THESIS

LINEAR MODELING OF ROTORCRAFT FOR
STABILITY ANALYSIS AND PRELIMINARY DESIGN

by

Walter M. Wirth, Jr.

September, 1993

Thesis Advisor: E. Roberts Wood

Approved for public release; distribution is unlimited.
This thesis investigates linear state space modeling of single main rotor helicopters culminating in a computer program that can be used for 1) stability and control analysis for any single main rotor helicopter or 2) preliminary design of a helicopter. The trim solution for a flight condition is found, the aircraft is perturbed about the nominal point, and the stability and control derivatives are determined. State space models and analysis tools are provided by the program. A notional attack helicopter designed for the 1993 American Helicopter Society Design Competition and a notional utility helicopter are used as examples.
Linear Modeling of Rotorcraft

ABSTRACT

This thesis investigates linear state space modeling of single main rotor helicopters culminating in a computer program that can be used for 1) stability and control analysis for any single main rotor helicopter or 2) preliminary design of a helicopter. The trim solution for a flight condition is found, the aircraft is perturbed about the nominal point, and the stability and control derivatives are determined. State space models and analysis tools are provided by the program. A notional attack helicopter designed for the 1993 American Helicopter Society Design Competition and a notional utility helicopter are used as examples.

I. INTRODUCTION

A. NATURE OF THE PROBLEM

"Life is too short to worry about helicopter dynamics."

Louis V. Schmidt
Professor Emeritus
Naval Postgraduate School

Helicopter dynamics, because of the complexity added by the high-mass, rotational components of the aircraft, namely the main and tail rotors, is often shunned by the aerodynamicist. The fact that main and tail rotors are the dominant contributors to flight dynamics makes the situation even worse. The understanding of flight mechanics, stability, and control is difficult enough without this added twist. As a result, courses in flight mechanics focus on solutions for fixed wing aircraft.

As will be shown, the flight mechanics of a helicopter are essentially no different than those of a fixed wing aircraft. The analysis of a helicopter in flight depends on solving the equations of motion, just like for a fixed wing aircraft. The key difference is the realization of a trimmed solution for the helicopter, which is an iterative process vice a straight forward, closed form solution as for the fixed wing aircraft. Once the trim solution is found, the evaluation of stability and control derivatives for the helicopter is done the same as for a fixed wing aircraft except that the derivatives for the main and tail rotors must also be evaluated.

An attempt was made in the preparation of this paper to be as consistent with fixed wing stability notation as possible. The large number of helicopter parameters which are unique or differ from fixed wing notation are listed in Appendix A. Additionally, the symbol $R$ is used for rolling moment instead of the more common $L$ to be consistent with Ray Prouty's notation, common to helicopter literature.
B. BACKGROUND

This project is the result of two needs at the Naval Postgraduate School.

1. MODELING OF ROTORCRAFT

Modeling of rotorcraft needs to be performed because the school is pursuing the acquisition of aircraft for flight testing of an auto-land helicopter system. The key deficiency in the use of simple, off-the-shelf rotorcraft is the lack of design data and theoretical analysis available for control system design. The modeling presented in this thesis is linear. Non-linear modeling can be performed on Flightlab which is available at the school.

2. SOFTWARE AVAILABILITY

Software available for preliminary helicopter design, such as HESCOMP or CAMRAD, is too complicated for students to use during a one quarter Helicopter Design course. The time required for a student to learn to use available software is prohibitive. The need for user friendly software, based on easily accessible programs such as MATLAB, culminated in two software packages being prepared for preliminary helicopter design. The first package JANRAD Performance [Ref. 1] solves the helicopter trim solution and is used to perform aerodynamic analyses. The second package comes from this study and is used to perform stability and control analysis, but uses the trim solution from JANRAD. Both packages require a working knowledge of MATLAB. MATLAB was used as the base program for these software packages because it is readily available and familiar to students because of its wide use at Naval Postgraduate School.

3. ASSUMPTIONS

The following assumptions were made in the foregoing analysis.

- A person using the program has a working knowledge of MATLAB.
- The aircraft trim condition is in level flight with climb angle ($\gamma_c$) equal to zero and no sideslip.
The main and tail rotors provide the only significant contribution to stability and control at a hover. Contributions of all other airframe components can be neglected at a hover.

Effects of the separate components of the helicopter contribute linearly to stability and control.

A single main rotor helicopter is used with a counter-clockwise (as viewed from above) rotating main rotor system.

The main rotor system is articulated, bearingless or rigid in plane.

Rotor blades are rigid.

The tail rotor rotates counter-clockwise as viewed from the left side of the helicopter.

The tail rotor is a teetering rotor with a delta-3 (pitch-flap coupling) hinge.

The tail rotor mast is perpendicular to the direction of flight.

Tail rotor coning can be approximated by using only tail rotor thrust and centrifugal forces.

The NOTAR™ boom is circular.

Inflow is uniform.

The fuselage of the helicopter is a rigid body and has aerodynamic characteristics similar to the Prouty example helicopter [Ref. 2].
II. SOFTWARE OVERVIEW

A. SOFTWARE ARCHITECTURE

The Joint Army/Navy Rotorcraft Analysis and Design program, or JANRAD, consists of two major subroutines with others under development. The first routine, JANRAD Performance, calculates the trim solution and various performance parameters of a helicopter. It is described in detail in Ref. 1.

The second major component is JANRAD Stability, written by the author, which 1) calculates all the stability derivatives of each component of the helicopter, 2) determines the linear state space model at any trimmable point in the forward flight regime, 3) provides the eigenvalues of the plant matrix and plots them in the Argand plane, and 4) determines the open loop transfer functions from control inputs to state outputs of the aircraft.

The basic architecture of the program is in Figure 2.1. The opening menu has the user enter data for performance calculations, then branches to either the performance or stability and control routines as desired. When the user selects the stability routines, additional input data is requested by the program for analysis. Data required for each major aircraft component is delineated under the chapters describing the stability and control solution for the component, and is listed in Appendix F.

