Acknowledgments

The authors would like to extend their appreciation to the following individuals: SGT Sean L. Wentworth, SPC Mark A. Kenzie, SPC Carri L. Haigh, and Ms. Deborah R. Towns. Their assistance contributed to the successful completion of the light intensity profile measurements.

Introduction

Image intensification (I²) technology has greatly enhanced U.S. Army aviation night operations since its acceptance into Army aviation's rotary-wing program. However, aircraft interior and exterior lighting can cause problems due to the I² device's inability to distinguish between light originating from the outside scene and light originating from other sources within its field-of-view (i.e., cockpit lighting, aircraft position lighting, and other auxiliary lighting). Such coincidental sources can cause a degradation in the resulting image, to the extent that visual information may be lost.

The compatibility problems associated with cockpit/interior lighting have been well documented, and alternative lighting techniques and devices have been investigated (Rash and Verona, 1989; Rash and Martin, 1991; Rash and Snook, 1992). MIL-L-85762A (Lighting, aircraft, interior, NVIS compatible) establishes night vision imaging systems (NVIS) compatibility requirements for cockpit/interior lighting. MIL-L-6503H (Lighting equipment, aircraft, general specification for installation of) is the primary exterior lighting specification used by the Army. This latter specification has not been revised to take into account present mission and training requirements in the I² environment. Exterior lighting compatibility problems have been recognized, but only limited technical evaluations have been performed. The Department of the Navy recognized exterior lighting compatibility problems during the Research, Development, Test, and Evaluation (RDT&E) of the A-12 program (Kinney and Simpson, 1992), and developed test procedures for evaluating lighting compatibility in an effort to integrate exterior lighting for I² operations. In 1990, the U.S. Army Aviation Training Brigade (ATB), Fort Rucker, Alabama, informally surveyed Army aviation field units to identify problems experienced with rotorcraft-mounted exterior lighting used during I² operations. Problems identified are summarized in Table 1 by rotorcraft type and light type. Table 2 specifies the numbers, colors, and locations for rotorcraft position lights as designated in applicable Army technical manuals (TMs).

In attempts to minimize the degradation of I² performance, modifications have been made to position lighting in Army aviation tactical and training environments. Dim mode operation of position lighting on Army rotorcraft is available to reduce the overall intensity of exterior lighting. Masking configurations also have been developed to decrease intensity and angular distribution of position lighting. Masking is achieved through taping or painting of the glass dome covering the position lights at specific areas where emitted light may enter the crew

<u>Table 1</u>.

Rotorcraft type	Left (red) lateral position light	Right (green) lateral position light	Rear (white) tail position light
UH-1	Too bright for formation flight.	No problems identified.	Too bright for formation flight.
UH-60	Too bright, creates excessive glare in aircraft crew compartment.	No problems identified.	Too bright for formation flight.
OH-58	Too bright for formation flight.	No problems identified.	Too bright for formation flight.
AH-1	Too bright, tends to draw attention of crew. Puts right side of aircraft in shadow.	No problems identified.	No problems identified.

Problems identified with rotorcraft exterior lighting when using I² devices.

<u>Table 2</u>.

Position light designations on U.S. Army rotorcraft.

Rotorcraft type	Position lights
UH-1	Eight visible units; two red on left above and below cabin door; two green on right above and below cabin door; two white on top of fuselage just inboard of red and green lights; one white on bottom center of fuselage; one white on tailboom vertical fin.
UH-60	Three visible units; one red on left and one green on right outboard of landing gear support; one white on top of tail pylon.
OH-58	Three visible units; one red on left tip of horizontal stabilizer; one green on right tip of horizontal stabilizer; one white on aft end of tail boom.
AH-1	Four visible units; one red on left wing tip; one green on right wing tip; two white, one on either side of tail boom.

L

compartment and distract trailing aircraft in formation. Figure 1 depicts proposed masking configurations for lateral and rear position lights. While dim mode operation and partial masking of position lights reduce degradation of I² imagery, this modified lighting becomes suspect with regard to continuing compliance with requirements established by the Federal Aviation Administration (FAA) for light distribution and intensities. Specifications in MIL-L-6503H are based upon these requirements.

Figure 1. Proposed masking configurations for lateral and tail position lights.

The FAA defines requirements for exterior lighting angular distribution and intensities to ensure that aircraft flying in civil airspace have sufficient exterior lighting to provide aircraft position information. Intensity distribution requirements are defined for aircraft position (lateral and rear) lights to augment visibility of air traffic from all angles. Paragraphs 1387 through 1393 of Federal Aviation regulations (FAR), sections 27 and 29 specify requirements for: position light system dihedral angles, position light distribution and intensities, minimum intensities in the horizontal plane of forward and rear position lights, and minimum intensities in any vertical plane of forward and rear position lights, respectively. Table 3 summarizes the required light intensities at specified dihedral angles for position lights as defined in the FARs. In general, the specifications state that position lights shall provide their greatest intensities in the forward (lateral) and rear directions of the aircraft during flight.

Table 3.

20° to 110° 5	5.0	0° 5° 10° 15° 20° 30° 40° 90°	5.0 (1.0 x) 4.5 (0.9 x) 4.0 (0.8 x) 3.5 (0.7 x) 2.5 (0.5 x) 1.5 (0.3 x) 0.5 (0.1 x) 0.25 (0.05x)
Tail position light:			
0° to 70° 20	0.0	0° 5° 10° 15° 20° 30° 40° 90°	20.0 (1.0 x) 18.0 (0.9 x) 16.0 (0.8 x) 14.0 (0.7 x) 10.0 (0.5 x) 6.0 (0.3 x) 2.0 (0.1 x) 1.0 (0.05x)

Minimum intensity distribution requirements for aircraft position lighting.

Note: Horizontal angles are to left/right of vertical plane, vertical angles are above/below horizontal plane.

The requirements listed in Table 3 were developed prior to the introduction of I^2 devices into aviation and are based on unaided (naked eye) viewing. In an I^2 environment, the spectral distribution and intensity requirements for aircraft exterior lighting can be detrimental and result in hazardous flying Army Regulation (AR) 95-2, paragraph 9-2, stipulates conditions. only limited exceptions for night vision device flight training in U.S. Army tactical helicopters operating in the National Airspace System (NAS). A FAA grant of exemption permits lightsout operations in certain phases of night vision device training within well-defined and controlled areas when two or more rotorcraft are involved, and with advanced coordination with other nonparticipating parties. For all other areas in the NAS, authorization may be given for position lights to be on dim at altitudes up to 400 feet above ground level (AGL). Problems arise when aided formation flights, operating with modified lighting (masked or dimmed lighting), transition from military airfields to training areas at altitudes above 400 AGL in compliance with local noise abatement practices. In these situations, there are concerns that unaided civilian traffic cannot visually acquire and appropriately respond to aircraft operating with modified lighting configurations.

