#### Abstract

A new method for the synthesis of poly(dichlorophosphazene) at ambient temperatures is described. It involves the initiation of  $Cl_3P=NSiMe_3$  with trace amounts of  $PCl_5$  in  $CH_2Cl_2$  to yield poly(dichlorophosphazene),  $[NPCl_2]_n$ , with narrow polydispersities. The molecular weight of poly(dichlorophosphazene) was controlled by altering the ratio of monomer to initiator. The polymer chains were found to be active after chain propagation since further addition of monomer resulted in the formation of higher molecular weight polymer. Integration of <sup>1</sup>H and <sup>31</sup>P NMR spectra of these reactions revealed that the polymerization follows first order reaction kinetics with respect to monomer concentration. Active polymer chains may be quenched or end-capped by the addition of trace quantities of  $Me_2(CF_3CH_2O)P=NSiMe_3$  or  $(CF_3CH_2O)_3P=NSiMe_3$ . Furthermore, PBr<sub>5</sub>, SbCl<sub>5</sub> and Ph<sub>3</sub>C[PF<sub>6</sub>] were also found to be effective initiators in CH<sub>2</sub>Cl<sub>2</sub> at room temperature.

#### Introduction

Polyphosphazenes are inorganic-organic polymers based on the repeating unit  $[N=PR_2]_n$ , where R can be halogeno, organic, or organometallic units. Macromolecular substitution reactions carried out on poly(dichlorophosphazene) have been the method of choice for preparing many polymers with side groups such as OR, NHR, or NRR' (Scheme 1). The properties of these polymers vary widely following changes in the side group (R). Properties such as hydrophobicity, hydrophilicity, crystallinity and optical characteristics can be controlled by the nature of the side group.<sup>1</sup>

The most fully developed and commercially feasible route to poly(dichlorophosphazene) makes use of the thermal ring-opening polymerization of hexachlorocyclotriphosphazene, (N=PCl<sub>2</sub>)<sub>3</sub>, at 250 °C, which yields poly(dichlorophosphazene) [N=PCl<sub>2</sub>]<sub>n</sub>, but with little or no molecular weight control and with large polydispersities.<sup>2</sup> Some molecular weight control can be achieved by the use of initiators such as OP(OPh)<sub>3</sub>/BCl<sub>3</sub> for the ring-opening process.<sup>3</sup> An alternative route to poly(dichlorophosphazene) is through the condensation polymerization of Cl<sub>3</sub>P=N-P(O)Cl<sub>2</sub>. In this case also some molecular weight control can be achieved, but high temperatures are required and the polydispersities of the resultant polymer are usually higher than 2.4 The reaction of PCl<sub>5</sub> with ammonium chloride at elevated temperatures has been described as an alternative pathway to low and medium molecular weight [N=PCl<sub>2</sub>]n.<sup>5,6</sup> Routes are also available for the direct synthesis of poly(aryl/alkyl)phosphazenes via the condensation polymerization of N-silylphosphoranimines at ca 200 °C, developed by Neilson and Wisian-Neilson,<sup>7,8</sup> which gives polymers with  $M_n \sim 10^5$  and with polydispersity indices of 1.5 - 3.0. Matyjaszewski and coworkers<sup>9</sup> have recently reported that phosphoranimine species, such as (CF<sub>3</sub>CH<sub>2</sub>O)<sub>3</sub>P=NSiMe<sub>3</sub>, undergo cationic polymerizations at 100 °C that produce  $[N=P(OCH_2CF_3)_2]_n$  with molecular weights  $(M_n)$  that approach 1.0 - 5.0 x 10<sup>4</sup> and with polydispersities of 1.2 to 2.5.

2

Because of the substantial number of polymers accessible through the macromolecular substitution of poly(dichlorophosphazene), improved methods for the synthesis of this polymer would be a significant development from both the scientific and industrial points of view. Moreover, the possibility for control of the molecular weight of poly(dichlorophosphazene) is a key requirement for the further development of this branch of polymer chemistry.<sup>10</sup> An ambient temperature polymerization route may also serve as an efficient method for the large-scale production of a wide variety of polymeric phosphazene systems including block copolymers.

In this paper, as a development of discoveries reported in our initial 1995 communication,<sup>11</sup> we report a new method for the synthesis of poly(dichlorophosphazene). This advanced synthesis takes place at ambient temperatures, allows molecular weight control, and provides polymers with narrow polydispersities. The process can also be used for the direct room-temperature synthesis of organic-substituted polyphosphazenes and for the preparation of block copolymers, as will be reported in another article.<sup>12</sup>

#### **Results and Discussion**

The phosphoranimine  $Cl_3P=NSiMe_3$  (1) is known to react with two equivalents of  $PCl_5$  to form  $[Cl_3P=N-PCl_3]^+[PCl_6]^-$  with the elimination of  $Me_3SiCl_1^{11,13}$  This ionic species will then interact with an additional equivalent of 1 to eliminate  $Me_3SiCl$  and form the short chain cationic species  $[Cl_3P=N-PCl_2=N-PCl_3]^+[PCl_6]^-$ . Oligomeric products can be obtained by the addition of further equivalents of 1 to this species. In view of these results it was postulated that the reaction of 1 with a trace amount of  $PCl_5$  should yield high molecular weight polymer.

