13. ABSTRACT (Maximum 200 words) The Intelligent Training Branch of the Armstrong Laboratory supports and conducts research in intelligent tutoring systems (ITSs). The purpose of this project was to apply this technology in the construction of an ITS which applied to Air Force Specialty Code (AFSC) 17XX, Air Weapons Personnel. The specific domain included task conducted on the E-3B/C Airborne Warning and Control System (AWACS) aircraft. Res: Its indicated the need for further development of the applicable software, but also indicated the plausibility for this type training in the selected domain.

AIRBORNE WARNING AND CONTROL SYSTEM (AWACS) INTELLIGENT TUTORING SYSTEM (ITS)

Background

The United States Air Force (USAF) at Tinker AFB, Oklahoma, trains USAF officers to fulfill the role of Weapons Directors (WDs) aboard the E-3B/C Airborne Warning and Control System (AWACS) aircraft. The AWACS platform supports Command, Control and Communications (C³) missions in the airborne environment. USAF Armstrong Laboratory, Crew Technology Division, Sustained Operations Branch (AL/CFTO), in cooperation with Systems Research Laboratories, Inc. (SRL), configured WD crewstations and affiliated systems in the Aircrew Evaluation Sustained Operations Performance (AESOP) facility to run defensive counter air (DCA) mission simulations. Teams of three WDs detect, identify, intercept, and destroy enemy aircraft attempting to attack friendly forces or penetrate friendly airspace. A Senior Director (SD) serves as the immediate supervisor in the chain of command. In a DCA mission, the SD oversees and coordinates WD efforts to execute the directives of the senior battle staff.

In cooperation with the Technical Training Research Division, Human Resources Directorate (AL/HRT), SRL began research and development of an Intelligent Tutoring System (ITS) in the Air Force Specialty Code (AFSC) 17XX C³ domain. The effort was to provide a proof of concept, with recommendations for future development.

Developing Criteria

One of the first tasks involved narrowing the instructional domain. The following criteria were established:

1. The domain was restricted to that of weapons controllers: WDs, SDs, Weapons Controllers (WCs), and Weapons Assignment Officers (WAOs).
2. Due to practical limitations on equipment and funds, interactive voice communications were not included.
3. The domain included areas that would fill an immediate need of the Air Force's 17XX operational training community.
4. The domain was limited in order to accomplish development in the time available.

5. The ITS was restricted to Initial Qualification Training (IQT). By focusing on initial training, changes in performance would be more dramatic and therefore easier to measure.
6. Finally, in order for the ITS to teach something more than a routine procedure, we wanted to incorporate some decision-making skills.

Using these criteria, training systems at Tyndall AFB and Tinker AFB were deemed appropriate for adapting to an ITS. At Tyndall AFB, all 17XXs receive their initial Air Force training in the weapons controller career field. After graduating from Tyndall's introductory course, some 17XXs continue to Tinker for initial WD training in AWACS.

After initial contacts with training sites, we chose to focus on Tinker's AWACS community. After a fact-finding trip to Tinker (11-13 August 1991), the main subject area for initial development was identified as *Block I, AWACS WD Initial Qualification Training*. This subject area is taught at Tinker in the mission simulations. It is an introduction to the switch actions a WD uses in performance of job tasks. Block I IQT met the first five criteria for narrowing down the domain for developing an ITS. In addition, the Director of Operations of the 552 Tactical Training Squadron indicated that an ITS for this instructional block would widen a traditional training bottleneck for AWACS WD training, thus fulfilling criterion # 3.

Criterion # 6, decision-making skills, was not met. However this criterion was of a lower priority for two reasons. First, only Block I IQT WD instructional materials were set and the AWACS WD training program was being rewritten to take into account lessons learned from Desert Shield/Storm. Second, there is an ongoing reorganization by the Air Force in the training of 17XXs.

Preparation

While at Tinker, SRL tried to ascertain how Instructor WDs (IWDs) taught and evaluated IQT WD students--particularly as related to Block I IQT WD training. Important findings included:

1. Time for task completion is ill-defined in early instructional blocks.
2. Number and types of errors are also ill-defined.
3. Window for task completion, while not critical at first, rapidly becomes more important than time for task completion. The size of the window remains ill-defined.

4. **Fighter Weapons School is considered more important for good experience in initial categorization of student abilities and capabilities than any other prior experience.**
5. **Students are not accelerated through training, even if they show exceptional skill or aptitude.**
6. **Prior experience and training records play a part in evaluating students, but is an exception, not a rule.**
7. **Only some IWDs used a dual tracking task in training of Block I IQT WDs, but this technique was being institutionalized as part of the formal program. The dual tracking task consists of a single piece of symbology on a single track in an oval orbit. The student is required to keep the symbology on the track throughout the lesson and while performing the procedures. This dual tracking task is not objectively measured, but subjectively indicates to the IWD that the student WD learned the lesson well.**
8. **Most switch actions are taught and used for two simulations in a row and then not trained or used until a student progression test is administered.**
9. **Most student evaluation is subjective.**

Benefits of an ITS

ITS can eliminate or ameliorate many obstacles to efficient and effective training, including those mentioned above. ITS can take full advantage of quantitative measures developed in cooperation with expert IWDs, allow individually paced escalation of complexity and volume of tasks, and implement consistent application of evaluation criteria. In addition:

- **ITS allows better use of manpower by enabling an IWD to manage the training of many student WDs rather than two or three. At the same time, ITS effectively allows a one-to-one student-to-teacher ratio.**
- **Because of the self-paced aspect of ITS, training can proceed at a faster rate for more able or experienced students and allow less able students ample practice time and opportunities to hone their skills.**
- **As the need for rapid response escalates, a WD must increase the work pace. This increase can occur only where there is spare capacity. The optimum area for this increase is that of console operations. ITS can**

objectively judge this spare capacity and thereby enhance WD training by developing high-performance knowledge and skills in console operations. ITS simulations can foster achievement of these skills through "consistent practice" (Regian, 1990).

- ITS allows a student WD to consistently build on recently acquired knowledge and skills rather than moving on to other tasks before these new skills are reinforced.

Designing the ITS

ITS Paradigm

The second task under this effort required the creation of a conceptual paradigm of an ITS. The five important elements that must be related to each other are:

- a Simulator,
- a Knowledge Domain,
- an Instructor Model,
- a Student Model, and
- an Intelligent Interface that links them together (Burns & Parlett, 1990).

These elements are graphically represented in Figure 1.

Figure 1. Intelligent Tutoring System Paradigm

Each of these five elements is interrelated to the others. A development in one element often requires a corresponding development in one or more of the other elements. In this way the different elements remain fitted together as a coherent whole. Take for example teaching the procedures for executing a *Commit* switch action. The procedural steps for executing this switch action must be included in the relevant Knowledge Domain. The Simulator must have this switch action and be able to execute it. The Instructor Model must indicate how, when, and where in the course of instruction to teach the *Commit* switch action. The how, when, and where of the instruction depends heavily on the Student Model. The Intelligent Interface must make the match of the Student Model to the student, pick the correct format of instructions for the lesson, execute the lesson on the simulator, and evaluate the student's progress.

Knowledge Domain

For practical reasons, the Knowledge Domain element comes first. Specifically, this is identified as the 552 AWACW IQT WD Block I, *Weapons Director Student Study Guide, Volume 1*, of training course E3000BQODX. This guide introduces students to AWACS, the WD Multi-Purpose Console (MPC), and several switch actions, building a declarative knowledge base and a procedural knowledge base. The emphasis is on procedural knowledge base, that is, how to perform certain WD switch actions. A specific list of these switch actions is found in Appendix A, a letter from Capt. Fowler, representative of the 552 AWACW/DOQMW office, which is responsible for the training course development at Tinker for WDs.

