19. ABSTRACT (Continue on reverse if necessary and identify by block number)

The Simulation Time History Computer Program, STH, has been developed at the Carderock Division of the Naval Surface Warfare Center to provide realistic, random wave time histories of the six-degree-of-freedom (6DOF) ship responses, i.e., surge, sway, heave, roll,pitch, and yaw. The 6DOF "origin" time histories are developed using transfer functions obtained from the Navy Standard Ship Motion Computer Program, SMP84. The random waves are simulated using a two-parameter Bretschneider wave spectral model. The random waves are represented as either undirectional (longcrested) or spread ± 90 degrees about a predominant direction (shortcrested).

A separate Access Time History Computer Program, ACTH, has been developed to provide additional displacements, velocities, and accelerations at various locations on the ship . Force time histories, which include gravity, are computed in the ship's body axis coordinate system. The ACTH program utilizes the origin time histories generated from the STH program. (continued)

ψ	Yaw angle
χ	Wave direction relative to predominant wave direction
ω	Wave frequency in radians per second
ω_E	Encountered wave frequency

ABSTRACT

The Simulation Time History Computer Program, STH, has been developed at the Carderock Division of the Naval Surface Warfare Center to provide realistic, random wave time histories of the six-degree-of-freedom (6DOF) ship responses, i.e., surge, sway, heave, roll, pitch, and yaw. The 6DOF "origin" time histories are developed using transfer functions obtained from the Navy Standard Ship Motion Computer Program, SMP84. The random waves are simulated using a two-parameter Bretschneider wave spectral model. The random waves are represented as either unidirectional (longcrested) or spread ± 90 degrees about a predominant direction (shortcrested).

A separate Access Time History Computer Program, ACTH, has also been developed to provide additional displacements, velocities, and accelerations at various locations on the ship. Force time histories, which include gravity, are computed in the ship's body axis coordinate system. The ACTH program utilizes the origin time histories generated from the STH program.

The computer programs, STH and ACTH, are written in FORTRAN 77. The response time histories are written from the ACTH program in binary format but can optionally be written instead in an ASCII format for ease in transferring between computers.

ADMINISTRATIVE INFORMATION

Funding for this project is authorized and provided by the Naval Sea Systems Command (NAVSEA) in FY88 under Work Request 10472, Project Element 63546N and in FY89 under Work Request 10447, Project Element 64270N, identified at the Carderock Division (CARDEROCKDIV) as Work Units 1561-810 and 1561-859, respectively. Additional funding to complete the documentation was provided by the Naval Research Laboratory (NRL) in FY92 under Work Request 20057, Project Element 62270N, identified at CARDEROCKDIV as Work Unit 1561-887.

INTRODUCTION

In 1981, CARDEROCKDIV* documented and released a frequency domain ship motion prediction program called the Navy Standard Ship Motion Program, SMP81.[1] This computer program, and the subsequently updated version, SMP84,[2] calculates the translational and angular ship statistical responses in irregular (random) seas.

* formerly the David Taylor Research Center (DTRC).

Although originally encompassed within the scope of the SMP developmental work, response time history generation has never been formally documented as a computer tool. In 1976, using the theory and equations from References 3 and 4, a longcrested, origin time domain data base was assembled for a set of destroyers and frigates. This data base, in turn, could be accessed and manipulated to obtain either longcrested or shortcrested response time histories via the Time History Access Program, THACP[5]. This report will provide the software and documentation for generating origin time histories and a new access program for utilizing them to obtain additional response time histories.

The need for a time domain versus a frequency domain methodology lies in the phase relationship between ship motions. Frequency domain analysis eliminates the phasing information while developing a universe of single amplitude, statistical answers for ship responses over a range of ship headings, ship speeds, and modal wave periods at specific wave heights. Frequency domain answers, such as those predicted in SMP84, are independent, earth-referenced, absolute or relative displacements, velocities, and accelerations at various locations on the ship.

On the other hand, time domain analysis retains the phasing of one motion with respect to another. Thus a data base of origin time histories can be operated upon at any point in time to obtain additional response time histories at various locations on the ship. It also allows for the translation from an earth-referenced system to a ship-referenced system whereby the forces on an object on the ship can be determined. This is required when evaluating forces, apparent in the ship's body axis coordinate system, due to the component of gravity contributed by angular displacements.

Applications for using time domain data are many and varied. For example, ship motion time histories can be

- o input to flight simulators for launch and recovery of aircraft on moving decks;
- o used for determining forces/effects on equipment, aircraft, munitions[6], or anything on or in the ship;

- o utilized for human factors considerations and the occurrence of Motion-Induced Interruptions (MII)[7];
- o helpful in developing/evaluating limitations on shipboard systems.

The remainder of this report is divided into four major sections:

Theoretical Background - a description of the theory used to develop ship response time histories in random waves. Expressions are provided to obtain responses at various locations on the ship. The transformation from earth coordinate system to ship coordinate system for forces is described.

Computer System - a description of the hardware and software used in the development/execution of the programs;

Simulation Time History Program, STH - a description of the program used to generate wave time histories and associated six-degree-of-freedom (origin) ship response time histories. Input and output for the STH program is discussed. An example of running the STH program is provided; and

Access Time History Program, ACTH - a description of the program used to compute ship response time histories at various locations on the ship from the data base of STH origin motion time histories. Input and output for the ACTH program is discussed. An example of running the ACTH program is provided.

This manual was written with the intention of providing simple, easy-to-use methods for generating ship response time histories in random seas. A necessary requirement is the availability of SMP84 Origin transfer functions for specific ships. Although time histories can be used for a wide range of purposes and each user's need may be different, careful reading and understanding of the illustrated examples is considered the fastest method for learning how to utilize the software tools.

THEORETICAL BACKGROUND

The theory necessary to develop ship response time histories in random seas is outlined in the following sections. These response time histories are generated using regular wave response transfer functions obtained from the Navy Standard Ship Motion Program, SMP.[1,2] A basic set of six response time histories is generated at the longitudinal center of gravity of the ship by the Simulation Time History Program, STH. This base set of time histories is then used to generate response time histories at other locations on the ship by the Access Time History Program, ACTH.

SHIP RESPONSES IN REGULAR WAVES

There are a basic set of six ship responses (surge, sway, heave, roll, pitch, and yaw) at the ship's longitudinal center of gravity (LCG) from which motions at all other locations on the ship can be developed. These responses are referred to as the six degrees of freedom (6DOF).

The strip theory of Salvesen, Tuck, and Faltinsen[8] is used to obtain the 6DOF responses for a ship advancing at constant forward speed with arbitrary heading in regular sinusoidal waves of unit amplitude. The theory of Reference 8 is implemented in the Navy Standard Ship Motion Computer Program SMP81[1] and the subsequently updated version, SMP84.[2]

The 6DOF responses are assumed to be small, linear, and harmonic with respect to a wave whose maximum elevation is located at the origin of the x,y,z coordinate system shown in Fig. 1. This right-handed coordinate system is moving at the constant mean forward speed with the origin lying in the undisturbed free surface and located at the LCG.

It should be noted that a ship advancing through regular waves responds to the wave frequency of encounter given by,

$$\omega_E = | \omega - (\omega^2 V/g) \cos(\mu) | \tag{1}$$

where V is the mean forward speed of the ship, μ is the heading angle, and ω is the wave frequency. The absolute value is taken to avoid using negative encounter frequencies. The definition of heading angle is shown in Fig. 2 for waves advancing from the starboard side of the ship.

