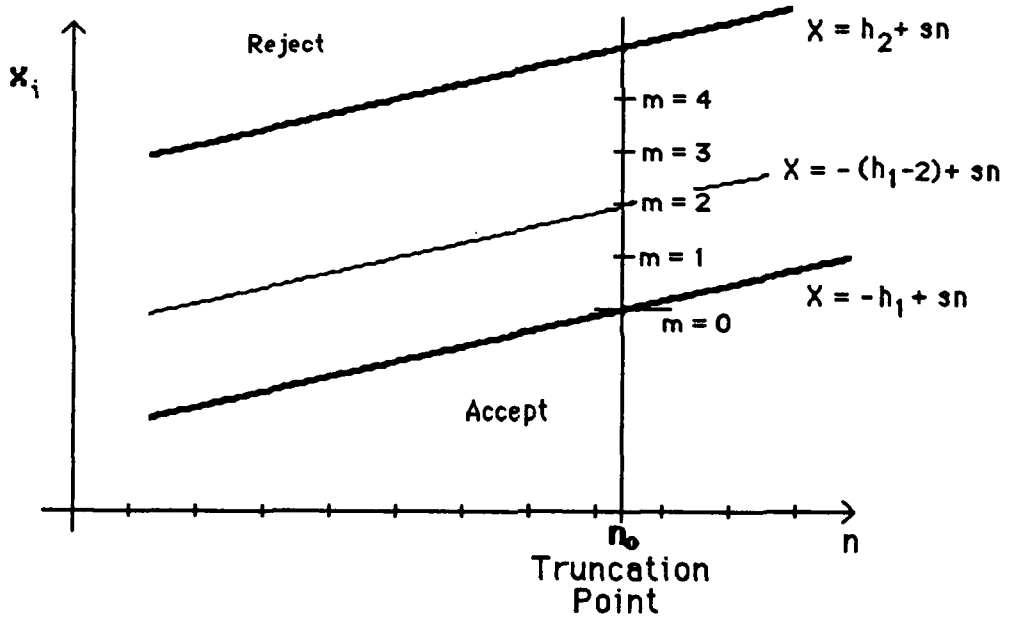

Figure 6 - AN EXAMPLE OF DIVIDING THE SAMPLING CHART USING THE (h_1 - m) ACCEPTANCE RULE.

Under this rule, if the natural truncation point is reached before a decision has been made, the null hypothesis is rejected only if the plot of the number of

nonconforming items found falls on or above the - (h_1-m)+sn dividing line. If the number of nonconforming items is less than -(h_1-m)+sn, then Ho is accepted.

The final rule that will be examined is an extension of the (h_1-m) acceptance rule and attempts to reduce the ASN of a plan by finding earlier truncation points.. Under this rule, one of the two desired errors is fixed and the other is allowed to vary in an attempt to lower the value of the truncation point. Petersen describes a sample number n_i^* which is strictly less than the NTP but at which we are assured that the probability of a Type I error will not exceed α . He also describes n_i^{**} which is the smallest sample number for which ß is not exceeded. These sample numbers can be found using the following equations:

$$n_i^* = \text{int}\left[\frac{\log[1-\alpha-Pr(\text{accept}@\,Ai \mid Ho)] + Ai\,\text{Log}(1-P1) - \log[Pr(X(Ai) = i+m)]}{\text{Log}(1-P1)}\right] \quad (11)$$

$$n_i^{**} = \text{int}\left[A_i + \frac{\text{Log}[\,\beta - Pr(\text{accept}\,@\,Ai \mid H_0)] - \text{Log}[\,Pr(X(Ai)=i+m)]}{\text{Log}(1-P1)} + 1\right] \quad (12)$$

where Pr($X(A_i) = i+m$) is the probability that the number of nonconforming items at acceptance point A_i will be less then or equal to i+m, given that the null hypothesis is true in Equation (11) and that the alternate hypothesis is true in Equation (12). [Ref. 5]

While the derivation of Equations (11) and (12) is fairly complicated and will not be discussed here, there are several items that should be noted about using the

extended (h_1-m) acceptance rule. The first item to note is that it is possible that n_i^* and n_i^{**} may not exist for every given sampling plan. Second is that if the new truncation points do exist, once n_i^* or n_i^{**} is reached, decisions are made in the same way as the non-extended (h_1-m) rule, and finally while this plan fixes one error at a desired value , the amount by which the alternate error will vary from its desired value is unknown and possibly can be quite large.