Upon data entry, the program performs either a hovering or forward flight stability analysis of the helicopter. For calculational purposes, hovering flight is any velocity less than 20 ft/sec or 12 knots. Each analysis requires a number of perturbations about the nominal flight condition, which is done by performing a perturbation, then by calling the TRIM subroutine to determine the new trim condition. This procedure is described in more detail in following sections.
Figure 2.1. Program Architecture.
After the stability and control analysis is performed, the user can select from five different screen outputs depending on his/her needs. Information not available from the output screens can be called from the workspace as described in section III.A.

The linear models provided by the software are saved in a MATLAB data file and can be used to perform simulations of aircraft response due to particular control inputs. This is described in the Software Use, and Examples chapters.

B. MODELLING CONVENTIONS

The coordinate system used in the modelling of the helicopter is the standard set of stability and control axes (Fig. 2.2). The x axis passes through the longitudinal axis of the helicopter with the positive direction to the front of the aircraft. The y axis passes through the lateral axis of the helicopter with the positive direction to the right of the aircraft. The z axis passes through the vertical axis with the positive direction to the bottom of the aircraft, or toward the earth if the aircraft is upright. This set of coordinates is standard in flight mechanics, though it may be a bit confusing initially.

The coordinate system describing the locations of various aircraft components is the same coordinate system used to compute weight and balance for an aircraft. The fuselage station (x axis) determines the longitudinal position of the component, the butline (y axis) determines the lateral position, and the waterline (z axis) determines the vertical component. The axes are oriented with the x axis parallel to the longitudinal axis of the aircraft with positive direction to the rear, the y axis is parallel to the lateral axis with the positive direction to the right side of the aircraft. The z direction is orthogonal to the x and y axis with the positive direction upward (Fig. 2.2).

Modelling of the helicopter was done in standard state-space format, where the dynamics of the aircraft are described by a system of differential equations, written as the following system of matrix equations.
$\dot{X} = [A] X + [B] u$
$y = [C] X + [D] u$

$X$ is the state vector which contains the current state of the system. States are selected which are the outputs of integrators and that describe the motion of the aircraft. For the complete coupled system, the following states were selected per Ref. 3.

$u$ - velocity of the aircraft in the positive $x$ direction
$w$ - velocity of the aircraft in the positive $z$ direction
$q$ - pitch rate of the aircraft
$\theta$ - pitch angle of the aircraft
$v$ - velocity of the aircraft in the positive $y$ direction
$p$ - roll rate of the aircraft
\( \Phi \) - roll angle of the aircraft

\( r \) - yaw rate of the aircraft

\( \Psi \) - yaw angle of the aircraft

The first four states are used to describe the longitudinal characteristics of the helicopter while the last five are used to describe the lateral-directional characteristics. A fully coupled system is also described using these states.

The vector \( u \) contains the inputs to the system. In the case of the helicopter, the inputs are

- \( \delta B_1 \) - change in longitudinal cyclic or elevator
- \( \delta \theta_{\text{cm}} \) - change in collective
- \( \delta A_1 \) - change in lateral cyclic or aileron
- \( \delta p \) - change in anti-torque pedals or rudder

\([A]\) is the plant matrix and describes the dynamics of the aircraft. The plant matrix is determined by using Newton’s laws to sum forces and moments about the helicopter at an equilibrium condition. This yields a system of differential equations. The system of equations is written in matrix form where the matrix relating the states \( X \) with the derivatives of the states is the plant matrix \([A]\). The plant matrix used is described in NASA Technical Memorandum 84281 [Ref. 3].

The \([B]\) matrix shows the contributions of the inputs \( u \) to the system. \([B]\) multiplies the input vector \( u \), and the result is added to the system. Each element of \([B]\) is the partial derivative of the corresponding state with respect to the input. For example \( B(1,2) \) would be the partial derivative of \( u \) with respect to collective, \( \partial u / \partial \theta_{\text{cm}} \).

The vector \( y \) is the output of the system. The desired output is described by using the \([C]\) and \([D]\) matrices. The matrix \([C]\) is used to determine the output of the system from the states \( X \). If the values of the state vector are the desired output, as in the case of this paper, then the matrix is an identity matrix the size of the plant matrix; however, the \([C]\) matrix does not have to be the identity.
matrix and can be set up to provide a wide variety of output. For example, if the desired output is to be lateral acceleration, or $\ddot{v}$, then the fifth row of the plant matrix, which corresponds to the equation

$$\dot{v} = \frac{\partial v}{\partial t} + \frac{\partial v}{\partial w} \frac{\partial w}{\partial t} + \frac{\partial v}{\partial \delta} + \frac{\partial v}{\partial q} \frac{\partial q}{\partial t} + \frac{\partial v}{\partial \phi} \frac{\partial \phi}{\partial t} + \frac{\partial v}{\partial \psi} \frac{\partial \psi}{\partial t}$$

would be used in the $[C]$ matrix to provide the output.

The final matrix, $[D]$, is the direct transition matrix for the input. It can be used to provide a direct feed from the input vector $u$ to the output vector $y$.

C. THE TRIM SOLUTION

Before a stability and control analysis can be performed on a helicopter, the trim solution for the main and tail rotors must be obtained. The trim solution solves for the collective pitch ($\theta_m$), the thrust moment of the blade ($T_m$), the first lateral harmonic of blade feathering ($A_1$), the first longitudinal harmonic of blade feathering ($B_1$), the rotor coning angle ($\alpha_{\text{con}}$) and the tip path plane angle ($\alpha_{\text{tip}}$) of the main rotor. When these values are solved for, the first coefficient of longitudinal blade flapping ($a_{1m}$), and the first coefficient of lateral blade flapping ($b_{1m}$), are then computed. Additionally, the trim solution for the tail rotor is needed to provide tail rotor collective ($\theta_{\text{t}}$), the first coefficient of longitudinal blade flapping ($a_{1t}$), the first coefficient of lateral blade flapping ($b_{1t}$), and the tail rotor coning angle ($\alpha_{\text{t}}$) for stability analysis.

The trim solution for the main rotor is solved by the TRIM routine in JANRAD. The values $a_{1m}$, $b_{1m}$ are then computed in the Stability and Control Routine. The tail rotor solution is approximated using closed form solutions in the Stability and Control Routine.