Although the 6DOF ship responses are assumed to be linear, experiments with ship models in regular waves, as reported in Reference 6, show that the roll response exhibits nonlinear behavior with increasing wave amplitude. In addition, the experiments of Reference 9 show that the roll damping coefficient of the equations of motion at the natural roll frequency tend to be nonlinear with increasing roll angle. This nonlinear behavior of roll is treated in SMP[1,2] through modifications made to the roll damping coefficient which is assumed to be a function of mean roll angle. SMP computes the lateral responses (sway, roll, and yaw) for a set of eight mean roll angles, 0.5, 1, 2.5, 5, 10, 15, 25, and 40 degrees.

The 6DOF ship responses to regular sine waves are defined as ship origin transfer functions which vary with wave frequency, ship speed, ship heading relative to the waves, and, in the case of the lateral responses, mean roll angle. The SMP84 program outputs a file of the 6DOF origin transfer functions (amplitude and phase) with respect to regular waves called the Origin file. This file is used to provide a data base of transfer functions which are used in the generation of time histories of ship responses in random seas which is discussed in a latter section.

SHIP RESPONSES IN RANDOM SEAS

The SMP84 program principally predicts the translational and angular ship statistical responses in random (irregular) seas using calculations performed in the frequency domain. Two basic assumptions are used in making ship motion predictions in random seas[10], namely:

1. The random sea waves can be represented as a sum of simple sine waves whose amplitudes are obtained from specified wave spectral densities and whose phases are random with a uniform distribution; and

2. The responses of a ship to the random sea waves can be obtained as the sum of the ship responses to the individual sine waves that compose the random sea.

The instantaneous wave elevations of the random seas have a narrow-banded Gaussian distribution with zero mean. The wave single amplitudes (1/2 the peak to trough values) have a Rayleigh distribution.

The responses of the ship in random seas represent a linear tranformation applied to the Gaussian random waves. Thus the instantaneous ship responses are assumed to be Gaussian with zero mean and the ship response single amplitudes are assumed to have a Rayleigh distribution.

Table 1 provides a set of single amplitude Rayleigh statistical constants which can be applied to either a wave or ship response standard deviation to obtain estimates of various amplitudes such as the average of the one-third highest amplitudes (significant value), the highest expected amplitude in 200 cycles, etc.

The roll single amplitudes are assumed to have an underlying Rayleigh distribution which is modified by the nonlinear behavior of roll damping with increasing roll amplitude. SMP84 provides roll predictions in random seas for a user-specified Rayleigh statistic, such as significant single amplitude, see Table 1, and a specified significant wave height (average of the one-third highest wave double amplitudes). The user is referred to the SMP81 user's manual[1] for more details concerning the method used to obtain roll predictions in random seas.

SEAWAY DESCRIPTION

A two-parameter Bretschneider wave spectral model is used to define the frequency content of the random sea waves. The two parameters are, by definition, significant wave height, $(\zeta_W)_{1/3}$, and modal (peak) wave period, T_O. The wave spectral density, $S_\zeta(\omega)$, is defined as:

$$S_\zeta(\omega) = A\omega^{-5} \cdot \exp(-B\omega^{-4}) \qquad \text{in } m^2\cdot s \text{ or } ft^2\cdot s \quad , \qquad (2)$$

where,

$$A = 487.0626 \cdot (\zeta_W)_{1/3}/T_O \qquad \text{in } m^2\cdot s \text{ or } ft^2\cdot s \quad , \text{ and} \qquad (3)$$

$$B = 1948.2444/T_O^4 \qquad \text{in } s^{-4} \quad , \tag{4}$$

and ω is the wave frequency in radians per second.

It should be noted that the area under the spectrum is equal to the variance or mean square value of the waves. The square root of the variance is called the standard deviation. The significant wave height is defined as four times the standard deviation. The wave spectral shape is a function of the modal wave period. Examples of the wave spectra are shown in Fig. 3 for modal wave periods of 7, 11 and 21 seconds. Note that the same significant wave height value of 12 feet is used for each of the three wave spectra shown.

The distribution of wave spectral energy as a function of heading with respect to the ship is considered either to be unidirectional (longcrested) or spread ± 90 degrees about a predominant direction (shortcrested). The shortcrested wave spectral density, $S_\zeta(\omega,\nu)$, is defined as:

$$S_\zeta(\omega,\nu) = B^2(\nu-\mu) \cdot S_\zeta(\omega) \quad , \tag{5}$$

where $S_\zeta(\omega)$ is the longcrested wave spectral density defined in Eq. 2. The cosine-squared spreading function, B^2, used to spread the wave energy from longcrested to shortcrested seas, is defined as:

$$B^2(\nu-\mu) = (2/\pi) \cdot \cos^2 (\nu-\mu) \quad . \tag{6}$$

The heading μ in the case of shortcrested seas represents the predominant heading containing the principal amount of wave energy. The heading angle ν represents one of the component heading angles.

SMP84 uses a 15-degree heading increment to define ν. Thus, there are thirteen component headings, six on either side of the predominant heading angle. The cosine-squared spreading function for each of these component headings is:

$$B_k^2 = (2/\pi)\int_{X_k - dX/2}^{X_k + dX/2} \cos^2 (X_k)dX \quad , \tag{7}$$

where $X_k = \nu_k - \mu$ is the wave direction relative to the predominant direction. Thus,

$$B_k^2 = 1/6 \cos^2 (X_k) \quad , \tag{8}$$

where $X_k = k\pi/12$, $k = -6,6$.

An example of the shortcresting method is shown in Fig. 4 for an output predominant heading angle of 45 degrees. Note that the heading convention for computational work in SMP84, as defined in Fig. 2, defines 180 degrees to be head seas, 90 degrees as starboard beam seas, and zero degrees as following seas. The heading angles presented in the SMP84 output however differ from the internal computational heading angle by 180 degrees, i.e.,

$$\mu_{output} = 180 - \mu_{computational} \quad . \tag{9}$$

Thus, for output purposes, zero degrees represents head seas, 90 degrees represents starboard beam seas (unchanged), and 180 degrees represents following seas. This output heading convention was selected to bring consistency between program output and conventions employed by the ship and aircraft operator communities.

DEFINITION OF TIME HISTORIES

Time histories in random seas are defined as time series sampled at equal time intervals for a period of time sufficiently long to provide stable statistical results. Typically this time duration is 15 minutes or longer. These time histories contain approximately 100 cycles which have varying amplitudes and periods. The amplitudes follow a Rayleigh distribution.

Wave Time Histories at the Origin

Time histories of encountered waves located at the origin of the fixed earth coordinate system which is moving at constant mean forward speed are computed for either longcrested or shortcrested seas using the method of Zarnick[3].

The longcrested (unidirectional) wave time history, $\zeta_{LC}(t)$, is defined as:

$$\zeta_{LC}(t) = \sum_{k=1}^{N} \{ (\zeta_k) \cos (\omega_{Ek} t + \gamma_k) \} \quad , \qquad (10)$$

where ω_{Ek} is the encountered wave frequency defined in Eq. 1 for wave frequency ω_k and γ_k is a random phase angle with uniform distribution at wave frequency ω_k.

The wave amplitude, ζ_k, at wave frequency ω_k is defined as

$$\zeta_k = [2 \int_{\omega_k - d\omega/2}^{\omega_k + d\omega/2} S_\zeta(\omega) d\omega]^{1/2} \quad , \qquad (11)$$

where $S_\zeta(\omega)$ is the wave spectral density defined in Eq. 2.