Theoretically the above truncation rules should reduce the ASN of an given plan by truncating a sampling process at a specific point while maintaining the desired operating characteristic. The following section will describe the experimental procedures and computer simulation used to test the validity of the claims made above.

IV. EXPERIMENTAL PROCEDURES

In any sequential sampling procedure, there are a number of steps that must be taken before the actual sampling and testing of items begin. First, the plan's parameters must be specified. Second, the definition of conforming and nonconforming must be clarified, and finally a procedure for random sampling and testing must be determined. It is only after these three steps have been accomplished that the actual testing may begin and decisions as whether to accept or reject lots may be made. The following section will discuss these three steps in detail as well as describe the computer simulation that was used to simulate the sampling process.

A. PARAMETER SPECIFICATION

Before the beginning of any sampling process , the parameters α , β , P1, and P2 must be specified. These values are used in Equations (6) , (7) , and (8) to compute the values of h_1 , h_2 , and s which in turn are used to determine the acceptance and rejection zones on the sequential sampling chart. For the work presented in this paper, α and β were set at 0.05 and 0.10 respectively and remained constant throughout the test. These values were selected because they are typical values used in quality control. For the parameters P1 and P2 , twenty six pairs of P1 and P2 values were arbitrarily selected. The values for P1 and P2 were selected to provide a good range for testing the truncation points and stopping rules. For ease of testing , the parameters were divided into four "Plan Sets" according to the four values of P1 that were used. Table I provides a list of the parameter pairs used as well as their

natural truncation point and extended rule truncation points n_i^*, and n_i^{**}. The truncation points for the extended rule were computed using the (h_1-1) extended rule for reasons that will be discussed later.

Table I - PARAMETER VALUES USED IN THE SIMULATION AND THEIR TRUNCATION POINTS.

B. DEFINITION OF CONFORMING AND NONCONFORMING

In quality control an item may be considered nonconforming if a specific measurement does not fall within required parameters. These parameters usually fall into one of two types of tests , one-way or two-way tests. A test that is one-way requires the item being inspected to meet some minimum or maximum limit. As long as this maximum or minimum is met, the item is considered good or

acceptable. For example, if a chain company may require a quarter-inch chain to have a minimum breaking strength of two thousand pounds, that is what they will test for. They may not care that the actual breaking strength is twenty-six hundred pounds , all they care is that the chains meet the minimum requirements.

A two-way test has two parameters that must be met, a minimum and a maximum. The most common two-way test measures to see if a specific characteristic of an item falls between these two parameters. If the measurement falls between the minimum and maximum , the item is considered acceptable, otherwise it is rejected as unacceptable . An example of a two-way test may be a potato chip company measuring to see if a twelve ounce bag of chips is actually being filled with 12 oz. of chips. If a bag has too few ounces of chips in it the law may not allow them to call it a 12 oz. bag. If a bag has much more then 12 oz. in it , the company may be losing money. Not wanting to break the law or lose money, the company specifies a minimum and maximum weight for the number of ounces of chips that a bag should have. The company then tests bags of chips one at a time. If enough bags of chips meet the specified requirements, the machine that fill the bags is working properly. On the other hand if enough bags of chips do not meet the requirements, the company may decide that the filling machine requires adjustments or repairs.

While the above two tests are not the only type of examinations used in quality control, they are probably the most common. For the purpose of this paper, the two-way test will be used in the examination of the proposed truncation rules. In a computer simulation, a lot of 5000 numbers will be created from a normal

distribution. Each number represents some attribute of the item being tested. From this lot of numbers, one item at a time will be drawn , without replacement , and compared to a set of parameters such that the probability of the items falling outside these parameters is a fixed and known. If the item falls within the specific parameters it is classified as acceptable or conforming, otherwise it is classified as a nonconforming item. Inspection continues one item at a time until a decision can be made. Details of the simulation will be discussed in the following section.