D. GENERAL PROCEDURE TO EVALUATE STABILITY DERIVATIVES

Stability derivatives are determined by using closed form solutions whenever possible, and by solving multiple trim solutions about a nominal point to solve for unknowns.
By using the TRIM routine in the JANRAD program, the trim solution for the desired flight condition is determined. The helicopter is then perturbed about this nominal condition and retrimmed. From these additional solutions, the basic stability derivatives for the main and tail rotors are solved for.

By solving for the basic stability derivatives first, the helicopter can be described by using the same states as in the a standard linear model of a fixed wing aircraft \([u \ v \ w \ p \ q \ r \ \Psi \ \Theta \ \Phi]'\). Without solving for the intermediate derivatives first, the helicopter would have to be described using additional states for the main rotor, \([a_{iM} \ b_{iM} \ C_{T}/\sigma_{M} \ C_{H}/\sigma_{M} \ C_{Q}/\sigma_{M} \ \mu_{M} \ \lambda_{M}]'\), and the tail rotor, \([a_{iT} \ b_{iT} \ C_{T}/\sigma_{T} \ C_{H}/\sigma_{T} \ C_{Q}/\sigma_{T} \ \mu_{T} \ \lambda_{T}]'\). Aside from the fact that a model described in this fashion is inconsistent with the standard flight mechanic description, the size of the system model becomes large and intimidating. This is part of the reason that helicopter flight mechanics are generally avoided.

After the basic stability derivatives are determined, intermediate derivatives are evaluated. Closed form solutions are used whenever possible to solve intermediate derivatives. After an intermediate derivative is determined, the basic derivative and the intermediate derivative are combined using the chain rule to form the complete stability derivative. An example solution of a main rotor derivative follows.

Wanted: \(\frac{\partial X}{\partial \theta_0}_M\)

Find from rotor plots or numerically: \(\frac{\partial C_y/\sigma}{\partial \theta_0}_M\), \(\frac{\partial C_H/\sigma}{\partial \theta_0}_M\), \(\frac{\partial a_{i1}}{\partial \theta_0}_M\)

Compute:

\[
\frac{\partial C_y/\sigma}{\partial a_{i1}}_M = C_y/\sigma \frac{a}{\delta} \lambda'
\]

\[
\frac{\partial X}{\partial \theta_0}_M = -pA_{\delta}(\Omega R)^2 \left[ \frac{\partial C_y/\sigma}{\partial \theta_0}_M \frac{\partial a_{i1}}{\partial \theta_0}_M \frac{\partial a_{i1}}{\partial \theta_0}_M \frac{\partial C_H/\sigma}{\partial \theta_0}_M \right]
\]
III. STABILITY AND CONTROL DERIVATIVES

A. MAIN ROTOR CONTRIBUTIONS

The main rotor is the key contributor to helicopter flight dynamics. The strong coupling between the states of the rotor produce complicated responses in many of the aircraft states at the same time. This can be visualized through the following example.

If collective pitch is increased in forward flight, the increased drag in the rotor system increases the amount of torque required from the engine; this results in a yaw of the helicopter. Simultaneously, since the tip path plane is tilted forward, the forward thrust increases which increases the advanced ratio. This increase in advance ratio results in differing amounts of lift on the advancing and retreating sides of the rotor disk which results in a pitching moment because of the phase lag of the blades. At the same time, the pitching moment changes the angle of attack on the fore and aft blades, which changes lateral flapping, which changes the rolling moment. Because of the cross coupling between lateral and longitudinal flapping, there is a change in longitudinal flapping. And so on.

The basic stability derivatives of the main rotor are described in terms of the partial derivatives of the standard helicopter coefficients, $a_{1M}$, $b_{1M}$, $C_{1}/\sigma_{M}$, $C_{2}/\sigma_{M}$, $C_{3}/\sigma_{M}$, $\mu_{M}$, $\lambda'$, $A_{1M}$, $B_{1M}$, and the main rotor blade stiffness

$$\left( \frac{dM}{da_{1}} \right)_M = \left( \frac{dB}{db_{1}} \right)_M = \frac{3 e A_s \rho R (\Omega R)^2 a}{4 R}$$
These basic main rotor derivatives are then combined as described in the prior section to form the main rotor stability derivatives. A detailed list of the basic main rotor derivatives and the stability derivatives is available in Appendix C.

To solve for the derivatives, JANRAD uses input data from the performance menu, and output computations from the TRIM section of the program. The input required for the trim solution is found in the JANRAD Performance thesis [Ref. 1]. Output from the performance routine and input from the Stability and Control Routine New File menu (Fig. 3.1) are used to solve for \( a_{im}, b_{im}, C_{r}/\sigma_{M}, C_{q}/\sigma_{M}, C_{d}/\sigma_{M}, \mu_{M}, \lambda', A_{i}, B_{i} \). Input data can be changed in the Stability and Control Additional Parameters Menu screen (Fig. 3.2).

Figure 3.1. Main Rotor New File Menu.

The perturbation solution in conjunction with the equations in Appendix C solve for the partial derivatives of \( a_{im}, b_{im}, C_{r}/\sigma_{M}, C_{q}/\sigma_{M}, C_{d}/\sigma_{M}, \mu_{M}, \lambda', A_{i}, B_{i} \) with respect to each other, thus completing the evaluation of the basic main rotor derivatives. The CRUISE.M and HOVER.M routines then combine the basic and intermediate derivatives to give a produce a complete set of main rotor derivatives.

Main rotor output is displayed in output screen 2 (Fig. 3.3). Derivatives are stored in the workspace. Because of the large number of derivatives, it is impractical to display all of them on the screen. Instead, key derivatives and control power are displayed in the Key Control Parameters output screen (Fig. 3.4) AFTER all contributions from other aircraft components are determined.

*** OUTPUT DATA INSTRUCTIONS (screen 1 of 3) ***

Because this subroutine generates a large number of single value data not shown on the output screen, a text file VARLIST.TXT is on this disk which lists the variable names for all the stability derivatives. Stability derivative contributions for all major aircraft components can be found by reading the text file VARLIST.TXT, then asking MATLAB the variable name corresponding to the derivative.

Press any key to continue

Figure 3.5. Output Data Instructions, Screen 1.