Simulator

The next element, the Simulator, is the nearest to completion. These are the C³ Generic Workstations (C³GWs) and the supporting AWACS Simulation software in the AESOP facility (Schiflett, Strome, Eddy, and Dalrymple, 1990). The C³GWs have most of the switch actions taught in Block I at Tinker AFB. The following list includes all the Block I switch actions that have not yet been implemented on the C³GW:

- Restricted Area
- RN/DES/NTN SD
- Add/Delete Airbase
- Area Define/Delete
- Corridor IFF SD
- Radar/IFF Tracking

These switch actions amount to 28% (6/21) of all the switch actions taught in Block I, IQT WD training. An estimated 280 man hours of programming development are needed to fully develop these switch actions. In all other respects, the Simulator element closely emulates the presentation and functions of an AWACS WD MPC.

Instructor Model

The Instructor Model element contains instructional goals, accounts for student attributes, structures the Knowledge Domain, and presents the structure. The goals center around transfer of knowledge from the Knowledge Domain to the student. Specifically, these goals are to teach the student:

1. The physical layout of the MPC, i.e., where the switch action buttons are located.
2. The procedural steps for executing MPC Console Checkout.
3. The procedural steps for executing the following switch actions:

Assign Console	TD Index
Line	Circle
Coordinate	Tactical Bearing & Range
Restricted Area	Bearing and Range
RN/DES/NTN SD	Initialize Special Point
Add/Delete Airbase	Area Define/Delete
Locate SIF	Corridor IFF SD
Request SIF	Initiate
Mode IV	Reinitiate
Radar/IFF Tracking	Assign/Defer
Request/Assign IFF/SIF	ADS Panel Channel activations

These goals lay the foundation for evaluating the student's performance. Acceptable execution of these procedures by a student WD indicates successful transfer of knowledge. However, defining acceptable execution involves several measures:

- time of complete task execution,
- time of execution of each step within the task,
- a time window for accepting task start and end, error toleration, and alternate step sequencing, when it exists.

The values that address these measures are not currently known with certainty. Therefore, our initial set of values for evaluation were determined by a Subject Matter Expert based on years of experience as a WD/SD/IWD. The set of values chosen for different students is based on student attributes.

Student Model

Accounting for student attributes requires recognizing appropriate student differences, setting appropriate goals based upon these student differences, and then selecting a mode of instruction that best matches both the student and the instructional goals. Recognizing appropriate student differences relies heavily upon the Student Model. A WD student is matched to his/her appropriate type in the Student Model. Once the student type is known, then the Instructor Model has the correct set of instructional goals to tie to that student type. Our prototype has only one set of instructional goals based on the lowest level of student type. Selecting a mode of instruction impacts how the Knowledge Domain is structured and how information is presented.

Necessary WD Knowledge/Skills

There are three distinct, but interrelated areas of knowledge/skill necessary to be a functioning and qualified AWACS WD. These are declarative knowledge, procedural knowledge, (Barr & Feigenbaum, 1981; Anderson, 1988) and operational skills.

Declarative knowledge refers to that specialized body of knowledge about the system, its purpose, components, events, and the relationships among them. A few examples are how radar works, the different types of intercept geometry, airpower doctrine, and brevity code words.

Procedural knowledge deals with task procedures needed to operate the equipment. Some examples include reading scope presentations, talking and listening using the communications equipment, and executing switch actions.

Operational skills encompass knowledge at both cognitive and meta levels (Burton, 1988). At the cognitive level, the WD needs to acquire some high level skills to cope with the demands of a complex task environment in order to properly apply the declarative and procedural knowledge in both normal and abnormal problem solving situations (Woods, 1988). Time management and cost-benefit analysis are two skills necessary for the proper coordination of multiple WD tasks in a complex and dynamic environment. Proper coordination is important because system events compete for the operator's attention. Other critical skills resulting from the dynamic, complex nature of the system include adaptiveness and disturbance management that are common to other complex systems. Two that are critical to the WD world include dichotic listening and three dimensional spatial orientation involving motion of objects while remaining stationary.

Meta skills concern knowledge about how to learn effectively. The body of knowledge the novice WD must learn can be overwhelming. Consequently, at the meta level, the WD

needs to know how to monitor the learning process and manage different activities to get the most out of training.

The declarative and procedural knowledge together form the domain knowledge the operator must have. Operational skill can be viewed as the operator's successful acquisition and application of the domain knowledge during training that transfers to the actual task environment.

Skill Levels

In each of the three areas, a WD is rated on a scale of 1-5, with 5 being the highest. Each numerical rating corresponds to a label ranging from 1-Naive, 2-Novice, 3-Journeyman, 4-Expert, and 5-Master. The following is a description of each label/rating:

- 1 NAIVE: Indicates a complete lack of knowledge and/or skill.
- 2 NOVICE: Has some knowledge and/or skill, but not enough to operate independently to complete assigned tasks in a timely manner. Does not recognize all patterns of stimuli. Does not know how to order behavioral actions in response to recognized patterns of stimuli.
- 3 JOURNEYMAN: Has enough knowledge (score 85% or better in written exams) and/or skill to operate independently to complete assigned tasks, but not always in a timely manner. Recognizes common stimuli variable patterns and applies domain rules of behavioral responses. Does not recognize situations in which the domain rules do not apply, and/or in which new variables or patterns exist. Perseveres in attempting to apply what is known. Not yet capable of solving difficult or complex problems or developing new rules.
- 4 EXPERT: Has superior knowledge and/or skill. Operates well independently to complete all assigned tasks in a timely manner. Recognizes common stimuli variable patterns and applies domain rules of behavioral responses. Recognizes existence of new variables and/or situations in which the domain rules no longer apply, and can usually develop a solution. Capable of solving most difficult or complex problems.

5 MASTER: Has superior knowledge and/or skill. Operates well independently to complete all assigned tasks in a timely manner. Recognizes common stimuli variable patterns and applies domain rules of behavioral responses. Recognizes existence of new variables and/or situations in which the domain rules no longer apply, and can develop new rules. Capable of solving difficult or complex problems.

The goal of the training in Block I AWACS WD training is to bring all students up to the NOVICE/level 2 for Procedural Knowledge, Declarative Knowledge, and Operational skill.

Course Structure

Since the Knowledge Domain consists largely of Procedural Knowledge, the required step sequences are already structured. Yet there is a need for a comprehensive course outline that addresses the goals of Procedural Knowledge to be taught in each lesson, how many lessons there will be, and how fast the pace of presentation will be. The course outline is currently taken from Appendix A and Appendix B, the IQT-WD READING GUIDE (6 JUN 90). Note that the maximum time allowed for the course is specified, but no minimum time is established.

Student Skills Assessment

For this proof of concept prototype, we developed a Student Skills Assessment module to categorize student WDs (from 1-Novice to 5-Master) according to experience and ability. This module consists of an Experience Questionnaire and a Switch Action Exercise that students complete on the console prior to the first lesson. A printed copy of this questionnaire is included as Appendix C. Although it is highly probable that the students taking this course are novice WDs just graduated from the introductory course at Tyndall AFB, exceptions occur with sufficient frequency that they must be addressed. For example, occasionally a student may have extensive experience either as a WD or as an aircraft controller and must be requalified as required by regulations. The multiple-choice questionnaire ascertains the same information usually gleaned from the student's records or informally gathered by the instructors during the lesson breaks. In addition, where the student indicates a proficiency above basic entry level, the Switch Action Exercise is presented to validate the evaluation. The normal Lesson One, Block I instruction is then presented.

The first lesson consists of three parts and is presented at only one pace of instruction. The Instructor Model does not evaluate the student during the lesson, only after the lesson is complete. The capability to evaluate the student during the lesson and the capability to change the lesson mode if necessary, need to be more fully developed.

Lesson One

The Simulator Model is the means of instructional presentation and involves five phases of instruction in this high performance Knowledge Domain (Fink, 1990):

- (1) Static overview knowledge,
- (2) General procedure-oriented knowledge,
- (3) Guided example exercises,
- (4) Unguided example exercises, and
- (5) Automated example exercises.