The Night Vision Device Branch (NVDB) of ATB is seeking to develop standardized methods for achieving lighting configurations which minimally degrade I² devices, while remaining within FAA regulations. ATB has requested that the U.S. Army Aeromedical Research Laboratory (USAARL) investigate the intensity distribution profiles of proposed masked position lighting configurations using criteria specified by the FAA. The original request, shown in Appendix A-1, asks for an evaluation of masked configurations for the aircraft position and anticollision lights. During preliminary test development, the anticollision light evaluation was eliminated due to the relatively small impact of this light and time limitations. The evaluation of dim mode intensity profiles was added. An amended tasking letter is shown in Appendix A-2.

This laboratory investigation evaluates the intensity distribution profiles of position lighting for the UH-1, UH-60, OH-58A, and AH-1 rotorcraft in dim mode and in proposed masked configurations. Baseline intensity distribution profiles were measured for each position light type operating in standard bright mode. Measured intensity profiles are compared to FAA requirements to determine the acceptability of dim mode operation and the impact of masking on light intensity distributions.

<u>Methodology</u>

Test Items

Two lateral and three tail position light units were supplied from four types of U.S. Army rotorcraft currently in use. Some position light fixture types are shared by multiple aircraft. Figure 2 shows lateral position light fixtures; the fixture shown on the left is used for the OH-58D and UH-60 rotorcraft, and the fixture shown on the right is used for the UH-1, OH-58A or C, and AH-1 rotorcraft. Figure 3 shows tail position light fixtures; the fixture shown on the left is used for the OH-58A, C, or D and AH-1 rotorcraft, the fixture shown in the center is used for the UH-1 rotorcraft, and the fixture shown on the right is used for the UH-60 rotorcraft. National stock numbers (NSNs) for the position light fixture types provided are listed in Table 4.

The lateral position light fixtures are identical for the left and right sides of the aircraft. When installed on the aircraft, the left and right fixtures mirror each other in orientation, and the left side orientation is configured with a red-colored dome filter while the right side orientation is configured with a green-colored dome filter.

One fixture is provided for the OH-58D/UH-60 lateral position light along with five different dome configurations. An unmasked dome configuration is provided in red and green colors. Figure 1a depicts a half-masked dome configuration also provided in red and green colors, and Figure 1b depicts a front-masked dome configuration provided in red only. Flat olive drab color paint is used to mask the inside surface of the half-masked dome, and flat gunmetal color paint is used to mask the outside surface of the front masked dome. Two fixtures are provided for the UH-1/OH-58A or C/AH-1 lateral position light along with two dome configurations, unmasked red and unmasked green. One fixture each is provided for the UH-1 and UH-60 taillights, and two fixtures are provided for the OH-58A, C, or D/AH-1 taillight. The taillight fixtures are configured with clear domes. Figure 1c depicts one proposed masked dome configuration provided for the OH-58A, C, or D/AH-1 tail position light. Green duct tape is used to mask the outside surface of the clear dome.

Each lateral position light fixture type uses a different bulb type. The OH-58D/UH-60 lateral position light uses a single filament, 40-watt bulb; and the UH-1/OH-58A or C/AH-1 lateral position light uses a single filament, 26-watt bulb. Table 4 lists the NSNs for the bulbs used in these fixture types. The two lateral position light bulb types have different reflector configurations. These configurations, shown in Figure 4,

TYPE III

Grimes type II and type III reflector configurations Figure 4. for lateral position light bulbs.

are designated type II (OH-58D/UH-60) and type III (UH-1/OH-58A or C/AH-1) by the bulb manufacturer, Grimes Aerospace Corporation*. All tail light types use the same dual filament, 25-watt bulb (Table 4). All position light bulbs have a rated voltage of 28 volts direct current (VDC) and are manufactured to specifications in MIL-L-6363F (Lamps, incandescent, aircraft service, general specification for).

*See Appendix B.

For single sample intensity profile measurements, one appropriate bulb type was supplied with each fixture type. Because there is possibility for variation in intensity profiles among bulbs of the same type, multiple samples of each type also were supplied. Fourteen samples each were supplied for the type II and III lateral position light bulbs, and 13 samples were supplied for the tail position light bulb. All bulbs were received new. Two 6.8 ohm resistors (MIL RW22V6R8) also were provided to simulate dim mode operation of the position lights. The resistors, light units, bulbs, and domes used in this investigation were supplied by training units at Fort Rucker.

Methods

<u>Measurement parameters</u>

Light intensity is the luminous flux emitted from a point source, where light flux is the rate of flow of visible energy. Intensity measurement of a light source generally is performed indirectly with instrumentation which measures illuminance. Illuminance is the density of luminous flux incident upon a surface. Intensity of a point light source can be calculated from illuminance using the inverse square law:

intensity of source (candelas)

Illuminance (footcandles) =

distance (feet)²

A technical definition for the relationship between intensity and illuminance is given in Appendix C.

To determine the intensity profiles for the different light units with respective dome configurations, measurements were made at horizontal and vertical angle combinations based on those stipulated in the FARs. Figure 5 defines the horizontal and vertical angular positions (with respect to the rotorcraft) and specifies the minimum intensity distribution requirements. In the horizontal direction, the highest minimum intensities are required between 0 to ± 20 degrees; beyond that, the intensity requirements drop off sharply. In the vertical direction, the highest minimum intensity is required at 0 degrees with respect to the horizontal plane of the aircraft centered at the lamp filament. At positions above and below 0 degrees vertical, the intensity requirements drop off as multiples of the highest value. Based on the distribution of intensity requirements, a critical region for the lateral position lights can be defined as the cone between 0 to ± 20 degrees in the horizontal and vertical angular directions. A critical region is not defined for the tail position lights because a constant minimum intensity value is specified across the horizontal direction.

Position light horizontal and vertical angular definitions and minimum intensity distribution reguirements. Figure 5.

.

Based on the minimum intensity requirement profile for the lateral position lights, measurements in the horizontal direction were made at 5 degree increments in the critical region; outside the critical region, the increment was extended to 20 degrees. Measurements were made in the horizontal direction at angles of 0, 5, 10, 15, 20, 40, 60, 80, 100, and 110 degrees with respect to the filament of the lamp. In the vertical direction, measurements were made at each of the angles stipulated in the FARs (Table 3) with the exception of 90 degrees vertical due to an instrument limitation which allowed measurement only to 75 degrees vertical. A measurement at 75 degrees vertical was acceptable because the same minimum intensity value is required between 40 and 90 degrees in the vertical direction. Table 5a shows a matrix for horizontal and vertical angle combinations where intensity data were collected for the lateral position lights.

Measurements for the tail position light were made in larger increments of 20 degrees since the intensity requirement remains constant throughout the horizontal direction. Measurements were made in the horizontal direction at angles of 0, 20, 40, 60, and 70 degrees in the clockwise and counterclockwise directions. Vertical direction measurements were made at those angles stipulated in the FARs, again with the exception of 90 degrees vertical. Table 5b shows a matrix for horizontal and vertical angle combinations where intensity data were collected for the tail position lights.

Sample size

Measurements were made on a single sample of each light fixture type for all dome configuration provided. In these measurements, for each light fixture type in all possible configurations, an appropriate bulb type was used. Variation is expected in the intensity profiles among bulbs of the same type. To determine how much variation occurs, a separate multiple bulb sample evaluation was performed. In this followup evaluation, multiple samples of each bulb type were measured for only one configuration each because of the time required to complete profile measurements. An analysis of variance was performed on multiple sample data to determine the amount of variability among bulbs of each type.