The number of frequencies, N, used to compute the wave time history should be large in order to obtain an representative Rayleigh distribution of single amplitudes. The value of N used in the Simulation Time History Program, STH, is 150.

The range of wave frequencies is determined in SMP84 when the origin transfer function file is generated. The frequency increment used to generate the wave time history is:

$$d\omega = (\omega_{max} - \omega_{min})/(N-1) \quad , \qquad (12)$$

where ω_{max} and ω_{min} are the maximum and minimum wave frequencies used in SMP84 for a particular ship. SMP84 uses different values for ω_{max} depending on the ship's roll period.

For most headings and ship speeds, the encounter frequencies computed by Eq. 1 and used in Eq. 10 are incommensurate. This is an important requirement which prevents the longcrested time histories from repeating after a period of time. This requirement is violated in beam seas or for a ship speed of zero knots. For this situation, the wave frequencies are adjusted slightly using a random frequency increment to guarantee that they are incommensurate as:

$$\omega_k = \omega_k - (d\omega/2) \cdot (1 - 2 \cdot RAND_k) \tag{13}$$

where $RAND_k$ is a random number selected at frequency ω_k with a value between 0 and 1 and which has a uniform distribution.

The shortcrested sea condition spreads the wave directions ± 90 degrees from a predominant wave direction relative to the ship. The shortcrested wave time history, $\zeta_{SC}(t)$, is defined as:

$$\zeta_{SC}(t) = \sum_{j=1}^{M} \sum_{k=1}^{N} \{ (b_j \cdot \zeta_k) \cos (\omega_{Ek} t + \gamma_{jk}) \} \quad , \tag{14}$$

where b_j is a factor for angular spreading of the wave energy (assumed independent of wave frequency). A cosine-squared function is used to spread the wave energy from longcrested to shortcrested seas, i.e.,

$$b_j = \{ (2/\pi) \int_{X_j - d\ /2}^{X_j + dX/2} \cos^2 (X_j) dX \}^{1/2} \quad , \tag{15}$$

where X_j is the wave direction relative to the predominant direction.

Origin Motion Time Histories

Time histories of ship responses to longcrested seas, $r_{LC}(t)$, are defined as:

$$r_{LC}(t) = \sum_{k}^{N} \{ (R_{Ak} \cdot \zeta_k) \cos (\omega_{Ek}t + \gamma_k + \epsilon_{Pk}) \} \quad , \tag{16}$$

where R_{Ak} is the amplitude of the ship response transfer function at the wave frequency of encounter, ω_{Ek}. The phase angles ϵ_{Pk} refer to the phase of the ship response with respect to the maximum elevation at the origin of the x,y,z coordinate system shown in Fig. 1.

Note that velocities and accelerations of the ship responses computed in the ACTH program are obtained by digital differentiation in the time domain.

Motions at a Point Time Histories

The translational displacement time histories of any point on the ship (x^*, y^*, z^*) are obtained as

$$EL_O(t) = x(t) - y^* \sin \psi(t) + z^* \sin \theta(t) + x^* [\cos \psi(t) + \cos \theta(t) - 2] \quad , \tag{17}$$

$$EL_A(t) = y(t) - z^* \sin \phi(t) + x^* \sin \psi(t) + y^* [\cos \phi(t) + \cos \psi(t) - 2] \quad , \tag{18}$$

$$EL_V(t) = z(t) - x^* \sin \theta(t) + y^* \sin \phi(t) + z^* [\cos \theta(t) + \cos \phi(t) - 2] \quad , \tag{19}$$

where EL_O, EL_A, and EL_V are the ship displacements in the longitudinal, lateral, and vertical directions, and x, y, z, ϕ, θ, and ψ are surge, sway, heave, roll, pitch, and yaw, respectively.

Wave Time Histories at a Point

Time histories of encountered waves at any point on the ship

(x^*, y^*) in longcrested seas are obtained as:

$$\zeta^*_{LC}(t) = \sum_{k=1}^{N} \{ \zeta_k \cos [\omega_{Ek} t - K(x^* \cos \mu + y^* \sin \mu) + \gamma_k] \} , \qquad (20)$$

where K is the wave number defined as $K = \omega^2/g$, and μ is the computational heading angle.

Encountered wave time histories at point (x^*, y^*) in shortcrested seas are obtained as:

$$\zeta^*_{SC}(t) = \sum_{j=1}^{M} \sum_{k=1}^{N} \{ (b_j \cdot \zeta_k) \cos [\omega_{Ejk} t - K(x^* \cos \mu_j + y^* \sin \mu_j) + \gamma_{jk}] \} . \qquad (21)$$

Relative Motion Time Histories

The relative motion of any point on the ship (x^*, y^*) is represented by:

$$RM(t) = EL_V(t) - \zeta^*(t) , \qquad (22)$$

where EL_V is the absolute vertical displacement and ζ^* is the undisturbed wave elevation at that point.

Ship System Force Time Histories

There are two types of forces applied to a body at any point (x^*, y^*, z^*) on the ship. The first type consists of the inertia forces due to the accelerations of the ship and the second type is due to the acceleration of gravity. No friction forces or wind drag forces are computed in the Access Time History Program, ACTH.

The forces per unit mass in the fixed earth coordinate system are defined as

$$FL_O(t) = -EL_{\ddot{O}}(t) \quad , \tag{23}$$
$$FL_A(t) = -EL_{\ddot{A}}(t) \quad , \tag{24}$$
$$FL_V(t) = -EL_{\ddot{V}}(t) - 1 \quad , \tag{25}$$

where $EL_{\ddot{O}}$, $EL_{\ddot{A}}$, and $EL_{\ddot{V}}$ are the earth system accelerations in the longitudinal, lateral, and vertical directions, and 1 represents the acceleration due to gravity (i.e., 1g). Note that the inertia forces are the negative of the ship accelerations.

The forces are more appropriately applied in the ship coordinate system where the longitudinal and lateral forces are parallel to the deck and the vertical force is normal to the deck. The ship system force time histories are obtained from the fixed Earth axis forces using an angular rotation matrix as:

$$\begin{bmatrix} SL_O(t) \\ SL_A(t) \\ SL_V(t) \end{bmatrix} = \begin{bmatrix} M_{11}(t) & M_{12}(t) & M_{13}(t) \\ M_{21}(t) & M_{22}(t) & M_{23}(t) \\ M_{31}(t) & M_{32}(t) & M_{33}(t) \end{bmatrix} \cdot \begin{bmatrix} FL_O(t) \\ FL_A(t) \\ FL_V(t) \end{bmatrix} \quad , \tag{26}$$

where SL_O and SL_A are the ship system forces in the longitudinal and lateral directions parallel to the deck, and SL_V is the ship system force normal to the deck. The angular rotation matrix elements M_{ij} are defined as:

$$M_{11}(t) = \cos\theta(t)\cos\psi(t) \quad , \tag{27}$$
$$M_{12}(t) = \cos\theta(t)\sin\psi(t) \quad , \tag{28}$$
$$M_{13}(t) = -\sin\theta(t) \quad , \tag{29}$$
$$M_{21}(t) = -\cos\phi(t)\sin\psi(t) + \sin\phi(t)\sin\theta(t)\cos\psi(t) \quad , \tag{30}$$
$$M_{22}(t) = \cos\phi(t)\cos\psi(t) + \sin\phi(t)\sin\theta(t)\sin\psi(t) \quad , \tag{31}$$
$$M_{23}(t) = \sin\phi(t)\cos\theta(t) \quad , \tag{32}$$
$$M_{31}(t) = \sin\phi(t)\sin\psi(t) + \cos\phi(t)\sin\theta(t)\cos\psi(t) \quad , \tag{33}$$
$$M_{32}(t) = -\sin\phi(t)\cos\psi(t) + \cos\phi(t)\sin\theta(t)\sin\psi(t) \quad , \tag{34}$$
$$M_{33}(t) = \cos\phi(t)\cos\theta(t) \quad , \tag{35}$$

where the rotation is in the order of first yaw, then pitch, and finally roll.

