Abstract

The Precision Linear Shaped Charge (PLSC) design concept involves the independent fabrication and assembly of the liner (wedge of PLSC), the tamper/confinement, and explosive. The liner is the most important part of an LSC and should be fabricated by a more quality controlled, precise process than the tamper material. Also, this concept allows the liner material to be different from the tamper material. The explosive can be loaded between the liner and tamper as the last step in the assembly process rather than the first step as in conventional LSC designs. PLSC designs are shown to produce increased jet penetrations in given targets, more reproducible jet penetration, and more efficient explosive cross sections using a minimum amount of explosive. The Linear Explosive Shaped Charge Analysis (LESCA) code developed at Sandia National Laboratories has been used to assist in the design of PLSCs. LESCA predictions for PLSC jet penetration in aluminum targets, jet tip velocities and jet-target impact angles are compared to measured data.

Precision Linear Shaped Charge Designs for Severance of Aluminum Materials

Introduction

Sandia National Laboratories (SNL)¹⁻⁹ is involved in the design of Linear Shaped Charge (LSC) components varying in size from 10 to 10,500 gr/ft. These LSC components are required to perform such functions as rocket stage separation, parachute deployment, parachute system release, flight termination, system destruct, bridge destruction, and system disablement. Most of the LSC components for these systems require precise and reproducible jet penetration using the minimum explosive and component weights.

Sandia National Laboratories is currently involved in a task to design Precision Linear Shaped Charges (PLSC).¹⁻⁹ The sweeping detonation and 3-dimensional collapse process of an LSC is a complex phenomenon. The Linear Shaped Explosive Charge Analysis (LESCA) code was developed at SNL to assist in the design of PLSC components. Analytical output from the LESCA code is presented and compared to experimental data for various PLSC designs in the 16 to 10,500 gr/ft explosive loading range. The LESCA code models the motion of the LSC liner elements due to explosive loading, jet and slug formation, jet breakup, and target penetration through application of a series of analytical approximations. The structure of the code is intended to allow flexibility in LSC design, target configurations, and in modeling techniques. The analytical and experimental data presented include LSC jet penetration in aluminum targets as a function of standoff, jet tip velocities and jet-target impact angles.

General Linear Shaped Charge

The parameters or variables for a general linear shaped charge cross section are illustrated in Figure 1. The large number of variables defining a cross section makes the design of "the" optimum LSC a very difficult task. Therefore, the scaling of LSCs is not a simple task. The larger core explosive loading (gr/ft) of similar LSCs from the same manufacturer do not necessarily produce deeper jet penetrations in a given target. The generic operational characteristics of an LSC are shown in Figure 2. A metal tube or sheath containing explosive is formed so that a wedge is created on one side. The LSC is typically point- or end-initiated and a detonation wave propagates along the axis. The wedge collapses on itself and forms a high velocity sheet of jet particles. In general the jet particles are not projected perpendicular to the original direction of the liner nor is the particle velocity perpendicular to the jet front.

The leading, relatively high velocity (3-5 mm/ μ s), main jet produces most of the jet penetration into the target. The slower (1-1.5 mm/ μ s) rear jet or slug is usually found embedded in the cavity generated in the target by the main jet. Severance of a finite thickness target results from both the penetration of the main jet and the fracture of the remaining target thickness. The fracture portion of the severed thickness usually varies and can be up to 50% depending on the target strength parameters.

Conventional Linear Shaped Charge

Typically, conventional LSCs are fabricated by loading a cylindrical tube with granular explosives, and then roll- or swage-forming the loaded tube to the familiar chevron configuration illustrated in Figure 3.

Some of the disadvantages of conventional LSC designs are as follows:

1. Nonsymmetrical cross section,
2. Nonuniform explosive density,
3. Nonoptimized explosive and sheath cross sections, and
4. Historically designed for nonprecise jet cutting.

The explosive and sheath cross section of a conventional 25 gr/ft, aluminum sheathed LSC loaded with HNS II explosive is shown in Figure 4. Figure 5 illustrates the test-to-test variations in jet penetration of an aluminum target for the 25 gr/ft LSC shown in Figure 4.