B. TAIL ROTOR CONTRIBUTIONS

Before stability contributions of the tail rotor can be determined, the tail rotor trim solution must be derived. Since only the main rotor trim solution is computed in the performance section of JANRAD, the tail rotor trim solution is solved in the following manner.
By assuming that the shaft axis of the tail rotor is perpendicular to the flight path of the
helicopter, the tip path plane angle ($\alpha_{\text{tip}}$) is equal to longitudinal flapping ($a_{\alpha_{\text{f}}}$). Additionally, no
longitudinal or lateral cyclic pitch is introduced by the control system, hence $B_{\text{t}}=0$ and $A_{\text{t}}=0$. This
reduces the inflow parameter with respect to the tip path plane from [Ref. 2:p. 189]

$$\lambda' = \mu \left[ \alpha_{\text{tip}} - (B_1 + a_{\alpha_{\text{f}}}) \right] - \frac{v_1}{\Omega R}$$

to

$$\lambda = - \frac{v_1}{\Omega R} = -\sigma_{\alpha} \frac{\sigma}{2\mu}$$

Tail rotor thrust $T$, is computed by using the main rotor torque from the main rotor trim
solution, length of the moment arm to the tail rotor, lift of the vertical tail, and length of the moment
arm to the vertical tail. The moment contributions of the tail rotor and vertical tail must equal the
torque of the main rotor. This yields

$$T_{\text{T}} = \frac{C_{\text{a}} \rho A_{\text{m}} (\Omega R)^2 - L_{\text{v}} l_{\text{v}}}{l_{\text{T}}}$$

Tail rotor coning is arrived at by using centrifugal forces and tail rotor thrust. This gives the
following, where $\gamma$ is the Lock number of the tail rotor blades [Ref. 2:p 171].

$$a_0 = \frac{2}{3} \gamma \frac{C_{\alpha} / \sigma}{a} - \frac{3}{2} \frac{g R^2}{(\Omega R)^2}$$

Longitudinal flapping is determined by writing the flapping equations for the tail rotor in terms
of $a_0$, $C_{\alpha} / \sigma$, $\mu$, and the tail rotor pitch-flap coupling angle $\delta_{\alpha}$. Furthermore, this allows the lateral
flapping to be determined in terms of the above values [Ref. 2:p 189].
\[ b_{1s} = \frac{4}{3} \frac{\mu a_0 + C_f/\sigma \alpha}{2 + \mu^2} + a_{1s} \tan \delta_3 \]

\[ a_{1s} = \frac{\frac{4}{3} \mu a_0 + C_f/\sigma \alpha}{2 + \mu^2} \frac{[2 - \frac{4\mu}{2 + 3\mu^2}] \tan \delta_3}{2 - \mu^2 + [1 - \frac{4\mu}{2 + 3\mu^2}] \tan^2 \delta_3} \]

To arrive at \( \theta_{\alpha T}, C_f/\sigma, \mu, \) tail rotor twist \( \Theta_{IT}, \) and \( \lambda \) are used yielding [Ref. 2:p 187].

\[ \theta_{av} = \frac{\frac{4}{3} C_f/\sigma}{a} \left( \frac{1}{2} \frac{\mu^2}{2} \right) \theta_1 - \mu b_{1s} \tan \delta_3 - \lambda = a_0 \tan \delta_3 \]

At a hover, there is no longitudinal or lateral flapping in the tail rotor. Because of this, the tail rotor equations can be resolved in terms \( a_0, \Theta_{\alpha T}, \Theta_{IT}, hT, I_t, \) and the main rotor trim conditions. This results in the following set of equations for the tail rotor at a hover.

\[ a_{1s} = 0 \quad b_{1s} = 0 \]

\[ \frac{C_T}{\sigma} = \frac{d}{4} \frac{v_1}{\Omega R} \sqrt{\frac{\sigma_M (C_f/\sigma)_M}{2}} \]

\[ \frac{C_Q}{\sigma} = \frac{C_T}{2} \frac{c_d}{8} \]

where \( c_d \) is approximated from

\[ c_d = c_d \left( \frac{6C_f/\sigma}{\pi e c_t R_t} \right) \]

16
Once a trim solution has been determined, stability derivatives are found in the same manner as for the main rotor, by perturbing about a nominal point. At a hover, the stability derivatives are computed in terms of the main rotor stability derivatives as in Ref. 2.

These equations may produce flapping magnitudes that are lower than more exact solutions, but since the trends of the perturbations are the same in both cases, we can use these trim equations as the basis for solving the basic derivatives of the tail rotor (Ref. 2: p. 189).

In addition to the tail rotor parameters input from the JANRAD opening menu, additional parameters are required for the stability and control analysis. Tail rotor inputs are entered in the Stability and Control Routine New File menu (Fig. 3.6) and changed in the Stability and Control Menu Additional Parameters menu, screen 1 (Fig. 3.7).

Input the parameter to change:

Figure 3.7. Additional Parameters Menu, Screen 1.

You must have a tail rotor or NOTAR/thruster!

Figure 3.8. Missing Component Warning.

Tail rotor output is displayed in Input Variable output screen 3 and in the Tail Rotor Calculated Data screen (Fig 3.9).

Tail rotor derivatives are solved for in the same manner as for the main rotor. A detailed listing of tail rotor derivatives is in Appendix C.

### C. FUSELAGE CONTRIBUTIONS

The fuselage contributions to stability and control are typically arrived at through empirical methods, so are best estimated initially by referring to characteristics of similar helicopters.
Lift and drag moments of the fuselage depend on the angle of attack $\alpha_F$, and the sideslip angle $\beta_F$ of the fuselage. Because of the downwash induced by the main rotor, $\alpha_F$ is estimated by

$$\alpha_F = \theta - \gamma_c - \epsilon_{M_r}$$

where $\theta$ is the fuselage pitch attitude, $\gamma_c$ is the climb angle, and

$$\epsilon_{M_r} = \frac{\nu_F}{\nu_i} \frac{T_M}{4 q A_M}$$

The value $\nu_F/\nu_i$, the fuselage downwash ratio, is the only fuselage stability parameter required to be input into the stability and control program. It can be estimated by methods outlined in Ref. 2. A typical value of 1.5 is recommended otherwise.
The other parameters input with fuselage data are the cg location, and moments of inertia of the aircraft.