COMPUTER SYSTEM

The Simulation Time History Program, STH, and the Access Time History Computer Program, ACTH, were developed on a COMPAQ 386 Personal Computer (PC) running at a machine clock speed of 20 MHz. This computer is compatible with the IBM Personal Computers. The operating system used was Microsoft Disk Operating System (MS-DOS), Version 3.31.[11] The computer had an INTEL 80387 co-processor installed to provide increased speed for floating point calculations.

Both the STH and ACTH programs were written in FORTRAN 77 using the Lahey Fortran Compiler.[12] The only special compiler option used was to make integer and logical variables four bytes each. The IBM Link program provided with the MS-DOS operating system was used to link the compiled versions of the STH and ACTH programs to obtain executable program files.

The STH and ACTH programs use a large number of files when they are executed. Fortunately, MS-DOS supports the use of directories, paths, and file names and extensions which allow the user to organize these files in a meaningful way. Generally, PC's are purchased with hard disks having a minimum capacity of 21 Mbytes. The MS-DOS operating system allows you to easily divide a hard disk into subsections called directories. Each directory is given its own unique name by the user. A path is defined as the series of commands and directions to the particular section of the disk or directory where a particular set of files is stored. Each file can have a name containing up to eight characters and an extension containing up to three characters.

The organization of directories and files used to develop the STH and ACTH programs is shown in Fig. 5. Files in this figure are denoted by extensions (e.g., .EXE) while directories and subdirectories carry no extensions. Details concerning the specific files used by the STH and ACTH programs are discussed in the latter sections of this report which describe these programs.

The hard disk on the COMPAQ 386 where these programs were developed had a 42-Mbyte capacity which was divided into two parts called volumes or drives in MS-DOS, each with a 21-Mbyte capacity. Each volume has its own drive letter where C is the drive letter for the first 21-Mbyte section and D is the drive letter for the second 21-Mbyte section. The first directory on a drive is called the ROOT directory. All other directories on the drive are called subdirectories. Note that subdirectories may also contain their own subdirectories. Refer to the COMPAQ MS-DOS Reference Guide[11] to obtain further information about directories and file naming conventions.

SIMULATION TIME HISTORY PROGRAM, STH

The Simulation Time History Program, STH, was developed to provide a data base of six-degrees-of-freedom (6DOF) ship response time histories (surge, sway, heave, roll, pitch, and yaw) in longcrested and shortcrested random seas. The STH program uses a file of 6DOF origin transfer functions output from the Navy Standard Ship Motion Program, SMP84, to generate the 6DOF ship response time histories. This 6DOF time history data base is then used by the Access Time History Program, ACTH, which is described in a later section of this report, to generate time histories for additional ship responses at various user-specified locations on the ship. The STH program takes a long time to execute, approximately 43 minutes for a 20-minute simulation run done at 3 samples per second. By contrast, the ACTH program executes very quickly, approximately 22 seconds to use the same 20-minute STH run to generate additional time histories.

In order to run the STH program you will need to set up various directories on your hard disk(s) to contain the executable program file, input files, and output time history files for the STH program. An example of this setup is shown in Fig. 5. The STH executable file, identified by the "EXE" extension, and input file, identified by the "INP" extension, are contained in the STH directory on the C drive. The STH output files, identified by the "DAT" and "TEX" extensions, are located on the D drive in a subdirectory called "SODD965A" under a directory called "STHDATA". The example ship name used for running the STH program is the "DD965" which is part of the subdirectory name. The letters "SO" in the subdirectory name are fixed and are shorthand for "simulation time history at the origin". The letter "A" following the ship name identifies a hull variant. A summary of files used by the STH program is provided in Table 2.

SMP84 will output different origin transfer functions depending on whether a ship is untrimmed, trimmed, has a different appendage suite, uses passive fins or active fin stabilization, etc. These variations of the same ship are called hull variants and are assigned different variant letters, A, B, C, etc. The SMP84 origin transfer function file for variant A of the DD965 ship, identified by the "ORG" extension, is located on the D drive in a subdirectory called "DD965" under a directory called "SMPDATA".

Both the STH and ACTH programs were designed to run in a BATCH mode. The information required to run each program is contained in a text file with an "INP" extension in the STH directory which the user edits using a screen editor (not provided) prior to running the programs. Both progams can then generate a number of origin or response time histories during one execution and thus may be left to run overnight. There are commercially available programs for PCs that allow multi-tasking which would allow the STH and ACTH programs to run in the background during the day. Note that the ACTH program requires origin time histories previously generated by the STH program.

STH INPUT DESCRIPTION

The input required to run the STH program is contained in a text (ASCII) file called STH.INP in the STH directory. There are 10 sets of information, called Data Sets, contained in this file. Each data set may contain one or more lines of information. The method used to describe each data set is to list each line, its FORTRAN format, and the variable(s) contained on it. A summary of the 10 STH data sets is provided in Table 3. An example of the STH.INP file is provided in Table 4. Note that comments may be added to the STH.INP input file after Data Set 10 to provide assistance in identifying the information on each data set when making changes.

Data Set 1, SMP Data Path

One Line - Format (A)

(1) SMPDATAS, alphanumeric, columns 1-80, path indicating where the SMP84 origin transfer function file can be found.

Data Set 2, STH Data Path

One Line - Format (A)

(1) STHDATAS, alphanumeric, columns 1-80, path indicating where the origin time history files output from the STH program will be saved.

Data Set 3, Ship Type

One Line - Format (A)

(1) SHIPTYPS, alphanumeric, columns 1-8, identifies ship type.

A convention used when running SMP84 is to identify each ship by its type. This name is used as a directory name where the SMP84 input files for ships of this type are stored.

Data Set 4, Ship Name

One Line - Format (A)

(1) SHIPS, alphanumeric, columns 1-5, identifies ship name.

Data Set 5, Hull Variant

One Line - Format (A)

(1) VARIANTS, alphanumeric, column 1, identifies hull variant.

The hull variant is used to distinguish between different SMP84 origin transfer function files which may have been generated for the same ship. For example the ship may have been run in SMP84 for different displacements, trims, appendage suites, or passive/active fin stabilizers.

Data Set 6, Cycle No

One Line - Format (A)

(1) CYCLES, alphanumeric, columns 1-2, cycle number.

A cyle number is assigned to the SMP84 input and text output files when SMP84 is run for a given ship. This cycle number is not assigned however to SMP84 data files, specifically the origin transfer function file.

Data Set 7, Units

One Line - Format (A)

(1) SUNITS, alphanumeric, columns 1-6, the desired displacement time history engineering units (feet or meters).

SMP84 can be run for a given ship using either feet or meters. The user can specify the engineering units to be used for the STH origin time histories which will overide the units used in the SMP84 run. Only the displacement motions, surge, sway, and heave, are affected by the selection of different units. Note that the units identified in this data set apply to the information contained in the succeeding data sets for the STH program as well as the data sets for the ACTH program.