#### Synthesis and Polymerization of the Phosphoranimine Cl<sub>3</sub>P=NSiMe<sub>3</sub> (1).

i) Synthesis and Purification. Compound 1 was synthesized initially from  $LiN(SiMe_3)_2$  and PCl<sub>5</sub> in hexane at -78 °C. A major challenge was the need to obtain 1 in

3

high purity. The monomer formed by this route did not polymerize in a reproducible manner when treated with trace amounts of PCl<sub>5</sub> in CH<sub>2</sub>Cl<sub>2</sub>. <sup>1</sup>H NMR spectra and mass spectrometry (CI-MS) revealed the presence of  $(Me_3Si)_2NCl$  as a side product. This species appears to inhibit polymerization. Multiple distillations did not remove  $(Me_3Si)_2NCl$  because this compound distills at a similar temperature and pressure to 1. Pure 1 was obtained by treatment of the mixture with PPh<sub>3</sub> (in an excess or stoichiometric amount relative to  $(Me_3Si)_2NCl$ ) in CH<sub>2</sub>Cl<sub>2</sub> to form Ph<sub>3</sub>P=NSiMe<sub>3</sub> and Me<sub>3</sub>SiCl.<sup>14</sup> The resultant mixture was then distilled at reduced pressure to yield pure 1. Alternatively, to avoid the additional purification step, 1 has also been obtained from the reaction of PCl<sub>5</sub> with N(SiMe<sub>3</sub>)<sub>3</sub> in hexane at -78 °C. Although this synthesis generated no  $(Me_3Si)_2NCl$  impurity, the yields of 1 produced via this route have not been optimized. Work toward the further development of this synthetic procedure is in progress and will be described in the near future.<sup>15</sup>

ii) Bulk Polymerization of Cl<sub>3</sub>P=NSiMe<sub>3</sub> (1). The addition of a trace of PCl<sub>5</sub> (ca. 10 mg) to pure 1 (1.0 g) at room temperature led within 24 h to the formation of a two-phase mixture. Both phases were clear and colorless, but the upper, more fluid layer was found by <sup>1</sup>H NMR spectroscopy to consist of Me<sub>3</sub>SiCl. A <sup>31</sup>P NMR spectrum of the entire tube contents comprised a sharp singlet with a chemical shift at -17.4 ppm that was characteristic of poly(dichlorophosphazene). Thus, the conversion of 1 to linear polymer was essentially quantitative. The product was treated with an excess of sodium trifluoroethoxide to replace the chlorine atoms by trifluoroethoxy groups and generate a hydrolytically stable derivative, and the resultant species yielded a <sup>31</sup>P NMR signal (-6.9 ppm) characteristic of the well-known polymer [N=P(OCH<sub>2</sub>CF<sub>3</sub>)<sub>2</sub>]<sub>n</sub> (2). Analysis of 2 by gel permeation chromatography (GPC) indicated that it possessed a high molecular weight fraction only , with M<sub>n</sub> = 1.2 x 10<sup>5</sup> and a polydispersity index (PDI = M<sub>w</sub>/M<sub>n</sub>) of 1.8 versus polystyrene standards. However, in subsequent attempts to obtain lower molecular weight poly(dichlorophosphazene) by decreases in the ratio of monomer to  $PCl_5$ , using the same solvent-free conditions, the initiator and initial cationic products remained primarily immiscible. The molecular weight values of the polymers produced were lower than described above but the GPC chromatogram in this case was multimodal in nature. These results suggested a lack of molecular weight control in the bulk phase due to the heterogeneous nature of the process.

iii) Solution Polymerization Cl<sub>3</sub>P=NSiMe<sub>3</sub> (1). In view of the heterogeneous nature of the bulk polymerization, solution reactions appeared to be a possible alternative for controlling the course of the polymerization. Various solvents were investigated for the polymerization of monomer 1 initiated by traces of PCl<sub>5</sub>. These included methylene chloride, cyclohexane, tetrahydrofuran, acetonitrile, and nitromethane to examine the effect of solvent polarity and dielectric strength on the rate of the polymerization. Reactions conducted with a 50:1 molar ratio of 1 to PCl<sub>5</sub> were monitored by  $^{31}P$  NMR spectroscopy. Only in CH<sub>2</sub>Cl<sub>2</sub> or cyclohexane did the polymerizations proceed quantitatively without side reactions. The polymerization in CH<sub>2</sub>Cl<sub>2</sub> was complete within 4 h at 25 °C, while in cyclohexane the polymerization reached completion in about 24 h. The reaction rate is thought to be faster in CH<sub>2</sub>Cl<sub>2</sub> than in cyclohexane because of the higher polarity, dielectric strength, and solvating ability of CH<sub>2</sub>Cl<sub>2</sub>. In the other media it appeared that the solvent itself reacted with either the monomer, the initiator, and/or the growing polymer chain (See Table I). Also, in the solution polymerization of 1 in CH<sub>3</sub>CN or CH<sub>3</sub>NO<sub>2</sub>, the poly(dichlorophosphazene) was not completely soluble. The presence of suitable donor solvents may accelerate the reaction by causing greater ion pair separation.

Structures 1 and 2 near here.

Table I near here.

However, the reaction of 1 with traces of PCl<sub>5</sub> in CH<sub>2</sub>Cl<sub>2</sub> resulted in a quantitative conversion to poly(dichlorophosphazene) as estimated by <sup>1</sup>H and <sup>31</sup>P NMR spectroscopy and by GPC analysis of the trifluoroethoxy derivative 2. Very narrow polydispersities (PDI < 1.32) were obtained. An increase in the ratio of phosphoranimine to PCl<sub>5</sub> in solution brought about an increase in the molecular weight, while still retaining narrow PDI values (see Table II).

The calculated molecular weights shown in Table I were predicted on the basis of monomer to initiator ratios, and these differed from the values determined by gel permeation chromatography (GPC). The molecular weight values obtained by GPC were estimated versus polystyrene standards and this could account for the difference between the calculated and the found values.<sup>16,17</sup> Molecular weights of short chain polymers and oligomers obtained by <sup>31</sup>P NMR spectroscopy based on the end group to middle unit ratios correspond more closely to the expected values. For example, a <sup>31</sup>P NMR spectrum of a 20:1 1:PCl<sub>5</sub> ratio sample contained small peaks at +9 ppm (d, *-PCl<sub>3</sub>* terminal), -14 ppm (t, *-PCl<sub>2</sub>*-PCl<sub>3</sub>), and -15 ppm (t, *PCl<sub>2</sub>*-PCl<sub>2</sub>PCl<sub>3</sub>), along with an intense peak at -17 ppm (br, s, -(PCl<sub>2</sub>)<sub>n</sub>-), characteristic of the known resonance for the middle units of the polymer chain [N=PCl<sub>2</sub>]<sub>n</sub>. The peak ratios determined by integration is 1:1:1:17, which corresponds well to the theoretical structure for a 40 repeat unit macromolecule.