Input for the fuselage is made in the Stability and Control Routine New File menu (Fig. 3.10) and changed in the Stability and Control Menu Additional Parameters menu, screen 3 (Fig. 3.11).

**Figure 3.11. Additional Parameters Menu, Screen 3.**

Stability derivatives from the fuselage are combined with the stability derivatives of other components for display in the Key Control Parameters output screen. The individual contributions
of the fuselage to stability can be pulled from the workspace by finding the variable name in VARLIST.TXT and calling the value as described in the Main Rotor section.

The values of the basic fuselage stability contributions are set in the program to typical values found in Ref. 2. If one desires to change these values, edit the subroutine CBODYGRP.M lines 17 through 22, substituting desired values for the defaults.

D. HORIZONTAL STABILIZER CONTRIBUTIONS

Contributions of the horizontal tail are computed as for a fixed wing aircraft with one exception. In a helicopter, the downwash created by the rotor is very large, and in nearly all modes of flight, the horizontal tail is in the downwash and is affected.

The effects of this are accounted for by adjusting the dynamic pressure on the horizontal tail by determining the dynamic pressure ratio $q_{d}/q$, and downwash angles due to the main rotor $\epsilon_{mH}$, and fuselage $\epsilon_{fH}$. These effects are generally evaluated in some empirical fashion, but some general guidelines follow.

The dynamic pressure at the horizontal and vertical tail is generally lower than free stream due to momentum loss from the fuselage and main rotors. A first guess for $q_{d}/q$ can be made by using Figure 8.9 Ref. 2. If no information is available, the author recommends a typical value of 0.6 be used.

The main rotor downwash ration for the horizontal tail has the form

$$\epsilon_{mH} = \frac{v_{H}}{v_{1}} \frac{v_{1}}{V} = \frac{v_{H} D.L.}{v_{1} 4q}$$

The ratio $v_{H}/v_{1}$ has a maximum theoretical value of two because of the maximum theoretical downwash velocity achieved by the main rotor using momentum theory, but empirical measurements
indicate that higher ratios are obtainable [Ref. 2]. The term $v_\text{h}/v_\text{i}$ can be estimated by using Fig 8.11 Ref. 2. The author recommends a typical value of 1.5 in the absence of more precise information.

The fuselage downwash ratio has the form

$$e_{r_\text{u}} = e_{r_{\text{u},\text{z}}} + \left( \frac{dx_{r_\text{u}}}{\frac{da_\text{r}}{a_\text{r}}} \right) a_\text{r}$$

The fuselage downwash ratio can be estimated using Fig 8.14 Ref. 2. The fuselage downwash ratio includes the effects of any wings since most wings installed on a helicopter are small and do not warrant a separate term for downwash effects. A typical value of 0.25 is recommended when no other information is available. Detailed discussion on determination of these effects are contained in Ref. 2 page 489.

The final effect to account for is the time lag for change in rotor downwash to reach the horizontal tail. This effect is accounted for through the time lag

$$\Delta t = \frac{l_\text{H}}{V}$$

yielding the following equation for the angle of attack for the horizontal tail

$$a_\text{H} = \theta + i_\text{H} - (e_{r_{\text{H},\text{z}}} + e_{r_\text{u}}) - \gamma_t - \left( \frac{\partial \eta_{M_2}}{\partial z} \right) \frac{l_\text{H}}{V}$$

These effects, when combined with typical computations for horizontal stabilizer stability analysis, yield the equations found in Appendix C.

Input for the horizontal tail is made in the JANRAD Performance input screen with additional input required for stability analysis entered in Stability and Control Routine New File menu (Fig.
Height above reference datum/waterline (ft):

0. NO CHANGES
Input the parameter to change:

Figure 3.13. Additional Parameters Menu, Screen 2.

Stability derivatives from the horizontal tail are combined with the stability derivatives of all other components for display in the Key Control Parameters output screen. The individual horizontal tail stability derivatives can be pulled from the workspace by finding the variable name in VARLIST.TXT and calling the value from the workspace.
E. VERTICAL STABILIZER CONTRIBUTIONS

The stability derivatives are evaluated in the same manner as the horizontal tail. The only differences are that the swirl from the main rotor downwash, the induced flow from the tail rotor, induced velocities from the fuselage and aircraft sideslip all create an effective sideslip (sidewash) angle on the vertical fin.

If the tail rotor is mounted close to the vertical fin, the form for the downwash effect is the same as for the main rotor downwash on the fuselage

\[
\eta_T = \frac{D.L.}{4 \left( \frac{q^V}{q} \right)}
\]

where

\[
D.L. = \frac{1}{A_T} \left[ \frac{Q_H - L_T}{L_T} \right]
\]

The parameter \( q^V/q \) can be estimated using Figure 8.9 in Ref. 2. A typical value of 0.6 is recommended otherwise.

The effect of aircraft sideslip on the vertical fin is negligible when the tail rotor is in close proximity to the vertical fin because the induced velocities of the tail rotor are much higher than the sideslip velocities typical in the linear region of this analysis. In the case where the tail rotor is far away from the vertical fin, or when a NOTAR" is used, a typical value of sideslip effect is assigned by the program in the form
\[ \frac{d\eta}{d\beta} = \frac{de}{da} = 0.06 \]

The induced sidewash from the main rotor and other factors affecting the tail vertical fin are evaluated by Stability and Control section of JANRAD and do not need to be input by the user. A detailed explanation of these effects is available in Ref. 2.

Input for the vertical tail is made in the JANRAD Performance input screen with additional input required for stability analysis entered in Stability and Control Routine New File menu (Fig. 3.14)

and changed in the Stability and Control Menu Additional Parameters menu, screen 1 (Fig. 3.15).

As with the horizontal tail, results for the vertical tail are combined with other stability derivatives for final output, but can be called from the workspace individually as outlined previously.

F. WING CONTRIBUTIONS

Most helicopters do not have wings, and the ones that do usually have wings only in the sense that the wings are aerodynamic hard points for weapon mounting. But compound helicopters do have wings that are designed to provide a large amount of lift for the helicopter.