Data Set 8, Title

One Line - Format (A)

(1) TRIALS, alphanumeric, columns 1-40, the ship title.

Data Set 9, Wave Point Input

First Line - FORMAT (A)

No variables, blank line used for spacing.

Second Line - Format (18X,I5)

(1) NWPOINT, integer, columns 19-23, number of wave points.

NWPOINT is set to zero if you do not want to compute relative motion time histories in the ACTH program. Note, however, that if relative motion is desired at a later date, the user must rerun the STH program and include the wave points where the relative motion is to be computed. Lines 3-5 are always included even if NWPOINT=0.

Third Line - FORMAT (A)

No variables, blank line used for spacing.

Fourth Line - FORMAT (A)

No variables, comment used to identify wave point table.

Fifth Line - FORMAT (A)

No variables, comment identifies columns for wave point table.

NOTE: The next line is included only if NWPOINT > 0. There is one line for each wave point.

Sixth Line - Format (I4,3F8.1,3X,A20)

(1) IWPNT, integer, columns 1-4, wave point number.

(2) WPNTXLOC, floating point, columns 5-12, x-coordinate of wave point (station number, where 0=Forward Perpendicular).

(3) WPNTYLOC, floating point, columns 13-20, y-coordinate of wave point (positive to port from centerline).

(4) WPNTZLOC, floating point, columns 21-28, z-coordinate of wave point (positive up from baseline).

(5) WPTNAMES, alphanumeric, columns 29-48, the name of the wave point.

The reference system used to input locations on the ship in the STH and ACTH programs is shown in Fig. 6. This input reference system is identical to the input system used in the Navy Standard Ship Motion program, SMP81.[1]

Data Set 10, Run Input

First Line - FORMAT (A)

No variables, blank line used for spacing.

Second Line - Free Format

(1) NRUNS, integer, number of STH runs

NOTE: The next line is repeated for each STH run.

Third Line - Free Format (variables separated by commas)

(1) RUNNUMBER, integer, the run number.

(2) SAMPLERATE, floating point, number of samples per second.

(3) TSTART, floating point, start time in seconds.

(4) TEND, floating point, stop time in seconds.

(5) SPEED, floating point, ship speed in knots.

(6) HEAD, floating point, SMP output heading in degrees. (0°=head seas, 90°=beam seas, 180°=following seas)

(7) SIGWH, floating point, significant wave height in feet or meters.

(8) TMODAL, floating point, modal wave period in seconds.

(9) STATIS, floating point, statistic used for roll iteration in irregular seas. For example, the statistic used for the significant roll single amplitude is 2 (twice the standard deviation for roll).

(10) SEATYPES, alphanumeric, seaway type. The seaway type is identified as LC (longcrested seas) or SC (shortcrested seas). The seaway type can be enclosed in double quotes but it is not necessary.

The selection of sample rate affects the resolution of the STH time histories as well as the amount of computer time required to run the STH program. For the majority of runs it is recommended that a sample rate of 2 samples per second be used. However, for high speeds in bow to head seas, encounter periods as low as one second or less may be computed which will require increasing the sample rate to 3 samples per second to avoid frequency aliasing.

STH OUTPUT DESCRIPTION

Information describing each STH run is displayed on the computer's screen. This information consists of:

1. STH program identification;
2. Date and time;
3. Ship identification and particulars, which include desired engineering units (feet or meters), gravity, ship length, longitudinal center of gravity, LCG, (referenced from the Forward Perpendicular), and the distance from the ship baseline to the waterline;
4. STH run identification which includes run number, comment, and sample rate. The run conditions are identified, which include ship speed, heading, seaway type (longcrested or shortcrested), significant wave height, modal wave period,

the statistic used for roll iteration, and the number of channels;

5. Listing of wave point locations (required for relative motion calculations in the ACTH program);
6. Listing of first 20 seconds of wave height at the LCG and the six degree of freedom responses (surge, sway, heave, roll, pitch, and yaw); [Note that the time histories for wave height at wave point locations are computed (optionally) but not shown on the screen. The screen is then blanked out until the run finishes]
7. Listing of the statistical results obtained from the time histories for wave height (LCG), the 6DOF responses, and wave heights at wave point locations; [These statistics include the mean, standard deviation, maximum and minimum values for each channel. The frequency domain predictions for the standard deviation for each channel are provided in the last column.]
8. The elapsed computer time for the particular STH run.

The information displayed on the screen is saved in a text (ASCII) file for each run. This file is called SRN.TEX where N is the run number. The SRN.TEX file is stored in a ship subdirectory under the STHDATA directory, e.g., D:\STHDATA\SODD965A. An example of this file for STH run number 3 is shown in Table 5.

The STH time histories are written to a standard FORTRAN sequential binary data file called SRN.DAT which is stored in the same subdirectory as the SRN.TEX file. The first record in this file contains two integer variables, the total number of samples and the number of channels. The remaining records, one for each sample, contain the time histories for all the channels in the desired engineering units.

A separate text file called STHLOG.TEX is updated for each run. This file contains a summary of the STH runs that have been made. The summary consists of a separate line for each run that contains the run number, data format type (binary), simulation run time in minutes, DATE-TIME-GROUP (day, hour, minute, L(local), month, and year), and the run comment. The run comment shows the seaway type, ship speed, heading angle, significant wave height, and modal wave period. An example of the STHLOG.TEX file is shown in Table 6. The STHLOG.TEX file is stored in the same subdirectory as the SRN.TEX and SRN.DAT files.

ACCESS TIME HISTORY PROGRAM, ACTH

The ACTH program uses (origin) time histories generated by the STH program to generate response time histories for a given ship at various locations on the ship. The STH time histories for various ships are located in ship subdirectories under the STHDATA directory. The ACTH program uses the STH data path described above to locate the STH time histories. For example, the STH data path shown in Fig. 5 is D:\STHDATA\SODD965A where D is the drive letter, STHDATA is the STH data directory, and SODD965A is the ship subdirectory for the DD965 ship.

The ACTH response time histories for various ships are located in ship subdirectories under the ACTHDATA directory. For example, the ACTH data path shown in Fig. 5 is D:\ACTHDATA\SPDD965A where the letters SP are the abbreviation for simulation response time histories at various locations on the ship. A summary of files used by the ACTH program is provided in Table 7.

ACTH INPUT DESCRIPTION

The information required to run the ACTH program is contained in a file called ACTH.INP located in the STH directory. This information is organized into 10 Data Sets described below and summarized in Table 8. An example of the ACTH.INP file is provided in Table 9.

Data Set 1, STH Data Path

One Line, Format (A)

(1) STHDATAS, alphanumeric, columns 1-80, path indicating where the origin time history files output from the STH program are located.

Data Set 2, ACTH Data Path

One line - Format (A)

(1) ACTHDATAS, alphanumeric, columns 1-80, path indicating where the ACTH response time histories will be saved.

Data Set 3, Ship Name

One Line, Format (A)

(1) SHIPS, alphanumeric, columns 1-5, identifies ship name.

Data Set 4, Output Data Format

One line, Format (7X,I5)

(1) ASCII, integer, columns 8-12, specifies data format to be used for the ACTH response time histories. Use 1 for binary output format and 2 for ASCII output format.

The ACTH response time histories are saved in either a binary format or an ASCII format. The default format is binary. The ASCII format is useful for transferring these time histories to other computers via either a modem or magnetic disks. Note that the ASCII format uses more storage (bytes) than the binary format and takes longer to write.

