Cross-Barrel Temperature Difference Due to Wall Thickness Variation

Nathan Gerber and Mark L. Bundy

U.S. Army Research Laboratory
ATTN: AMSRL-WT-PB
Aberdeen Proving Ground, MD 21005-5066

Advances in manufacturing techniques have reduced, but not eliminated, cross-barrel wall thickness variation in the production of gun barrels. Structurally, these small variations will not appreciably diminish the strength of the barrel, and are, therefore, not a firing safety concern. However, even small variations will produce cross-barrel temperature differences that can increase with the number of rounds fired, and thereby produce thermal distortion of the barrel, which degrades gun accuracy. This investigation presents a theoretical (finite difference) analysis of the cross-barrel temperature difference expected to occur as a result of typical and atypical wall thickness variation in production-line guns. The results indicate that typical tolerances will not incur an appreciable thermal bend due to wall thickness variation. However, current manufacturing tolerances would allow an atypical barrel to be fielded that could undergo significant thermal distortion due to a cross-barrel temperature difference created by asymmetric wall thickness.

ACKNOWLEDGMENTS

The authors would like to thank the following U.S. Army Research Laboratory* (ARL) co-workers: James Bradley (PFD) for programming the finite-difference solution; John Petresky (contractor) for his help in getting the program to run on the ARL supercomputer; Emily Hsi (contractor) for graphical sketches; and Paul Conroy and George Keller (PFD) for interior ballistics input and funding, respectively. They would also like to thank Britt Overocker, Watervliet Arsenal, for his input on the gun manufacturing process.

* Note: The U.S. Army Ballistic Research Laboratory (BRL) was deactivated on 30 September 1992 and subsequently became a part of ARL on 1 October 1992.
1. INTRODUCTION

Outwardly, gun barrels appear axially symmetric. Yet, when a gun is fired, the barrel temperature rise is typically not axisymmetric. For instance, instead of the temperature rising uniformly at a given axial location, firing may elevate the barrel temperature more on the left side than on the right in one area, and more on the bottom than the top in another area, or vice versa. Any cross-barrel temperature difference (CBTD) will produce a cross-barrel thermal expansion difference that causes off-axis bending of the barrel during firing. This thermal bending/distortion decreases tank gun accuracy and is, therefore, a situation to be avoided. (The CBTD referred to here, $\Delta T_o$, is defined as the difference between the temperatures at the two intersection points on the outer wall of the barrel formed by a line in the transverse plane passing through the center of the bore. A similar CBTD for the inner wall, $\Delta T_i$, will be introduced later. The difference between the lengths of the two segments between inner and outer walls formed by this same line is called the "wall thickness variation." )

The terms "bore centerline" (or "centerline") and "centerline deviation" are now introduced. Consider an infinite set of planes intersecting the gun barrel so that the inner wall forms a circle in each plane. Then the locus of the centers of these circles is the three-dimensional centerline curve. When there is no bending of the gun tube, the centerline is straight, coinciding with the rotation axis of the machining tool. In a given longitudinal plane through the rotation axis, the centerline trace is a curve that deviates slightly from the rotation axis; the amount of displacement (normal to the rotation axis) is the centerline deviation.

The source of CBTD has long been a topic of discussion/speculation (Manaker and Croteau 1976; Bundy 1987a, 1987b). For example, in the case-study of Bundy (1987b), test results indicated a possible correlation between CBTD and the centerline deviation. (In a plane passing through the rotation axis, the temperature rise was generally greater on the same side of the rotation axis as the centerline deviation.) Apparent correlations and speculations aside, we shall show that wall thickness variation will indeed produce CBTD.

To predict the CBTD due to wall thickness variation during firing, we shall solve the time-dependent, two-dimensional (radial and circumferential) equations that govern heat transfer
into, through, and out the gun barrel by the method of finite differences. Primarily, results will be computed for a specific, but typical, production-line M256 120-mm gun barrel and for a service-acceptable, yet atypical, production-line barrel.

To provide some understanding of the origins of wall thickness variation, we shall briefly describe the gun barrel manufacturing process. It will become apparent that wall thickness variation and centerline deviation are related, to some degree, as a consequence of the manufacturing process. Thus, the apparent correlation noted by Bundy (1987b) between CBTD and centerline deviation may—more fundamentally—be a correlation between CBTD and wall thickness variation.

2. THE GUN BARREL MANUFACTURING PROCESS

Much effort has been devoted in the manufacturing process of large-caliber guns to minimizing lateral wall thickness variation. In general, circularity of the inner and outer surface is not the problem—circularity is. That is, wall thickness variation is caused primarily by the non-alignment of the axes of rotation of the inner and outer surfaces of revolution during their machining. It is conjectured that this comes about as follows.

After removal from the forge and heat treatment (to relieve residual forging stress), the barrel is ready to be "finished" (a multistep process to bring the rough forged barrel to its final design/drawing specifications). The inner surface is finished first, which means that it is bored, honed, swaged, and thermally treated to help relieve swaging stress, then bored again, and honed again. It has a relatively straight centerline before finishing work is begun on the outer surface. Initially, the axis of rotation for machining the outer surface is the same as the axis of the inner surface (i.e., the bore centerline, see Figure 1a). However, when metal is removed by turning down the outer surface, it relieves non-uniform residual swaging stress, which causes the barrel to "spring" or bend off-axis. Whenever and wherever this happens during machining, it misaligns the bore centerline from the rotational axis of the yet-to-be finished outer surface, and thus produces both lateral wall thickness variation and bore centerline deviation in the gun barrel. As illustrated in Figure 1b, the wall thickness variation will be twice the centerline deviation at—and only at—the place where material is being cut,
Figure 1. Schematic representation of outer-wall gun barrel machining, a) before and b)–d) after "springing" due to residual stress relief caused by removal of material from the outer wall.
since stress relief at a new cut site will change the centerline deviation everywhere along the barrel including previous cut sites (Figure 1c). Furthermore, it is common practice to attempt to mechanically straighten a gun barrel (with a hydraulic press) during or after machining. Nevertheless, we might expect that some residual correlation between centerline deviation and wall thickness variation will remain along the finished barrel, as illustrated in Figure 1d.

In Figures 2 and 3 we have plotted the centerline deviation and wall thickness variation along the bore for a typical production-line M256 gun tube, serial number 4251. Due to the limitations of the centerline measurement technique, the centerline deviation is plotted relative to the line joining its two end measurements. To be consistent, we have likewise plotted the wall thickness variation relative to its two end measurements. Clearly, centerline deviation and wall thickness variation are not correlated by the simple 2:1 ratio indicated in Figure 1b (where stress is relieved at only one location along the barrel), yet the two factors do tend to oppose each other in a fashion consistent with Figure 1d (where stress has been relieved at multiple locations). That is, the wall thickness variation is generally positive where the centerline deviation is negative (see Figures 2 and 3), which implies the thinner wall is on the same side of the axis of rotation as the centerline deviation.

Lastly, in the manufacturing process, the outer surface is ground slightly (while turning), followed by chrome plating of the inner surface. These finishing steps can also change the wall thickness variation and the centerline curvature, but the change is usually less than 25%.

For the M256 gun barrel, specifications (McDermott 1991) call for the wall thickness variation to be no more than 1.5 mm over most of the barrel (with the exception of the chamber area, which has closer tolerances). In actuality, however, most M256 barrels are manufactured, like serial number 4251 (Figures 2 and 3), with less than 0.5 mm wall thickness variation (Overocker 1991).