C. COMPUTER SIMULATION

A computer program was written to simulate the Wald SPR sampling process and compute the ASN and its standard deviation , the Operating Characteristic, and number of times the stopping rule was utilized for each SPR plan. The computer simulation was written in VS FORTRAN 77 and utilized the AMDAHL 5990-500 Dual-Processor mainframe computer system at the Naval Postgraduate School (NPS) Computer Center during the period of April to September 1992. The simulation also utilized the NPS Random Number Package with double precision written by P.A. Lewis and L. Uribe.

The input variables for the simulation consisted of five parameters denoted by P1 , P2 , Pa , NTP , and Za. With the exception of Za, all the parameters are the same as the ones discussed earlier in this paper. The parameter Za is the measurement parameter used in the two-way test discussed above such that the probability that an items measurement falls outside -Za and Za is Pa.

As discussed before, twenty-six pairs of parameters P1 and P2 were used in the

simulation and were divided into four "Plan Sets" according to the four different values of P1 that were used. Each pair of parameters P1 and P2 within a Plan Set is called a plan since each different pair of P1 and P2 will have a different OC curve. For each plan , six to eighteen OC points, designated by Pa, were used to develop each Plan's OC and ASN curves. Table II gives an example of two plans and the values for Pa that were used in the simulation.

Table II - EXAMPLE OF THE PARAMETERS FROM PLAN SET 1
PLANS C AND D

Plan C			Plan D		
P1	P2	Pa	P1	P2	Pa
0.005	0.03	0.005	0.005	0.04	0.005
		0.007			0.007
		0.010			0.010

		0.030			0.031
					0.034
					0.037
					0.040

A lot of 5000 random numbers was created from a normal distribution with a mean of zero and variance of one for each value of Pa. Each number represented an arbitrary measurement of some attribute of the items being tested. From one lot at a time, items were randomly selected one item at a time without replacement and tested against the parameter Za. This selection process continued until a decision as

whether to accept or reject the lot could be made. The process was then repeated 5000 times so that the final estimate of each OC point was the result of 5000 lots of 5000 items going through the SPR process.

One of the sets of rules that should be kept in mind when conducting any random sampling process is that the method by which items are selected should ensure that each member of a lot has an equal chance of being selected. It should also avoid using any method of selection that associates the selection of the item with the classification of the item being selected. Since the items in the lots came from a normal distribution a sampling order was created for each lot from a uniform[0,5000] distribution. By selecting items according to a sampling order from a different distribution, we were assured that the sampling process was as close to random as possible.

V. RESULTS AND CONCLUSIONS

When a Wald SPR sampling process is truncated its operating characteristics will vary with the location of the truncation point and the type of acceptance rule used. As the location of the truncation point becomes larger, the true values of the OC curve will approach the values of the OC curve of the nontruncated sampling plan. For this paper, the values obtained from the simulation for the OC and ASN curves will be known as the true values for a plan. These values will be compared to the values of the nontruncated SPR sampling process obtained from Equations (10) and (11). The values for the OC curve and ASN obtained from Equations (10) and (11) will be known as a plan's theoretical values.

A. NATURAL TRUNCATION POINT

As discussed earlier in this paper, the first truncation and acceptance rule examined was an automatic rejection of a lot if the sampling process reaches the NTP . The normal approximation for the two-sided test for the Difference of Two Proportions (DTP) , at a 0.05 level of significance, was used to compare the theoretical and true values of the operating characteristic at each value of Pa such that:

$$\text{Ho: } P(\text{accept} \mid Pa)_{true} = P(\text{accept} \mid Pa)_{theo.}$$

$$\text{Ha: } P(\text{accept} \mid Pa)_{true} \neq P(\text{accept} \mid Pa)_{theo.}$$

According to test statistics, there appears to be no difference between the theoretical

and true values for any of the plans tested. In other words, for plans with parameter values in the range of those studied here, the NTP stopping rule provides a point at which the SPR sampling process can be truncated while maintaining the errors of the first and second kind at their desired values. The results of the above testing can be found in Tables III and IV of Appendix B under the heading m=0.