Data Set 5, Wave Point Input

First Line - FORMAT (A)

No variables, blank line used for spacing.

Second Line - Format (18X,I5)

(1) NWPOINT, integer, columns 19-23, number of wave points.

NWPOINT is set to zero if you do not want to compute relative motion time histories in the ACTH program. Note, however, that if relative motion is desired at a later date, the user must rerun the STH program and include the wave points where the relative motion is to be computed. Lines 3-5 are always included even if NWPOINT=0.

Third Line - FORMAT (A)

No variables, blank line used for spacing.

Fourth Line - FORMAT (A)

No variables, comment used to identify wave point table.

Fifth Line - FORMAT (A)

No variables, comment identifies columns for wave point table.

NOTE: The next line is included only if NWPOINT>0. There is one line for each wave point.

Sixth Line - Format (I4,3F8.1,3X,A20)

(1) IWPNT, integer, columns 1-4, wave point number.

(2) WPNTXLOC, floating point, columns 5-12, x-coordinate of wave point (station number, 0=Forward Perpendicular).

(3) WPNTYLOC, floating point, columns 13-20, y-coordinate of wave point (positive to port from centerline).

(4) WPNTZLOC, floating point, columns 21-28, z-coordinate of wave point (positive up from baseline).

(5) WPTNAMES, alphanumeric, columns 29-48, the name of the wave point.

Wave point locations are required to be input only if relative motion time histories are desired. Wave time histories at these points must have been previously generated by the STH program. The same wave point locations should have been used in the STH input. The ACTH program compares the wave point locations used in the ACTH and STH input and stops if they are not identical.

Data Set 6, Point Input

First Line - FORMAT (A)

No variables, blank line used for spacing.

Second Line - Format (13X,I5)

(1) NPOINT, integer, columns 14-18, number of points on the ship where response time histories are computed.

NPOINT is set to zero if you do not want to compute response time histories at a point. Lines 3-5 are always included even if NPOINT=0.

Third Line - FORMAT (A)

No variables, blank line used for spacing.

Fourth Line - FORMAT (A)

No variables, comment used to identify point table.

Fifth Line - FORMAT (A)

No variables, comment used to identify columns for point table.

NOTE: The next line is included only if NPOINT>0. There is one line for each wave point.

Sixth Line - Format (I4,3F8.1,3X,A20)

(1) IPNT, integer, columns 1-4, point number.

(2) PNTXLOC, floating point, columns 5-12, x-coordinate of point (station number, 0=Forward Perpendicular).

(3) PNTYLOC, floating point, columns 13-20, y-coordinate of point (positive to port from centerline).

(4) PNTZLOC, floating point, columns 21-28, z-coordinate of point (positive up from baseline).

(5) PNTNAMES, alphanumeric, columns 32-51, the name of the point.

Data Set 7. Channel Input

First Line - FORMAT (A)

No variables, blank line used for spacing.

Second Line - Format (15X,I5)

(1) NCHAN, integer, columns 16-20, number of channels.

Third Line - FORMAT (A)

No variables, blank line used for spacing.

Fourth Line - FORMAT (A)

No variables, comment used to identify channel table.

Fifth Line - FORMAT (A)

No variables, comment used to identify columns for channel table. There is one line for each channel.

Sixth Line - Free Format

(1) ICHN, integer, channel number.

(2) IRSP, integer, response number.

1 = surge; longitudinal response at a point (earth system); longitudinal force at a point (ship system)

2 = sway; lateral response at a point (earth system); lateral force at a point (ship system)

3 = heave; vertical response at a point (earth system); vertical force at a point (ship system)

4 = roll; relative motion at a point (earth system)

5 = pitch

6 = yaw

7 = wave height at the origin or at a wave point location.

(3) ITYP, integer, response type.

1 = displacement

2 = velocity

3 = acceleration

4 = angle

(4) ISYS, integer, response system.

1 = earth system

2 = ship system

(5) IPNT, integer, response point number from Data Set 5 or 6.

The method used to select the ACTH channels is outlined in Table 10. Each channel is defined by five numbers; channel number, response number, response type number, reference system desired, and point location. The first step is to select a point number. If the point number is zero, the response numbers are limited to 1-6 for the 6DOF reponses and 7 for wave height at the LCG. Only the earth reference is allowed. Displacement, velocity, or acceleration (types 1,2,3, respectively) are allowed for any of these responses.

If user selects a point number greater than zero, then both earth and ship reference systems are allowed. The available response numbers for the earth system are 1-3 corresponding to longitudinal, lateral, and vertical responses at a point, 4 for relative motion at a wave point, and 7 for wave height at a wave point. Displacement, velocity, or acceleration (types 1,2,3, respectively) are allowed for any of these responses. If the user selects the ship reference system, then the response numbers allowed are 1-3 for the longitudinal, lateral, and vertical forces at a point. The response type is restricted to 3 which is acceleration (force per unit mass).

Data Set 8. Start ACTH Run

First Line - FORMAT (A)

No variables, blank line used for spacing.

Second Line - Format (15X,I5)

(1) STARTRUN, integer, columns 16-20, start ACTH run number.

Data Set 9. No of ACTH Runs

One Line - Format (16X,I5)

(1) NRUNS, integer, columns 17-21, number of ACTH runs

Data Set 10. STH Run Input

First Line - FORMAT (A)

No variables, blank line used for spacing.

Second Line - FORMAT (A)

No variables, comment used to identify STH run input.

There is one line for each STH run.

Third Line - Free Format

(1) STHRUN, integer, STH (origin) time history run number.

ACTH OUTPUT DESCRIPTION

The ACTH program only displays three items on the screen for each run; the ACTH program identification, the total number of ACTH runs to be made, and the run that the ACTH program is currently working on. An example of the ACTH screen display is provided in Table 11.

The information describing each ACTH run is written to a text file called ARM.TEX where M is the run number. The ARM.TEX file is stored in a ship subdirectory under the ACTHDATA directory, e.g., D:\ACTHDATA\SPDD965A. An example of this file for ACTH run number 3 is shown in Table 12. The ARM.TEX file is comparable to the SRN.TEX file written by the STH program. The information contained in the ARM.TEX file consists of:

1. DATE-TIME-GROUP;
2. Ship identification;
3. ACTH run identification which includes run number, comment,

sample rate, and run times (the corresponding STH run number is identified);

4. Ship particulars;
5. Run particulars including ship speed, heading, sea type, etc.;
6. Table of STH statistical results which compares time domain and frequency domain calculations of the standard deviation for the STH channels;
7. Listing of wave point locations (required for relative motion calculations in the ACTH program);
8. Listing of point locations (required for motions, velocities and accelerations at a point and forces in the ship system);
9. Listing of channels and there associated points (the channel number, name, type, unit, system, and the point number and the point location associated with the channel are also given);
10. Listing of the statistical results obtained from the ACTH time histories (these statistics include the mean, standard deviation, maximum and minimum values for each ACTH channel);
11. The total number of samples for the run.

The ACTH time histories are written in one of two possible formats depending on the value of the variable ASCII in Data SET 2 of the ACTH input. If the user chooses ASCII=1, then the time histories are written to a standard FORTRAN sequential binary data file called ARM.DAT. The first record in the file contains two integer variables, the total number of samples and the number of channels. The remaining records, one for each sample, contain the time histories for all the ACTH channels in the desired engineering units. The ARM.DAT file is stored in the same subdirectory as the ARM.TEX file.