Instrumentation

Measurement instrumentation

Illuminance was measured with a Photo Research* Spectra® Pritchard model 1980A-PL photometer with a 7 inch, f/3.5 objective lens and IB-80 illumination baffle; measurements were validated with a Minolta* model T-1H illuminance meter. The photometer was supported on a motor-driven platform which positioned the instrument horizontally and vertically. An Optron* Hercules model 5292 tripod, marked in angular increments for pan (horizontal rotation) and tilt (vertical rotation), was used as a platform for the light fixtures to achieve horizontal and vertical angular positions. Direct current (DC) power was supplied through a Hewlett-Packard* model 6291A DC power supply. A Fluke* model 8020B multimeter was used to verify the operating voltage at the light source.

Position light mounting fixtures

Two mounting fixtures in opposing orientation were designed and fabricated for each of the lateral position lights, and mounting fixtures were designed and fabricated for the tail position lights to simulate appropriate orientation on the rotorcraft and to provide repeatability of setup. The mounting fixtures were constructed of two pieces of plywood with dimensions of 4-inches by 4-inches by 4-inch. One piece was drilled through the center with a 1-inch hole for tripod mounting. A second piece was drilled through with a hole large enough to accommodate the back side of the light fixtures, and as low as possible to minimize unwanted angular displacement when rotated in the vertical direction (tilt). To mount the light fixtures in place, additional holes were drilled in the second piece to coincide with existing holes in the fixtures. The two pieces were attached perpendicularly so that, when the light unit was installed in the mounting fixture, its orientation corresponded to that on the airframe, and the bulb filament was located directly over the center of horizontal rotation (pan) of the tripod. Figure 6 shows a lateral position light unit attached to its mounting fixture and positioned on the tripod. The mounting fixtures were painted flat black to minimize reflection of light.

Positioning devices

The mounted light units were positioned on a tripod marked in 1-degree angular increments of pan and tilt. For horizontal rotation (pan), the tripod could be rotated ±360 degrees. For vertical rotation (tilt) the tripod could be rotated only to 75 degrees. Therefore, to measure the top and bottom halves of each bulb, the light units were physically removed from the mounting fixture and rotated 180 degrees. For the lateral position light units, two opposite mounting fixtures were used to properly orient the light on the tripod.

The photometer head was mounted to a motor driven horizontal translator designed specifically to support it. Figure 7 shows the setup of the photometer and tripod for light measurements. Once positioned, the distance between the photometer and the tripod was maintained. The walls and floors surrounding the measurement area were covered with black cloth to minimize reflection of light.

ligure ... Likeratery set up for jr f.le measurements.

Procedures

General measurement procedures

Illuminance measurements were made using a 3-degree aperture and illuminance baffle with the photometer. The prescribed methods for instrument set up and calibration were followed. The calibration factor for the IB-80 illuminance baffle is 1×10^{-3} . The photometer was calibrated prior to measurement of each light unit and each bulb sample. Each bulb sample was inspected visually prior to measurement. Both the general condition of any reflective coating and the glass dome as well as the orientation of the filament were noted.

At least two operators were required to perform the intensity profile measurements. One operator positioned the light unit on the tripod and another aligned the photometer aperture with the bulb filament with the setting of each angular position. A light unit was set in place on the tripod by squaring the bottom edges of its mounting fixture with the top plate of the tripod and securing it with the tripod mounting screw. The zero point on the tripod was adjustable so initial "zero" alignment was performed by having the photometer operator observe through the viewing eyepiece while the tripod mounted light unit was displaced equally in small horizontal increments to either side of an approximate "zero" point. When the horizontal displacements appeared equivalent about a "zero" point, that point was locked in place. This zero alignment point on the tripod remained fixed throughout the measurements since all mounting fixtures were designed to position the light bulb filaments directly over the horizontal center of rotation of the tripod.

The initial measurement position was made at the "zero-zero" position. At this position, distance was measured, in feet, from the filament of the bulb to the objective lens of the photometer. Intensity measurements were made in consecutive sequences of horizontal and vertical angles. The first measurement was made at (0,0) (horizontal angle, vertical angle); the next was at (0,5); then at (0,10), and so on, to (0,75). Once the 0 degree horizontal series was completed, the 5 degree horizontal series was measured, and so on, until all the horizontal series were measured.

Left side (red dome) configured light units were rotated to the clockwise direction horizontally when measuring the top half of an intensity profile. To measure the bottom half of a profile, the same light unit was placed in an opposite mounting fixture and rotated to the counterclockwise horizontal direction. The right side (green dome) configured light units were just opposite of the left side. Therefore, they were rotated to the counterclockwise direction when measuring the top and the clockwise direction for measurement of the bottom intensity profile. There was only one orientation for the tail position light units. These units were rotated 180 degrees in the same mounting fixture to measure top and bottom profiles in the clockwise and counterclockwise directions. The clockwise direction was designated by positive angular values, and the counterclockwise direction was designated by negative angular values.

Ideally, the bulb filament (center of the light source) should have been placed at the center of rotation of the tripod in order to eliminate angular displacement. However, this position could not be achieved so, as a light unit was displaced vertically and horizontally in angular combinations, minor adjustments were required to keep the bulb filament centered within the photometer aperture. Any vertical adjustments were made at the tripod and any horizontal adjustments were made with the photometer translator.

When data for a complete illuminance profile were collected, intensity values were calculated by multiplying each illuminance value by the calibration factor for the illuminance baffle (1 x 10^{-3}) and by the distance squared between the objective lens of the photometer and the filament of the light source. The initial intensity values then were verified with the illuminance meter. Intensity was calculated from these values (in candela units) by multiplying distance squared between the light source filament and the measuring plane of the illuminance meter.

<u>Single sample measurement procedures</u>

Intensity profiles for one of each light fixture type and corresponding dome configuration were measured with an appropriate bulb type operating in both bright and dim modes. Table 6 lists all light units and corresponding dome configurations measured in this single sample evaluation. A total of 11 different configurations were measured in bright mode: 5 configurations for the OH-58D/UH-60 lateral position light, 2 configurations for the UH-1/OH-58A or C/AH-1 lateral position light, 2 configurations for the OH-58A, C, or D/AH-1 tail position light, and 1 configuration each for the UH-1 and UH-60 tail position lights. A total of eight different configurations were measured in dim mode: two each for the OH-58D/UH-60 and UH-1/OH-58A or C/AH-1 lateral position lights, two for the OH-58A, C, or D/AH-1 tail position light, and one each for the UH-1 and UH-60 tail position lights.

<u>Table 6</u>.

Light type	Bright mode	Dim mode				
Lateral position lights						
OH-58D/UH-60	Red unmasked Red half-masked Red front-masked Green unmasked Green half-masked	Red unmasked Green unmasked				
UH-1/OH-58AC/AH-1	Red unmasked Green unmasked	Red unmasked Green unmasked				
Tail position lights

UH-60	Clcar unmasked	Clear unmasked				
OH-58ACD/AH-1	Clear unmasked Clear masked	Clear unmasked Clear masked				

Lateral and tail position light configurations profiled in this evaluation.