Static overview knowledge consists of a general description of the salient parts and features of the particular piece of equipment on which the task will be performed. This static overview is not included in the prototype. Instead, it is left to the written material found in the IQT WD Student Study, Vol. I.

General procedure-oriented knowledge consists of a description of the steps that must be performed in executing the procedure being taught. Parts of the equipment involved and the motivation or effect for each step are indicated. Each of the lessons should start here for the lowest level student. The first part of Lesson One describes the steps and indicates where the switches are. It doesn't give any motivations for each step or each step's effect on the overall status of the goal.

Guided example exercises provide the student with the opportunity to practice with specific examples while being prompted and coached in order to develop accuracy in the skill. The second part of Lesson One presents a procedure the student must perform on the Simulator. Instructions guiding the student are presented, but the student is not evaluated during the lesson.

Unguided example exercises provide the student the opportunity to practice the whole process with specific examples without interruption in order to develop speed with accuracy. This is the third and final part of the Lesson One. The student is given ten minutes to execute the Console Checkout while reading and following the Console Checkout checklist. After ten minutes, the lesson is terminated and the data on student performance is gathered and evaluated. In future ITS development, this process should be automated.

Automated-example exercises provide the student the opportunity to practice the entire process with specific examples while doing another task. These types of exercises allow the WD to develop the capability to perform tasks automatically. The first lesson is not designed to use this phase. However, Console Checkout is done at the beginning of each and every lesson. As the lessons proceed, the time for this procedure's completion will narrow down from ten minutes to three minutes.

Developing the Software

The development of this prototype was accomplished with a minimum amount of coding change to the existing AWACS Simulation software. Rather than having the two pieces of software integrated, the ITS software executes as a separate process from the simulation, but uses the data collected in the Logger File as input for evaluation. The intent is to have both pieces of software execute in an alternating fashion so the results of one can be used in the next execution of the other. Hence, the ITS software brackets the simulation to provide the appearance of an imbedded simulation without actually accomplishing the imbedding process. On the front end, the ITS software provides the interaction necessary to instruct and evaluate the student before selecting an appropriate scenario for the AWACS Simulation. Then on the back end, the ITS software evaluates the student's performance during the simulation before presenting the appropriate follow-on instruction area.

Admittedly, using two computers systems to provide the functionality for the AWACS ITS is not the ideal solution. However, it does provide a flexible test platform upon which to develop some quantitative metrics for estimating the skills of the student WD. While pedagogy suggests the development of high-performance skill is best accomplished via consistent practice, establishing the criteria to judge the WD student still requires significant amounts of definition and refinement.

AWACS ITS Program Documentation

The software for the AWACS ITS was developed on both the UNIX based Silicon Graphics (SG) 4D/50 and the DEC VAX 780 computers using C and the *Curses* screen handling package. With the exception of the simulation graphics (SG only), all user interaction can be accomplished using either the SG graphics or DEC VT200 series terminals. Source files are included as Appendix D.

The AWACS ITS operates as three separate parts.

1. The SG 4D/50 software provides the instructional capability for the ITS.

2. The Simulation software provides the hands-on aspect of the WD's console operation.
3. The VAX 780 software is the first iterative trial to evaluate a WD's actual console operation.

Since the Simulation software is documented elsewhere, it will not be reiterated and documentation of the remaining two functions follows¹. An ITS User's Guide is included as Appendix E.

Silicon Graphics Software

As developed, the software exists in 7 source files and have the following functional relationships:

- itsdef.h: Header file for the ITS software.
- ITS.c: The overall controlling function
- its_rutns.c: Common functions shared by the software
- instructor.c: Controls the presentation of the test material.
- instr_rutns.c: Common functions shared in the instructor function.
- student.c: Provides the student interface and student function.
- stdt_rutns.c: Common functions shared in the student function.

All source and executable files exist on the SG 4D/50 called *Picard*. In addition, there is an ancillary file, called ITS.mak, that can be used with the UNIX *Make* utility to control the compilation and linking of the modules that are required to form the executable.

Documentation for the calls to the Curses screen management package can be found in the IRIS-4D Programmer's Guide Vol. II and the IRIS Programmer's Reference Manual, Vol. II, Sec. 3, Curses(3X).

¹ Systems Research Laboratories, Inc.: "Research and Development Computer Software Report, Delivery Order 0008, Attachment 2, Sequence 1", Contract No. F33615-87-D-0601, September 1990.

Implementation

In order to provide a means of presenting a flexible curriculum, the `instruct.blk` file was created. This file exists in the *Instructor* directory and contains a catalog of available instruction blocks (max = 50) and the individual lessons (max = 50) that comprise each instruction block. Each catalog entry (logical record) is a string of 634 characters that consists of 52 fields as follows:

1. Brief description of the instruction block (max = 80 characters).
2. A two digit field containing a count of the lessons in this instruction block.
- 3-52. 50 10-character fields containing the names of the lesson files.

Additionally, each field is separated by a |. As developed, each catalog entry can thought to be an instructional block comprised of one or more lessons. Wherein, each lesson consist of a series of text and questions.

Since the intent was to create a subject matter independent ITS, the majority of the intelligence has been placed in the formation of the lesson file. Consequently, the lesson file has a "programmable" flavor to its format and usage. Currently, each lesson file can be created by specifying the following types of `text_types` via the use of the "vi editor".

- a) Each `text type` is separated by a `Ctrl-L` character. In addition, this character also causes a form feed when the file is printed.
- b) The first line of each `text type` has the following format:

`numeric_id text_type`

where:

`numeric_id` = a decimal value that uniquely identifies (within a given lesson context) the `text_type`.

`text_type` = one of the following:

1. `text`
2. `multiple choice`
3. `true/false`
4. `yes/no`
5. `noscore`
6. `score`
7. `instruct/lesson`

For example, suppose you wanted to specify a multiple choice presentation and 4 other displays already exist in the lesson. Additionally, let the previous presentations be numbered 1, 10, 20, and 30, respectively, then this multiple choice presentation could be specified as:

12 multiple choice

- c) The second line of each **text type** has the following format:

numeric_id₁ numeric_id₂ numeric_id₃ numeric_id₄ numeric_id₅

where:

numeric id = the numeric_id of a **text type** that is associated with a given "knowledge level" where level 1 corresponds to the lowest and 5 to the highest.

Continuing the previous example, suppose we plan to advance to **text type** identified as 11 for knowledge levels 1 through 3, and 15 for all others. Our example would now appear as:

12 multiple choice
11 11 11 15 15

- d) If the **text type** is that of **text**, then the third line contains a count of the number of lines in the presented text that follows it.

Varying our example slightly to account for the **text** specification, the example would appear as:

12 text
11 11 11 15 15
36
This is a test example of the text ...

where the ellipsis indicates the continuation of 36 lines of text as specified by the third line of our example.

- e) For the remaining **text types**, the third line consists of multiple occurrences of the format:

z)y

For the **score** and **noscore** types, the y_n values are maximums for intervals that are used in the determination of upgrades in knowledge level, i.e.,

$0 < \text{score} \leq y_1$ -> knowledge level 1
 $y_1 < \text{score} \leq y_2$ -> knowledge level 2
 $y_2 < \text{score} \leq y_3$ -> knowledge level 3
 $y_3 < \text{score} \leq y_4$ -> knowledge level 4
 $y_4 < \text{score} \leq y_5$ -> knowledge level 5

For example, these options could appear as:

12 score
11 11 11 15 15
1)10 2)20 3)30 4)40 5)50
or
12 noscore
11 11 11 15 15
1)10 2)20 3)30 4)40 5)50

Whereupon, if the student's accumulated score were 23, then the next display would be the one that is annotated as 11.

For the **instruct/lesson** type, the z_n is the index of an instruction block and the associated y_n is also an index of the appropriate lesson within the instruction block.