If the user instead chooses ASCII=2, then the time histories are written to a formatted FORTRAN sequential ASCII data file called ARM.ASC as:

Record 1. Header

One Line - Format (2I5)

(1) COUNT, integer, columns 1-5, total number of samples.

(2) NCHAN, integer, columns 6-10, number of channels.

Records 2-(COUNT+1), ACTH time history data

Line 1 - Format (2I5,8F8.3)

(1) CNT, integer, columns 1-5, sample number.

(2) KL, integer, column 10, line number (set to 1).

(3) ACTHDATA, floating point, columns 11-18, 19-26, etc., up to eight channels of ACTH time histories at sample CNT. The time histories are in engineering units.

A second line is required if there are more than eight channels.

Line 2 - Format (5X,I5,8F8.3)

(1) No variable, first 5 columns skipped.

(2) KL, integer, column 10, line number (set to 2).

(3) ACTHDATA, floating point, columns 11-18, 19-26, etc., remaining channels of ACTH time histories at sample CNT.

An example of the ARM.ASC file is shown in Table 13. The ARM.ASC file is stored in the same subdirectory as the ARM.TEX file.

A separate text file called ACTHLOG.TEX is updated for each run. This file contains a summary of the ACTH runs that have been made. The summary consists of a separate line for each run that contains the ACTH run number, data format type (binary or ASCII), simulation run time in minutes, DATE-TIME-GROUP (day, hour, minute, L(local), month, and year), and the run comment. The run comment shows the seaway type, ship speed, heading angle, significant wave height, and modal wave period. An example of the ACTHLOG.TEX file is shown in Table 14. The ACTHLOG.TEX file is stored in the same subdirectory as the ARM.TEX file.

There is also a file called ERROR.TEX that is created when the ACTH program is executed. This formatted sequential file contains any error messages that may have occurred while the program was executing. A message telling the user that all STH runs were successfully completed is written if no errors occurred . A summary of the error messages is provided in Table 15. The ERROR.TEX file is stored in the STH directory.

PROCEDURE USED TO DEVELOP SHIP RESPONSE TIME HISTORIES

The ACTH program is used to develop response time histories in random seas at various locations on the ship. In order to run the ACTH program the user must perform a number of tasks which involve:

1. Selection of ship,
2. Reviewing SMP84 output/running SMP84 program,
3. Reviewing STH runs/running STH program,
4. Editing ACTH input/running ACTH program.

The input required to run each of the three programs, SMP84, STH, and ACTH is specific to a particular ship. Each program however uses a generic input file name, SMP.INP, STH.INP, and ACTH.INP, respectively. The user must maintain these input files using both generic names as well as ship specific names. In order to change a ship, the user should first save the generic input files for the current ship to files that are identified by the ship name. For example, using the MS-DOS copy command at the MS-DOS prompt,

```
C:\COPY C:\STH\STH.INP C:\STH\DD965A.STH,
```

where the extension STH would identify the file as the STH input for the DD965A ship. The extensions SMP and ATH should be used for the input files for the SMP84 and ACTH programs. Next the user should copy the input files for the new ship to the generic files, i.e.,

```
C:\COPY C:\STH\FFG8A.ATH C:\ACTH.INP,
```

where the new ship is the FFG8A.

SMP84 is a frequency domain program that predicts statistical ship responses in random seas at various locations on the ship. The SMP input consists of ship offsets as a function of station, and loading information such as nominal GM, displacement, roll radius of gyration. Other input information describes the appendage suite, point locations for ship responses, and sea conditions. The information required to run the SMP84 program can be found in References 1 and 2.

A file called the origin file, DD965A.ORG for the DD965A ship, is output from SMP84 and stored in the SMPDATA subdirectory. This file contains the 6DOF (surge, sway, heave, sway, heave, roll, and yaw) transfer functions computed at the LCG of the ship in the waterplane as a function of ship speed, heading, wave frequency, and mean roll angle. This file is required by the STH program to develop 6DOF time histories for specified speeds, headings, and sea conditions.

An additional text file containing the statistical ship responses is output from SMP84 and stored in the SMPDATA subdirectory. This file is called DD965AN.OUT where N is a cycle number which represents the last SMP84 run made for the DD965A ship. This output file can provide assistance in selecting conditions for which STH runs can be made. Note that one of the reasons for running the STH program is to obtain phase correlation between responses which is not provided in the SMP84 statistical tables. The statistical tables do identify the speeds, headings, and the modal wave periods where the maximum values occur for a large number of responses. Examples of the statistical response tables for roll as well as the vertical velocity at the helicopter deck bullseye are shown in Tables 16 and 17, respectively.

Once the STH run conditions have been selected from the SMP84 output and the SMP84 Origin file has been saved, the next task is to edit the STH input file. The user can review the STHLOG.TEX file to determine which STH runs have already been made. Note that the STHLOG.TEX file is located in the DD965A subdirectory of the STHDATA directory. The STH runs take a long time to execute, approximately 43 minutes per run on a 20-Mhz COMPAQ 386 personal computer, and should be run overnight or over a weekend.

The STH time histories form the data base from which response time histories are developed in the ACTH program. Once the STH time histories have been run, the last task is to edit the ACTH input file to select the point locations on the ship and the desired responses. The ACTH program executes very quickly, approximately 1 to 2 minutes for 16 channels, and can easily be run many times using different ACTH run numbers for different sets of channels or point locations.

TIME HISTORY EXAMPLE

SELECTION OF SHIP AND SEAWAY PARAMETERS

The DD965 destroyer is the example ship used to demonstrate the procedure required to develop response time histories. Four locations were selected as shown in Fig. 7. These locations are identified as:

1. Sonar dome,
2. Starboard side of the bridge,
3. Helicopter deck bullseye,
4. Port side of the stern.

The following nine responses were selected for running in the SMP84 and ACTH programs:

1. Wave height,
2. Roll angle,
3. Pitch angle,
4. Heave,
5. Relative motion at the sonar dome,
6. Earth system vertical acceleration on the starboard side of the bridge,
7. Earth system vertical velocity at the helicopter deck bullseye,
8. Earth system lateral acceleration at the helicopter deck bullseye,
9. Ship system lateral force at the helicopter deck bullseye.

The SMP84 program was run using a significant wave height of 12 feet and a roll statistic of 2. The origin transfer function file was saved as DD965A.ORG and the statistical response results were saved in the DD965A6.OUT output file. The input used for running SMP84 is shown in Table 18. A plot of the hull lines is shown in Fig. 8 and the ship hydrostatics are shown in Table 19. SMP84 optionally outputs the 6DOF Response Amplitude Operator (RAO) magnitudes and phases as a function of encountered wave frequency, ship speed, and relative wave heading. Note that the RAO magnitude is the square of the transfer function magnitude. An example of the RAO magnitudes and phases for the 6DOF responses is shown in Table 20 for a ship speed of 20 knots and a relative wave heading of 45 degrees (bow waves).

Three representative STH runs were made using ship/sea conditions selected from the SMP84 statistical response tables. Shortcrested seas were used for all three runs. The significant wave height used was 12 feet. The modal wave period used was 9 seconds which is the most probable wave period for this significant wave height. The ship conditions selected were:

1. Beam seas (90 degrees), zero knots was used for STH run 1 to illustrate the wave time history,
2. Bow seas (45 degrees), 20 knots was used for STH run 2 to illustrate large pitch and vertical mode response time histories, and
3. Quartering seas (135 degrees), 20 knots was used for STH run 3 to illustrate large roll and lateral mode response time histories.