Bright mode measurement procedures

Bright mode was defined as operation at the normal operating voltage of the rotorcraft which was 28 VDC. Bright mode operation was simulated in the laboratory with a DC power source set to deliver 28 VDC at the light unit. The voltage was verified with a multimeter. To monitor any incidental changes in voltage, a measurement was made and recorded prior to each light sample measurement. Intensity profile measurements proceeded as described previously.

Dim mode measurement procedures

Dim mode is selected in the rotorcraft via a three-position switch. When switched to dim mode, a 6.8 ohm resistor is connected in series between the power source and the light unit. In the laboratory, an actual rotorcraft resistor was connected in line between the DC power source and the light unit. Before connecting the resistor, a voltage measurement was made at the light source to verify that the power source was delivering 28 VDC. With the resistor in line and power on, the effective voltage delivered to the light units was measured and recorded. Intensity profile measurements proceeded as previously described.

Multiple sample measurement procedures

Multiple bulb samples were measured to determine the amount of variability among bulbs of the same type. This set of bulb samples was independent of those used in the single sample measurements, and was measured solely for the purpose of determining variation among the same type bulbs. The two lateral position light types (OH-58D/UH-60 and UH-1/OH-58A or C/AH-1) use different bulb types; all tail position light types use the same bulb type. All multiple sample measurements were made with light units in one configuration for each bulb type. Each lateral position light type was configured with an appropriate red, unmasked dome operating in dim mode. The tail position light type was configured with a clear, unmasked dome operating in dim mode in an OH-58A, C, or D/AH-1 tail position light fixture.

Measurement of the lateral position light bulb types were performed in alternating sessions by four operators. The same two operators were assigned to measure one bulb type each to minimize the possibility of any variation due to measurement procedures. Due to time constraints, the tail position light bulb type was measured by four different operators in groups of two, measuring in alternating sessions. One complete bulb profile (top and bottom) was measured in each session.

<u>Results</u>

Measured data

Intensity values were calculated from measured illuminance values by multiplying the IB-80 calibration factor (1×10^3) by the distance squared between the objective lens of the photometer and the filament of the light bulb. Intensity profiles were plotted from the calculated data, and the FAA minimum intensity requirements were overlaid for comparison.

By specification, the intensity profiles for position light bulbs are to be symmetrical about a defined center point (center of the bulb filament as oriented for rotorcraft in the normal flying position). However, the masked dome configurations in this investigation were intended to modify the profiles. Therefore, top and bottom designations were assigned to the lateral light units depending on the orientation of the unit on the rotorcraft as dictated by the dome configuration (red or green). For the tail position lights, arbitrary top and bottom designations were assigned for the fixture since the units were symmetrical when oriented on the rotorcraft. A weld on the tail position light bulb arbitrarily was designated to indicate the top of the bulb. All light units were oriented as they would be on the rotorcraft.

Single sample data

Data in this section are presented by light unit type and represent only one sample measurement for each configuration (red, green, or clear; unmasked or masked; bright or dim). The same appropriate type bulb was measured in each configuration for each light fixture type. Intensity is plotted across the horizontal angular positions. Each vertical angular position is represented in a separate plot.

Figures D-1 to D-4 (Appendix D) represent intensity profiles for the OH-58D/UH-60 left (red) lateral position light for bright mode, unmasked, half-masked, and front-masked dome configurations; and dim mode, unmasked dome configuration. Table D-1 (Appendix D) presents measured illuminance and calculated intensity data for these lateral position light profiles in the order of configurations listed.

Figures E-1 to E-3 (Appendix E) represent intensity profiles for the OH-58D/UH-60 right (green) lateral position light for bright mode, unmasked and half-masked dome configurations; and dim mode, unmasked dome configuration. Table E-1 (Appendix E) presents measured illuminance and calculated intensity data for these lateral position light profiles in the order of configurations listed.

Figures F-1 and F-2 (Appendix F) represent intensity profiles for the UH-1/OH-58A or C/AH-1 left (red) lateral position light for bright mode, unmasked dome configuration; and dim mode, unmasked dome configuration. Table F-1 (Appendix F) presents measured illuminance and calculated intensity data for these lateral position light profiles in the order of configurations listed.

Figures G-1 and G-2 (Appendix G) represent intensity profiles for the UH-1/OH-58A or C/AH-1 right (green) lateral position light for bright mode, unmasked dome configuration; and dim mode, unmasked dome configuration. Table G-1 (Appendix G) presents measured illuminance and calculated intensity data for these lateral position light profiles in the order of configurations listed.

Figures H-1 to H-4 (Appendix H) represent intensity profiles for the OH-58A, C, or D/AH-1 tail position light for bright and dim mode, unmasked and masked configurations. Table H-1 (Appendix H) presents measured illuminance and calculated intensity data for these tail position light profiles in the order of configurations listed.

Figures I-1 to J-2 represent intensity profiles for the UH-1 and UH-60 tail position lights, respectively, for bright mode, unmasked dome configuration; and dim mode, unmasked dome configuration. Tables I-1 and I-2 present measured illuminance and calculated intensity data for these tail position light profiles in the order of configurations listed.

Multiple sample data

Time constraints precluded a repeated measures analysis of light fixtures and masking designs. Sources of variation in intensity profiles include variability in lighting fixtures, bulbs, and masking technique (the actual application of the tape or paint). It is likely that variation between the physical characteristics of the light fixtures is minimal. And since applying the mask is a function of the performing individual, this variability would be difficult to assess. However, the variation between bulbs can be investigated.

Variability between intensity profiles of the same type bulbs can occur due to the physical characteristics of the bulbs (i.e., filaments, reflective coating, glass, etc.). Although bulbs are required to meet military specifications, manufacturer's quality control methods do not require inspection of all samples. To determine if any significant differences existed between bulb intensity profiles, multiple bulb sample measurements were made for the three bulb types. Data in this section are presented by bulb type and represent multiple sample measurements in one configuration each, per bulb type in an appropriate fixture type. Intensity is plotted across the horizontal angular positions. Each vertical angular position is represented in a separate plot.

Figure 8 presents intensity profiles for 14 samples of the Type II reflector lateral position light bulb measured in the OH-58D/UH-60 fixture in dim mode with an unmasked, red dome configuration. Table K-1 (Appendix K) presents measured illuminance and calculated intensity data for these 14 samples.

Figure 9 presents intensity profiles for 14 samples of the Type III reflector lateral position light bulb measured in the UH-1/OH-58A or C/AH-1 fixture in dim mode with an unmasked, red dome configuration. Table L-1 (Appendix L) presents measured illuminance and calculated intensity data for these 14 samples.

Figure 10 presents intensity profiles for 12 samples of the tail position light bulb measured in the OH-58A, C, or D/AH-1 fixture in dim mode with an unmasked dome configuration. Sample #10 was rejected prior to measurement because visual inspection revealed a significant flaw in the glass dome of the bulb. Table M-1 (Appendix M) presents measured illuminance and calculated intensity data for these 12 samples.