An example of this type may appear as:

12 instruct/lesson
1 1 1 10 20
0)0 0)0 0)0 1)0 2)0

Whereupon, if the student were estimated to have a knowledge level of 5, then the next instruction block to be presented has an index of 2 within which the lesson having the index of 0 will be used. Furthermore, the display annotated as 20 will be the beginning presentation.

- f) For the **text** type of **multiple choice**, **true/false**, and **yes/no**, the fourth line specifies the number of lines in the text that follows it.
- g) The **text** type of **score** and **noscore** resulted from attempted use of a lesson. The **noscore** type uses the accumulated score to branch to an appropriate

follow-on text/question. Whereas, **score** updates the knowledge level variable in the student's data base and resets the accumulated score to zero.

Each of the lesson files that are created using the above format must also reside in the Instructor directory along with the file labeled **welcome**. This file is another lesson file and contains the queries for the Experience Questionnaire.

In addition to the Instructor directory and its associated files, a *Student* directory must also exist. This contains a file that is associated with each student that uses the system. The purpose of each student file is to house the critical values from each student's run. However, these critical values have yet to be determined so each student file is for all practical purposes empty.

Each student's file is labeled as **sdb_XXXX**. Wherein, the **XXXX** field consist of the last four digits of the student's SSAN.

Program Documentation

itsdef.h

This is the header file for this portion of the ITS software. It contains the definitions of the variables and structures that are common to a large majority of the modules.

ITS.c

This file contains the basic controlling logic for the appropriate calling the of the Instructor and Student functions. It also presets some of the global variables.

its_rutns.c

This module contains those functions that are, generally, common to all the other modules and functions in this portion the ITS.

Contains the following functions:

```
void cntr ln(int y_coord, char *txt_str)
```

This function will center the text in **txt_str** in the line specified by **y_coord**.

void get_path_str(char *directory, char *path_str)
This function queries the user for the full directory path for **directory** and returns the full path string in **path_str**.

void file_str(char *path, char *filename, char *fullstr)
This function returns the full file string in **fullstr** from **path** and **filename**.

void its_stop()
This function cause the appropriate escape from Curses and terminates the execution of the program.

int chk_file(char *path, char *filename)
This function checks the accessibility of the file specified from the conjunction of **path** and **filename**.

void lesson_blk_io(char io_type, int ndx)
This function provides the read/write function for the **instruct.blk** file. (See section on the **instruct.blk** for full description of this file.) By specifying a **R** or **W** for the read or write function, respectively, this function will read/write the record that is indexed by **ndx**.

void work_msg()
This function presents a blinking "Working..." message while some time consuming operation is being performed.

void getstr_echo(char *str)
This function echoes the contents of the character string **str** as it is being entered.

void strg_blk_pad(char *strng, int str_len)
This function pads a left justified string, **strng**, with blanks until the specified length, **str_len**, is attained.

instructor.c

As currently implemented, this routine provides the maintenance functions (add, delete, and modify) for the entries in the **instruct.blk** file. Consequently, it is used to govern the flow of presentations for the ITS.

As seen on the main selection menu, provisions do exist for:

- a. reviewing a prepared instruction block,
- b. reviewing a student's record, and

- c. adjusting a student's record, i.e., examining the scores that have the student has accumulated and adjusting these values as required.

Regrettably, none of these options were implemented because of the lack of quantifiable information concerning the criteria that could be used to appraise the skills of a WD student. It is hoped that with continued development these criteria will be further defined. Whereupon or concurrent with this development, the contents of the student record would be established as well as the methods and content of the material to be taught.

`instr_rutns.c`

These routines support the `instructor.c`.

`void lesson_blk_rec_init(int ndx)`

This function initializes the record in `instruct.blk` that is specified by `ndx`.

`int lesson_list(max_cnt)`

This function presents a list of the available instruction blocks, as specified by `max_cnt`, in `instruct.blk` and returns the index of the selected record.

`void lesson_blk_chk()`

This function is a debug tool that will display a selected record from `instruct.blk`.

`void instr_blk_vis(int ent_no)`

This function displays a record from `instruct.blk` that is specified by `ent_no`.

`void make_pos(int ndx, int *y_pos, int *x_pos)`

This function will provide the screen coordinates, `x_pos` and `y_pos`, relative to the `instr_blk_vis` display that corresponds to index `ndx` of the desired lesson.

`student.c`

This routine uses a lesson file to present the material in a manner that resembles the traversal of a decision tree. The working version of this decision tree is included as Appendix F. The combined use of *knowledge level* and *accumulated score* are the attributes that key the order of presentation to the student.

It should be noted that there exists a software imposed limit of 100 entries (occurrences of `text type`) per lesson file. This limit can be easily changed as required. Also, the software does not preclude the concatenated presentation of multiple lesson files.

Consequently, the 100 entry limit can be circumvented by the subdivision of a large lesson file into smaller files.

`stdt_rutns.c`

Contains the following functions:

`void student_ident(char *name_str, char *id_str)`
This routine queries the user for the student's name and SSAN and returns the values in `name_str` and `id_str`, respectively.

`void get_ssan(char *a_strng)`
This function controls the user's specification of a SSAN and returns the value in `a_strng`.

`void student_blk_io(char io_type, int rec_ndx)`
This function provides the equivalent I/O capabilities as found in `lesson_blk_io`, but these apply to a student data base.

`void read_prsnt_txt(int map, int *file_offset, int *disp_map, int *disp_ndx, char *disp_str)`
This routine reads a line of text, pointed to by `file_offset`, from a streamed file into a buffer that is pointed to by `disp_str`. If `map` equals a -1, then the entry that is indexed by `disp_ndx` in the seek address list, `disp_map`, is built. And in all cases, the next value of `file_offset` is computed.

`int prsnt_txt(int map_ndx)`
This routine presents a text that is pointed to by `map_ndx`, which is an index into another list that contains some positional information about each block of text in a given lesson.

`int score_txt(int map_ndx)`
This routine uses the lesson map entry, indexed by `map_ndx`, to score the preceding portion of a lesson block. It also asks the user to review any preceding answers before scoring the section.

`int lesson_txt(int map_ndx)`
This routine uses the lesson map entry, indexed by `map_ndx`, to determine the next instruction/lesson block to be presented based upon the user's knowledge level.

`void get_max_min(int map_ndx)`

This routine uses the lesson map entry, indexed by `map_ndx`, and determines the highest and lowest values that are in the answer set. The sum of the max and min values are stored in the user's data base.

`void reply_pos(int map_ndx)`

This routine uses the lesson map entry, indexed by `map_ndx`, to position the cursor in the appropriate screen position for a user's response to either a multiple choice, true/false, or yes/no type of question.

DEC VAX 780

As stated earlier, the interviews with several IWDs were inconclusive in the attempt to establish some quantifiable criteria for measuring the developing skills of a student WD. But these interviews did indicate that a common appraisal basis did exist in a non-verbal context. Consequently, the approach of this development was to provide a first approximation and target for criticism using "timely completion of an action" as a starting criterion in order to elicit critiques from the IWDs. In turn, these comments would be used to improve the criteria, find new metrics, and improve the expert model. Hence, several versions of the software are expected to evolve. So rather than saying that the software "evaluates ...", the term "attempts to evaluate ..." is applied to connote that major revisions to this software are expected with the possibility that our initial criteria could be decomposed, tossed out, or embellished.

As developed, this software exists in 3 files and have the following functional relationships:

`sdt_eval.h`: This is the header file for the DEC VAX 780 portion of the software.

`sdt_eval.c`: This is the overall controlling function for this portion of the software. It attempts to evaluate the switch responses of the WD user.

`eval_rtns.c`: These are the common functions that are used in `sdt_eval.c` during the evaluation process.

Implementation

In order to evaluate the output from an AWACS scenario in the most flexible manner possible, the software uses a script to evaluate a WD's console operation skills. This script can consist of one or more user-supplied events that are described to the software by the use of keyword values. All these values are taken from either a streamed file called `switches.dat` or are part of the software.