A wall thickness variation of 1.5 mm will correspond to less than 10% of the total wall thickness, depending on the location along the barrel. However, such a wall thickness variation will produce an equivalent variation in the temperature rise between one side and the
Figure 2. Centerline deviation and wall thickness variation (right side minus left) for an M256 barrel, serial number 4251.

Figure 3. Centerline deviation and wall thickness variation (top minus bottom) for an M256 barrel, serial number 4251.
other. For instance, if the nominal barrel temperature rise from firing a round is 10° C at a location where the wall thickness varies by 10% between one side and the other, then the CBTD will be approximately 1° C at this site. This CBTD will increase if the gun is fired rapidly. For reference, Bundy (1987b) showed that a 2° to 3° C change in the CBTD over a relatively short length of the barrel (<1 m) will produce a muzzle angle change of several tenths of a miliradian. We shall show that almost any "fast" rate of fire will yield a CBTD of several degrees if the wall thickness variation approaches the maximum allowed by current manufacturing guidelines.

3. THE HEATING MODEL

We shall compute the CBTD for multiple firings by employing an extension of the model used in Gerber and Bundy (1991). The following assumptions apply here:

(1) Temperature gradients in the longitudinal direction are neglected in comparison with those in the radial direction. (The longitudinal axis is taken to be a locally straight segment at the transverse plane under consideration.)

(2) Axisymmetric heat input is assumed, and gravity effects in the cooling process are neglected.

(3) Feedback of barrel heat to flow in the gun bore is neglected, so that the same bore temperature and convective heat transfer coefficient histories (for a single round) furnish the input data for every round calculated.

(4) Friction heating is neglected.

(5) Thermal expansion of the barrel is not considered to have an effect on the heat transfer process.

(6) The thermal conductivity, k, the specific heat, c_p, and the density, ρ, of the metal are constants (see Chapter 5).
(7) The offset distance \( E \) between the axes of the inner and outer walls is very small compared to the radii of the walls themselves. For example, in the extreme case for the M256 120-mm gun, the axes displacement would be less than 1 mm, while the inner radius of the barrel would be at least 60 mm.

4. FORMULATION OF THE PROBLEM

4.1 Statement of Problem. We state our problem in terms of cylindrical coordinates \( r, \phi, \) and \( z \). Figures 4a and 4b show the transverse plane viewed from the muzzle. The axial coordinate \( z \) is taken to be zero at the gun's breech (Figure 4c). The \( z \)-axis coincides with the centerline of the bore (i.e., the axis of the inner wall surface), which intersects the \( r, \phi \) plane at the origin, \( O \). (Note, the right-handed coordinate system that we have chosen is consistent with the reference system of most interior ballistics models. However, it differs from the so-called gunner's coordinate system, which chooses the positive \( x \)-axis to lie on the gunner's right, which is our negative \( x \)-axis.) The radii of the inner and outer walls, referenced to their individual axes of rotation, are \( R_i \) and \( R_o \), respectively. In our model we assume that the axis of the outer wall is displaced to the right of the axis of the inner wall by a distance \( E \) to simulate the imperfection of manufacture. The radius of the outer wall relative to the origin will be designated by \( r = r_o (\phi) \).

At a given axial location, \( z \), the gun barrel temperature, \( T(r,\phi,t) \), is determined by the following differential equation of heat conduction for a stationary, homogeneous, isotropic solid with no internal heat generation (Holman 1981, p.6):

\[
\frac{\partial^2 T}{\partial r^2} + \frac{1}{r} \frac{\partial T}{\partial r} + \frac{1}{r^2} \frac{\partial^2 T}{\partial \phi^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t},
\]

where \( t = \) time from the initiation of the first round. The constant \( \alpha = \kappa (\rho C_p) \) is the thermal diffusivity.

Let \( T_\infty \) designate the ambient temperature of the atmosphere (assumed to be constant). Then the initial condition is
Figure 4. Transverse cross section of a gun barrel of nonuniform thickness, viewed in a) and b) from the muzzle, and in c) from an oblique angle of the breech.
\[ T(r,\phi) = T_{\infty}, \quad t = 0, \quad R_i \leq r \leq r_o(t) \quad (z = \text{const}). \quad (2) \]

The boundary conditions at the inner and outer walls are obtained by Newton's law of cooling (see, e.g., Özisik [1968]). The axisymmetric boundary condition at the inner wall is

\[ k \frac{\partial T}{\partial r} - h_g T = -h_g T_g \quad r = R_i, \quad t > 0 \quad (z = \text{const}), \quad (3) \]

where \( T_g(t,z) \) is the cross-sectional average temperature of the flow in the bore, and \( h_g(t,z) \) is the coefficient of heat transfer between the gas-particle mixture in the bore and the inner wall of the barrel. \( T_g(t,z) \) and \( h_g(t,z) \) are known from interior ballistic computations and thus constitute input.

The outer wall boundary condition introduces azimuthal variation into the problem. The outer wall equation is

\[ r_o = [R_o^2 - \varepsilon^2 \sin^2 \phi]^{1/2} + \varepsilon \cos \phi. \]

We restate one of the basic assumptions,

\[ \varepsilon << R_i, R_o \quad (4) \]

and retain only terms through first order in \( \varepsilon \). Then for the outer wall,

\[ r_o = R_o + \varepsilon \cos \phi. \quad (5) \]

The boundary condition here, which includes both convective and radiative cooling (Özisik 1968, Equations 1–28 and 8–137c; Gerber and Bundy 1992, Equation 4), is

\[ -k \frac{\partial T}{\partial n} = h_w(T - T_{\infty}) + F_0(T^4 - T_{\infty}^4) \quad r = r_o, \quad t > 0 \quad (z = \text{const}), \quad (6) \]

where \( \partial T/\partial n \) is the component of grad \( T \) normal to the barrel surface, and \( h_w = h_w(z) \) is the coefficient of convective heat transfer between the barrel wall and the surrounding...
atmosphere. $F$ is the radiation interchange factor between the barrel outer wall and the environment (in our case, we assume $F = 0.95$), and $a$ is the Stefan-Boltzmann constant $[= 5.669 \times 10^{-8} \ J/(m^2 \ s \ K^4)]$.

A unit outward vector normal to the outer wall (correct through $O(\epsilon)$) is $U_n = [1, \epsilon(1/r) \sin \phi]$; then, $\partial T/\partial n = U_n \cdot \nabla T$ in Equation 6. On the line $r = R_o + \epsilon \cos \phi$, Equation 6 becomes

$$- k \left[ \frac{\partial T}{\partial r} + \left( \frac{\epsilon}{r^2} \right) \sin \phi \frac{\partial T}{\partial \phi} \right] = h_m (T - T_m) + F \sigma (T^4 - T_m^4)$$

(7)

Applying the expansion

$$F_n(r = R_o + \epsilon \cos \phi) = F_n(R_o) + (\partial F_n/\partial r)R_o \epsilon \cos \phi + O(\epsilon^2),$$

(where $F_n$ is any function of $r$) to Equation 7 leads to

$$- k \left[ \frac{\partial T}{\partial r} + \left( \frac{\epsilon}{r^2} \right) \sin \phi \frac{\partial T}{\partial \phi} \right] = h_m \left[ T - T_m + \epsilon \cos \phi \left( \frac{\partial T}{\partial r} \right) \right] + F_o \left[ T^4 - T_m^4 + 4 \epsilon \ T^3 (\partial T/\partial n) \cos \phi \right] + O(\epsilon^2) \quad \text{at } r = R_o.$$  

(8)

To retain linearity in the outer wall boundary condition, we apply the reasonable approximation that $|T^{m+1} - T^m| \ll T^m$ at $r = R_o$. Here the superscript $m + 1$ refers to the current time step of calculation, while $m$ denotes the immediately preceding time step when $T$ is known. Thus,

$$T^{m+1}_{N_i+1} = 4 \left( T^m_{N_i+1} \right)^3 T^{m+1}_{N_i+1} - 3 \left( T^m_{N_i+1} \right)^4,$$

which is linear in $T^{m+1}_{N_i+1}$. The subscript $N_i + 1$ denotes $r = R_o$. 