Figure 10c. Intensity profiles for tail position light bulb (12 samples) in OH-58A, C, or D/AH-1 fixture, unmasked in dim mode; bottom, vertical angles 0 to 15 degrees. Intensity expressed in candelas. Note: bulbs #1, 2, and 3, represented by dashed lines, are eliminated in statistical analysis.

Figure 10d. Intensity profiles for tail position light bulb (12 samples) in OH-58A, C, or D/AH-1 fixture, unmasked in dim mode; bottom, vertical angles 20 to 75 degrees. Intensity expressed in candelas. Note: bulbs #1, 2, and 3, represented by dashed lines, are eliminated in statistical analysis.

Bulb variability analysis

An analysis of variance (ANOVA) was performed on the calculated intensity values to determine if any significant variation existed among bulbs of the same type. The goal of the analysis of variance is to determine whether variation among bulb sample means is significantly different than variation within bulb sample means. If the among sample means variation is greater than within sample means variation, it is concluded that at least one sample is significantly different from all other samples of the same bulb type. For this analysis, bulb intensity data are grouped by angular positions where similar intensity requirements are specified by the FAA. Within each of the groups, for each bulb sample type, it is assumed that intensity values are normally distributed and variances are the same.

As shown in Figure 5 and Table 3, the FAA specifies different intensity requirements at locations around the position lights in the horizontal and vertical planes. Therefore for this analysis, intensity data are grouped by positions where similar intensities are required. For the lateral position lights, the data are broken down into three groups in the horizontal angular Table K-1 (Appendix K) shows that the first direction. horizontal group consists of data points in the positions between 0 to ± 10 degrees horizontal (values in dotted line box); the second group consists of data points in the positions between +15 to +20 and -15 to -20 (± 15 to ± 20) degrees horizontal (values in double line box); the third group consists of data points in the positions between +40 to +110 and -40 to -110 (\pm 40 to \pm 110) degrees horizontal (values in dashed line box). Data are grouped further by vertical angular position at 0, ± 5 , ± 10 , ± 15 , ± 20 , ± 30 , ± 40 , and ± 75 degrees vertical. For the tail position lights, all positions in the horizontal angular direction are grouped together between 0 to ± 70 degrees (Table M-1) since the intensity requirement is the same across the horizontal direction. Data also are grouped by vertical angular position.

The first two samples of each bulb type are eliminated from the analysis of variance because these measurements were considered practice runs. Any other samples where variation is suspected to be attributed to causes other than the bulb effects also are eliminated.

Figure 8 shows the intensity profiles for all samples measured of the type II lateral position light bulb. Samples #1, 2, 3, 8, and 9 (represented by dashed lines in the figure) are eliminated from this analysis. In the measurement of sample #3, the photometer was discovered to be out of alignment with the light unit; for bulbs #8 and 9, the power to the light unit was inadvertently increased so that the resulting profiles are shifted up in intensity as can be seen in the plots. The analysis of variance for the nine remaining bulb samples indicates that at least one bulb sample is significantly different (0.01 confidence level) at the positions between ± 15 to ± 20 degrees horizontal and ± 40 degrees vertical.

Figure 9 shows the intensity profiles for all samples measured of the type III lateral position light bulb. Samples #1, 2, 7, and 8 (represented by dashed lines in the figure) are eliminated in this analysis. In the measurement of samples #7 and 8, the power to the light unit was inadvertently increased so that the resulting profiles are shifted up in intensity as shown in the plots. The analysis of variance for the 10 remaining bulb samples indicates numerous positions where at least 1 bulb sample is significantly different at a 0.05 confidence level. Statistically significant differences exist at positions between 0 to ±10 degrees horizontal and 0, ±5, and ±20 degrees vertical; between ±15 to ±20 degrees horizontal and 0, ±5, ±10, ±40, and ±75 degrees vertical; and between ±40 to ±110 degrees horizontal and ±10, ±15, ±20, ±30, ±40, and ±75 degrees vertical.

Figure 10 shows the intensity profiles for all samples measured of the tail position light bulb type. Samples #1, 2,and 3 (represented by dashed lines in the figure) are eliminated in this analysis. Sample #10 was rejected prior to measurement due to a large area of distortion on the bulb surface. Following the measurement of sample #3, the dimming resistor failed. Ά second resistor, with a 1.5 VDC difference in resulting voltage drop, was used in subsequent measurements of the tail position light bulb type. Figure 10 shows that intensity profiles for bulbs #1, 2, and 3 are slightly higher than for other bulbs, especially for the bottom half of the bulbs. The analysis of variance for the nine remaining bulb samples indicate that for positions between ±70 degrees horizontal and ±30 degrees vertical, at least one bulb sample is significantly different at the 0.05 confidence level.

Discussion

Position light configurations

Figures D-1 to D-4 (Appendix D) show single sample intensity profiles for the OH-58D/UH-60 lateral position light in the left side (red) configuration. Figure D-1 depicts the profile for this light, with an unmasked dome in bright mode. In this configuration, intensity values exceed minimum requirements except at ± 110 degrees horizontal where intensities are marginal when standard deviations at these positions are considered. Figure D-2 depicts the profile for the half-masked, red dome

configuration in bright mode. This profile shows that at the masked positions for this light, minimum intensity requirements are not met. Also, in comparison to the bright mode, unmasked configuration, the intensities in this half-masked profile generally are lower due to absorption of light by the black paint masking on the inside surface of the dome. This decrease in visible light energy causes intensity to be only marginally passable beyond 60 degrees horizontal in the unmasked portion of this light. Figure D-3 depicts the profile for this light in a frontmasked, red dome configuration in bright mode. Again, the intensities at the masked positions for this configuration do not meet minimum requirements. However, at the unmasked positions, the intensities comply with minimum requirements. Figure D-4 shows that for this light in an unmasked, red dome configuration in dim mode, intensities in the critical region (within 0 to ± 20 degrees horizontal and vertical) are marginally passable to failing.

Figures E-1 to E-3 show single sample intensity profiles for the OH-58D/UH-60 lateral position light in the right side (green) configuration. The intensity profiles for this light in the green configuration are similar to corresponding profiles in the red configuration. The same bulb and light fixtures were used for both red and green dome configurations. Figures E-1 and E-2 depict profiles for this green light in bright mode with the unmasked and half-masked domes, respectively. As with the red light, intensities in the unmasked portions of the light meet or exceed the FAA requirements. The half-masked domes (red and green) are hand painted so that the profiles in Figures D-2 and E-2 are somewhat dissimilar. Differences occur around the edge of the paint masking and are most prevalent in the critical region. Figure E-3 shows that, as with the unmasked, dim mode configuration for the red light, intensities for this green light in dim mode do not meet FAA minimum requirements inside the critical region. Outside this region, the intensities are marginally passable.

Figures F-1 and F-2 show single sample intensity profiles for the UH-1/OH-58A or C/AH-1 lateral position light in the left side (red) configuration. Figure F-1 shows that, in bright mode with an unmasked dome, the intensities for this configuration fail the minimum requirements in the critical region between 0 to ± 20 degrees horizontal for all vertical angular positions. In the noncritical regions, the intensity profiles are passable to marginally passable. The profiles for this light configuration in dim mode are similar in shape with lower intensity values. As shown in Figure F-2, intensities do not meet minimum requirements in the critical regions and are only marginally passable in the noncritical regions.