The keyword values that are taken from **switches.dat** consist of the names, coded values, and code ids of the:

- a. Feature and Category Select switches
- b. Alarm/Display Control Panel switches
- c. Function Select Panel switches

All fields are left-justified and separated with the | character to assist with visual discrimination. The format of each record is as follows.

Field 1 (27 characters): This is the name of the switch as they are identified on a WD's workstation console.

Field 2 (4 characters): A 4-digit field that corresponds to numerical value of the switch as it is encoded in the Simulation software (See file **switches.h**).

Field 3 (3 characters): When available, these characters correspond to an abbreviated value used by the **switches.c** software in its output to the Logger file.

For example the specification of *Bearing & Range* function switch appears as:

```
BEARING RANGE           |23 |B-R
```

Those keyword values not taken from the **switches.dat** file are coded into the software. These consist of the terms:

- a. Checkout Console: Used to demarcate an event consisting of the Console Checkout procedure.
- b. Done: Used to indicate the termination of a script.
- c. Window: Used to specify a maximum period of time (no. of seconds) during which an event should occur.
- d. Key: Used to specify the numerical value that is associated with an event on a logger file.
- e. Text: Used to specify a text value that can be used for additional discrimination.

- f. **Alternate:** Used to specify a function switch action. In addition, this option can be specified in groups such that each group represents an another method of performing an equivalent action.

Each user-supplied event is listed in a file and separated from each other by an empty line. In addition, each event is tagged with a field [1-4 characters] that must start with a numeric and is terminated with a `:`. The follow-on field can be either:

- a. A label [1-27 characters]
- b. Keyword value **Checkout Console**, **Done**, or those that are found in the `switches.dat` file.

Thus, an event is denoted by a line that has the follow specification:

tag: {label, appropriate keyword}

where one of the fields enclosed between {...} is necessary, but interchangeable. Additionally, if a label is used, then the use of the **key**, **text**, and **alternate** options are also required.

For example, suppose we wanted to describe the Console Checkout event follow by some event called "Find and Tag a Tanker." These could appear as:

```
1: Checkout Console
  . ] Other options
  .
  .

2: Find & Tag Tanker
  . ] Other options
  .
  .
```

The next line that is associated with the specification of an event has the following format.

```
window = xxx.xx
```

where the field `xxx.xx` denotes the specification of a floating point value indicating the number of seconds within which the associated event must be completed.

In our example this specification would appear as:

```
1: Checkout Console
  window = 180.0
  :
  : ] Other options
  :
```

```
2: Find & Tag Tanker
  window = 60.0
  :
  : ] Other options
  :
```

The **key** option line has the following format.

```
key = xxxx
```

where the field **xxxx** is an integer value that corresponds to a keyword value that is found in the **keywords.h** file from the Simulation software.

For our example, if each event were tied to a message, then they would appear as:

```
1: Checkout Console
  window = 180.0
  key = 1014
  :
  : ] Other options
  :
```

```
2: Find & Tag Tanker
  window = 60.0
  key = 1014
  :
  : ] Other options
  :
```

The **text** option line has the following format.

`text = '{text string (1-27 characters)}'`

where the text string that is enclosed between single quotes consist of the same or all of the leading characters in the free text portion of a logger file record.

Again, in our example this specification would appear as:

```
1: Checkout Console
  window = 180.0
  key = 1014
  text = 'a text string'

2: Find & Tag Tanker
  window = 60.0
  key = 1014
  text = 'another text string'
  .
  .
  . ] Other options
```

The specified **key** and **text** values are use to find the next occurrence of these values in the logger file and constitutes the start of an event. Whereupon, the use of one or more groups of the **alternate** option takes place.

For the **Checkout Console**, the use of the next option is recognized. However, it is limited to the specification of the **Assign Console** switch action. This feature was added so that the **Assign Console** switch action could be tied to the **Checkout Console** event.

Each **alternate** option line has the following format.

`alternate {tag} = {switch action keyword}`

where:

tag = 1-8 character field that must start with a numeric.

switch action keyword = the name of a switch that is found in the **switches.dat** file.

A group can consist of one or more repetitions of the **alternate** keyword. For example, suppose an event called "Find & Tag a Tanker" could be identified by the message "01 FIND & T", and could be accomplished using either the **Request SIF SD**, **Locate SIF**, or

Re-Init switch actions. In addition, suppose that this event had to be done in one minute from the time of the message. The event could appear in a script as:

```
1:    Find & Tag a Tanker
      window = 60.0
      key = 1014
      text = ""01 FIND & T""
      alternate 1 = Request SIF SD
      alternate 2 = Locate SIF
      alternate 3 = Re-Init
```

Now suppose that a fourth method of accomplishing the same event required two switch actions called **Switch 1** and **Switch 2**, then the same event would appear as:

```
1:    Find & Tag a Tanker
      window = 60.0
      key = 1014
      text = ""01 FIND & T""
      alternate 1 = Request SIF SD
      alternate 2 = Locate SIF
      alternate 3 = Re-Init
      alternate 4 = Switch 1
      alternate 4 = Switch 2
```

It should also be noted that the total number of **alternate** options that can be specified in any single event has a software limit of 25.

Another file of interest is the **logger file**. This file is a derivative of the original **logger.out** file that is produced during an execution of the Simulation software. This **logger file** is the output of the **Pass 6** operation from the REDUCE software² and represents the all the captured data in a time order manner.

Program Documentation

sdt_eval.h

This is the header file for this portion of the ITS software. Like **itsdef.h**, it contains the definitions of the variables and structures that are shared by the programs in the application, i.e., **sdt_eval.c** and **eval_rtns.c**.

²Systems Research Laboratories, Inc.: "Research and Development Computer Software Report, Delivery Order 0008, Attachment 2, Sequence 1", Contract No. F33615-87-D-0601, September 1990, pp. 22-26.

Of the structures that are included in this file, the `evnt_skel` specification and its use as `evnt_desc` requires some explanation. As `evnt_desc`, this structure contains the controlling information for the analysis of an event. The values are initialized and loaded from the event script file for each event at the onset of processing. The following is an explanation of this structure's usage.

`evnt_seq`: This is a 4 character array that contains the tag value that is associated with the event.

`struct evnt_var evnt_label`: This structure contains the information extracted for the event demarcation line, the **Window**, **Key**, and **Text** specification options.

`no_var`: This contains the number of variations that were specified via the **alternate** options. Suppose that the following event specification were used.

```
1:    Find & Tag a Tanker
      window = 60.0
      key = 1014
      text = "01 FIND & T"
      alternate 1 = Request SIF SD
      alternate 2 = Locate SIF
      alternate 3 = Re-Init
      alternate 4 = Switch 1
      alternate 4 = Switch 2
```

The value of `no_var` would be 4.

`step_per_var`: This is an array of 5 integer values. Each represents the number of function switch actions that comprise each specified alternate. In the above case, the assigned values would be 1, 1, 1, 2, and 0 for each of the entries in `step_per_var`.

`struct evnt_var variant`: This is an array of structures that contains the function switch action information for each of the **alternate** option specifications. Again for the cited example, the first 5 structures would contain the appropriate values.

`sdt_eval.c`

This program provides the controlling logic for the evaluation of the acquired console operation data.

eval_rtns.c

This is a collection of routines that perform a partial evaluation of the data collected in the logger file.

void `cntr_ln(int y_coord, char *txt_str)`

This routine is identical to that found in `its_rtns.c`. It centers the text in `txt_str` in the line specified by `y_coord`.

void `quick_exit()`

This routine calls the `endwin()` function to clean up the Curses software before exiting.

void `get_fil_str(char *filename)`

This routine prompts the user for an appropriate filename and store the requested string in `filename`.

void `open_err(char *filename)`

This routine prints a message indicating that an error occurred while opening the file specified in `filename`.

void `read_swt_data(FILE *switch_fp, struct switch_ent *swt_ptr)`

This routine reads a record from the file pointed to by `switch_fp`, `switches.dat`, loads the values into the entry of the table that is pointed to by `swt_ptr`.

void `read_log()`

This routine reads a line from the logger file and partially parse the data into the appropriately labeled variables found in the structure of `cur_log_rec`. It also ensures that all fields are null terminated strings.

