## PREFACE

This report was prepared under NUWC Detachment New London Project No. S0223, *Automatic Detection and Automatic Classification*, principal investigator M. R. Leask (Code 2123). The sponsoring activity was the Naval Sea Systems Command (NAVSEA 63D), program manager Dr. Y. Yam (Code 06UR).

The technical reviewer for this report was Dr. W. K. Fischer (Code 2121).

For their review of the manuscript as well as several invaluable suggestions, the author expresses his appreciation to Dr. John P. Beam (Code 3314), Mr. Stephan A. Dzerovych (Code 2123), Dr. G. Clifford Carter (Code 21), and Mr. Harold J. Teller (Code 2123), all of NUWC Detachment New London.

**REVIEWED AND APPROVED: 25 MAY 1994**

**W. J. Coggins**  
**Acting Head, Submarine Sonar Department**

# DETERMINATION OF THE DISTANCE AND VELOCITY OF AN ACOUSTIC SOURCE FROM BEARING AND FREQUENCY MEASUREMENTS

## INTRODUCTION

A technique that uses bearing and frequency measurements to determine the distance between an observer and a sinusoidal acoustic source moving at constant velocity relative to the observer is developed in this report.

## THEORETICAL ANALYSIS

Consider a sinusoidal acoustic source with period  $T_e$  and fixed relative velocity  $\vec{v}_R$  (having a nonzero transverse component) with respect to an observer with known velocity  $\vec{v}$ . Let  $\vec{r}$  be the position vector of the source from the observer. We wish to determine the position vector  $\vec{r}$  and the relative velocity  $\vec{v}_R$  of the source relative to the observer from bearing  $\theta$  and frequency  $f_e$  measurements. The absolute velocity  $\vec{v}_s$  of the source is also determined.

Since we are interested in obtaining kinematic quantities subject to the constraint that the acceleration is zero, let us examine this aspect of the problem. For convenience, we use plane polar coordinates. For the position vector, we have

$$\vec{r}(\theta) = r \hat{r}(\theta) \quad , \quad (1)$$

where

$$\hat{r}(\theta) = \hat{i} \cos \theta + \hat{j} \sin \theta \quad (2)$$

and

$$\hat{\theta}(\theta) = -\hat{i} \sin \theta + \hat{j} \cos \theta \quad . \quad (3)$$

Differentiating the unit vectors with respect to  $\theta$ , we have

$$\frac{\partial \hat{r}}{\partial \theta} = \hat{\theta} \quad (4a)$$

and

$$\frac{\partial \hat{\theta}}{\partial \theta} = -\hat{r} \quad . \quad (4b)$$

The time derivative of  $\vec{r}$  is

$$\frac{d\vec{r}}{dt} = \frac{d\vec{r}(\theta)}{dt} = \dot{r} \hat{r} + r \dot{\theta} \hat{\theta} \quad (5)$$

Differentiating again, we have

$$\ddot{\vec{r}} = (\ddot{r} - r \dot{\theta}^2) \hat{r} + (r \ddot{\theta} + 2 \dot{r} \dot{\theta}) \hat{\theta} \quad (6)$$

Since by construction the relative velocity between the source and the observer is fixed, the acceleration must be identically zero. Consequently, all linearly independent components of the acceleration must be zero. Thus, we obtain the following expressions:

$$\ddot{r} = r \dot{\theta}^2 \quad (7)$$

and

$$r = -2 \dot{r} \dot{\theta} / \ddot{\theta} \quad (8)$$

The quantities  $\dot{\theta}$  and  $\ddot{\theta}$  are obtained from measurements of  $\theta$ . The quantities  $\dot{r}$  and  $\ddot{r}$  are not measurable but are related to changes in the observed acoustic frequency of the source. Therefore, we seek the relationship involving  $\dot{r}$ ,  $\ddot{r}$ , and the measured frequency and its time derivatives.

At time  $t_0$ , let the sinusoidal source emit a "pulse" and let  $\vec{r} = \vec{r}_1$  so that the magnitude of  $\vec{r}$  is  $r_1$ . After one period  $T_e$ , the source again emits a pulse at time  $t_0 + T_e$ . Let  $\vec{r} = \vec{r}_2$  so that the magnitude of  $\vec{r}$  is  $r_2$ . Suppose that the first pulse is heard by the observer at time  $t_1$  and the second pulse at time  $t_2$ . Denoting the speed of sound as  $c$ , we have