Stability and control analysis for a wing is the same as for a fixed wing aircraft, except that large amounts of rotor downwash must be accounted for. Rotor wash is accounted for in the same fashion as for the horizontal tail and the fuselage. The dynamic pressure at the wing is adjusted by

3. State Matrices.
4. Eigenvalues of the plants and plots of the roots.
5. Key control parameters.
6. Open loop transfer plots.

0. Exit screen view.

Enter a number;

Figure 4.6. Screen View Menu.

Selection 1, Input Data, is self explanatory, and will be skipped in the interest of brevity.

Selection 2, Calculated Data, has two screens. The first screen (Fig. 4.7) gives the calculated main rotor parameters of interest. Note that since the helicopter is hovering, many of the quantities are equal to or near zero. The second screen has calculated data for the anti torque system (Fig. 4.8). Again note that many parameters are zero since the aircraft has no forward velocity.

Selection 3 provides the state matrix representations of the longitudinal, lateral and coupled plants as well as the input matrices (Figs. 4.9, 4.10, and 4.11). The states are listed under each heading for convenience. These matrices can be used after exiting the program to simulate aircraft response to impulses, steps or any other variety of input. These matrices can also be used to develop
response to impulses, steps or any other variety of input. These matrices can also be used to develop state feedback control for the aircraft.

Selection 4 displays the eigenvalues and the root loci of the uncoupled and coupled plants. Before doing this, an instruction screen is displayed to assist in understanding the format of the output (Fig. 4.12).

The second screen displays the longitudinal and the lateral uncoupled eigenvalues, then immediately plots the roots (Fig. 4.13). The plots are META filed by MATLAB after display. To recover them on a hard copy, one must use the Graphics Post Processing (GPP) utility after exiting.

\end{bmatrix}
\]

Figure 4.10. Lateral/Directional State Matrix Representation.

The first root in the lateral directional plant is an artifact of the system representation and has no physical meaning. The other modes are the Dutch-roll and spiral modes. The longitudinal modes shown are the short period and phugoid.
Comparing the root estimates of the longitudinal and lateral plants with the roots of the coupled plant in the third screen shows close correlation.

The plots of the eigenvalues are in the Argand plane (Figs 4.15, 4.16, and 4.17). Note that the plant has some unstable roots. This is typical of helicopters. Very rarely are all the modes stable without some form of stability augmentation.
After you view the root loci plot, a meta file is made. When you are done a screen will tell you the file names of the meta files. To get a hard copy of the plots, you must graphics post process (GPP) the files for your particular printer set-up then, print.

NOTE: If ALL roots are real, MATLAB will NOT plot them in the Argand plane, but will plot the root against its position in the vector (e.g. the first root would be plotted as (1,root))

Figure 4.15. Longitudinal Roots.

Plots are saved under the following filenames:

- Longitudinal roots - rootlon.met
- Lateral/Directional roots - rootlat.met
- Coupled roots - rootcoup.met

Figure 4.18. Eigenvalues Closing Screen.
MIL-H-8501 has been superseded by ADS-33C, the numbers still provide information on the damping characteristics and control power of the helicopter.

The last selection, open loop transfer plots, provides the transfer function from a control input to a state output. The purpose of these plots is to allow the designer to design automatic flight control systems and analyze the best techniques for controlling unstable modes. For example, to see the
### Key Control Parameters (Screen 1 of 2)

**Cross Coupling**

- Designed damping:
  - Pitch: \(-35513.5\) ft-lbs/(rad/sec)
  - Roll: \(-35957.8\) ft-lbs/(rad/sec)
  - Yaw: \(-116759.1\) ft-lbs/(rad/sec)

**Control Power**

- Pitch: \(-17351.2\) ft-lbs/in
- Roll: \(10672.0\) ft-lbs/in
- Yaw: \(45355.3\) ft-lbs/in

---

Figure 4.19. Key Control Parameters, Screen 1.

### Key Control Parameters (Screen 2 of 2)

**Cooper Harper Pilot Ratings**

- Damping/moment of inertia:
  - Pitch: \((-0.89\) ft-lbs/(rad/sec))/(slug ft^2)
  - Roll: \((-1.03\) ft-lbs/(rad/sec))/(slug ft^2)
  - Yaw: \((-3.34\) ft-lbs/(rad/sec))/(slug ft^2)

- Control power/moment of inertia:
  - Pitch: \((-0.43\) ft-lbs/in)/(slug ft^2)
  - Roll: \(0.30\) ft-lbs/in)/(slug ft^2)
  - Yaw: \(1.30\) ft-lbs/in)/(slug ft^2)

---

Figure 4.20. Key Control Parameters, Screen 2.

Effects of collective pitch on forward velocity, \(u\), select the longitudinal set of plots from the screen (Fig. 4.21) and page through the plots until you get to "Collective Pitch to \(U\)." It can be seen as shown in Fig. 4.22, that there is little control gain from collective to forward velocity at a hover. Obviously, collective would be a poor choice for controlling fore and aft motion at a hover.

If one looks at "Longitudinal Cyclic to \(U\)," it can be seen that there is high gain from input to output, especially at the short period frequency (Fig. 4.23). This shows that longitudinal cyclic is probably a good choice for controlling fore and aft motion.
After you view a bode plot of the transfer function from input to state output, a meta file is made. When you exit, a screen will tell you the file names of the meta files. To get a hard copy of the plots, you must graphics post process (GPP) the files for your particular printer set-up then print.

While viewing a plot, press any key to go to the next plot.

Do you want to see longitudinal or lateral/directional plots?

1. Longitudinal (eight plots total).
2. Lateral Directional (ten plots total).

Enter a number:

Figure 4.21. Open Loop Transfer Plots, Screen 1.

Figure 4.22. Collective to Forward Velocity.

Another observation from this plot is that at low frequencies (e.g. when you hold the cyclic steady) there is good control response. This is consistent with flight experience. When the cyclic is displaced forward, the aircraft pitches forward as the cyclic is moved, until some equilibrium pitch attitude is reached. When the cyclic is stopped, the attitude remains fixed and the aircraft moves forward. Likewise, when the cyclic is moved back and forth very rapidly, the aircraft may vibrate, but the pitch attitude remains essentially fixed because the aircraft cannot move as quickly as the...
control input, hence, the aircraft does not change its average velocity.