In addition, this routine also counts excessive pushing of the **message acknowledge** button. (The term "excessive" means pushing the button when no message acknowledgement is required.) Three or more excessive depressions will trigger the start of the computation to determine the tapping variability and the occurrence of the next message will trigger the print of the variability statistic.

void `left_just(char *txt_str)`

This routine will left-justify the text in `txt_str`.

int swt_label_match(struct switch_ent *swt_tab_ptr,
int swt_cnt, int ent_no)

This routine will search the function switch table, with **swt_cnt** many entries, that is pointed to by **swt_tab_ptr** for a matching value in the **evnt_desc** structure. If **ent_no** is a -1, then the switch keyword specified in the event demarcation line is used. Otherwise, the name specified in the **alternate** line is used. Moreover, along with the indication that a match has occurred, the associated switch number and abbreviated switch name are also returned.

void blink_msg_on(int line_no, char *txt_str)

This routine will present the text in **txt_str** in a blinking format on the line specified by **line_no**.

void blink_msg_off(int line_no)

This routine clears and turns off the blinking message on line number **line_no**.

void read_event()

This routine reads the event script file and loads the **evnt_desc** structure that describes the desired event to the software. It is the values in this **evnt_desc** structure that are used to evaluate an event.

void opt_chk()

This routine is called by **read_event** to load the **evnt_desc** structure with the values taken from the **Window**, **Key**, **Text**, and **Alternate** option specifications.

void swt_state()

This routine gets the state (on or off) of the category and feature select switches as they exist prior to the use of the simulation by the WD.

void console_chk()

Currently, this routine attempts to identify the correct execution and completion of steps that affect the category and feature select switches on the Console Checkout checklist. Consequently, this routine's execution is contingent upon the specification of the **Checkout Console** event in a script file.

However, certain empirical assumptions were made as to the action that constitutes the end of the **all switches on** and **all switches off** process. Currently, the completion of the **all switches off** is indicated when the first feature select switch goes to the **on** position and the **all switches on** is indicated when the first function switch action is taken.

In addition, the inclusion of the **alternate** option specifying the **Assign Console** switch action is allowed with the event specification. Hence, taking this switch action is an optional part of the Console Checkout process.

void switch_chk(struct evnt var *swt_ent)

This routine checks for the selection and **complete** status return of a function switch action, pointed to by **swt_ent**, within a specified time window. This check also exists for a follow-on switch action in which the antecedent switch action remains in effect.

In addition, some very minor checking of some associated switch options were included for only a few of the function switches. This was done as a check of the feasibility of including more expanded option checking.

void csl_chk(int ndx)

This routine is one of the attempts to expand the option checking capability of the application. It tries to examine the **Assign Console** switch action for the WD station indicated by **ndx**.

void cmt_chk()

This routine is an attempt to expand the checking associated with the **Commit** switch action. It tries to identify the pairing, intercept, and mission that were specified.

void win_chk()

This routine is an attempt to expand the **Init** switch action. It tries to determine the object whose symbology was initiated.

void wmc_chk()

This routine is an attempt to expand the **Mode IV** switch action. It tries to determine the object of the mode check.

void multi_switch()

This routine provides the controlling logic to check the **alternate** option specifications that can be associated with an event.

Recommended Development

The following are some suggested software improvements that are directed toward the development of a functional AWACS ITS.

1. Integrate the AWACS Simulation and ITS software into a single package so that it will qualify as an expert system that is limited to switch action procedures. This limitation obviates the knotted problems that are often associated with the inclusion of strategy.

For the start of this effort, the current ITS operation will be continued, i.e., maintain execution in batch fashion, and improve the software so it can reliably detect the beginning and ending responses to events. In turn, each established detection scheme will be coded into the Simulation software so that the end result should be the limited expert system that is desired.

2. Using the just described, limited expert system as a kernel, this development would add the capability to detect and suggest solutions to switch action procedural problems while the Simulation is running.

Knowing that the Simulation software controls the scenario presentation to the student and that it can now determine the correctness of switch action procedures, it is now possible to determine the appropriateness of proffered switch action procedures in response to controlled scenario situations. This development would allow the software to passively monitor a student's actions and provide real-time diagnostics as procedural errors occur.

3. Incorporate a reactive Instructor and Student Model into the software that was developed during Step 2.

Since the software can now monitor a student's switch actions to known situations, this would begin the development of both the Instructor and Student Model software. Essentially, the software will be given the capability to evaluate a student and determine whether the student requires either advancement, remediation, or be kept at status quo. These software decisions will be based upon actions that were taken. Consideration of actions that were omitted will be avoided unless outcomes are blatantly obvious.

The following are suggested changes to the existing software.

1. Besides determining the start and stop of each switch action, each of the of the associated switch-checking modules could be made considerably more intelligent, e.g., devise methods of linking such things as time delays and erroneous inputs with help messages and switch menus. This would, in effect, provide an interim capability for both the student and instructor to review performance.
2. Provide a better prompt for Control key paging functions. This may entail just displaying paging options in appropriate places on the screen, i.e., **Ctrl-P**, **up-arrow**, **Ctrl-B** at the top of the screen and **Ctrl-N**, **down-arrow**, **Ctrl-F** at the bottom of the screen.
3. Options to develop:
 - a. Establish a criteria for those values that are to be scored and stored.
 - b. Provide a mechanism for the student to review material and answers, but preclude the capability to change original values.
 - c. Establish criteria for demotion, promotion, or instructor intervention based upon scores.
4. Build a utility to assist in the development of a lesson and/or instruction block so the instructor's attention can be focused on content and not procedure.

Appendix A

3 SEP 91 Ltr from Capt. Fowler

3 Sep 91

Matt,

As promised, here's a breakout of the switch actions taught during Block I of the new IQT WD course, which I believe will enter tryout in late Oct/early Nov. Sorry for the delay; seems something always comes up and obscures little projects like this.

Let me know if I can be of any more assistance. My new number is DSN 884-7232, but Roy Houchin and Tina Livingston are still at the old number (DSN 884-7785).

*Regards,
Keith Fowler*

- Day 1 - Course Orientation; Pubs Posting
- Day 2 - Sim Safety; Console Checkout; Assign Console S/A
- Day 3 - Assign Console S/A; TD Index S/A; Line S/A; Circle S/A; Coordinate S/A; Tactical Brg/Rng
- Day 4 - Same as Day 3, but add ADS Panel familiarization
- Day 5 - Restricted Area S/A; Bearing and Range S/A; RN/DES/NTN SD S/A; Initialize Special Point S/A; Add/Delete Airbase S/A
- Day 6 - Same as Day 5, but add Area Define/Delete S/A, Locate SIF S/A; Corridor IFF SD S/A
- Day 7 - Request SIF S/A; Initiate S/A; Mode IV S/A; Reinit S/A
- Day 8 - Same as Day 7, but add Radar/IFF Tracking S/A; Assign/Defer S/A; Request/Assign IFF/SIF S/A; and study of track blocks.
- Day 9 - Building database and situational awareness through use of previously-taught switch actions; using assigned radios; performing flight follow missions
- Day 10 - Flight follow; inflight separation; inflight emergencies; and completion of mission related paperwork
- Day 11 - Same as Day 10
- Day 12 - Practice for unit proficiency check
- Day 13 - Block I proficiency check

circles are switch actions we don't have in our Sim

Appendix B
IQT-WD READING GUIDE

IQT-WD READING GUIDE
(AS OF 6 JUN 90)

This guide lists the required daily reading for the IQT-WD course. The daily reading should be accomplished prior to each day training.