$$t_1 = t_0 + \frac{r_1}{c} \quad (9)$$

and

$$t_2 = t_0 + T_e + \frac{r_2}{c} \quad (10)$$

The period  $T_r$  of the acoustic signal as seen by the observer is

$$T_r = t_2 - t_1 \quad (11)$$

Substitution of the expressions for  $t_1$  and  $t_2$  in equations (9) and (10) into equation (11) yields

$$T_r = T_e + \frac{r_2 - r_1}{c} \quad (12)$$

The ratio of  $T_r$  to  $T_e$  is

$$\frac{T_r}{T_e} = 1 + \frac{r_2 - r_1}{cT_e} \quad (13)$$

In equation (13), we identify an expression for the radial velocity  $\dot{r}$  as follows:

$$\dot{r} = \frac{r_2 - r_1}{T_e} \quad (14)$$

Thus, we obtain

$$\frac{T_r}{T_e} = 1 + \frac{\dot{r}}{c} \quad (15)$$

Letting  $f_e = 1/T_e$  and  $f_r = 1/T_r$ , we have

$$f_e = f_r \left( 1 + \frac{\dot{r}}{c} \right) \quad (16)$$

Differentiating equation (16) with respect to time, we obtain

$$\frac{df_e}{dt} = \frac{\partial f_r}{\partial t} + \frac{\dot{r}}{c} \frac{\partial f_r}{\partial t} + \frac{f_r}{c} \frac{\partial \dot{r}}{\partial t} \quad (17)$$

Since  $f_e$  is constant by hypothesis, some rearrangement yields

$$0 = \frac{\partial f_r}{\partial t} + \frac{\dot{r}}{c} \frac{\partial f_r}{\partial t} + \frac{f_r}{c} \frac{\partial \dot{r}}{\partial t} \quad (18)$$

and

$$\frac{\partial f_r}{\partial t} = - \frac{\dot{r}}{c} \frac{\partial f_r}{\partial t} - \frac{f_r}{c} \ddot{r} \quad (19)$$

Substituting in the expressions obtained above for  $\dot{r}$  (eq. 8) and  $\ddot{r}$  (eq. 7), we have

$$\frac{\partial f_r}{\partial t} = - \left( - \frac{r\ddot{\theta}}{2\dot{\theta}} \right) \frac{1}{c} \frac{\partial f_r}{\partial t} - \frac{f_r}{c} (r\dot{\theta}^2) \quad (20)$$

We solve this to obtain an expression for  $r$  as follows:

$$\frac{\partial f_r}{\partial t} = r \frac{\ddot{\theta}}{2\dot{\theta}} \frac{1}{c} \frac{\partial f_r}{\partial t} - r \frac{f_r}{c} \dot{\theta}^2, \quad (21)$$

$$\frac{\partial f_r}{\partial t} = r \left[ \frac{\ddot{\theta}}{2\dot{\theta}} \frac{\partial f_r}{\partial t} - f_r \dot{\theta}^2 \right], \quad (22)$$

$$r = c \frac{\partial f_r}{\partial t} \left[ \frac{\ddot{\theta}}{2\dot{\theta}} \frac{\partial f_r}{\partial t} - f_r \dot{\theta}^2 \right]^{-1}. \quad (23)$$

Note that, in this equation for  $r$ , all the independent parameters are known or may be determined from measurements. The sound speed  $c$  is generally known *a priori*. The quantities  $\theta$  and  $f_r$  are measurable, and  $\ddot{\theta}$ ,  $\dot{\theta}$ , and  $\partial f_r / \partial t$  can be determined from these measurements.

Since  $\theta$  may be measured directly and  $r$  may be calculated from measured quantities, we have the position vector  $\vec{r}$  of the source with respect to the observer. If we determine the position vector at two instants  $t_2$  and  $t_1$ , we may calculate the relative velocity  $\vec{v}_R$  of the source as follows:

$$\vec{v}_R = \frac{d\vec{r}}{dt} = \frac{\vec{r}_2(\theta_2) - \vec{r}_1(\theta_1)}{t_2 - t_1}. \quad (24)$$

Recall that the relative velocity  $\vec{v}_R$  of the source from the perspective of the observer is

$$\vec{v}_R = \vec{v}_s - \vec{v}. \quad (25)$$

Therefore, if the relative velocity  $\vec{v}_R$  and the absolute velocity  $\vec{v}$  of the observer are known, then the absolute velocity of the source may be obtained:

$$\vec{v}_s = \vec{v}_R + \vec{v}. \quad (26)$$

## CONCLUSIONS

We have shown how to calculate the distance, the relative velocity, and the absolute velocity of an acoustic source having a fixed velocity relative to an observer from measurements of its bearing and frequency.