Figures G-1 and G-2 show single sample intensity profiles for the UH-1/OH-58A or C/AH-1 lateral position light in the right side (green) configuration. Figure G-1 shows that this configuration, in bright mode with an unmasked dome, is marginally passable in the horizontal critical region (0 to ±20 degrees), with the exception of positions 0 to -20 degrees horizontal at +10 to +20 degrees vertical, top. In the horizontal noncritical regions (±30 to ±110 degrees), the intensities meet or exceed FAA minimum requirements. Overall, the bright mode intensities for this green dome configuration are higher than for the red dome configuration. Figure G-2 shows that in dim mode, the intensities in the horizontal critical region fail minimum requirements through all vertical angles. In the horizontal noncritical regions, the intensities are failing to marginally passable.

Figures H-1 to H-4 show single sample intensity profiles for the OH-58A, C, or D/AH-1 tail position light for unmasked and masked clear dome configurations. Figure H-1 depicts the profile for the light as unmasked and in bright mode. All FAA minimum intensity requirements are met in this configuration. As shown in Figure H-2, when masked with tape in the configuration shown in Figure 1c, intensities are generally below 3 candelas except at positions not covered by tape (at 0 horizontal between 10 to 30 degrees vertical, bottom). Minimum intensity requirements are met only between 15 to 30 degrees vertical (bottom) within the horizontal critical region due to the small size of the unmasked region of the light. Intensities in the unmasked regions of this light are approximately 10 candelas lower than at corresponding positions in the unmasked configuration due to absorption of light by the masking tape. As heat built up and was absorbed, the tape masking began to melt and contract around the edges. The leaking of light is revealed by intensity spikes at the extreme horizontal and vertical angular position. Figure H-3 shows that in dim mode with an unmasked dome, the intensities for this light are failing to marginal across all horizontal angles for 0 to ±15 degrees in the vertical direction. Figure H-4 depicts the profiles for this light in dim mode with a masked In the masked region of this configuration, the intendome. sities are generally below 1 candela. In the unmasked region, at the bottom half of the light, intensity is only marginally passable at 0 horizontal between 20 and 30 degrees vertical.

Figures I-1 and I-2 show single sample intensity profiles for the UH-1 tail position light for the clear dome configuration. Figure I-1 depicts the profile for the light unmasked and in bright mode, and Figure I-2 depicts the same configuration in dim mode. These profiles are similar in shape and intensity to corresponding profiles for the OH-58A, C, or D/AH-1 tail position light. The bright mode intensities meet or exceed requirements. The dim mode intensities are failing to marginal in the vertical critical region between 0 and ±15 degrees vertical. Figures J-1 and J-2 show single sample intensity profiles for the UH-60 tail position light for the clear dome configuration. Figure I-5 depicts the profile for the light unmasked and in bright mode, and Figure I-6 depicts the same configuration in dim mode. These profiles are similar in shape and intensity to corresponding profiles for the OH-58A, C, or D/AH-1 and UH-1 tail position lights, with the exception of horizontal positions ±60 and ±70 degrees. The intensities decrease at these positions due to a physical obstruction in the light fixture design which can be seen in Figure 3. The bright mode intensities meet or exceed requirements. The dim mode intensities are failing to marginal in the vertical critical region between 0 and ±15 degrees vertical.

These measured intensity profiles show that masking of the position light domes diminishes emitted intensity of light by absorbing or obstructing light energy. Paint or tape is used to mask the position light domes. Paint obstructs and absorbs light energy as evidenced by the lower intensity values for the halfmasked dome profiles versus the unmasked dome profiles in red and green configurations (Figures D-1 and D-2, E-1 and E-2; Tables D-1 and E-1). Green "100-mile an hour" duct tape obstructed almost all light from being emitted in masked regions as shown by the minimal intensity values of the OH-58A, C, or D/AH-1 tail light profiles (Figures H-2 and H-4 and Table H-1). Measurements of masked configurations, in bright mode, shows that any masking (paint or tape) modified emitted light intensity in the obstructed areas so that FAA requirements are not achieved. Masked dome configurations were also operated in dim mode. The masked, dim mode configuration was not evaluated for all masking schemes. Based on masked and dim mode configurations data collected, position lights in this configuration will not meet FAA requirements.

Single sample bright mode and masked configuration profiles for the different position light types can be evaluated by extrapolating appropriate standard deviation values from the multiple bulb sample analysis of variance. For each bulb type, Table 7 lists the standard deviations and coefficients of variation determined in the multiple bulb sample analysis of variance. The coefficient of variation (CV) values allow comparison of variation of intensity values by angular position.

Bulb variability

The analysis of variance performed on the multiple sample bulb data demonstrates that, in general, the intensity distributions among the samples measured of the type II lateral position light bulb and the tail position light bulb are not <u>Table 7</u>.

Position light bulb types analysis of variance statistics summary.

significantly different. This fact established, these two bulb types (in dim mode with a red dome filter for the lateral light or clear dome filter for the tail light) can be represented by a mean intensity profile where an average value for each position is calculated from bulb sample data included in the analysis. The mean intensity profiles for these two bulb types are shown in Figures 11 and 12, respectively, with error bars representing one standard deviation at each position. The analysis of variance for the 14 samples of the Type III lateral position light bulb type indicates that significant variation does occur among bulbs of this type. Although variation is known to exist (e.g., filament and reflector differences), the bulb type intensity profile (in dim mode with a red dome filter) can be represented by the average value of the measured samples when variability around each position is considered. Figure 13 shows the mean intensity profile for the type III position light bulb type with error bars which represent one standard deviation at each position.

Variation in measured intensity can be attributed to numerous causes such as photometer/sample alignment, photometer calibration drift, or measurement differences due to operators. Bulb attributes such as filament orientation (i.e., alignment or canting), bulb surface shape, reflective coating application, or stray light from reflections also can contribute to variations in measured intensity. Figures 14 and 15 show multiple reflections on the back surfaces of type II and type III lateral position light bulbs, respectively. The position of the bulb in Figure 14a is (0,0), Figure 14b is (10,20), Figure 15a is (0,0), and Figure 15b is (5,5). Each reflection contributes additional light energy which results in higher photometer illuminance readings. As the photos show, the multiple reflections occurred at varied locations and to different extents based on the shape of the bulb surface. Spikes appeared in the intensity profiles at positions where reflections occurred (Figures 8 and 9). The tail light bulb type was not reflectorized so that filament orientation did not have critical impact upon intensity. This can be seen in the relatively flat profiles in Figure 10.

I² compatibility

User data presented in Table 1 indicate that the red and clear filtered lights on the exterior of the aircraft cause problems in operations with image intensifiers, while the green filtered lights do not. This phenomenon is attributable to the average luminous transmittance and spectral emittance of the filters and the spectral sensitivity of the I² tubes. Second generation I² tubes are responsive to light emitted between the wavelengths 380 nanometers (nm) to 850 nm, and third generation I² tubes are responsive to light emitted between the wavelengths 450 nm to 950 nm.