10
4.2 Special Form of Solution. When a solution of the form

\[ T = T_1(r,t) + \varepsilon \cos \phi T_3(r,t) \]  

is substituted into Equations 1, 2, 3, and 8, the 2-D problem is reduced to two one-dimensional (1-D) problems by collecting terms for each power of \( \varepsilon \cos \phi \). The statements of these two problems now follow:

\[ \frac{(1/\alpha)}{(1/\alpha)} \partial T_1/\partial t = \partial^2 T_1/\partial r^2 + (1/r) \partial T_1/\partial r \]  

(10a)

\[ T_1(r,t) = T_m \quad t = 0, \; R_i \leq r \leq R_o \]  

(10b)

\[ k \partial T_1/\partial r = h_g (T_1 - T_g) \quad r = R_i, \; t > 0 \]  

(10c)

\[ k \partial T_1/\partial r + [h_m + 4F\sigma (T_1)^3]T_1 = h_m T_m + F\sigma [T_m^4 + 3(T_1)^4] \quad r = R_o, \; t > 0 \]  

(10d)

and

\[ \frac{(1/\alpha)}{(1/\alpha)} \partial T_3/\partial t = \partial^2 T_3/\partial r^2 + (1/r) \partial T_3/\partial r - (1/r^2) T_3 \]  

(11a)

\[ T_3(r,t) = 0 \quad t = 0, \; R_i \leq r \leq R_o \]  

(11b)

\[ k \partial T_3/\partial r = h_g T_3 \quad r = R_i, \; t > 0 \]  

(11c)

\[ \partial T_3/\partial r + (h_m + 4F\sigma T_1^3) T_3/k = W(T_1) \quad r = R_o, \; t > 0 \]  

(11d)

where

\* The choice of \( T_3 \) instead of \( T_2 \) for the perturbation was made to maintain consistency with the nomenclature of the computer program.
\[
W(T_1) = -\partial^2 T_1 / \partial r^2 - (\frac{h_m}{\pi} + 4 Fo T_3)(\partial T_1 / \partial r) / k
\]

\[r = R_o, \ t = t^{m+1}. \quad (12)\]

The first problem is the axisymmetric problem previously solved (Gerber and Bundy 1991, 1992). The second problem is coupled to the first through the outer wall boundary condition (Equation 11d). The function \(W(T_1)\) is a known quantity at the time of solution, so that the two problems can be solved in tandem.

4.3 **Transformed Radial Coordinate.** We introduce a transformation, as in Gerber and Bundy (1991, 1992),

\[r = r(\xi) \quad (0 \leq \xi \leq 1), \quad (13)\]

so that the constant increment \(\Delta \xi\) will cluster the nodal points closely together near the inner wall, where \(T_1(r,t)\) gradients are largest, and spread them out away from there. We define the transformation in the following two steps:

\[
\zeta (\xi) = \gamma \xi + (1 - \gamma) \xi^\beta \quad (0 < \gamma \leq 1, \ \beta > 2), \quad r = D\zeta + R_i, \quad (14)
\]

where \(D = R_o - R_i\), and \(\gamma\) and \(\beta\) are chosen constants. We have used \(\gamma = 0.092, \ \beta = 2.25\). Note that \(r = R_i, R_o\) correspond to \(\xi = 0, 1\), respectively. The actual computations are then carried out in the \((\xi, \eta)\) space; a restatement of the problems in \(\xi\) and \(t\) is provided in Appendix A.

4.4 **Wall Temperatures.** The wall temperatures are of particular interest, especially that of the outer wall, which is the most easily measurable. At the inner wall,

\[
T_i = T(r = R_i) = T_1 (R_i, t) + \varepsilon \cos \phi \ T_3 (R_i, t). \quad (15)
\]

At the outer wall,

\[
T_o = T(r = R_o + \varepsilon \cos \phi) = T_1 (R_o, t) + \varepsilon \cos \phi \ [\partial T_1 / \partial r + T_3]_{r = R_o}. \quad (16)
\]

where \((\partial T_1 / \partial r)\) at \(r = R_o\) is given by Equation 10d (or Equation B-11a).
A diameter cutting across the gun barrel is properly described by the angles \( \phi' = \phi_1' \) and \( \phi' = \phi_2' + \pi \) (see Figure 4b). Since \( \phi = \phi' + O(\varepsilon) \) (Figure 4b), \( \phi \) may be replaced by \( \phi' \) in Equations 15 and 16 without changing the accuracy of the approximation.

Equation 9 indicates that the entire azimuthal variation of temperature is contained in the \( \cos \phi \) factor. Since \( T_3(r, \theta) < 0 \) in Figure 5, Equations 15 and 16 show that \( T_i \) and \( T_o \) vary from a maximum at \( \phi = \pi \) to a minimum at \( \phi = 0 \). The maximum changes in temperature across the diameters of the inner and outer walls are, respectively,

\[
\Delta T_i = T_i(\phi = \pi) - T_i(\phi = 0) = -2 \varepsilon T_3(R_i, t) \quad (17a)
\]

\[
\Delta T_o = T_o(\phi = \pi) - T_o(\phi = 0) = -2 \varepsilon [T_3 + \partial T_1 / \partial r]_{r=R_o} \quad (17b)
\]

Calculations indicate that generally \(|(\partial T_1 / \partial r) / T_3|_{R_o} \leq 0.005\), so that

\[
\Delta T_o \equiv -2 \varepsilon T_3(R_o, t) .
\]

Thus, at a given station, \( z \), for a particular round, the maximum CBTDs are proportional to \( \varepsilon \), to the order of our approximation.

5. INPUT DATA

A detailed discussion of the input to the computations is given in Gerber and Bundy (1991). Briefly, however, \( T_g \) is computed at chosen stations along the bore from the NOVA code (Gough 1980) and \( h_g \) is computed from the Veritay code (Chandra and Fisher 1989a, 1989b), which uses \( T_g \) and other NOVA variables to determine \( h_g \) by the method of Stratford and Beavers (1961).

* \( T_3 \) can actually become positive late in a long cooling cycle (see Chapter 7).
Figure 5. Single-round histories of $T_3$ at inner and outer walls at two axial stations.

Figures 6a and 6b show representative $T_g$ and $h_g$ histories at two stations on an M256 120-mm gun barrel. It is seen that $T_g$ and $h_g$ remain constant until the base of the projectile passes the given station at time $t = t_d$. At this time, these variables rise suddenly, then they decrease more gradually with $h_g$ decaying significantly faster than $T_g$.

All the computations reported here were performed for the case of an M256 120-mm tank gun firing a DM13 round.* However, the results are not expected to change significantly for other round types. The values of properties of the gun barrel metal are taken to be

\[ c_p = 469.05 \text{ J/(kg K)} \]

\[ k = 38.07 \text{ J/(m s K)} \]

\[ \rho = 7827.0 \text{ kg/m}^3 \].

* Table I of Gerber and Bundy (1991) describes the shape and size of the gun barrel.
Figure 6a. Bore gas temperature histories at two axial stations.