The true ASN and theoretical ASN at each value of Pa were also compared but this time a one-sided Paired Difference T test (PDT), at a 0.05 level of significance, was used. The associated hypothesis test was

$$\text{Ho: } ASN_{true} = ASN_{theo.}$$
$$\text{Ha: } ASN_{true} < ASN_{theo.}$$

which when rewritten as a PDT is

$$\text{Ho: } (ASN_{true} - ASN_{theo.}) = 0$$
$$\text{Ha: } (ASN_{true} - ASN_{theo.}) < 0 .$$

The paired difference statistic has a student's t distribution with n-1 degrees of freedom. In the above testing, n=5000 and the therefore the t statistic is essentially normal. Results of the tests using the normal distribution can be found in Tables VI, IX, XII, and XV of Appendix B and showed that in almost all of the plans , the true ASN did not show any statistical savings over the theoretical values.

There are two items worthy of noting when discussing the two comparison tests used above. The first item is that the use of a two-sided test is not entirely appropriate for the DTP test because at different areas of the OC curve the alternate

hypothesis , $P(\text{accept} \mid Pa)_{true} \neq P(\text{accept} \mid Pa)_{theo.}$, may be desirable. For example, it may be desirable for the $P(\text{accept} \mid Pa \text{ is near } P1)_{true} > P(\text{accept} \mid Pa \text{ is near } P1)_{theo.}$ or $P(\text{accept} \mid Pa \text{ is near } P2)_{true} < P(\text{accept} \mid Pa \text{ is near } P2)_{theo.}$ because then the probability of either type of error would be less than required and therefore better. The second item worthy of noting is that while the differences between the true and theoretical values of a number may be statistically significant, the numerical differences may often be fairly small. When the sample size being used in the test is large, in this case 5000 , a small difference between numbers may often lead to rejection of the null hypothesis. It is therefore important to look at the actual numerical differences as well as the Z values obtained from the test statistics. These items will also hold true in the following sections.

B. THE $(h_1 - m)$ ACCEPTANCE RULE

The second truncation and acceptance rule examined was the $(h_1 - m)$ acceptance rule. As discussed before, if no decision has been made prior to reaching the NTP the lot is accepted if the number of nonconforming items found up to that point is less then $-(h_1 - m) + sn$, where n is the NTP. If the number of nonconforming items found up to that point is equal to or greater then $-(h_1 - m)+sn$ the lot is rejected. For this set of rules, the simulation was run using the same lots and sampling order used to test the first rule but was with m=1 , m=2 , m=3 , and then m=4. Using the same lots and sampling order allowed direct comparison between runs with different values of m.

The results from this set of tests can also be found in Tables XVII through XX of Appendix B and show that as m increases in value, the probability of a Type I error decreases at a decreasing rate. That is for every increase in m , the decrease in the probability of a Type I error becomes smaller and smaller and approaches zero as m approaches (h_2 - (-h_1)). On the other hand, as m increases in value, the probability of a Type II error increases. Like the decreases in the probability of a Type I error, the increases in the probability of a Type II error becomes smaller as m increases but do not approach zero as quickly as alpha. In other words, every increase in the probability of a Type II error is not necessarily accompanied by an equal decrease in the probability of a Type I error.

For all values of m>0 the Pr(accept Ho | Pa =P2) was greater than ß. The differences between the true values of the probability of a Type II error and their desired values are statistically significant in all the plans tested but as discussed above, the actual numerical differences are not always that great. It is therefore necessary to make a decision as to how much you may be willing to let the probability of a Type II error vary from its desired value of ß in order to obtain some improvement in the probability of a Type I error. Since all the true values along a given the OC curve varied similarly when m is changed , the 95% confidence interval (CI) for the probability of a Type II error and a number of other OC points was computed for the different values of m. The computed CI for the probability of a Type II error at m=1 was {0.106 , 0.118} with a maximum value of 0.128. The CI for the probability of a Type II error at m=2 was {0.12 , 0.137} with a maximum value of 0.148. Since the true values for ß and the other OC points using m=1 are generally

very close to the theoretical values, the (h_1 - 1) truncation and acceptance rule is recognized as a reasonable truncation and acceptance rule for a Wald SPR sampling process. Unlike the m=1 rule , the deviations of the theoretical OC values from the true OC values for the rules using $m \geq 2$ are considered too great and therefore the (h_1 - m) truncation and acceptance rule for $m \geq 2$ is rejected as reasonable truncation and acceptance rule. Results of testing can be found in Tables V through XVI of Appendix B.