Photopic and scotopic luminous transmittances of the red, green, and clear dome filters were measured with a Photo Research 1980A photometer and an EG&G Gamma* RS-10 tungsten reference light source. The photopic and scotopic transmittances for the dome filters are: for the red dome, 29 and 2 percent; for the green dome, 18 and 40 percent; and for the clear dome, 89 and 88 percent, respectively. Figure 16 shows the relative spectral response of the Class A third generation image intensifier with relative spectral emittances of the red, green, and clear dome filters. In the relative response plots, it is apparent that the Class A night vision imaging systems (NVIS), with the 625 nm minus-blue filter, are highly responsive to light emitted through the red and clear filters, but not to light emitted through the green filter. Second generation I² tubes are responsive to light transmitted through the red, clear, and green filters due to their wide sensitivity range extending across the visible spectrum.

Conclusions and recommendations

The Army aviation community seeks a standard, permanent lighting strategy to satisfy training and mission needs for I² devices while maintaining adequate position light intensity distributions for detectability of aircraft while flying in the NAS. As stated earlier, certain exceptions are granted for training with lights out or on dim within restricted training areas. However, situations arise where, in transitioning from a staging area to a training area, controlled and uncontrolled airspace must be passed through at higher altitudes due to noise abatement programs. In these situations, light 1g must be sufficient for unaided traffic detection.

The intensity distribution requirements for aircraft exterior position lighting are designed to provide optimum visibility for aircraft operating in the national airspace system. Current requirements were developed for civil airspace operations prior to the introduction of I² devices into aviation. These standards were defined with the intentions of maximizing unaided detection of aircraft in periods of reduced visibility and low illumination.

Nighttime operations, with or without image intensifiers, are distinct capabilities of U.S. Army aviation. In order for missions to be performed safely and efficiently, aircraft position lighting must be compatible in both the civilian and military operating arenas. The integration of image intensifiers into Army aviation has greatly expanded mission capabilities. However, due to the operating

characteristics of I^2 devices, the prevailing configuration for position lighting is not compatible with and can have a negative impact on the safety of mission execution. A field survey (see Table 1) and this investigation show that the intensity and spectral distribution of the red and clear filtered position lights, in bright mode, are detrimental to I² operation. In attempts to alleviate the degradation of I² imagery by position light sources, the Army aviation community has modified lighting strategies to include operating with position lights in dim mode and operating with masked position lights in bright and dim modes.

Experience information in Table 1 shows that the impact of position light intensities on I^2 operations is most significant in formation flying. Members of the Army aviation community have applied masking techniques and operate with position lights in dim mode to alleviate problems with I^2 devices in formation flying. The objective intensity distribution measurements performed in this laboratory investigation show that in dim mode intensities do not meet FAA requirements in the critical regions of the individual light units.

Dim mode is one of three selectable positions on Army rotorcraft (bright, dim, and off). Although intensities in the current dim mode fall below FAA requirements for flying in the NAS, incrementally dimmed steps between bright and dim modes are potentially feasible and offer a potential solution to the problem. Naval rotorcraft use a seven-step dimming switch where intensity at each dimming step is one-half that of the next higher step (Kinney and Simpson, 1992). The primary exterior lighting specification for naval aircraft is MIL-L-006730C, which is based upon the same FAA intensity requirements as the Army specification MIL-L-6503H. Variable dimming on Army rotorcraft would allow flexibility for I² operations in variable and restrictive environments.

The measured intensity distribution profiles for the masked configurations evaluated show that paint and tape masking modify the position light intensity distributions in such a way that requirements in applicable FARs are no longer achieved in all areas of the distribution profiles. The paint and tape materials used in these masking configurations are very dense and decrease light intensity by blocking or by absorbing light energy. As an alternative to this type of masking, a lighter frost coating could be applied to the red and clear position light domes. Transmittance is decreased through a frosted dome and emitted light is diffused so that mean light intensity is diminished. The color of emitted light will not be modified by a frosted dome.

Currently, the FARs define intensity requirements for individual light units measured from "dead ahead" within angular cones of 110° horizontal by ±90° vertical for the lateral position lights and 140° horizontal by ±90° vertical for the tail position lights. With these requirements as they are defined, any masking of the position lights is unacceptable with respect to FAA regulations. It may be possible to develop acceptable modified lighting for I² compatibility via the modification of the current requirements definition and/or a compromise of the requirements. This could be achieved by defining a positionable center of measurement for the intensity cone which would grant the flexibility of allowing partial masking. For instance, allowing the cone vertex to be positionable within the light bulb front perimeter and perpendicular to the front vertical plane of each position light (as mounted on the rotorcraft in normal flying orientation) would allow masking configurations, such as those in Figures 1a and 1c-e, to be feasible. However, because the horizontal and vertical angular intensity requirements are designed to optimize aircraft visibility in all directions within a 360° sphere, moving of angular cone vertices alone will not qualify partial masking. A compromise on intensity distribution requirements would be necessary.

The problem of light flooding into the cockpit/crew compartment from the lateral position lights on the UH-1 and UH-60 is attributable to the location of the light units above and/or below the crew doors (Table 2). FARs specify that forward position lights be spaced as far apart laterally as practicable. On the UH-1 and UH-60 rotorcraft, the greatest lateral distances are across the midsection of the fuselage since there are no wings or horizontal stabilizers in the forward area as there are with the OH-58, AH-1, and fixed-wing aircraft. An alternative to masking for alleviating this problem would be to relocate the lateral position light units so that light emitted into the cockpit/crew compartment is reduced or eliminated.

MEMORANDUM FOR DIR, USAARL

SUBJECT: Aircraft Position and Anticollision Light Masking

1. The Night Vision Device Branch (NVDB) of the Aviation Training Brigade is developing a standard masking configuration of position and anticollision lights of Army helicopters (TAB A). These masked lights will be used principally for night vision goggle single-ship and multi-ship operations. The goal of this project is to provide Army aviation units an external light configuration which may be applied permanently and which will satisfy unit training needs as well as the lighting requirements of the Federal Aviation Administration (FAA).

2. The enclosed extract of the applicable Federal Aviation Regulations (FARs) (TAB B) states the specifications for civil rotorcraft external lighting requirements. The enclosed sketches of proposed modifications <u>may not</u> meet the minimum requirements of the FARs. Therefore, I request that external aircraft lights with these modifications applied be measured using a criteria similar to those listed in the FARs.

3. POC: CW4 Colbert, NVDB, 5858/5812.

MEMORANDUM FOR DIR, USAARL

SUBJECT: Aircraft Adaptive Position Lighting for Night Vision Goggle Flight

1. The Night Vision Device Branch (NVDB) of the Aviation Training Brigade seeks to develop an Adaptive position lighting policy for night vision goggle (NVG) flight. Adaptive position lighting strategies include, but are not limited to, dim mode operation, partial masking, and aided/unaided compatible filtering of helicopter position lighting. The goal of this project is to provide Army aviation units with adaptive lighting configurations which may be applied to satisfy unit training needs as well as Federal Aviation Administration (FAA) lighting requirements.