These effects can be seen in the control responses of all the controls. In the lateral-directional plant, the response from lateral cyclic to sideslip, \( \psi \), has the same type of peak near the Dutch-roll mode, but response above the Dutch-roll frequency is reduced (Fig. 4.24).

---

**Figure 4.23.** Longitudinal Cyclic to Forward Velocity.

**Figure 4.24.** Lateral Cyclic to Lateral Velocity (Sideslip).
A complete set of Bode plots for the prouty helicopter can be found in Appendix G. The shapes of these curves is typical of helicopters with single main rotors and a tail rotor.

Hard copies of the plots are obtained in the same manner as the root locus plots. A complete list of command response META files is located in Appendix E.

The output from the screens is written to a diary after exiting the Screen View menu. The Output Data Instruction menus in Figs. 4.25 through 4.27 explain the data recovery procedures.

*** OUTPUT DATA INSTRUCTIONS (screen 1 of 3) ***

Because this subroutine generates a large number of single value data not shown on the output screen, a text file VARLIST.TXT is on this disk which lists the variable names for all the stability derivatives. Stability derivative contributions for all major aircraft components can be found by reading the text file VARLIST.TXT, then asking MATLAB the variable name corresponding to the derivative.

Figure 4.25. Output Data Instructions, Screen 1.

*** OUTPUT DATA INSTRUCTIONS (screen 2 of 3) ***

A. Data from the output screen saved to a file named: "filenamel.stb"

B. This is a text file, use the TYPE command to view the file or use a text editor to view/print the file.

C. Matrix and vector data saved to a default file named: "mstabdat.mat"

D. This is a "mat" binary file, use the LOAD command to retrieve the data for plotting.

E. Rename "mstabdat.mat" to another "mat" file. The file "mstabdat.mat" will be overwritten when the program is executed.

F. Do not rename the file as "filenamel.mat" The file "filenamel.mat" is already on disk and used for future editing.

Figure 4.26. Output Data Instructions, Screen 2.
B. A HELICOPTER WITH NOTAR™

A final example will be a notional helicopter designed for the 1993 annual American Helicopter Society (AHS) Design Competition, the Arapaho. The forward flight mode of the helicopter will be used. Since the procedures for entering and displaying data have been covered, only the salient points of the design will be addressed.

The helicopter incorporated a NOTAR™ tailboom. As a result, the tail rotor derivatives are unusual as are the command transfer Bode plots.

The Output file will have a zero displayed for all tail rotor computations except the tail rotor thrust. The thrust displayed in this case will be the NOTAR™ thruster force (Fig 4.28).

By comparing the longitudinal control matrices with and without a tail rotor (Fig. 4.10 and 4.29) it can be seen that a change in tail rotor thrust has a pitching moment contribution (look at the B(3,4) term). Because the tail rotor rotates about an axis that is parallel to the Y control axis, this contribution is to be expected with a change in tail rotor thrust requirement. In contrast, the NOTAR™ does not have this contribution because the thruster fan rotates on an axis parallel to the X control axis.
*** CALCULATED DATA (screen 2 of 2)***

arapac

Tail Rotor (zero if NOTAR)

tail rotor thrust = 264.2 lbs

Figure 4.29. Arapaho Control Matrix.

Figure 4.30 demonstrates the difference in flight control response with airspeed. In the hover case, longitudinal cyclic has little direct effect on vertical velocity. But notice that in the forward flight regime, a longitudinal deflection has a great effect on vertical velocity. A zoom climb can be done in forward flight but not at a hover.
Figure 4.30. Longitudinal Cyclic to Vertical Velocity.
V. CONCLUSIONS AND RECOMMENDATIONS.

A. CONCLUSIONS

The aerodynamicist should not be intimidated by the complexity of helicopters. The complexities of determining the stability characteristics of a helicopter are formidable, but helicopter flight dynamics are essentially no different than fixed wing flight dynamics. Modern software reduces helicopter analysis to a routine procedure, making the analysis of these characteristics much less time consuming.

B. RECOMMENDATIONS

To improve the fidelity of JANRAD Stability and Control, the following actions are recommended.

a) Expand the state matrix to include $a_{int}$, $b_{int}$, $C_r/\sigma_m$, $Ch/\sigma_m$, $Cq/\sigma_m$, $\mu$, $\lambda$, $a_{int}$, $b_{int}$, $C_r/\sigma_r$, $Ch/\sigma_r$, $Cq/\sigma_r$, $\mu_r$ and $\lambda_r$ for the tail and main rotors. This representation would allow students to run simulations on MATLAB that could show rotor flapping, cyclic pitch changes, and fluctuations in the coefficients of torque, thrust and H-force.

b) Expand the input screens to allow selecting different lift and drag characteristics for the fuselage. Even though this type of information is derived empirically, studies of existing helicopter with appropriate flight test data could be done without the added artificiality of a particular fuselage configuration. JANRAD currently uses fuselage aerodynamic characteristics of the Prouty sample helicopter as outlined in section III. C.

c) Improve the fidelity of the tail rotor trim solution. The method used to derive the tail rotor trim solution is extremely rough compared to the trim solution of the main rotor.
d) Expand the wing inputs to include dihedral mounted wings and wing sweep. Even though most helicopters do not use wings for lift or control, compound helicopters are likely to require a higher fidelity wing solution.

APPENDIX D. VARIABLE LIST.