Figure 6b. Convective heat transfer coefficient histories at inner wall of gun barrel at two axial stations.
The diffusivity is thus

\[
\alpha = 1.03698 \times 10^{-5} \text{ m}^2/\text{s}.
\]

The ambient condition constants are

\[
T_\infty = 294.4 \text{ K (unless otherwise stated)}
\]

\[
h_\infty = 6.0 \text{ kg/(s}^3 \text{ K).}
\]

The above value of \(c_p\) was measured in 1990 by Joseph Cox, Benet Weapons Laboratory, for M256 gun barrel steel (assumed to be ASI 4340) at 295 K. The values for \(k\) and \(\rho\) were obtained from Talley (1989) for 4335 steel. The value for \(h\) was obtained from experiments conducted by Bundy on a shrouded M256 barrel.

6. FINITE-DIFFERENCE CALCULATION

For the finite-difference calculations, the interval \(0 \leq \xi \leq 1\) (corresponding to \(R_1 \leq r \leq R_2\)) is divided by equally spaced nodal (or grid) points into \(NI\) subintervals. The constant \(\xi\) increment is \(\Delta \xi = 1/NI\), and location of the nodes is given by \(\xi_j = (j - 1) \Delta \xi (j = 1, 2, ..., NI + 1)\). Derivatives at node \(j\) are approximated as follows (for \(H = T_1, T_2\)):

\[
(\partial H/\partial \xi)_j = (-3 H_j + 4 H_{j+1} - H_{j+2})/(2 \Delta \xi) \quad (j=1) \quad (18a)
\]

\[
(\partial H/\partial \xi)_j = (H_{j+1} - H_{j-1})/(2 \Delta \xi) \quad (j = 2, ..., NI) \quad (18b)
\]

\[
(\partial H/\partial \xi)_j = (H_{j-2} - 4 H_{j-1} + 3 H_j)/(2 \Delta \xi) \quad (j = NI + 1) \quad (18c)
\]

\[
(\partial^2 H/\partial \xi^2)_j = (H_{j-1} - 2 H_j + H_{j+1})/(\Delta \xi)^2 \quad (j = 2, ..., NI). \quad (18d)
\]
If we let the time increment be \( \Delta t = t^{m+1} - t^m \), then, in the Crank-Nicolson scheme employed here (Özisik 1968, p. 402) to obtain the solution at time \( t = t^{m+1} \),

\[
\begin{align*}
(1/2) \left[ (\partial H/\partial t)_m + (\partial H/\partial t)_{m+1} \right] &= (H^{m+1} - H^m) / \Delta t.
\end{align*}
\] (19)

The finite difference approximations to the equations and boundary conditions are produced by substituting the derivative approximations of Equations 18 and 19 into Equations A-4 and A-5, and then collecting terms. After some labor, one obtains the following two sets of linear equations for \( T_{1n}^{m+1} \) and \( T_{3n}^{m+1} \):

\[
\begin{align*}
\sum_{n=1}^{Nl-1} A_{jn} T_{1n}^{m+1} &= d_j \quad (j = 1, 2, \ldots, Nl+1) \quad (20) \\
\sum_{n=1}^{Nl+1} B_{jn} T_{3n}^{m+1} &= e_j \quad (j = 1, 2, \ldots, Nl+1). \quad (21)
\end{align*}
\]

The coefficients \( A_{jn}, B_{jn}, d_j, \) and \( e_j \) are given in Appendix B. The \( d_j \)'s and \( e_j \)'s involve \( T_1 \) and \( T_3 \) values calculated for the previous timestep \( t = t^m \). A standard FORTRAN routine is applied to solve Equations 20 and 21; in most cases, we have used \( Nl = 100 \).

There are essentially two time scales in the present problem: 1) the duration of the firing (roughly 100 ms) and 2) \( t_f \), the time between firings (usually 5 seconds or more when firing large guns). The \( \Delta t \) should be sufficiently small to resolve the phenomenon in case 1 but should be larger in case 2 to save time in computation. The program contains a subroutine prescribing \( \Delta t \) as a function of \( t \) within a firing cycle (see Appendix C).

The coefficients in the heat conduction equation and boundary conditions are known functions of \( t \). Thus, only a single iteration is required to obtain the solution to the finite-difference equations. The Crank-Nicolson method is stable for all values of \( \Delta t \), and there are no restrictions on the relative sizes of \( \Delta t \) and \( \Delta \xi \).
7. COMPUTATIONS

We apply our numerical simulation to an investigation of the nonaxisymmetric barrel temperature resulting from an imperfect alignment of inner and outer wall barrel axes in an M256 120-mm gun. Most of the CBTD plots that follow are shown for $\varepsilon = 1$ mm. The CBTD for any other displacement is readily obtained from these plots by multiplying the temperature difference values by $\varepsilon$ in millimeters, since $\Delta T_I$ and $\Delta T_o$ are both proportional to $\varepsilon$ (Equation 17).

First, we show results for a single round. Figure 7 presents unperturbed (axisymmetric) barrel temperature histories, $T_1$, while Figure 5 includes the variation of the perturbation function, $T_3$, at the same location. In both instances, the functions tend to approach constant values across the barrel in finite times, as evidenced by the coalescing of the curves for the inner and outer walls. The time for the radial equilibration of $T_1$ was referred to as the outer-wall rise time, $t_r$, in Gerber and Bundy (1991). For consistency, we shall continue to use this designation here. Furthermore, we shall refer to the radial equilibration time of $T_3$ as the rise time $t_{3r}$. There is no exact criterion for defining rise time; an estimate can be made on the basis of inspection of the curves. For the example shown in Figures 5 and 7, $t_{3r}$ is considerably larger than $t_r$. The $\cos \phi$ factors in Equations 15 and 16 prevent circumferential equilibration as long as $T_3$ is non-zero. In Figure 5, $T_3$ appears to approach zero with time.

Next, we consider constant rate-of-fire. The first example (at $z = 4.30$ m) deals with slow rate-of-fire (i.e., $t_r$ and $t_{3r} < t_f$, where $t_f$ is the time interval between successive rounds). Here $t_f = 60$ s, $t_r = 26$ s, and $t_{3r} = 45$ s. Rise times are essentially independent of number of rounds fired, but they depend on local barrel thickness. Figure 8 shows $T_1$, the symmetric part of $T$, at the inner and outer walls as functions of time. The upward-facing spikes for the inner wall represent the rapid rise in temperature produced at the time of firing; the succeeding rapid decline occurs when heat input stops and heat is conducted into the interior of the barrel. It is seen that $T_1 (R_0)$ lags behind $T_1 (R_I)$ in each cycle in the rise from its pre-firing value. This lag is a consequence of the time required for a significant effect of the thermal disturbance applied at the inner wall to reach the outer wall.
Figure 7. Single-round histories of unperturbed temperature, $T_1$, at three radial locations.

$T_{1\text{ (in)}} : r = 0.060 \text{ m}$

$T_{1\text{ (out)}} : r = 0.083 \text{ m}$

$t_f = 60 \text{ s}$

Figure 8. Axisymmetric temperature histories on inner and outer walls at $z = 4.30 \text{ m}$, slow rate-of-fire.
Figure 9 presents the ΔTᵢ and ΔTₒ histories for this same case. The inner and outer wall curves coincide roughly over the latter portion of each firing cycle because the firing interval is large enough so that radial equilibration is reached before the next round is fired. Except for the first round, when ΔTᵢ = ΔTₒ = 0 prior to firing, there is a downward-facing spike at the inner wall coinciding in time with the input of heat from the combustion. This is understandable; heat flux from the bore gas to the barrel is proportional to \((T_g - Tᵢ)\), and thus, more heat will be flowing into the thicker, cooler side, raising \(Tᵢ\) faster there than on the thinner, hotter side. This will decrease ΔTᵢ for an initial period of time. However, since the cooler side is thicker, the rise in \(Tᵢ\) will eventually be less on that side, thus accounting for the overall positive ΔTᵢ following the initial downward-facing spike.