2. Partially masked and dim mode position light configurations are frequently used during NVG multi-aircraft operations. Enclosed are sketches of commonly used masked aircraft position light configurations.

3. NVDB requests a laboratory evaluation of the enclosed configurations and the dim position light mode utilizing the requirements specified in the attached Federal Aviation Regulations (FAR) extracts.

4. POC CW4 Colbert, NVDB, 5858/5812.

Appendix C.

Light intensity definition

Light intensity is the luminous flux being emitted from a point source, where light flux is the rate of flow of visible energy. The basic unit of flux is the lumen, which by definition is equal to $\frac{1}{2}\pi$ times the total flux emitted by a uniform point source of one candelas. The flux emitted by a point source per unit solid angle (steradian) is called intensity. A steradian is defined as that solid angle originating at the center of a sphere and subtending an area on the sphere surface equal to the square of the sphere radius (Figure C-1). Intensity is measured in lumens per steradian, and a uniform point source equal to one candela has an intensity in every direction of one lumen per steradian. Intensity in a given direction is usually expressed in candela and is often called candlepower.

The luminous flux density received on a surface (illuminance) varies with the intensity of the source and inversely as the square of the distance from the source to the surface. Illuminance is expressed in lumens per unit area or footcandles. Figure C-1 shows that as the distance from a source increases, one lumen is spread over increasing areas, and the illuminance decreases. The relationship between illuminance and distance from the source is referred to as the "inverse square law." The illuminance from a given source on a surface varies inversely as the square of the distance between the source and the surface.

The measurement of intensity of a source is generally done indirectly with instrumentation which measures illuminance. Therefore, using the inverse square law and knowing the distance between the source and the instrument detector, intensity of the light source can be calculated by multiplying measured illuminance (in footcandles) times the distance squared to get intensity (in candela).

intensity of source (candelas)

Illuminance (footcandles) =

distance (feet)²

<u>Appendix E</u>.

Intensity profiles, illuminance measurements, and calculated intensities for OH-58D/UH-60 right (green) lateral position light.

•

•

•.

Figure E-1a. Intensity profiles for OH-58D/UH-60 green, unmasked lateral position light in bright mode; vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure E-1b. Intensity profiles for OH-58D/UH-60 green, unmasked lateral position light in bright mode; vertical angles 20 to 75 degrees. Intensity expressed in candelas.

.

Figure E-2a. Intensity profiles for OH-58D/UH-60 green, halfmasked lateral position light in bright mode; vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure E-2b. Intensity profiles for OH-58D/UH-60 green, halfmasked lateral position light in bright mode; vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Figure E-3a. Intensity profiles for OH-58D/UH-60 green, unmasked lateral position light in dim mode; vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure E-3b. Intensity profiles for OH-58D/UH-60 green, unmasked lateral position light in dim mode; vertical angles 20 to 75 degrees. Intensity expressed in candelas.

۰.

Table E-1a.

:

•

Measured data and calculated intensity values for OH-58D/UH-60 lateral position light, green dome configurations, single samples; unmasked and half-masked, bright. Intensity expressed in candelas.

<u>Appendix G</u>.

Intensity profiles, illuminance measurements, and calculated intensities for UH-1/OH-58A or C/AH-1 right (green) lateral position light.

•

.

Figure G-1a. Intensity profiles for UH-1/OH-58A or C/AH-1 green, unmasked lateral position light in bright mode; vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure G-1b. Intensity profiles for UH-1/OH-58A or C/AH-1 green, unmasked lateral position light in bright mode; vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Figure G-2a. Intensity profiles for UH-1/OH-58A or C/AH-1 green, unmasked lateral position light in dim mode; vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure G-2b. Intensity profiles for UH-1/OH-58A or C/AH-1 green, unmasked lateral position light in dim mode; vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Table G-1.

Measured data and calculated intensity values for UH-1/OH-58A or C/AH-1 lateral position light, green dome configurations, single samples; unmasked, bright and dim. Intensity expressed in candelas.

Appendix H.

Intensity profiles, illuminance measurements, and calculated intensities for OH-58A, C, or D/AH-1 tail position light.

Figure H-1a. Intensity profiles for OH-58A, C, or D/AH-1 unmasked tail position light in bright mode; top, vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure H-1b. Intensity profiles for OH-58A, C, or D/AH-1 unmasked tail position light in bright mode; top, vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Figure H-1c. Intensity profiles for OH-58A, C, or D/AH-1 unmasked tail position light in bright mode; bottom, vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure H-1d. Intensity profiles for OH-58A, C, or D/AH-1 unmasked tail position light in bright mode; bottom, vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Figure H-2a. Intensity profiles for OH-58A, C, or D/AH-1 masked tail position light in bright mode; top, vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure H-2b. Intensity profiles for OH-58A, C, or D/AH-1 masked tail position light in bright mode; top, vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Figure H-2c. Intensity profiles for OH-58A, C, or D/AH-1 masked tail position light in bright mode; bottom, vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure H-2d. Intensity profiles for OH-58A, C, or D/AH-1 masked tail position light in bright mode; bottom, vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Figure H-3a. Intensity profiles for OH-58A, C, or D/AH-1 unmasked tail position light in dim mode; top, vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure H-3b. Intensity profiles for OH-58A, C, or D/AH-1 unmasked tail position light in dim mode; top, vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Figure H-3c. Intensity profiles for OH-58A, C, or D/AH-1 unmasked tail position light in dim mode; bottom, vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure H-3d. Intensity profiles for OH-58A, C, or D/AH-1 unmasked tail position light in dim mode; bottom, vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Figure H-4a. Intensity profiles for OH-58A, C, or D/AH-1 masked tail position light in dim mode; top, vertical angles 0 to 15 degrees. Intensity expressed in candelas.

.....

Figure H-4b. Intensity profiles for OH-58A, C, or D/AH-1 masked tail position light in dim mode; top, vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Figure H-4c. Intensity profiles for OH-58A, C, or D/AH-1 masked tail position light in dim mode; bottom, vertical angles 0 to 15 degrees. Intensity expressed in candelas.

Figure H-4d. Intensity profiles for OH-58A, C, or D/AH-1 masked tail position light in dim mode; bottom, vertical angles 20 to 75 degrees. Intensity expressed in candelas.

Table H-1a.

Measured data and calculated intensity values for OH-58A, C, or D/AH-1 tail position light, single samples; unmasked, bright. Intensity expressed in candelas.

Appendix L.

Measured illuminance and calculated intensity data for 14 samples of Type III reflector lateral position light bulb used in the UH-1/OH-58A or C/AH-1 fixture in dim mode with an unmasked, red dome configuration.

•

Table L-1a.

.

,

2

Measured data and calculated intensity values for type III lateral position light bulb, multiple samples; bulbs #1 and 2. Intensity expressed in candelas.

Appendix M.

^

Measured illuminance and calculated intensity data for 12 samples of the tail position light bulb used in the OH-58A, C, or D/AH-1 fixture in dim mode with an unmasked dome configuration. Table M-1a

Measured data and calculated intensity values for tail position light bulb, multiple samples; bulbs #1 and 2. Intensity expressed in candelas.