Precision Linear Shaped Charge

For PLSC the liner, explosive, and tamper materials can be assembled as illustrated in Figure 6. The liner, tamper, and explosive are manufactured independently to allow the required control of fabrication methods which result in a more precise component. The quality control of the liner is most important in the performance of LSC devices.

An extruded, machined, buttered, or cast explosive is loaded or assembled between the liner and tamper components after these other two components are fabricated. The explosive can be loaded using single or multiple extrusions or by a "buttering" manual technique, if necessary. Assembly aids, such as the use of vacuum, are also useful.

The LESCA code has been used to improve the PLSC parameters. The explosive charge to liner mass ratio can be designed to optimize the transfer of energy from the detonation wave through the liner to the high-velocity jet. The explosive charge to tamper mass ratio can be designed to optimize the tamper material and thickness. The maximum tamper thickness is defined as that thickness beyond which no additional gain in the liner collapse velocity is obtained. The tamper can be made of a different material than that for the liner in order to:

1. Fit different configurations,
2. Allow for buttering of explosive,
3. Allow selection of tamping characteristics in material,
4. Allow for built-in shock mitigation properties, and
5. Allow for a built-in standoff housing free of foreign materials and water which degrade jet formation.

Linear Explosive Shaped Charge Analysis (LESKA) Code

The Linear Shaped Charge Analysis Program (LSCAP) was renamed the Linear Explosive Shaped Charge Analysis (LESKA) code. Therefore, throughout this report, LSCAP and LESKA code modeling, simulation, and predictions are interchangeable.

The modeling capabilities of the LESKA code include:

1. Sweeping/tangential detonation propagation,
2. Jet-target impact angles,
3. Liner acceleration and velocity,
4. Jet formation process,
5. Jet penetration process including layered targets,
6. Jet breakup stress model, and
7. Target strength modeling.

The code is inexpensive relative to hydrocodes, can be easily used to conduct parametric studies, and is interactive. The LESKA modeling of half of an LSC cross section (symmetry is assumed) is illustrated in Figure 7. Figure 8 shows sample LESKA output illustrating an LSC with a variable standoff to an aluminum target, sweeping detonation, a jet front envelope of 26.7 degrees, jet particle path relative to the target, and a comparison of the predicted and experimental target-jet penetration at 8 and 24 microseconds, respectively.

The jet tip envelope angle, theta, and jet particle velocity vector angle, alpha, are shown in Figure 9 for two different LSCs. Measured data from Cordin rotating mirror camera film records were used in the angle comparisons with LSCAP (LESCA) code predictions listed in Table I.

Assuming a symmetrical liner collapse process, typical LESCA code graphical representations are shown in Figure 10 for two different times. The LSC jet, slug, liner, tamper, and detonation product gases are shown in Figure 10.

LESCA code predicted jet penetration versus standoff data are shown in Figure 11 for configurations with the detonator at the minimum versus maximum standoff as illustrated in the top half of Figure 11. Experimental data are also compared to the LESCA code predictions in Figure 11.

"Flange" Type PLSC Results

The "flange" type PLSC design shown in Figure 12 was designed to allow the extrusion of the LX-13 explosive from one end of the liner and tamper assembly. The length that can be extruded varies with the area or size of cavity between the liner and the tamper materials.

25 gr/ft PLSCO

The LESCA code jet penetration versus standoff data are compared to measured data in Figure 13 for the conventional, 25 gr/ft, LX-13 explosive, copper liner, aluminum tamper LSC cross section shown in the figure. A similar PLSC was designed to compare jet penetration performance with the conventional LSC shown in Figure 13. Aluminum liner and tamper materials were used. The liner apex angle was 90 degrees. The explosive was LX-13 for the PLSC and HNS II for the conventional LSC. The LX-13 and HNS II explosive metal driving ability is about the same. The measured jet penetration into an aluminum 6061-T6 target versus standoff data are compared in Figure 14. The PLSC jet penetration was 40% greater than for the conventional LSC.