For each round, the ΔTₒ will begin to rise after the heat pulse from the inner wall reaches the outer wall on the thinner side (located at \(x₄ = -Rₒ + ε\) in Figure 4). The effect of the wall thickness asymmetry is then propagated inward, and the time taken for the resulting perturbation to spread to the inner wall accounts for the lag in Figure 9 of the rise of ΔTᵢ behind that in ΔTₒ. \(Π(x₄)\) and \(Π(x₃)\) (Figure 4) reach maxima because the energy input is finite; ΔTₒ = Π(x₄) - Π(x₃) eventually peaks and then decreases as the barrel cools and CBTD equilibrates. At the inner wall, the heat perturbation due to the asymmetry is experienced at \(x₂\) sooner than at \(x₁\); ΔTᵢ = Π(x₂) - Π(x₁) varies in a manner similar to that of ΔTₒ, its amplitude in a firing cycle being less than or equal to ΔTₒ.

Figure 10 shows inner and outer wall maximum CBTDs at \(z = 4.30\) m for a fast rate-of-fire. Again, the downward-facing spikes occur on the ΔTᵢ curve. In this case, however, \(tᵢ < t₃\); thus, there is insufficient time during a round for the radial equilibration of \(T₃\) to be reached. The ΔTᵢ does not attain a maximum, and ΔTₒ always remains larger than ΔTᵢ.

Figure 11 shows the CBTDs at a different station, \(z = 2.78\) m, where the nominal wall thickness \(D = 0.050\) m, in contrast to \(D = 0.023\) m at \(z = 4.30\) m. Even though \(tᵢ = 60\) s here as in Figure 9, the \(t₃\) is large enough so that \(tᵢ < t₃\) and a fast rate-of-fire heating pattern results. Note that the CBTDs are much smaller at \(z = 2.78\) m than at \(z = 4.30\) m.

Next, we simulate an actual firing scenario (Table 1) in which there are fast and slow firing rates and cool-down periods. The gun is an M256 120-mm tank gun, serial number 4251, firing DM13 rounds. Note, this is the same gun barrel that was used earlier to illustrate
Figure 9. Histories of $\Delta T_i$ and $\Delta T_o$ at $z = 4.30$ m, slow rate-of-fire.

Figure 10. Histories of $\Delta T_i$ and $\Delta T_o$ at $z = 4.30$ m, fast rate-of-fire.
Figure 11. Histories of $\Delta T_r$ and $\Delta T_o$ at $z = 2.78$ m, fast rate-of-fire.

(Figures 2 and 3) wall thickness variation ($= 2\varepsilon$) and centerline deviation for a typical M256 barrel. Table 2 shows the variation of $\varepsilon$ (without regard to its angular orientation, $\varepsilon_x$ and $\varepsilon_y$) and barrel average thickness, $D = R_o - R_i$, along the gun. Figure 12 shows the inner and outer wall CBTDs computed, for example, at $z = 3.950$ m for the firing sequence of Table 1. For the fast- and slow-fire bursts, the curves resemble, qualitatively, corresponding plots shown in the previous figures. Radial equilibration ($\Delta T_r = \Delta T_o$) takes place early in the cooling cycles.

Figure 12. Histories of $\Delta T_f$ and $\Delta T_o$ at $z = 3.95$ m, firing scenario of Table 1, with cooling to environment.
A notable feature in Figure 12 is that $\Delta T_o$ becomes negative on two occasions ($t \approx 3,700 \text{ s}; 5,800 \text{ s}$). The physical implication here, recalling the definition of $\Delta T_o$ in Equation 17b, is that the thin side ($\pi/2 \leq \phi \leq 3\pi/2$) is originally hotter in a firing cycle than the thick side ($-\pi/2 \leq \phi \leq \pi/2$), but actually becomes cooler than the thick side later in the cycle. Basically, the reason that this happens is: at high temperatures, heat efflux from the barrel to the environment is higher than circumferential (equilibrating) heat flux within the barrel. Since the thin side has less thermal mass, its temperature drops faster from heat loss to the environment than on the thick side. Eventually, the temperature on the thin side is lower than that of the thick side, so that a reverse circumferential heat flow is required to bring about an even temperature distribution. If there were no heat loss to the surroundings, the latter phenomenon would not occur, and $\Delta T_o$ would not change sign, as is demonstrated in Figure 13.

Figure 13. Histories of $\Delta T_i$ and $\Delta T_o$ at $z = 3.95 \text{ m}$ for an adiabatic outer wall condition, firing scenario of Table 1.
Theoretical support for the above discussion on the sign change in $\Delta T_o$ can be drawn from an approximate analysis for cool-down that yields an analytical solution to the heat transfer problem. This model, which omits radiation cooling for simplification, is outlined in Appendix D. It estimates the time of crossover of $\Delta T_o$ when there is convective cooling to the environment. It also demonstrates the absence of an undershoot without convective cooling; thus, in Equation D-10, $t_u \to \infty$ as $h_\infty \to 0$.

8. CBTD DUE TO WALL THICKNESS VARIATION IN PRODUCTION LINE M1A1 GUN BARRELS

A wall thickness variation on the order of 2 mm ($\epsilon = 1$ mm) can create a substantial CBTD after repeated firings (e.g., Figure 9). However, most M256 gun barrels manufactured since the late 1980s have a wall thickness variation far below this value, as discussed in Chapter 2. This chapter investigates the CBTD that can be expected from 1) "today's" typical production-line M256 barrels, and 2) an atypical barrel that has the maximum allowable wall thickness variation.

To illustrate the typical case, we have again chosen gun tube serial number 4251, manufactured in September 1987, and described in Chapter 2 (Figures 2 and 3) and Chapter 7 (Table 2). The magnitude of the CBTD will increase with $\epsilon$ and decrease with $D$. One of the largest $\epsilon$'s and smallest $D$'s for this barrel occurs at $z = 4.45$ m, where $\epsilon = 0.1$ mm and $D = 22.65$ mm. To assess the greatest CBTD buildup that could be expected to occur at this location, we have chosen the worst-case firing scenario used in Gerber and Bundy (1992) and enumerated in Table 3. The firing sequence represents (approximately) the case where all rounds in the M1A1 tank are fired as fast as possible. Figure 14 shows the computed CBTD at this location for the firing scenario of Table 3. It can be seen that the maximum excursion in CBTD is less than 1.5° C. Such a small temperature change for this worst-case scenario indicates that thermal distortion due to wall thickness variation in this, or any similarly made, barrel will not be a serious problem.

On the other hand, if, on the rare occasion, a gun barrel is manufactured with the maximum allowable wall thickness variation of 1.5 mm ($\epsilon = 0.75$ mm) at this same location, then the CBTD for the firing scenario of Table 3 would be 7.5 times larger than that shown in
Table 3. Worst Case Firing Scenario

1. 17 rounds at 7 rounds/min
2. 5 minute cool-down
3. 17 rounds at 7 rounds/min
4. 5 minute cool-down
5. 7 rounds at 7 rounds/min
6. Cool-down

---

Figure 14. Worst case CBTD for M256 gun barrel, serial number 4251 (typical production line barrel).