Section I lists the reading for Block I (Training Days 1-13). The left column shows the lesson title or switch action and the right column shows the required reading. The documents you'll be reading for Block I are broken down into two volumes (student study guides) and the 28AD HB 55-1, Vol II 20/25.1), also known as the "Positional". The abbreviation (SG) followed by a number tells you which chapter(s) to reference in the study guides. Read the information in the chapter(s) and positional to better prepare yourself for academics and simulator instruction. Many switch actions take up entire chapters. The abbreviation (P) followed by a number tells you on what page the information begins in the "Positional". Some (P) references list specific sections to read. The abbreviation (M) refers to the specific study module that relates to that subject. Again, accomplish all related reading before class.

Day 13	Written Eval and Critiques			

SECTION II

Section II lists the reading for Block II (Training Days 14-27). The left column gives the lesson titles while the right column shows the required reading. The following abbreviations will be used: (55-3) refers to TAC Regulation 55-3 and associated supplements/attachments, (55-79) refers to Joint Regulation 55-79 and associated documents, (T.O.) refers to Technical Order 1-E-3A-43-1-2, (M) refers to the individual student modules, and (SDC) refers to the Readiness Enhancement Program modules. The SDC readings are optional but do contain valuable information. They are located in the Boeing Learning Resources Center.

Day 14	Mission Flow/WD Responsibilities ADS Panel 1v1 Cutoff Geometry	M 55-3 T.O. 55-3 M M 55-79	WIL:CC03 Daily Training Missions Ch 5-2c pgs 5-5 - 5-7 Pgs 1-166-1-181,5-16& 17 Ch 5-3e pg 5-16 WIL:CMO1 Audio Distribution System ACC:CCO Crew Coordination Chs 2, 5 & 7 (TAC)

Characteristics

Appendix C
Experience Questionnaire

EXPERIENCE QUESTIONNAIRE

1. Have you ever been Mission Ready (MR) qualified as a 17XX ?
 - A. Yes
 - B. No

2. Were you MR as a _____ ?
 - A. U.S. or NATO E-3 WD/IWD/SD/ISD
 - B. U.S. or NATO E-3 ASO
 - C. Other

3. You are here because _____ .
 - A. You've been DNIF for more than 180 days.
 - B. You failed an EVAL and are being retrained.
 - C. You've only been NATO qualified.

4. Do you have any other 17XX experience ?
 - A. Yes
 - B. No

5. Your other 17XX experience includes _____ .
 - A. MCE
 - B. 407L CRC/CRP WC/WAO
 - C. 407L CRC/CRP ASO
 - D. NORAD/ICELAND/ALASKA ROCC/SOCC WC/WAO
 - E. NORAD/ICELAND/ALASKA ROCC/SOCC ASO
 - F. Manual Radar (FACP/TSP-43E)
 - G. Other

6. Does your other 17XX experience include a stint as an exchange officer with the US Navy in the E-2C ?
 - A. Yes
 - B. No

7. Did you graduate from Tyndall's Basic WC Course (E30BP-1741A-004)?
 - A. Yes
 - B. No

8. Were you _____ ?
- A. a Distinguished Graduate
 - B. in the top 25% of your class
 - C. average
 - D. barely passed
9. Did you take the automated course?
- A. Yes
 - B. No
10. Were you prior enlisted?
- A. US Air Force
 - B. US Navy
 - C. US Army
 - D. US Marine
 - E. No
11. Are you a former 16XX ?
- A. Yes
 - B. No
12. While you were prior enlisted in the Air Force, did you have the AFSC _____ ?
- A. 11XXX
 - B. 276XX
 - C. 30XXX (Air Traffic Controller at a RAPCON)
 - D. Other
13. While you were prior enlisted in the Army, did you have a previous job as _____ .
- A. Helicopter pilot
 - B. Fire control officer for Patriot or I-HAWK battery
 - C. Radar Air Traffic Controller
 - D. Joint Stars operator
 - E. Other
14. While you were prior enlisted in the Navy, did you have a previous job in _____ .
- A. Radar Air Traffic Control
 - B. Air Intercept Control
 - C. Other

15. While you were prior enlisted in the Marines, did you have a previous job in _____ ?
- A. Radar Air Traffic Control
 - B. Air Intercept Control
 - C. Other
16. Are you an exchange/liaison officer from _____ ?
- A. the U.S. Army
 - B. the U.S. Navy
 - C. the U.S. Marines
 - D. another nation
17. In the US Army, your previous jobs included _____ .
- A. Pilot
 - B. Joint Stars
 - C. Air Defense Artillery
 - D. Radar Air Traffic Control
 - E. ASOC (Air Support Operations Center)
 - F. Other
18. In the US Navy, your previous jobs included _____ .
- A. Pilot
 - B. Radar Intercept Officer
 - C. E-2C Naval Flight Officer
 - D. Radar Air Traffic Control
 - E. Air Intercept Control
 - F. Other
19. In the US Marines, your previous jobs included _____ .
- A. Pilot
 - B. Air Defense Artillery
 - C. Radar Air Traffic Control
 - D. F-4 Weapons System Operator (WSO)
 - E. MACS 5/6/7 Radar Control/Air Intercept Control
 - F. Other
20. You are a _____ officer.
- A. United Kingdom
 - B. Canadian
 - C. French
 - D. German
 - E. Other

21. You have experience in/as _____ .
- A. Pilot/Navigator
 - B. Weapons System Officer (WSO) in F-4/Tornado IDS
 - C. Schackelton AEW.2
 - D. NATO E-3 or UK E-3D AEW.Mk.1 ASO
 - E. NATO E-3 or UK E-3D AEW.Mk.1 WC/WAO
 - F. Other Radar Control Air Defense Work
 - G. Other (work not involving Radar)
22. You have experience in/as _____ .
- A. U.S. E-3 ASO
 - B. NATO E-3 WC/WAO
 - C. NATO E-3 ASO
 - D. NORAD ROCC/SOCC
 - E. Ground Radar Weapons Controller
 - F. Other
23. You have experience in/as _____ .
- A. Pilot/Navigator
 - B. NATO E-3 WC/WAO
 - C. NATO E-3 ASO
 - D. NADGE WC
 - E. Other
24. You have experience in/as _____ .
- A. Pilot/Navigator
 - B. French E-3F WC/WAO
 - C. French E-3F ASO
 - D. Other
25. Are you a Fighter Weapons Instructor Course graduate?
- A. Yes
 - B. No

Appendix E
ITS User's Guide

Intelligent Tutoring System

User's Guide

You may run the ITS program using a SGI terminal even though its software is spread across a SGI/UNIX and DEC/VMS based system. Functionally, the software is used as follows:

- The presentation of the questionnaire function is accomplished using only the SGI/UNIX system.
- The presentation of the Simulation is accomplished using a combination of both the SGI/UNIX and DEC/VMS systems.
- The presentation of the evaluation software is accomplished using only the DEC/VMS system.

Each function is started separately. While having to start each function is not ideal, the modularity did provide a better software development environment with no impact to the existing Simulation software.

Questionnaire Function

To begin the Questionnaire Function, you must have the "ITS Window" on the screen. This window is sized to an 80 character by 24 line (80x24) display for the presentation of questionnaire material. Enter the following command to initiate this window:

```
wsh -n 'ITS Window' -p175,300 -s80,24
```

Enter ITS at the prompt within the window.

ITS prompts you as follows:

1. Use cursor to select:
Instructor Student
then press 'Enter'

The desired selection is highlighted on the screen.

If you select the **Instructor** option, continue with Step 2.

If you select the **Student** option, continue with Step 13.

2. At this point, nothing on the screen changes. However, ITS expects you to enter the proper password before continuing. Entry of any other value causes the program to terminate without any indication. Once you enter the proper password, continue with Step 3.

3. ITS displays the following prompt:

Enter index of desired option:

1. Add an instruction block
2. Delete an instruction block
3. Modify an instruction block
4. Review an instruction block
5. Review a student's performance
6. Adjust a student's instruction

Selection:

Enter the desired option by specifying 1, 2 etc.

Note: Only options 1-3 are implemented. Selections 4-6 are not implemented at this time.