Variable list for JANRAD Stability Routine

A - rotor disk area
Ab - area of blades
Abt - area of tail rotor blades
Ap - projected area of fuselage under rotor
A1 - lateral cyclic pitch
als - longitudinal flapping
a - main rotor blade lift curve slope
Ah - area of the horizontal stab
ah - lift curve slope of the horizontal stab
alph - angle of attack of horizontal stab
alphas - angle of attack WRT shaft axis
alphoh - alpha-zero-lift of the horizontal stab (at the trim condition)
alphov - alpha-zero-lift of the vertical stab
alphow - alpha-zero-lift of the wing
alpvs - angle of attack of vertical stab
alpw - angle of attack of wing
altpp - mean alpha TPP
ao - main rotor coning angle
aot - tail rotor coning angle
At - disc area of the tail rotor
at - tail rotor blade lift curve slope
at - tail rotor blade lift curve slope
Av - area of the vertical stab
av - lift curve slope of the vertical stab
Aw - area of the wing
aw - lift curve slope of wing
B1 - longitudinal cyclic pitch
bls - lateral flapping
beta - trim sideslip angle
bh - span of the horizontal stab
bv - semispan of the vertical stab
bw - span of the wing
c - main rotor chord
cdoh - Cdo of the horizontal stab
cdow - Cdo of the wing
ch - coefficient of ????
chsig - Ch/sigma
clvertmax - maximum cl of the vertical stab with full rudder defl
cmu - circulation coefficient for NOTAR™
cmun - design Cmu for NOTAR™ boom in hover (.3-.6)
cot - tail rotor chord
cpipitch - Control power/inch pitch
cpiroll - Control power/inch pitch
cpiyaw - Control power/inch pitch
cppitch - Control power pitch
cproll - Control power roll
cpyaw - Control power yaw
c - coefficient of thrust
ctsig - Ct/sigma
ctsigt - Ct/sigma of the tail rotor
ctr - wing root chord
ctw - wing tip chord
cq - coefficient of torque
cqsig - Cq/sigma
deldv - biplane effect (mutual interference of tail rotor and vertical stab)
delih - span efficiency factor of the horizontal stab
deliv - span efficiency factor of the vertical stab
deliw - span efficiency factor of the wing
delta3 - tail rotor delta-3 angle
delvmax - maximum rudder deflection on the vertical stab
desdmdq - designed pitch damping (dM/dq)
desndr - designed yaw damping (dN/dr)
desdrdp - designed roll damping (dR/dp)
deltafalphp - fuselage downwash ratio for the horizontal stab
deltafalpff - fuselage downwash ratio for the wing
deltafalpfb - fuselage sideslip ratio (= depsilondalpha)
di - NOTAR® boom diameter
e - blade offset
GW - gross weight
g - acceleration due to gravity
hh - horizontal stab vertical offset
hhd - height from waterline to horizontal tail
hm - main rotor vertical offset
hmh - height from waterline to main rotor hub
hs - total of slot heights for NOTAR® boom
ht - tail rotor vertical offset
htd - height from waterline to tail rotor hub
htn - NOTAR® thruster vertical offset
hv - vertical stab vertical offset
hvd - height from waterline to vertical fin
hw - wing vertical offset
hw - height from waterline to wing
htnd - height from waterline to NOTAR®
Ib - blade flapping inertia
Ibt - tail rotor blade flapping moment of inertia
Ix - mass moment of inertia about x axis
Iy - mass moment of inertia about y axis
Iz - mass moment of inertia about z axis
Izz - mass moment of inertia about z axis
Ic - Ixx*Izz
i - shaft incidence main rotor
ih - angle of incidence of horizontal stab
iw - angle of incidence of wing
lamp - lambda' - inflow ratio WRT TPP
lh - horizontal stab longitudinal offset
lhd - fuselage station of horizontal tail
lm - main rotor longitudinal offset
lmd - fuselage station of main rotor hub
lt - tail rotor longitudinal offset
ltd - fuselage station of tail rotor hub
ltt - NOTAR™ thruster longitudinal offset
lttd - fuselage station of NOTAR™ boom
lttnd - fuselage station of NOTAR™ thruster
lv - vertical stab longitudinal offset
lvd - fuselage station of vertical tail
lw - wing longitudinal offset
lwd - fuselage station of wing
lockno - main rotor lock number
locknot - tail rotor lock number
lt - tail rotor longitudinal offset
lv - vertical stab longitudinal offset
maxr - maximum rudder deflection
mu - advance ratio
mut - tail rotor advance ratio
n - a counter in CTPLOTS.M
nt - number of tail rotor blades
ohm - omega
ohmt - tail rotor omega
phin - NOTAR™ thruster sleeve rotation angle
pho - roll trim attitude (euler angle)
pppitch - Pilot rating (dM/dq)/lyy)
prroll - Pilot rating (dR/dp)/lxx)
pryaw - Pilot rating (dN/dr)/lzz)
q - dynamic pressure, 1/2 rho V^2
qhq - horizontal tail dynamic press ratio (qh/q)
qvq - vertical tail dynamic press ratio (qv/q)
qvin - dynamic press due to downwash at the NOTAR™ slots
R - blade radius
Rt - tail rotor blade radius
rho - air density
sidearm - maximum pedal travel or twist grip deflection
sigma - solidity
sigmat - tail rotor solidity
swirl - mean swirl angle off main rotor measured at the NOTAR™ slots
T - thrust
Tt - thrust of the tail rotor
thetal - main rotor blade twist
thetal1 - tail rotor blade twist
thetao - blade pitch at root
thetat - induced angle at the tip
tho - trim pitch attitude (euler angle)
V - forward velocity
vi - induced flow velocity at a hover
vlf - approximation for vi at forward airspeed
vfvi - rotor downwash ratio for the fuselage
vhvi - rotor downwash ratio for horizontal stab
vwvi - rotor downwash ratio for wing
uo - x initial velocity
wo - y initial velocity
wo - z initial velocity
xcg - height from waterline to cg
xcouple - designed cross coupling
Ytmaxn - maximum Y force from NOTAR\(^7\) thruster
ycg - length from buttline to cg
Yv - side-force of vertical stab
yhd - length from buttline to horizontal tail
ym - main rotor lateral offset
ymd - length from buttline to main rotor hub
ytd - length from buttline to tail rotor hub
ytnd - length from buttline to NOTAR\(^7\)
ywd - length from buttline to wing
yvd - length from buttline to vertical tail
zcg - fuselage station of cg
Zh - vertical force of horizontal stab
Zw - vertical force of wing

APPENDIX H. COMPUTER CODE.

Computer code for JANRAD Stability

A. STAB.M

% STAB.M
% NPS Helo Preliminary Design Program
% Stability and Control Routines
% Written by MAJ Walter M. Wirth, Jr.
% September 1993

% This program was designed as an interactive preliminary
design tool for stability and control analysis of a single
main rotor conventional or compound helicopter. The
program provides stability derivatives, roots of the aircraft
plant, plots of various control parameters as well as open loop
control bandwidths from control inputs to aircraft response.