A parametric study was conducted incorporating the following variables into the 25 gr/ft, LX-13 explosive, flange PLSC designs similar to Figure 12:

1. Explosives
 - a. LX-13/XTX-8003/PBXN-301
2. Liner materials
 - a. Copper
 - b. Aluminum
 - c. Nickel

3. Tamper/confinement material
 - a. Aluminum

4. PLSC Geometry
 - a. Liner apex angles (β):
70, 90 and 105 degrees
 - b. Liner thicknesses (t):
.004, and .010 inches

The PLSC materials, liner thickness (t), and apex angles (β) were varied as listed in Table I. The PLSC jet tip velocity (V_j), jet envelope angle (Θ), jet-target impact angle (α), jet penetration into an aluminum 6061-T6 target (P), and optimum standoff (S.O.) are listed in Table I. The LESCA predicted data are compared to the experimental values for most of the parameters. The effect on jet penetration versus standoff due to variations in some of the PLSC cross-section parameters were published in Reference 1.

65 gr/ft PLSC7

The 65 gr/ft "flange" type PLSC7 cross section is shown in Figure 15. The jet penetration into a thick aluminum (6061-T6) target versus standoff data predicted by the LESCA code are compared to experimental data in Figure 16. The PLSC7 configuration includes a 0.012 inch thick copper liner, LX-13 explosive, and an aluminum tamper.

"W" Type PLSC Results

20 gr/ft PLSC5

The "W" type PLSC design shown in Figure 17 was designed to allow the explosive to be manually loaded in the liner in a buttering technique. This loading technique is required for relatively small PLSC cross sections where long segments are desired. The 20 gr/ft PLSC5, LESCA code predicted, jet penetration versus standoff data are compared to measured data in Figure 17. The PLSC5 configuration includes a 0.008 inch thick copper liner, LX-13 explosive, and aluminum tamper. The apex angle was 75 degrees.

30 gr/ft PLSC6

The "W" type design, 30 gr/ft PLSC6 cross section and copper liner actual cross section are shown in Figure 18. The LESCA-code-predicted jet penetration into an aluminum 6061-T6 target versus standoff data are compared to measured data in Figure 18. The PLSC6 configuration includes a 0.008 inch thick copper liner, LX-13 explosive, an aluminum tamper, and a 77 degree liner apex angle.

The test-to-test reproducibility for the PLSC6 design is illustrated in Figure 19. The measured jet penetration versus standoff data are compared for two tests. The measured jet penetration versus distance along the target data are shown in Figure 20 for two different tests and for a constant standoff of 0.100 inches.

Conclusions

Precision Linear Shaped Charge liner, tamper, and explosive fabrication processes have been demonstrated to produce increased jet penetrations in aluminum targets, more reproducible jet penetrations, and more efficient explosive cross sections compared to equivalent commercial LSCs.

The LESCA predicted jet tip velocities are within 20% of the experimental values (Table I). The predicted jet envelope angles relative to the PLSC are within 20% of the photometrically measured values (Table I). The measured jet-target angles are within 11% of the predicted values (Table I). Data for PLSC jet penetration into an aluminum target was presented demonstrating a 10% reproducibility for a given test (Figure 20). Data were presented to illustrate 40% improvement in jet penetration for a PLSC design compared to an equivalent 25 gr/ft conventional LSC design (Figure 14).

Jet penetration versus explosive loading data are summarized in Figure 21 and Table II for the PLSC designs for which data were presented in this report. The target material was aluminum 6061-T6. The explosive was LX-13. The tamping material was aluminum, copper or Lexan. The data include both "flange" and "W" PLSC designs. Both "W" and "flange" PLSC designs performed equally well. Data for fracture, which is part of the total severance thickness, of the target was not included in the jet; only penetration data were presented throughout this report.

A parametric study with the LESCA code to determine "the" optimum PLSC design is very difficult because of the large number of interrelated variables. This does, however, emphasize the importance of LESCA in obtaining a more optimized design than is currently available from conventional LSC designs. For a given, new component, once the customer requirements are defined (constraining or fixing some PLSC parameters), then the LESCA code can be used to optimize the remaining parameters.

The PLSC designs similar to those presented here have recently been incorporated in Sandia National Laboratory (SNL) systems. The Explosive Components Department plans to use PLSC designs in all future SNL systems requiring jet severance of materials including metals, Kevlar parachute suspension lines, and graphite-epoxy motor cases.