Figure 14 (based on the fact that $\Delta T_o$ is proportional to $\varepsilon$ [Equation 17]). In this case, the CBTD would be greater than $10^6$ C, and according to our earlier discussion, the change in muzzle pointing angle would probably exceed 0.5 mrad, noticeably degrading gun accuracy.
In summary, the CBTD that arises during firing due to wall thickness variation is expected to be relatively small for most gun barrels manufactured today. However, the current tolerances would allow a gun barrel to be put into service that could develop a large CBTD during firing and hence, perform poorly from a thermal distortion/accuracy standpoint. Thus, consideration should be given to lowering the acceptable wall thickness variation to the same level that most barrels now have, viz., $\varepsilon \leq 0.25$ mm outside the chamber.

INTENTIONALLY LEFT BLANK.
APPENDIX A:

STATEMENT OF PROBLEMS IN $\xi$, $t$ VARIABLES
We repeat the transformation of Equation 14:

$$\zeta (\xi) = \gamma \xi + (1 - \gamma) \xi^\beta \quad (0 < \gamma \leq 1, \beta > 2) \quad r = D \zeta + R_1.$$  \hfill (A-1)

Then

$$\frac{d\zeta}{d\xi} = \zeta' = \gamma + \beta(1-\gamma)\xi^{\beta-1} \quad \frac{d^2\zeta}{d\xi^2} = \zeta'' = \beta(\beta-1)(1-\gamma)\xi^{\beta-2}$$

$$\zeta' (0) = \gamma, \quad \lambda_1 = \zeta' (1) = \gamma + \beta(1-\gamma)$$

$$\lambda_2 = \zeta'' (1) = \beta(\beta-1)(1-\gamma).$$  \hfill (A-2)

We define $f_1(\xi)$ and $f_2(\xi)$:

$$f_1 = 1/(\zeta')^2,$$  

$$f_2 = (D/\zeta')/(D\xi + R_1) - \zeta''/(\zeta')^3.$$  \hfill (A-3)

The transformed problem for $T_1$ is

$$\frac{\partial T_1}{\partial t} = (\alpha/D^2)[f_1(\xi) \frac{\partial^2 T_1}{\partial \xi^2} + f_2(\xi) \frac{\partial T_1}{\partial \xi}] = G(\xi, t).$$  \hfill (A-4a)

$$k \frac{\partial T_1}{\partial \xi} - D h_\gamma \gamma T_1 = -Dh_\gamma \gamma T_g \quad \xi = 0, t > 0.$$  \hfill (A-4b)

$$[k/(D\lambda_1)] \frac{\partial T_1}{\partial \xi} + [h_\omega + 4 Fa (T_1^m)^3] T_1 = h_\omega T_\omega + Fa[T_\omega^4 + 3 (T_1^m)^4]$$

$$\xi = 1, t > 0.$$  \hfill (A-4c)

33
The transformed problem for $T_3$ is

$$\frac{\partial T_3}{\partial t} = \frac{\alpha}{D} \left[ f_1 \frac{\partial^2 T_3}{\partial \xi^2} + f_2 \frac{\partial T_3}{\partial \xi} \right] - \frac{\alpha}{r^2} T_3,$$  \hspace{1cm} (A-5a)

$$[k/(D\gamma)] \frac{\partial T_3}{\partial \xi} - h_g T_3 = 0 \quad \xi = 0, \ t > 0, \hspace{1cm} (A-5b)$$

$$\frac{1}{\left(\frac{D\lambda_1}{k}\right)} \frac{\partial T_3}{\partial \xi} + \left(h_m + 4 F_o T_1^3\right) T_3 = W(T_1)$$

$$\xi = 1, \ t > 0, \hspace{1cm} (A-5c)$$

where $r$ is given in Equation A-1, $\lambda_1$ is given in Equation A-2. $T_g$ and $h_g$ are known functions of $t$. $W(T_1)$ is defined in Equation 12 and is evaluated in Equation B-11e.

The initial conditions are

$$T_1 = T_w \quad t = 0, \quad 0 \leq \xi \leq 1$$

$$T_3 = 0 \quad t = 0, \quad 0 \leq \xi \leq 1. \hspace{1cm} (A-6)$$
APPENDIX B:

COEFFICIENTS IN EQUATIONS 20 AND 21
The following functions of $\xi$ are defined in Equations A-1, A-2, and A-3: $\zeta, r, \zeta', \zeta'', f_1, f_2$. Also defined are $\gamma = \zeta'(0), \lambda_1 = \zeta'(1), \lambda_2 = \zeta''(1)$. The equations are solved for $t = t_{m+1}$; $t_{m}$ denotes the preceding time step, when all quantities are known.

Three additional functions of $\xi$ are as follows:

\[
\begin{align*}
\phi_1 &= (\alpha/D^2) \left[ f_1/(\Delta \xi)^2 - f_2/(2 \Delta \xi) \right], \\
\phi_2 &= -(2 \alpha/D^2) f_1/(\Delta \xi)^2, \\
\phi_3 &= (\alpha/D^2) \left[ f_1/(\Delta \xi)^2 + f_2/(2 \Delta \xi) \right].
\end{align*}
\]

(B-1)

The coefficients $A_j$ and $d_j$ in Equation 20 are now given:

\[
\begin{align*}
A_{11} &= 3 + 2 \Delta \xi \, D \, \gamma \, h \, g/k, \quad A_{12} = -4, \quad A_{13} = 1, \\
A_{Nt+1, Nt-1} &= 1, \quad A_{Nt+1, Nt} = -4, \\
A_{Nt+1, Nt+1} &= 3 + \left[ 2 \Delta \xi \, D \lambda_1 / k \right] \left[ h_{\infty} + 4 \sigma (T_{Nt+1}^m)^3 \right] \text{ at } t = R_0.
\end{align*}
\]

(B-3)

For $2 \leq j \leq Nt$,

\[
\begin{align*}
A_{j+1, j-1} &= - \left( \Delta t/2 \right) \phi_1(\xi_j), \quad \xi_j = (j-1) \Delta \xi, \\
A_{j+1, j} &= 1 - \left( \Delta t/2 \right) \phi_2(\xi_j), \quad A_{j+1, j+1} = - \left( \Delta t/2 \right) \phi_3(\xi_j).
\end{align*}
\]

(B-4)
All other coefficients $A_{jn}$ are equal to zero.

$$d_1 = 2 \Delta \xi D \gamma h_g T_g / k,$$

$$d_{Ni+1} = (2 \Delta \xi D \lambda_1 / k) \{ [h_m T_m + F \sigma \{ T_m^4 + 3 (T_{Ni+1}^{m+1})^4 \} ] \}. \quad (B-5)$$

For $2 \leq j \leq Ni$,

$$d_j = T_j^m + (\Delta t/2) G_j^m, \quad (B-6a)$$

where

$$G_j^m = g_1(\xi_j) T_{j-1}^m + g_2(\xi_j) T_j^m + g_3(\xi_j) T_{j+1}^m. \quad (B-6b)$$

Now the coefficients $B_{jn}$ and $e_j$ in Equation 21 are given:

$$B_{11} = A_{11}, \quad B_{12} = A_{12}, \quad B_{13} = A_{13}, \quad (B-7)$$

$$B_{Ni+1,Ni-1} = 1, \quad B_{Ni+1,Ni} = -4, \quad (B-8)$$

$$B_{Ni+1,Ni+1} = 3 + (2 \Delta \xi D \lambda_1 / k) \{ [h_m + 4 F \sigma (T_{Ni+1}^{m+1})^3 ] \}. \quad (B-8)$$

For $2 \leq j \leq Ni$,

$$B_{j,j-1} = A_{j,j-1}, \quad B_{j,j} = A_{j,j} + (\alpha \Delta t/2)/r_j^2, \quad B_{j,j+1} = A_{j,j+1}. \quad (B-9)$$