#### Table II near here.

#### iv) Effect of the Type of Initiator on the Solution Polymerization of 1.

A number of initiators have been examined for the ambient temperature polymerization of 1 including Lewis acidic main group and transition metal chlorides, as well as a number of trityl cations (see Table III). Phosphorane species such as  $PX_5$  (X = Cl, Br) rapidly initiate the polymerization of 1. Previous work has shown that the reaction of the phosphoranimine 1 with two equivalents of PCl<sub>5</sub> results in the formation of [Cl<sub>3</sub>P=N-PCl<sub>3</sub>]<sup>+</sup> [PCl<sub>6</sub>]<sup>-.11,13</sup> Successive additions of 1 and 2 equivalents of 1 yield the oligomeric species  $[Cl_3P(NPCl_2)_x-NPCl_3]^+[PCl_6]^-$ , with x = 2 and 3, respectively.<sup>11</sup> A reaction of 1 with PhPCl<sub>4</sub> in a 10:1 molar ratio produced poly(dichlorophosphazene) which, after treatment with NaOCH<sub>2</sub>CF<sub>3</sub> was found to possess a  $M_n = 1.2 \times 10^3$  and PDI = 1.03. This suggests that the cationic initiation method is relatively insensitive to the nature of the phosphorane employed. Other Group V chlorides such as SbCl<sub>5</sub> were also found to be efficient initiators for the polymerization of 1. For example, in an attempt to compare the reactivity of PCl<sub>5</sub> and SbCl<sub>5</sub> toward 1, two separate samples of 1 were treated with 5 % molar equivalents of PCl<sub>5</sub> and SbCl<sub>5</sub> in CH<sub>2</sub>Cl<sub>2</sub>. Both reactions proceeded at similar rates and were complete within 1.5 h, as indicated by the disappearance of the <sup>31</sup>P NMR resonance for 1 at -54 ppm. After treatment of the resultant  $[N=PCl_2]_n$  with sodium trifluoroethoxide, the GPC molecular weights and polydispersities for the PCl5- and SbCl5induced polymerizations were found to be very similar. The PCl<sub>5</sub>-induced polymerization produced  $[N=P(OCH_2CF_3)_2]_n$  (2) with an  $M_n$  of 2.3 x 10<sup>4</sup> (PDI = 1.03) within 1.5 h and the SbCl<sub>5</sub>-initiated polymerization produced a counterpart with a  $M_n$  of 1.8 x 10<sup>4</sup> but with a slightly higher PDI value (PDI = 1.11) within the same 1.5 h. Interestingly, high oxidation state transition metal halides such as TiCl<sub>4</sub>, Cp<sub>2</sub>TiCl<sub>2</sub>, TaCl<sub>5</sub>, WCl<sub>6</sub>, VCl<sub>4</sub> and main group Lewis acids, such as dibutylboron triflate (Bu2BOSO2CF3), POCl3, AlCl3, Et2AlCl, SnCl4 and SnCl<sub>2</sub>, did not initiate the polymerization of 1 at room temperature but instead reacted with Cl<sub>3</sub>P=NSiMe<sub>3</sub> in *refluxing* CH<sub>2</sub>Cl<sub>2</sub> to produce macromolecules with lower molecular weights and broader polydispersities than those obtained by the ambient temperature route. For example, a 20:1 ratio of 1:VCl4 at 60 °C yielded poly(dichlorophosphazene) which, after treatment with NaOCH<sub>2</sub>CF<sub>3</sub>, had an  $M_n$  of 6.0 x 10<sup>3</sup> (PDI = 1.23). These differences in initiation behavior suggest that a key requirement for polymerization initiation is the ability of the initiator to form multiple bonds with nitrogen in a similar fashion to the formation of the cationic species [Cl<sub>3</sub>P=N-PCl<sub>3</sub>]<sup>+</sup> [PCl<sub>6</sub>]<sup>-.11</sup> Previous phosphoranimine reactivity studies have shown that the phosphoranimine 1 reacts with  $BX_{3}$ ,<sup>18</sup> WCl<sub>6</sub>,<sup>13</sup> or TaCl<sub>5</sub><sup>19</sup> to form stable neutral adducts Cl<sub>3</sub>P=N-MX<sub>n</sub> (M = B, X<sub>n</sub> = X<sub>2</sub>; M = W, X<sub>n</sub> = Cl<sub>5</sub>; M = Ta, X<sub>n</sub> = Cl<sub>4</sub>).