Enter one of the options 1-3, continue with Step 4.

Note: If you enter any value other than 1-6, ITS displays **Invalid response**. Press the **Enter** key to acknowledge and ITS displays the following message:

Terminate ITS [Y/N]:

If you enter any value other than Y, ITS interprets it as a N response and returns to the start of this Step. If you enter Y, the program terminates.

4. ITS prompts you for the specification of the path to the **Instructor** directory. However, if you have already accomplished this Step (on a previous pass through the program), ITS continues with Step 5. If not, the following display appears:

Enter path to "Instructor" file directory
->

You may either specify the **Instructor** file directory or press the **Enter** key to get the default value as stipulated by **instr_path_def** in **itsdef.h**. In both cases ITS prompts you to verify the specification:

Is path correct? [Y/N/Q]:

If you enter **Q**, the program terminates.

If you enter **N**, this Step is repeated.

If you enter **Y**, continue with Step 5.

5. ITS displays titles of existing **Instruction Blocks**¹ along with the following message:

Use cursor to position, 'Enter' to select, or 'Q' to quit

If you selected option 1 in Step 3, **Add an Instruction Block**, ITS displays a reminder of existing titles. For options 2 or 3, you may choose the **Instruction Block** that is to be modified or deleted, respectively.

If you selected option 1 in Step 3, continue with Step 6.

If you selected option 2, **Delete an instruction block**, ITS continues with Step 9.

If you selected option 3, **Modify an instruction block**, ITS continues with Step 12.

6. ITS asks you to enter a title to the new instruction block:

Enter title (max = 80 chars):

Enter the title and continue with Step 7.

¹ Refer to the section *Implementation* under **Silicon Graphics Software** of this document.

7. ITS asks you if there are any lessons² associated with this Instruction Block:

Any lessons in this instruction block [Y/N]:

You may create the instruction block entry by entering a **N** and ITS continues with Step 3, or if lessons are to be added, enter **Y** and continue with Step 8.

8. ITS displays the title of the instruction block and a numbered list of empty lesson entries, followed by the prompt:

Enter lesson name (max = 10 char):

Enter the names of the lessons that are to comprise this instruction block. When you have finished, terminate this Step by entering a **q** to lesson name and ITS continues with Step 3.

9. ITS displays the title of the instruction block and a numbered list of the lessons in the block along with the following prompt:

Do you want to delete lessons? [Y/N]:

If you want to delete only the Instruction Block, enter **N** and ITS continues with Step 3.

If you also want to delete lesson files, enter **Y** and continue with Step 10.

10. ITS displays the following prompt:

Delete (a)ll or s(ome) of these lessons:

If you want to delete **a**ll the lesson files listed, enter **a** and ITS continues with Step 3.

If you want to selectively delete **s**ome of the lesson files, enter **s** and continue with Step 11.

² Refer to the section *Implementation* under **Silicon Graphics Software** for additional details.

11. ITS displays the following prompt:

Enter index of lesson to be deleted:

Enter the number that appears with the lesson name.

Note: The numbered list is reordered after each deletion so indices can change for each specified deletion.

When you are finished deleting, enter **q** and ITS continues with Step 3.

12. ITS displays the title of the instruction block and a numbered list of the lessons in the block along with the following prompt:

Modifying (t)itle or (l)esson:

If you want to modify the title of the instruction block, enter a **t** and the prompt **Enter title** will overwrite the previous prompt and allow you to specify a new title. ITS continues with a repetition of this Step.

If you want to modify a lesson, enter **l** and ITS displays the following prompt:

Enter index of lesson to be changed:

Enter the number associated with the lesson to be changed and ITS displays the following prompt:

Change: (d)elele, (m)odify, (i)nsert:

If you want to delete the selected lesson, enter **d** ITS continues with the repetition of this Step.

If you want to insert or modify a lesson, enter **m** or **i**. ITS displays the prompt **Enter lesson name**. Modify or Insert the lesson name and ITS continues with a repetition of this Step.

To terminate this Step, enter a **q** and ITS continues with Step 3.

13. ITS asks you to specify the path for the **Instructor** and **Student** directories. If one or both use the default values, the values for the **instructor** and **student** paths are taken from the **instr_path_def** or the **stdt_path_def** values in **itsdef.h**, respectively.

For the **instructor path**, ITS displays:

Enter path to "Instructor" file directory
->

For the **student path**, ITS displays:

Enter path to "Student" file directory
->

Both are followed by the prompt:

Is path correct? [Y/N/Q]:

If you enter **Q**, the program stops.

If you enter **N**, this Step is repeated.

If you enter **Y**, then:

- a. If this response is to the **instructor path** prompt, ITS continues with a request for the **student path**.
- b. If this request is to the **student path** prompt, ITS continues with Step 14.

14. ITS prompts you (the student) for identification:

Enter name and SSAN:

Name:

ITS asks you to verify identification:

Is name spelled correctly? [Y/N]

If you answer **N**, this request is repeated.

If you answer **Y**, ITS requests your Social Security Number (SSAN):

SSAN: xxx-xx-xxxx

Verify your entry by answering:

Is SSAN correct? [Y/N]

If you enter **N**, SSAN portion of the this Step is repeated.

If you enter **Y**, continue with Step 15.

15. If the student is **new**, ITS displays the following verification step:

Are you a new student? [Y/N]

If you enter **N**, ITS repeats Step 14. Otherwise, if the student is either new, as indicated by a **Y** reply, or has not completed the Experience Questionnaire, as indicated in the student's database, ITS presents the questionnaire.

At the conclusion of the questionnaire, ITS begins the Simulation. If the student is above the base entry level, then the Simulation is used to present a scenario to try and validate the determined level. Otherwise, the Simulation consists of the **Console Checkout** lesson.

Simulation Function

Documentation for the Simulation Function can be found in:

Systems Research Laboratories, Inc.: "Research and Development
Computer Software Report, Delivery Order 0008, Attachment 2,
Sequence 1", Contract No. F33615-87-D-0601, September 1990.

Evaluation Function

To execute the Evaluation Function, you must be in a window with access to the VAX. It is also assumed that the student has completed a session with the Simulation. Prior to running the software to evaluate the student's performance, the data captured by the Simulation must be preprocessed so it is time ordered. This is accomplished by executing the following command on the **logger file**.

```
reduce "mindisk 0 f 1 l 6 sim 90 dir [logger file directory string] status"  
go  
quit
```

Upon completion of the **REDUCE** run, begin the evaluation by entering:

```
run sdt_eval
```

Processing continues with the following steps.

1. ITS asks you to specify the location of the output of the previously mentioned **REDUCE** process.

Enter name of the data file
Name:

Enter the catalog/file string of the **Pass 6 logger file** from **REDUCE**.
Upon completion, ITS asks you to verify that the file specified is a **REDUCE pass 6** output.

2. ITS asks you to specify the number of WDs tested:

Enter the number of WDs that were tested:

3. ITS asks you to associate the WDs with a specific console number by answering the following query for the each WD tested:

Enter console no. of xxx WD:

4. ITS asks you to specify the WD id number for each console that contained a tested WD.

Enter WD id no. for console x:

where x is substituted with the appropriate console number.

5. For this Step, ITS displays the following:

Select skill level for evaluation:

- 1) Naive
- 2) Novice
- 3) Journeyman
- 4) Expert
- 5) Master

Selection:

Enter an appropriate value. At this time, this value is not used. The intent is to provide multiple criteria when evaluating the scenario from a Simulation run.

6. ITS asks for the location of the event script file³:

Enter name of event script file
Name:

Upon answering the name of the event script file, processing continues until the event script is exhausted. As the absence or presence of each event is detected, a brief message about the condition is displayed. You must acknowledge each message with the Enter key before the program continues. Currently, display of the captured data is limited to the screen. However, recording these data to a file could be easily accomplished.

³ Refer to the section *Implementation* under DEC VAX 780 for an explanation of the event script file.