All other coefficients $B_{jn}$ are equal to zero.

$$e_1 = 0, \quad e_{Ni+1} = 2 D \lambda_1 \Delta \xi W (T_{Ni+1}^{m+1}), \quad (B-10)$$

38
where \( W(T_{1N+1}^{m+1}) \), defined in Equation 12, is approximated by the following sequence, evaluated at \( t = t^{m+1} \), where \( r \) and \( \xi \) subscripts denote partial differentiation:

\[
k T_{1r}(\xi = 1) = h_w T_w + F \sigma \left[ T_w^4 + 3 (T_{1N+1}^m)^4 \right] - \left[ h_w + 4 F \sigma (T_{1N+1}^m)^3 \right] T_{1N+1}^{m+1},
\]

(B-11a)

\[
T_{1\xi}(\xi = 1) = D \lambda T_{1r}(\xi = 1),
\]

(B-11b)

\[
T_{1xx}(1) = \left[ 1/(2(\Delta \xi)^2) \right] \left[ 8 T_{1Nl} - T_{1Nl-1} - 7 T_{1Nl+1} \right] + (3/\Delta \xi) T_{1x}(1),
\]

(B-11c)

\[
T_{1\eta}(1) = (1/D)^2 \left[ (1/\lambda^2) T_{1xx}(1) - (\lambda_2/\lambda^3) T_{1x}(1) \right],
\]

(B-11d)

\[
W(T_{1N+1}^{m+1}) = -T_{1\eta}(1) - \left[ h_w + 4 F \sigma (T_{1N+1}^m)^3 \right] T_{1r}(1) / k.
\]

(B-11e)

For \( 2 \leq j \leq Nl \),

\[
e_j = T_{3j}^m + (\Delta v_2) \bar{G}_{j}^m - (\Delta v_2) (\alpha r_j^2) T_{3j}^m,
\]

(B-12)

where

\[
\bar{G}_{j}^m = g_1(\xi_j) T_{3j}^m + g_2(\xi_j) T_{3j}^{m-1} + g_3(\xi_j) T_{3j}^{m-2}.
\]

(B-13)
INTENTIONALLY LEFT BLANK.
APPENDIX C:

TIME SCALE
Here, time = \( t' \) will refer to time within one firing cycle; \( t' = 0 \) at the beginning of the cycle.

Six constants are given: \( t_d, t_f, t'_{1}, t'_{2}, \Delta t'_{1}, \) and \( \Delta t'_{2} \). Here, \( t_d \) is the delay time for the rapid rise in \( T_g \) and \( h_g \) from initial conditions, and \( t_f \) is the time between successive firings. The time increment \( \Delta t (t') \) is given by the following function:

\[
\begin{align*}
\Delta t &= t_d - \Delta t'_{1} & 0 \leq t' \leq t_d - \Delta t'_{1} \\
\Delta t &= \Delta t'_{1} & t_d - \Delta t'_{1} \leq t' < t'_{1} \\
\Delta t &= C_1 + C_2 t' & t'_{1} \leq t' < t'_{2} \\
\Delta t &= \Delta t'_{2} & t'_{2} \leq t'.
\end{align*}
\]

where

\[ C_2 = (\Delta t'_{2} - \Delta t'_{1})/(t'_{2} - t'_{1}) \] and \( C_1 = \Delta t'_{2} - C_2 t'_{2} \)

(If \( t' + \Delta t'_{2} > t_f \), set \( \Delta t = t_f - t' \)).

A typical set of values of the parameters would be the following:

\[ t'_{1} = 0.018 \text{ s}, \quad t'_{2} = 10.0 \text{ s}, \quad \Delta t'_{1} = 0.00025 \text{ s}, \quad \Delta t'_{2} = 6.0 \text{ s}. \]
INTENTIONALLY LEFT BLANK.
APPENDIX D:

ANALYTICAL MODEL OF COOLING
INTENTIONALLY LEFT BLANK.
The coalescence of the inner and outer wall cooling curves in Figures 5, 7, and 12 suggest that temperature may be approximated at fixed z by the following expression after radial equilibration in $T_1$ and $T_3$ is attained:

$$T = \overline{T}_1(t) + (\epsilon \cos \phi) \overline{T}_3(t).$$

where $\overline{T}_1$ and $\overline{T}_3$ are $T_1$ and $T_3$ values for $t > t_r, t_3$ that are constant at this time. We consider a control volume of unit axial length and a quadrant cross-section bounded by:

1. $r = R_l$; 2. $r = r_o = R_o + \epsilon \cos \phi$; 3. $\phi = 0$; 4. $\phi = \pi/2$. We shall retain terms only through $O(\epsilon)$. In addition, we assume

$$T_g = T_m, \quad h_g = h_m.$$  \hspace{1cm} (D-2)

The rate of change of heat energy in the control volume is

$$\dot{H}_b = \int_0^{\pi/2} \int_{R_l}^{R_o + \epsilon \cos \phi} \rho c_p (dT/dt) r dr d\phi \quad \text{J/s.}$$

Heat flux through the inner wall is

$$\dot{H}_i = \int_0^{\pi/2} h_g (T_m - T) R_l d\phi \quad \text{J/s.} \quad \hspace{1cm} (D-4)$$

Heat flux through the outer wall, neglecting radiation, is

$$\dot{H}_o = \int_0^{\pi/2} h_m (T_m - T) (R_o + \epsilon \cos \phi) d\phi \quad \text{J/s.} \quad \hspace{1cm} (D-5)$$

There is no heat flow across $\phi = 0$ because of the physical symmetry in the problem. The heat flow rate across the plane $\phi = \pi/2$ is

$$\dot{H}_\phi = \int_{R_l}^{R_o + \epsilon \cos \phi} (k/r) (\partial T/\partial \phi)_\phi = \pi/2 dr \quad \text{J/s.} \quad \hspace{1cm} (D-6)$$
The energy balance equation is
\[ \dot{H}_b = \dot{H}_i + \dot{H}_o + \dot{H}_h . \] (D-7)

Equation D-1 is substituted into Equations D-3, D-4, D-5, and D-6. When these equations are substituted into Equation D-7, and coefficients of like powers of \( \varepsilon \) are collected, we obtain linear first-order ordinary differential equations for \( \bar{T}_1 \) and \( \bar{T}_3 \). The solution is
\[ \bar{T}_1 = T_\omega + [T_1(t_a) - T_\omega] \exp[-c_1(t - t_a)] . \] (D-8a)
\[ \bar{T}_3 = c_2 \exp[-c_1(t - t_a)] + [T_3(t_a) - c_2] \exp[-c_3(t - t_a)] , \] (D-8b)
where
\[ c_1 = 2 \frac{h_\omega}{[p c_p(R_o - R_i)]} , \] (D-9a)
\[ c_2 = (h_\omega/k)(R_o + R_i)[T_1(t_a) - T_\omega]/[(R_o - R_i) \ln(R_o/R_i)] , \] (D-9b)
\[ c_3 = c_1 + [2k \ln(R_o/R_i)]/[p c_p(R_o^2 - R_i^2)] . \] (D-9c)

The quantities \( T_1(t_a) \) and \( T_3(t_a) \) are finite-difference results for \( r = R_o \) at a time \( t = t_a (> t_r, t_{r3}) \), chosen so that \( T_3(t_a) < 0 \) (or \( \Delta T_o > 0 \)). The time of undershoot, \( t_u \), is found by setting \( \bar{T}_3 \) in Equation D-8b equal to zero:
\[ t_u = t_a + [p c_p(R_o^2 - R_i^2)/\{2k \ln(R_o/R_i)\}] \times \ln \left[ 1 - \frac{T_3(t_a)k}{h_\omega} \frac{(R_o - R_i) \ln(R_o/R_i)}{(R_o + R_i)(T_1(t_a) - T_\omega)} \right] . \] (D-10)
As an example, assume a scenario in which five rounds are fired 120 seconds apart before the final cooling starts. In this case, Equation D-8 would predict $\Delta T_o$ as shown in Figure D-1. The agreement between analytical and numerical solutions for $\Delta T_o (= -2\varepsilon T_3(R_o))$ is very good.