Several trityl salts were also found to react with 1 at 25 °C. Reaction of Ph<sub>3</sub>C[PF<sub>6</sub>] (5 mol %) with 1, followed by polymerization for 4 h and halogen replacement, yielded 2 in ca. 80 % yield ( $M_n = 1.6 \times 10^4$ ; PDI = 1.08), with the remaining 20 % consisting of the cyclic species (N=PCl<sub>2</sub>)<sub>x</sub> identified by their <sup>31</sup>P NMR resonances (x = 3, 20.8 ppm and x = 4, -7.1 ppm respectively).<sup>20</sup> In a similar experiment 1 was treated with Ph<sub>3</sub>C[SbCl<sub>6</sub>] (20) mol %) in CH<sub>2</sub>Cl<sub>2</sub> and the reaction was monitored by <sup>31</sup>P NMR spectroscopy over a 24 h period. The hexachloroantimonate trityl salt produced mainly cyclic species (N=PCl<sub>2</sub>)<sub>3,4</sub> and linear oligomers as determined by GPC and <sup>31</sup>P NMR experiments. The fact that the trityl-based cations produce cyclic phosphazenes may provide evidence for an alternative mechanism when these carbocations are present. The carbocations may simply react with 1 via attack at nitrogen to produce a reactive intermediate such as {Cl<sub>3</sub>P=N<sup>+</sup>}, as reported for the high temperature cationic polymerization of tris(organo)phosphoranimines by Matyjaszewski and coworkers.<sup>9</sup> Such an intermediate in our polymerizations would then interact with further equivalents of 1 via reaction at phosphorus to produce Me<sub>3</sub>SiCl and a growing, even-numbered oligomer [N=PCl<sub>2</sub>]<sub>n</sub>. This proposed mechanism contrasts with the PCl5-induced polymerizations in the sense that, with phosphorane catalysts, odd numbered chains are produced, such as  $[(Cl_2P=N)_x-PCl_3]^+[PCl_6]^-$  (x = 1, 2, etc.), thus limiting the opportunity for even-numbered oligomeric species to be formed, and this could favor the formation of cyclic species via back-biting or other cyclization reactions (see Scheme 2). Also, in the high temperature cationic polymerizations that employ Ph<sub>3</sub>C[SbCl<sub>6</sub>] as an initiator, the trityl salt was reported not to be the active initiator, but rather SbCl<sub>5</sub> formed through an equilibrium with the hexachloroantimonate salt.<sup>9</sup> Clearly no such equilibrium exists in our ambient temperature polymerizations based on the efficiency of SbCl<sub>5</sub>-induced polymerizations of 1 mentioned earlier (see Table III).

#### Table III near here.

v) Effect of Temperature on the Solution Polymerization of 1. The influence of temperature changes on the solution polymerization of 1 were examined with a 20:1 ratio of monomer 1 to PCl<sub>5</sub> in CH<sub>2</sub>Cl<sub>2</sub>. The polymerizations were monitored by <sup>1</sup>H and <sup>31</sup>P NMR spectroscopy from 15 to 35 °C over the course of the polymerization (See Table IV). Lowering of the temperature increased the times needed for completion of the polymerization, while temperature increases decreased the polymerization times. The PCl<sub>5</sub>-induced polymerization of 1 proceeded to completion within 2 h at 15 °C, 1 h at 25 °C, 40 min at 30 °C, and 35 min. at 35 °C. Thus, below room temperature, the polymerization is slow and at even lower temperatures it may be brought to a halt. The measured molecular weight of the polymer increased slightly as the temperature was lowered, but these results are within experimental error.

The effect of temperature decreases on the inhibition of polymerization for a 100:1 **1** to PCl<sub>5</sub> ratio reaction was examined at -50 °C and at 25 °C, and was monitored by <sup>1</sup>H and <sup>31</sup>P NMR spectroscopy. The polymerization at 25 °C was complete in less than 9 h but after the same time at -50 °C only monomer was detected. However, on warming this mixture to 25 °C the monomer was converted to polymer in less than 9 h. Similarly, a 10:1 ratio of **1** to PCl<sub>5</sub> was monitored at low temperatures. The polymerization was about 75% complete as determined by <sup>31</sup>P NMR spectroscopy. At -10 °C the polymerization had slowed dramatically, but was not completely inhibited. The mixture was then cooled to -52 °C and the propagation reaction ceased. The reaction mixture was monitored by <sup>31</sup>P NMR spectroscopy. The poly(dichlorophosphazene) was monitored by <sup>31</sup>P NMR spectroscopy. The polymerization was inhibited completely at -52 °C. However, again on warming to 25 °C, the propagation resumed and was complete in less than one hour. Thus,

#### Table IV near here.

vi) Activity of the Chains. A solution of poly(dichlorophosphazene) in  $CH_2Cl_2$  was prepared via the reaction of 1 with PCl<sub>5</sub> in a 9.3:1 ratio in which all the phosphoranimine had been converted to polymer, as determined by <sup>1</sup>H and <sup>31</sup>P NMR spectroscopy. A portion of this sample was subjected to halogen replacement replacement as described above to yield a trifluoroethoxy-substituted polymer 2 with  $M_n = 1.1 \times 10^4$  and PDI = 1.09. Further addition of phosphoranimine to the remaining polymerization mixture to generate a molar ratio of  $1:[NPCl_2]_n$  of 5:1, resulted in the continued conversion of 1 to polymer over 24 h. The GPC analysis of the trifluoroethoxy-derivatized polymer 2 formed from this solution showed the presence of polymer with  $M_n = 4.4 \times 10^4$  and PDI = 1.17 with no evidence for the presence of the lower molecular weight polymer. Thus, it appears that the active chain ends can resume chain growth following the addition of more monomer. This opens up many possibilities for control of the chain length and for coupling of the chain ends to other monomers or polymers. In addition, the active chains may be quenched or end-capped with suitable reagants, allowing further molecular weight control and the possibility of further functionalization of the macromolecules.

One possible end-capping species is a tris(organo)phosphoranimine such as  $(CF_3CH_2O)_3P=NSiMe_3$ ,<sup>21</sup> where the presence of the SiMe<sub>3</sub> group permits reaction with the polymeric cation, while the absence of a chlorine unit at phosphorus should result in termination. Indeed, when a polymerized solution of 1, initiated with a 2 % molar equivalent of PCl<sub>5</sub> in CH<sub>2</sub>Cl<sub>2</sub>, was treated with trace quantities of  $(CF_3CH_2O)_3P=NSiMe_3$  at regular intervals during the polymerization, the growth of the polymeric cation was quenched as monitored by <sup>31</sup>P NMR spectroscopy. GPC examination of the resultant