C. THE EXTENDED (h_1 - m) ACCEPTANCE RULE

As discussed earlier , the extended (h_1 - m) acceptance rule attempts to reduce the ASN of a plan by finding truncation points which are strictly less then the NTP. To do this, only one of the true errors will be guaranteed to equal the desired value. The point n_i^* holds alpha constant, for it is smallest sample number at which the probability of a Type I error is equal to alpha. The point n_i^{**} holds beta constant for it is the smallest sample number at which the probability of a Type II error is equal to beta. Since only the (h_1 - 1) acceptance rule is being recognized as an acceptable truncation and acceptance rule , the values for n_i^* and n_i^{**} were computed only for the extended (h_1 - 1) acceptance rule.

The performance of the extended (h_1 - 1) acceptance rule in most test cases was poor. While it did a good job holding one error close to the required value , the

other operating characteristics quickly deviated from their theoretical values so that by the time the alternate error was reached, its true value was usually more than twice its desired value. In addition, for most cases the extended acceptance rule provided only a small savings in ASN , and for a small number of points, the ASN for the nonextended acceptance rule was actually smaller. Results of the testing can be found in Tables XVII through XX of Appendix B.

Overall, the performance of the extended (h_1 - 1) acceptance rule was poor and the rule is not recommended as a truncation and acceptance rule with one possible exception. If the difference between P1 and P2 is large and it is known that Pa is very close to P1, then using the extended acceptance rule may provide some savings in ASN. In all other cases, the nonextended m=0 or m=1 rule is recommended.

D. PROBABILITY OF IMPLEMENTING (h_1 - 1) ACCEPTANCE RULE

The probability that a truncation and acceptance rule will need to be implimented depends greatly on the true value of the actual proportion of noncomforming items in the lot, Pa , which is itself a unknown. Even though the actual probability of implimenting a truncation and acceptance rule is unknown, it is possible to get a rough upper limit for it by using some known parameters such as P1 , P2 , and s.

We have seen that as the difference between P1 and P2 increases, the ASN of a plan decreases and that the maximum value for the ASN of a plan occurs when Pa is approximately equal to s. It is when Pa is approximately equal to s that we have the greatest probability of reaching a truncation point and therefore a need to impliment a truncation and acceptance rule. Using this knowlege and the computed

probabilities of implimenting a truncation rule found from the simulation , a number of models were fitted to the values P1 , P2 , and s using the SAS stepwise logistic regression [Ref. 7] resulting in the following fitted model

$$\widehat{Pr}(\text{reaching NTP}) = \frac{Exp[-2.3415+0.294113Ln(P2-P1)-0.158121Ln(s)]}{1+Exp[-2.3415+0.294113Ln(P2-P1)-0.158121Ln(s)]} \quad .(13)$$

The Chi-square test for goodness-of-fit for the Equation (13) resulted in p-value , 0.0001 and testing of the equation against the actual results from the simulation proved it to be quite accurate over the simulated range. Results of this testing can be seen in Table XXI of Appendix E. Further testing showed that it provided reasonable predictions for parameter set outside of the simulation range. A 95% confidence limit for the maximum probability was also computed and found to be approximately [0.101 , 0.138].

One point to remember is that this equation only provides a rough upper limit for the probability of implimenting a truncation rule and that if Pa is closer to P1 or P2, the actual probability will most likely be quite a bit smaller. graphs of the actual probabilities for each plan can be found in Appendix E, Figures 46 through 51.

E. AREAS FOR FURTHER STUDY

This paper studied the curtailed Wald SPR sampling plan using only one set of values for alpha and beta. A further area of studied might be on how changing the values of alpha and beta impacts on these test results. It is hoped that the work provided in this paper will be beneficial to those interested in sequential sampling and quality control.