Figure D-1. **Comparison of $\Delta T_o$ cooling histories for analytical model and numerical output ($t_o = 1,000$ s).**

$z = 4.30$ m,  No radiat.
$\varepsilon = 0.0001$ m
INTENTIONALLY LEFT BLANK.
LIST OF SYMBOLS

A<sub>jn</sub>, B<sub>jn</sub> coefficients in linear equations for T<sub>1</sub> and T<sub>3</sub>, Equations 20 and 21

C<sub>p</sub> specific heat of gun barrel (Joules/[kg K])

c<sub>1</sub>, c<sub>2</sub>, c<sub>3</sub> constants defined in Equations D-9

CBTD cross-barrel temperature difference

d<sub>j</sub>, e<sub>j</sub> coefficients in linear equations for T<sub>1</sub> and T<sub>3</sub>, right-hand sides of Equations 20 and 21

D = R<sub>o</sub> - R<sub>i</sub> [m, mm]

f<sub>1</sub>, f<sub>2</sub> given functions of ξ, Equation A-3

F radiation interchange factor, Equation 6

G<sub>1</sub>, G<sub>2</sub>, G<sub>3</sub> functions of ξ, defined in Equation B-1

G(ξ, t) function of ξ and t, defined in Equations A-4a and B-6

Ḡ(ξ, t) function of ξ and t, defined in Equation B-13

h<sub>g</sub>(t, z) heat transfer coefficient - bore gas to gun barrel (Joules/[m<sup>2</sup> s K])

h<sub>wa</sub>(z) heat transfer coefficient - gun barrel to ambient air (Joules/[m<sup>2</sup> s K])

j subscript index indicating radial location of a nodal point

k thermal conductivity of gun barrel (Joules/[m s K])

m superscript index indicating time value

n arc length along line normal to the surface of the outer wall

N<sub>i</sub> number of intervals in R<sub>i</sub> ≤ r ≤ R<sub>o</sub> formed by the nodal points

r radial coordinate in transverse plane [m, mm] (r = 0 at axis of gun bore)

r' radial coordinate in transverse plane (r' = 0 at axis of outer wall)

r<sub>o</sub> = r<sub>0</sub>(ϕ) = radial coordinate of outer wall = R<sub>o</sub> + ε cos ϕ

R<sub>i</sub> radius of circular inner wall [m, mm]
\( R_o \) \hspace{1cm} \text{radius of circular outer wall [m, mm]}
\( t \) \hspace{1cm} \text{time from initiation of first round [s, ms, min]}
\( t_a \) \hspace{1cm} \text{initial time for analytical model, Equations D-8 [s]}
\( t_d \) \hspace{1cm} \text{delay time at given z for rapid rise in } T_g \text{ and } h_g \text{ [s, ms]}
\( t_f \) \hspace{1cm} \text{time interval between successive rounds}
\( t_r \) \hspace{1cm} \text{rise time for } T_1 \text{ [s, ms]}
\( t_{33} \) \hspace{1cm} \text{rise time for } T_3 \text{ [s, ms]}
\( t_u \) \hspace{1cm} \text{time at which } \Delta T_o \text{ changes sign, Equation D-10 [s]}
\( t' \) \hspace{1cm} \text{time measured within a firing cycle [s, ms]}
\( t_1', t_2' \) \hspace{1cm} \text{two prescribed time values in Timescale formula, Appendix C [s]}
\( T \) \hspace{1cm} \text{temperature in the gun barrel [K]}
\( T_g = T_g(t) \) \hspace{1cm} \text{temperature in the bore at a fixed z-value [K]}
\( T_{i}, T_{o} \) \hspace{1cm} \text{temperatures at inner and outer walls, respectively, of gun barrel [K], Equations 15 and 16}
\( T_1 \) \hspace{1cm} \text{axisymmetric contribution to barrel temperature, Equation 9 [K]}
\( T_3 \) \hspace{1cm} \text{function furnishing non-axisymmetric contribution to barrel temperature, Equation 9 [K/m]}
\( \overline{T}_{1}, \overline{T}_{3} \) \hspace{1cm} \text{analytical approximation to } T_1 \text{ and } T_3 \text{, respectively, Equation D-1}
\( T_{\infty}, T_{\text{inf}} \) \hspace{1cm} \text{temperature in ambient air [K]}
\( \mathbf{U}_n \) \hspace{1cm} \text{unit vector normal to the outer wall}
\( \mathcal{W}(T_1) \) \hspace{1cm} \text{function of } T_1 \text{ defined in Equation 12, evaluated in Appendix B}
\( z \) \hspace{1cm} \text{axial coordinate (} z = 0 \text{ at breech) [m]}
\( \alpha = k/(\rho c_p) \) \hspace{1cm} \text{thermal diffusivity of gun barrel [m}^2\text{/s]}
\( \beta, \gamma \) \hspace{1cm} \text{prescribed constants in transformation formula, Equation 14}
\( \Delta t \) \hspace{1cm} \text{time increment for calculation of temperature profile, Equation 19 [s]}

52
\( \Delta t_1', \Delta t_2' \)  
Two prescribed time increments in the Timescale formula, Appendix C [s]

\( \Delta T_1 \)  
Temperature difference between points \( x_2 \) and \( x_1 \) in Figure 1, see Equation 17a

\( \Delta T_0 \)  
Temperature difference between points \( x_4 \) and \( x_3 \) in Figure 1 see Equation 17b

\( \Delta \xi \)  
Constant increment in \( \xi \) in range \( 0 \leq \xi \leq 1; \Delta \xi = 1/N \)

\( \epsilon \)  
Distance between the centers of the inner and outer walls of a gun barrel [m]

\( \zeta \)  
Transformation variable, given in Equation 14, also Equation A-1

\( \lambda_1, \lambda_2 \)  
\( \zeta' (1), \zeta'' (1) \) - - constants defined in Equation A-2

\( \xi \)  
Transformed radial variable, Equations 13 and 14, also Equation A-1

\( \rho \)  
Density of gun barrel metal [kg/m³]

\( \sigma \)  
Stefan-Boltzmann constant = \( 5.669 \times 10^{-8} \) J/(m² s K⁴)

\( \phi \)  
Azimuthal coordinate in transverse plane

\( \phi' \)  
Azimuthal coordinate in transverse plane relative to origin at center of outer wall (Figure 1b)

USER EVALUATION SHEET/CHANGE OF ADDRESS

This Laboratory undertakes a continuing effort to improve the quality of the reports it publishes. Your comments/answers to the items/questions below will aid us in our efforts.

1. ARL Report Number ARL-TR-100 Date of Report March 1993

2. Date Report Received

3. Does this report satisfy a need? (Comment on purpose, related project, or other area of interest for which the report will be used.)

4. Specifically, how is the report being used? (Information source, design data, procedure, source of ideas, etc.)

5. Has the information in this report led to any quantitative savings as far as man-hours or dollars saved, operating costs avoided, or efficiencies achieved, etc? If so, please elaborate.

6. General Comments. What do you think should be changed to improve future reports? (Indicate changes to organization, technical content, format, etc.)