polymers after chlorine replacement with NaOCH<sub>2</sub>CF<sub>3</sub> showed a consistent range of molecular weights for the endcapped polymerization (see Table V, Figure 1). Unfortunately, the presence of the terminal -N=P(OCH<sub>2</sub>CF<sub>3</sub>)<sub>3</sub> group in the end-capped polymer could not be confirmed from the <sup>31</sup>P NMR spectrum of an oligomeric sample of poly(dichlorophosphazene) synthesized from treatment of 1 with a 20% molar equivalent of PCl<sub>5</sub>. The resonance for the terminal -N=P(OCH<sub>2</sub>CF<sub>3</sub>)<sub>3</sub> species was perhaps concealed by resonances for the oligo(dichlorophosphazene) species. In a further effort to confirm the presence of such endcapping groups, an oligomeric sample of [N=PCl<sub>2</sub>]<sub>n</sub>, synthesized by treatment of 1 with a 10% molar equivalent of PCl<sub>5</sub>, was treated with Me<sub>2</sub>(CF<sub>3</sub>CH<sub>2</sub>O)P=NSiMe<sub>3</sub>.<sup>21</sup> Examination of this endcapped species by <sup>31</sup>P NMR spectroscopy revealed the terminal -N=PMe<sub>2</sub>(OCH<sub>2</sub>CF<sub>3</sub>) species from a doublet resonance at 9.4 ppm (Figure 2). The M<sub>n</sub> of this endcapped oligomer was found to be 5.9 x 10<sup>3</sup> (PDI = 1.05, by GPC) after macromolecular substitution with NaOCH<sub>2</sub>CF<sub>3</sub>.

#### Table V near here.

vii) Molecular Weight Changes as a Function of Polymerization Time. The solution polymerization of 1 with a 46:1 monomer to  $PCl_5$  initiator ratio in  $CH_2Cl_2$  was monitored as a function of time. Aliquots were removed at regular intervals and the chlorine atoms were replaced by treatment with NaOCH<sub>2</sub>CF<sub>3</sub>. The molecular weights of the resultant polymers were then estimated by GPC. One of the characteristics of a living polymerization is a linear increase in molecular weight with respect to time. This is the situation with this system, as illustrated in Figure 3.

viii) Percent Monomer Conversion Versus Time. Another characteristic of a living polymerization is that the reaction should follow first order kinetics with respect to monomer concentration. The polymerization of a 100:1 1:PCl<sub>5</sub> sample was monitored with <sup>1</sup>H and <sup>31</sup>P NMR spectroscopy. A plot of ln[monomer] versus time (Figures 4 and 5) showed a linear relationship and this suggests first-order kinetics. The first order rate constant for this polymerization was found to be  $k_{297} = 3.0 \times 10^{-3} \text{ s}^{-1}$ .

ix) Evidence for Macrocondensation. Samples of poly-(dicholorophosphazene) that were not subjected to halogen replacement immediately following complete conversion of monomer, but instead were maintained for several days at 25 °C before being substituted, showed a change in molecular weight distribution. GPC chromatograms consisted not of a single sharp peak as expected, but a peak with a higher molecular weight shoulder. The shoulder corresponded to approximately twice the molecular weight of the original peak. This occurred for several monomer to initiator ratios, and suggested a macrocondensation reaction in which two polymer chains join together to form a single polymer of twice the molecular weight. In order to study this phenomenon, a polymerization experiment was conducted with a 23:1 1:PCl<sub>5</sub> ratio sample. The polymerization solution was divided into two equal parts. The first sample was treated with NaOCH<sub>2</sub>CF<sub>3</sub> in dioxane immediately after conversion of the monomer to polymer. The GPC chromatogram of this substituted polymer 2 contained one sharp peak that corresponded to values of  $M_n = 2.0 \times 10^4$  and PDI = 1.09, as seen in Figure 6. The second sample was not substituted, but was stirred at 25 °C for 20 days in the [N=PCl<sub>2</sub>]<sub>n</sub> form. It was then treated with NaOCH<sub>2</sub>CF<sub>3</sub> in dioxane to produce polymer with  $M_n = 2.2 \times 10^4$  and PDI = 1.17. However, the GPC chromatogram of this polymer had an additional high molecular weight shoulder at approximately twice the molecular weight of the first polymer. This suggests that [N=PCl<sub>2</sub>]<sub>n</sub> macrocondensation can occur over time. A possible mechanism for this process is hydrolytic coupling of two polymer chains to give a macromolecule with a molecular weight twice that of the original. Another possibility is the coupling of two neutral chain ends (Cl<sub>3</sub>P=N-) to form a dimeric species. This dimerization is illustrated in Scheme 3. Thus, in order to obtain controlled molecular weight polymers, it is essential to substitute the polymer immediately after complete conversion of monomer or to store the material at temperatures below 0 °C.

High Molecular Weight Polymers. X) Polymerizations at higher ratios of 1 to PCl<sub>5</sub> than 150:1 in CH<sub>2</sub>Cl<sub>2</sub> were attempted in order to obtain very high molecular weight polymers. The molecular weights obtained at these higher monomer ratios were not reproducible. However, an alternative method of synthesis provided high molecular weight products, but with a multimodal molecular weight distribution. A 25:1 monomer to initiator sample was allowed to react until complete conversion to polymer had occurred at 25 °C. A fraction of the mixture was then removed for NMR analysis. More monomer 1 was then introduced to the system. <sup>1</sup>H and <sup>31</sup>P NMR analysis showed that this monomer was also quantitatively converted to polymer. Four additional charges of 1 were added in this fashion over the course of one week (each ca. 25:1 1: [PCl<sub>5</sub>]<sub>initial</sub>). The resultant polymer was then treated with NaOCH<sub>2</sub>CF<sub>3</sub> to provide high molecular weight polymer 2 (multimodal GPC trace with peaks at  $M_n = 1.2 \times 10^6$ , PDI = 1.18;  $M_n = 3.7 \times 10^4$ , PDI = 1.47;  $M_n =$ 8.8 x  $10^3$ , PDI =1.01). The highest molecular weight fraction has a molecular weight comparable to that of poly(dichlorophosphazene) formed by the classical ring-opening polymerization method.