The STH input file is shown in Table 4. Note that two wave point locations, for the sonar dome and the port side of the stern, were used in the input in order to compute relative motion time histories at these points in the ACTH program. Each STH run took 43 minutes to execute for a total of 129 minutes. Each STH data file, SRN.DAT, used 133,900 bytes of storage.

Finally, three ACTH runs were made using the three STH runs as input. Response time histories were generated for the 9 responses previously identified. The ACTH input is shown in Table 9. Each ACTH run took 22 seconds for a total of 66 seconds using the binary data format option. The data storage for ARM.DAT was 133,900 bytes. If the ASCII data format is selected, the ACTH run time increases to 60 seconds per run and the ARM.ASC storage increases to 345,700 bytes.

ANALYSIS

Beam Sea Wave Time History

A 20-minute wave time history was computed at 3 samples per second in STH run 1 for a ship speed of zero knots in shortcrested beam seas with a significant wave height of 12 feet and a modal wave period of 9 seconds. The first 300 seconds of this wave time history is shown in Fig. 9a. As shown in Fig. 9b, a power spectrum of the wave channel as well as a bimodal distribution of wave amplitudes (by single amplitude and period) was computed for the entire 20-minute duration of the run. There were a total of 158 cycles, where the period of each cycle is defined by three consecutive zero-crossings.

A comparison between the power spectrum computed from the wave time history and the Bretschneider wave spectral model is shown in Fig. 10a. The instantaneous wave elevations are compared with a Gaussian distribution in Fig. 10b. Finally, a comparison of the wave single amplitude distribution is compared with a Rayleigh distribution in Fig. 10c.

These comparisons show that the wave time history developed by the STH program does represent a random sea whose instantaneous wave elevations have a Gaussian distribution and whose single amplitudes have a Rayleigh distribution. Note that the Bretschneider wave spectrum, and the Gaussian and Rayleigh distributions represent averages from a large collection of time histories. The results obtained from any one time history for a specific set of random numbers (see Eq. 10) can be larger or smaller than these curves. However, the results should have the same general trends as the theoretical curves.

Since the linear superposition principle was used to obtain the ship response time histories to the random seas, it follows that the response elevations will also have a Gaussian distribution and the response single amplitudes will have a Rayleigh distribution. The single amplitudes for roll will have a modified Rayleigh distribution because of the increase in roll damping with increasing significant wave height.

Ship Response Time Histories in Bow & Stern Quartering Seas

Nine response time histories, including the encountered wave time history, were generated by the ACTH program at 3 samples per second for 20 minutes in a shortcrested sea with a significant wave height of 12 feet and a modal wave period of 9 seconds. ACTH run 2 represents a bow sea (45 degree) ship heading and ACTH run 3 represents a stern quartering sea (135 degrees). Both runs are for a ship speed of 20 knots. The minimum analysis (standard deviation and peak values) of the nine responses for both ACTH runs is shown in Table 21.

A comparison of these responses for bow and stern quartering seas is provided in Figure 11. Time histories are shown for the encountered wave, roll angle, pitch angle, heave displacement, relative motion at the sonar dome, vertical acceleration at the starboard side of the bridge, and vertical velocity, lateral acceleration (earth-reference), and lateral force (ship-reference) for the center of the helicopter deck bullseye.

A representative 200 second section from each the 20 minute runs is compared in this figure. Note first that the encountered wave frequencies in bow seas are higher than for stern quartering seas at the ship speed of 20 knots. In fact there is not enough wave energy near the natural roll frequency (0.4 rps) in bow seas at this speed to excite the ship in roll. In general, the ship responses related to the vertical mode, i.e., pitch, heave, relative motion, and vertical velocity and acceleration are larger in bow seas than in stern quartering seas. Likewise, the ship responses related to the lateral mode, i.e., roll, lateral acceleration, and ship lateral force are larger in stern quartering seas where the encountered wave frequencies are smaller (longer periods) compared to bow seas. Vertical responses at point locations on the ship which are off centerline contain a roll component, and can thus show a resonance due to roll in stern quartering seas. Finally, note that the lateral force in the ship system is larger than the lateral acceleration in the earth system due to the component of gravity times the sine of the roll angle, which is much larger in stern quartering seas than in bow seas.

CONCLUDING REMARKS

The methods/programs described in this report provide a rational approach to the generation of simulated ship motions in random seas. These ship motion time histories in turn can be used to develop realistic ship motion specifications to which any ship subsystem can be designed. The [illegible]tion in developing this tool is to allow a potential user to concentrate on developing the model of his subsystem and not on the generation/accuracy of the ship motion data base which will be used to drive the subsystem.

No software remains static. Future enhancements or expansion of these programs will depend not only on theoretical and technological improvements, but will rely heavily on the requirements of the users. It is, therefore, important that feedback be provided the authors so that later versions of the programs presented will meet the needs of the U.S. Navy.

Table 1. Constants for single amplitude Rayleigh statistics.

SINGLE AMPLITUDE STATISTICS	
Root mean square amplitude, RMS	1.00 σ
Average amplitude	1.25 σ
Average of highest 1/3 amplitudes, significant	2.00 σ
Highest expected amplitude in 10 successive amplitudes	2.15 σ
Average of highest 1/10 amplitudes	2.55 σ
Highest expected amplitude in 30 successive amplitudes	2.61 σ
Highest expected amplitude in 50 successive amplitudes	2.80 σ
Highest expected amplitude in 100 successive amplitudes	3.03 σ
Highest expected amplitude in 200 successive amplitudes	3.25 σ
Highest expected amplitude in 1000 successive amplitudes	3.72 σ

DEFINITIONS

σ^2 = Statistical variance of time history.

N = Number of successive amplitudes.

CONSTANT = $\sqrt{2} (\ln N)^{1/2}$, where CONSTANT relates σ to the highest expected amplitude in N successive amplitudes.

NOTES:

1. The highest expected amplitude in N amplitudes is the most probable extreme value in N amplitudes. This value may be exceeded 63 percent of the time.

2. To obtain wave height or double amplitude statistics from RMS values, multiply single amplitude constants by 2.0.

Table 10. Method used to select ACTH channels.

Select Point No

Point no = 0 - Location (Origin) is at LCG in the waterplane

SYSTEM = EARTH

Select Response No
1 - Surge
2 - Sway
3 - Heave
4 - Roll
5 - Pitch
6 - Yaw
7 - Wave Height at LCG

Select Type
1 - Displacement/Angle
2 - Velocity
3 - Acceleration

Point no > 0 - Any location on the ship

Select system

SYSTEM = EARTH

Select Response No
1 - Longitudinal reponse at a point
2 - Lateral " "
3 - Vertical " "
4 - Relative motion at a wave point
7 - Wave height at a wave point

Select Type
1 - Displacement
2 - Velocity
3 - Acceleration

SYSTEM = SHIP

Select Response No
1 - Longitudinal force at a point
2 - Lateral " "
3 - Vertical " "

Select Type
3 - Acceleration (force per unit mass)

NOTES: 1) VERTICAL RAOS (SURGE,HEAVE,PITCH) ARE LINEAR AND INDEPENDANT OF SEA STATE.
2) LATERAL RAOS (SWAY,ROLL,YAW) ARE NONLINEAR AND CHANGE WITH SEA STATE AND STATISTIC.
3) AMPL. IS IN (PHYS.UNITS/FOOT)**2 AND PHASE IS IN DEGREES.
4) HEADING CONVENTION: 0 DEG=HEAD, 90 DEG=STBD BEAM, 180 DEG=FOLLOWING SEAS.