xi) Room Temperature Polymerization of Organic-Substituted Phophoranimines. The procedures discussed above also allow organicsubstituted monomers such as  $PhCl_2P=NSiMe_3$ ,  $Ph_2ClP=NSiMe_3$ ,  $Me(Et)ClP=NSiMe_3$ , and  $(CF_3CH_2O)_2BrP=NSiMe_3$  to be polymerized in the same way to give polymers  $[N=P(Ph)(OCH_2CF_3)]_n$ ,  $[N=P(Ph)_2]_n$ ,  $[N=PMe(Et)]_n$ , and  $[N=P(OCH_2CF_3)_2]_n$  This aspect has also been developed in detail, and will reported in a forthcoming publication.<sup>12</sup> Summary The cationic polymerization of  $Cl_3P=NSiMe_3$  (1), initiated by phosphoranes such as PCl<sub>5</sub>, provides access to poly(dichlorophosphazene) with controllable molecular weights and narrow polydispersities. The PCl<sub>5</sub>-induced polymerization of 1 has also been shown to display living characteristics. This new synthetic route for the production of well-defined poly(dichlorophosphazene), a key intermediate for the synthesis of hundreds of different macromolecules, has widespread implications for the industrial and academic development of polyphosphazenes. In addition, the ambient temperature method provides an effective direct route to poly(organophosphazenes), via the PCl<sub>5</sub>-induced polymerizations of mono- and diorgano-substituted phosphoranimines, an approach that will be discussed in a forthcoming publication.<sup>12</sup> Current work is also focused on the synthesis of phosphazene-based copolymers, including the development of phosphazene-phosphazene and phosphazene-organic block copolymers via this polymerization method.

#### **Experimental Section**

**Materials** Lithium bis(trimethylsilyl)amide, TiCl<sub>4</sub>, Cp<sub>2</sub>TiCl<sub>2</sub>, TaCl<sub>5</sub>, WCl<sub>6</sub>, VCl<sub>4</sub>, SbCl<sub>5</sub>, dibutylboron triflate (1M solution in dichloromethane), POCl<sub>3</sub>, AlCl<sub>3</sub>, Et<sub>2</sub>AlCl (1.8M solution in toluene), SnCl<sub>4</sub>, SnCl<sub>2</sub>, 2,2,2-trifluoroethanol, sodium metal, and chlorine gas were obtained from Aldrich and were used without further purification. Phosphorus pentachloride (Aldrich) was sublimed under vacuum. PhPCl<sub>4</sub>,<sup>22</sup> sodium trifluoroethoxide,<sup>23</sup> Me<sub>2</sub>(CF<sub>3</sub>CH<sub>2</sub>O)P=NSiMe<sub>3</sub>,<sup>21</sup> and (CF<sub>3</sub>CH<sub>2</sub>O)<sub>3</sub>PNSiMe<sub>3</sub><sup>21</sup> were synthesized and purified by literature procedures. 1,4-Dioxane, tetrahydrofuran, and hexane (Aldrich) were distilled into the reaction flask from sodium-benzophenone ketyl in an atmosphere of dry argon. Dichloromethane (Aldrich) was dried and distilled from CaH<sub>2</sub> and then from P<sub>2</sub>O<sub>5</sub> into the reaction flask. Acetonitrile, nitromethane, and cyclohexane (Aldrich) were distilled from P<sub>2</sub>O<sub>5</sub> into the reaction flask.

All glassware was dried overnight in an oven, or flame dried under vacuum before use. The reactions were performed using standard Schlenk techniques or in an inert atmosphere glove box (Vacuum Atmospheres) under an atmosphere of dry argon or nitrogen.

Equipment <sup>31</sup>P, <sup>13</sup>C, and <sup>1</sup>H spectra were recorded with use of a Bruker WM-360 NMR operated at 146, 90.27, and 360 MHz respectively. <sup>29</sup>Si NMR spectra were recorded with use of a Bruker AM-300 NMR operated at 59.6 MHz and were referenced externally to SiMe<sub>4</sub>. <sup>1</sup>H and <sup>13</sup>C NMR spectra are referenced to an internal CDCl<sub>3</sub>. <sup>31</sup>P NMR chemical shifts are relative to 85% phosphoric acid as an external reference, with positive shift values downfield from the reference. Molecular weights were estimated using a Hewlett-Packard HP 1090 gel permeation chromatograph equipped with an HP-1047A refractive index detector, American Polymer Standards AM gel 10 µm and AM gel 10 µm 10<sup>4</sup> Å column, and calibrated versus polystyrene standards (Polysciences). The samples were eluted with a 0.1% by weight solution of tetra-n-butylammonium nitrate (Aldrich) in THF (OmniSolv).

**Preparation of Cl\_3P=NSiMe\_3 (1).** Compound 1 was synthesized as reported previously,<sup>13</sup> with the modification that the distilled mixture of 1 and  $(Me_3Si)_2NCl$  was treated with PPh<sub>3</sub> (amount as determined by <sup>1</sup>H NMR integration) and the resultant mixture was redistilled at reduced pressure.

For 1; Yield 43%. <sup>1</sup>H-NMR (CDCl<sub>3</sub>):  $\delta = 0.18$  ppm (d, <sup>4</sup>J<sub>PH</sub> = 1 Hz); <sup>31</sup>P-NMR (CDCl<sub>3</sub>):  $\delta = -54$  ppm. <sup>13</sup>C-NMR (CDCl<sub>3</sub>): 1.9 ppm (d, <sup>4</sup>J<sub>CP</sub> 7 Hz, Si-CH<sub>3</sub>); <sup>29</sup>Si (CDCl<sub>3</sub>):  $\delta = 0.27$  (d, <sup>2</sup>J<sub>PSi</sub> = 11 Hz). MS. (CI, Isobutane): m/z = 224 (MH<sup>+</sup>, 98 %), 208 (M<sup>+</sup> - Me, 82 %), in good agreement with isotopic abundance calculations.

Polymerization of 1 in Solution and in the Bulk Phase. a) A solution of 10 mg (0.048 mmol) of PCl<sub>5</sub> in 3 mL of  $CH_2Cl_2$  was placed in a Schlenk flask in a glove

box and was stirred with use of a magnetic stirrer. A solution of 0.2 g (0.89 mmol) of 1 in 2 mL of CH<sub>2</sub>Cl<sub>2</sub> was then added to the flask. The reaction mixture was monitored by <sup>1</sup>H and <sup>31</sup>P NMR spectroscopy. After complete conversion of 1 to polymer, all volatiles were removed at reduced pressure. The polymer was then dissolved in 10 ml of dioxane and treated with 2.5 M sodium trifluoroethoxide (10 mmols) in dioxane (4 mL). The mixture was then refluxed for 1 hour, and stirred at 25 °C for 24 hours. The polymer was then precipitated into deionized water (3x) and hexane (2x): Yield 72%. In order to control the molecular weight, the ratio of monomer to initiator was varied by changing the amount of monomer while keeping all other amounts constant.

b) For the polymerization study in a variety of solvents, the above procedure was followed. However, 0.21 g 1 (0.94 mmol) was dissolved in 2.0 mL of solvent followed by the addition of 1.0 mL of 19 mM PCl<sub>5</sub> (0.0192 mmol) in each respective solvent of i) CH<sub>2</sub>Cl<sub>2</sub>, ii) cyclohexane, iii) THF, iv) CH<sub>3</sub>CN, and v) CH<sub>3</sub>NO<sub>2</sub>. In all the polymerizations, the resulting [N=PCl<sub>2</sub>]<sub>n</sub> was treated with NaOCH<sub>2</sub>CF<sub>3</sub> and was examined by GPC: i)  $M_n = 4.2 \times 10^4$  and PDI = 1.18, ii)  $M_n = 3.3 \times 10^4$  and PDI = 1.06, iii)  $M_n = 4.4 \times 10^4$  and PDI = 1.15, iv)  $M_n = 5.3 \times 10^4$  and PDI = 1.02 and v)  $M_n = 2.0 \times 10^4$  and PDI = 1.03.

c) The variable temperature experiments were conducted in a 5 mm NMR tube with D<sub>2</sub>O in a sealed glass capillary tube as an internal reference at i) 15 ii) 25, iii) 30, and iv) 35 °C. 1 (0.05 g, 0.22 mmol) was dissolved in CH<sub>2</sub>Cl<sub>2</sub> (0.5 mL) and placed in a closed tube with a rubber septum followed by the addition via syringe of 0.5 mL of 24 mM PCl<sub>5</sub> in CH<sub>2</sub>Cl<sub>2</sub> at -78 °C. The mixture was immediately warmed to the appropriate temperature in the NMR spectrometer and the reactions were monitored by <sup>31</sup>P and <sup>1</sup>H NMR spectroscopy. The polymerizations were rapid and complete in i) 120, ii) 60, iii) 40, and iv) 35 min. Treatment with NaOCH<sub>2</sub>CF<sub>3</sub> of the resulting poly(dichlorophosphazene) was then followed by characterization by GPC: i)  $M_n = 2.5 \times 10^4$  and PDI = 1.06, ii)  $M_n = 2.4 \times 10^4$  and PDI = 1.01, and iv)  $M_n = 2.2 \times 10^4$  and PDI = 1.01.

Similar procedures were followed for the 100:1 and 10:1 inhibition experiments with 1 (0.05 g, 0.22 mmol) where PCl<sub>5</sub> (0.1 mL 24 mM) in CH<sub>2</sub>Cl<sub>2</sub> followed by the addition of CH<sub>2</sub>Cl<sub>2</sub> (0.9 mL) and PCl<sub>5</sub> (1.0 mL 24 mM) in CH<sub>2</sub>Cl<sub>2</sub> respectively.

d) To a stirred solution of 1 (0.4 g, 1.8 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (2 ml) was added a 5 % molar equivalent of i) PBr<sub>5</sub> (0.01 g, 0.04 mmol), ii) SbCl<sub>5</sub> (0.01 g, 0.04 mmol), iii) Ph<sub>3</sub>CPF<sub>6</sub> (0.02 g, 0.04 mmol), iv) Ph<sub>3</sub>CSbCl<sub>6</sub> (0.03 g, 0.04 mmol), v) POCl<sub>3</sub> (ca. 0.007 g, 0.04 mmol), vi) AlCl<sub>3</sub> (ca. 0.005 g, 0.04 mmol), vii) SnCl<sub>4</sub> (0.01 g, 0.04 mmol), viii) SnCl<sub>2</sub> (0.007 g, 0.04 mmol), ix) TaCl<sub>5</sub> (0.02 g, 0.04 mmol), x) VCl<sub>4</sub> (0.008 g, 0.04 mmol), xi) WCl<sub>6</sub> (0.02 g, 0.04 mmol), xii) TiCl<sub>4</sub> (0.009 g, 0.04 mmol), xiii) Cp<sub>2</sub>TiCl<sub>2</sub> (0.01 g, 0.04 mmol), and xiv) Bu<sub>2</sub>BOSO<sub>2</sub>CF<sub>3</sub> (40  $\mu$ L of 1.0 M solution in CH<sub>2</sub>Cl<sub>2</sub>, 0.04 mmol). In the case of i) - iii) the polymerizations proceeded rapidly to completion {for i) - ii} within 1.5 h; 3.5 h for iii)} and treatment of the resultant [N=PCl<sub>2</sub>]<sub>n</sub> with NaOCH<sub>2</sub>CF<sub>3</sub> produced **2** thus permitting molecular weight determination by GPC.

GPC for 2: i)  $M_n = 1.8 \times 10^4$  and PDI = 1.13, ii)  $M_n = 1.8 \times 10^4$  and PDI = 1.11, iii)  $M_n = 1.6 \times 10^4$  and PDI = 1.06. In the case of iv) only oligomeric species and cyclic species,  $(N=PCl_2)_{3,4}$ , were produced based on the solubility of the resultant products in hexanes and upon confirmation by <sup>31</sup>P NMR and GPC. In the case of v) - xiv) no polymerization behavior was detected over 48 h when monitored periodically by <sup>31</sup>P NMR. In addition, polymerization of 1 was attempted with a 15 % molar amount of VCl<sub>4</sub> in refluxing CH<sub>2</sub>Cl<sub>2</sub> over the span of 4 hrs produced [N=PCl<sub>2</sub>]<sub>n</sub> which was substituted with NaOCH<sub>2</sub>CF<sub>3</sub> and was found to possess  $M_n = 6.0 \times 10^3$  (PDI = 1.23).

Attempted Endcapping of the PCl<sub>5</sub>-induced Polymerization of 1 with the Phosphoranimine Species  $(CF_3CH_2O)_3P = NSiMe_3$  and  $Me_2(CF_3CH_2O)P = NSiMe_3$ . a) To a stirred solution of 1 (1.1 g, 4.9 mmol) in 1 ml CH<sub>2</sub>Cl<sub>2</sub> was added a 2 % molar equivalent of PCl<sub>5</sub> (ca. 0.02 g, 0.1 mmol) at room temperature. At various time intervals, an aliquot of the reaction mixture was treated with

 $(CF_3CH_2O)_3P=NSiMe_3$  (ca. 0.02 g) and was examined by <sup>31</sup>P NMR spectroscopy immediately and again 24 h later to ensure termination. The reaction mixture was found to contain: i) at 1.25 h [N=PCl<sub>2</sub>]<sub>n</sub> (30 %) and 1 (70 %); GPC: M<sub>n</sub> = 2.6 x 10<sup>4</sup> and PDI = 1.06. ii) at 2.5 h [N=PCl<sub>2</sub>]<sub>n</sub> (36 %) and 1 (64 %); GPC: M<sub>n</sub> = 3.2 x 10<sup>4</sup> and PDI = 1.05. iii) at 3.75 h [N=PCl<sub>2</sub>]<sub>n</sub> (95 %) and 1 (5 %); GPC: M<sub>n</sub> = 3.8 x 10<sup>4</sup> and PDI = 1.03.; and iv) at 24 h [N=PCl<sub>2</sub>]<sub>n</sub> (100 %); GPC: M<sub>n</sub> = 4.0 x 10<sup>4</sup> and PDI = 1.02. The relative quantities of [N=PCl<sub>2</sub>]<sub>n</sub>:1 remained consistent over a 24 h period as monitored by <sup>31</sup>P NMR spectroscopy. The presence of the terminal -N=P(OCH<sub>2</sub>CF<sub>3</sub>)<sub>3</sub> in these experiments could not be confirmed by <sup>31</sup>P NMR.

b) To a stirred solution of 1 (0.2 g, 0.9 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (1 ml) was added a 10 % molar equivalent of PCl<sub>5</sub> (ca. 0.02, 0.1 mmol) at room temperature. After 30 min. an aliquot of the reaction mixture was quenched with Me<sub>2</sub>(CF<sub>3</sub>CH<sub>2</sub>O)P=NSiMe<sub>3</sub> (ca. 0.02 g) and was examined immediately by <sup>31</sup>P NMR spectroscopy. <sup>31</sup>P-NMR (CH<sub>2</sub>Cl<sub>2</sub>):  $\delta = 9.4$  (d, <sup>2</sup>J<sub>PP</sub> = 40 Hz, -N=PMe<sub>2</sub>(OCH<sub>2</sub>CF<sub>3</sub>)), -14.2 (t, <sup>2</sup>J<sub>PP</sub> = 43 Hz, -N=PCl<sub>2</sub>-N=PMe<sub>2</sub>(OCH<sub>2</sub>CF<sub>3</sub>)), -15.2 (d, <sup>2</sup>J<sub>PP</sub> = 40 Hz, [-N=PCl<sub>2</sub>-N=PCl<sub>2</sub>-N=PMe<sub>2</sub>(OCH<sub>2</sub>CF<sub>3</sub>)]) and -16.6 - -17.3 (br s, [N=PCl<sub>2</sub>]<sub>n</sub>). Subsequent substitution with NaOCH<sub>2</sub>CF<sub>3</sub> resulted in the formation of **2**. GPC: M<sub>n</sub> = 5.9. x 10<sup>3</sup> and PDI = 1.05.

## **Retention Time (minutes)**

Figure 6. Evidence for macrocondesation. Top GPC chromatogram is the polymer upon immediate substitution with Na[OCH<sub>2</sub>CF<sub>3</sub>]. Bottom chromatogram is obtained after the polymer has been stirred in the poly(dichlorophosphazene) form for 20 days and then substituted with Na[OCH<sub>2</sub>CF<sub>3</sub>].

R = OR', NHR', NR'R"

### **TECHNICAL REPORT DISTRIBUTION LIST - GENERAL**

#### (For **complete** technical reports)

Office of Naval Research Physical Science S & T Division 331 800 North Quincy Street Arlington, VA 22217-5660	(1)*	Dr. Richard W. Drisko Naval Facilities & Engineering Service Center Code L52 Port Hueneme, CA 93043	(1)
Defense Technical Information Center	(2)	,	
Building 5, Cameron Station Alexandria, VA 22314		Dr. Eugene C. Fischer Code 2840	(1)
		Naval Surface Weapons Center	
Dr. James S. Murday	(1)	Carderock Division Detachment	
Chemistry Division, Code 6100 Naval Research Laboratory		Annapolis, MD 21402-1198	
Washington DC 20375-5342		Dr. Bernard E. Douda Crane Division	(1)
Dr. John D. Fisher, Director Chemistry Division 474220D Naval Air Warfare Center Weapons Division China Lake, CA 93555-6001	(1)	Naval Surface Warfare Center Crane, Indiana 47522-5000	
Dr. Peter Seligman NCCOSC RDT&E DIV 521	(1)
