October 1997

ABSTRACT

Data are presented on the cost and on the benefits of research performed by the graduate students and faculty of the resident schools of the Air Force Institute of Technology (AFIT) at Wright Patterson AFB, Ohio (WPAFB). Costs are calculated by allocating direct and indirect costs of operation to the research function. Research costs per student year for 1996 were found to be \$17,809. This is benchmarked against data from the American Society for Engineering Education's Annual Directory of Engineering Graduate Studies and Research where the average of 353 institutions' spending for research per student year was found to be an almost identical \$17,840. Benefits were measured from an analysis of seven years (1990 - 1996) of research customer responses to a research assessment form sent to all research sponsors. Both quantitative and qualitative measures of research benefits were extracted from the responses. Quantitative responses for the estimated contract cost of the research averaged \$99,182 per MS thesis and \$181,000 per Ph.D. dissertation. The qualitative measure of benefits consists of comments of research sponsors about the finished research. Over 100 of these comments are presented in the Appendices. These comments, taken as a whole, may be a better measure of benefit than the quantitative dollar numbers.

1. Introduction

The Air Force Institute of Technology (AFIT) has been conducting advanced research for the Air Force and other DoD agencies since World War I. The AFIT organizations primarily responsible for conducting this research are its two graduate schools, the School of Engineering (EN) and the School of Logistics and Acquisition Research (LA). Although AFIT's primary product has always been the students who have graduated from AFIT programs, these students have conducted valuable research in scientific, technical, and managerial areas in the process of completing their program requirements. This research has been conducted under the supervision and with the assistance of AFIT faculty and research partners.

Many times in recent years attempts have been made to determine the value of AFIT research in an effort to place an exact dollar value on AFIT research. Unfortunately, there is no precise, reliable metric that can convert research work hours or research results directly into dollar values. However, the lack of a precise, reliable metric does not mean that some approximate assessment of AFIT research value cannot be made. In fact, AFIT has been gathering data pertaining to research value since 1979. This report describes the AFIT assessment of research efforts since 1990.

2. Background

Assessment of AFIT research is an ongoing concern. The basic AFIT research assessment instrument is a research assessment form (Fig. 7) attached to every AFIT master's thesis or doctoral dissertation. Most AFIT research is sponsored by an Air Force or DoD agency; the average sponsorship rate since 1990 has been 75%. Sponsors of AFIT research receive copies of theses and dissertations and are asked to provide their estimates of the value of AFIT research both in quantitative and qualitative form.

Sponsors are asked to provide quantitative data by estimating the value in terms of dollar amounts and man-hours of work they believe the research represents. Sponsors provide qualitative data in the form of written comments describing their perception of the significance and impact of the research. Sponsors have not always returned the assessment forms, nor in some cases have they completed all portions when they have returned them. But a significant

percentage has been returned (67% for EN; 50% for LA) that provide support for the discussion of AFIT research data that follows.

3. AFIT History

While the quantitative assessment of AFIT research is a recent practice, AFIT's contribution to the Air Force through research is long established. AFIT traces its roots to the early days of powered flight when it was apparent that the progress of military aviation depended upon special education in this new science. In 1919, the Air School of Application was established at McCook Field in Dayton, Ohio, the home of Orville and Wilbur Wright.

When Congress authorized creation of the Air Corps in 1926, the school was renamed the Air Corps Engineering School and moved to Wright Field in 1927. Shortly after the American entry into WWII, the school suspended classes, but it reopened as the Army Air Forces Engineering School in 1944 to conduct a series of accelerated courses to meet emergency requirements.

After World War II, 1946, the Army Air Force Institute of Technology was established. The Institute was composed of two colleges: Engineering and Maintenance, and Logistics and Procurement. These colleges were later re-designated the College of Engineering Sciences and the College of Industrial Administration. When the Air Force became a separate service in 1947, the Institute was renamed the Air Force Institute of Technology. That same year the School of Civil Engineering Special Staff Officers Course began.

The Institute established a logistics education program at WPAFB in 1955, and The Ohio State University conducted the first courses on a contract basis. In 1958, AFIT began a series of short courses in logistics as part of the Air Force Logistics Command (AFLC) Education Center. Later that year, the School of Logistics became a permanent part of AFIT.

In 1954, the 83d Congress authorized the Commander, Air University, to confer degrees upon graduates of the AFIT Resident College. The college was later divided into the School of Engineering, the School of Logistics, and the School of Business. The first undergraduate engineering degrees were granted in 1956, and the first graduate degrees in business in 1958. The School of Business programs were transferred to civilian universities in 1960. In 1963, the

School of Logistics was re-designated the School of Systems and Logistics. The Civil Engineering Center was also re-designed as the Civil Engineering School.

In 1992 the continuing education and degree functions of the School of Systems and Logistics were split. The continuing education curricula retained the name, School of Systems and Logistics, and the degree curricula were moved to a new School of Logistics and Acquisition Management. With this change AFIT consisted of four schools, two devoted to professional continuing education in logistics, acquisition, and civil engineering, and two devoted to graduate degree programs. That structure remains intact today.

This report on research cost and benefit applies only to the two graduate degree schools, Engineering (EN) and Logistics and Acquisition Management (LA). Most EN master's degrees are 18 months in length, and most LA master' degree programs are 15 months in length. A formal thesis reflecting sound research is a requirement for graduation. EN also offers a Ph.D. degree, typically three years in length which requires a dissertation.

In 1995 The Graduate School of Engineering was a founding partner in the creation of the Dayton Area Graduate Studies Institute (DAGSI). The other two partners were the graduate engineering schools of Wright State University and the University of Dayton. AFIT's involvement permits part time and full time enrollment in AFIT courses by base military and civilian personnel as well as local contractor personnel involved in defense support. It also permits all AFIT students to enroll in courses offered by the other partners, as well as partner school enrollment in AFIT courses. AFIT receives tuition for all DAGSI enrollments. The partnership also encourages joint faculty research projects.

4. Current Demographics

AFIT students consist primarily of junior Air Force officers with backgrounds in engineering, applied science, logistics and acquisition. A small percentage of students come from other services, international military services and civilians working for the government. The September 1996 enrollment in EN was 462 full time equivalent (FTE) graduate students of which 30 FTEs represented DAGSI enrollments. Other than DAGSI students, there were no other part-time students. The September 1996 enrollment in LA was approximately 120 (all full time).

The number of EN faculty on 2 April 1997 was 97. This number included 47 military professors and 50 civilian professors. Their academic rank distribution is shown in Figure 1. Academic rank corresponds roughly (but not exactly) with professorial experience. The number of LA faculty on 1 October 1996 was 35 which included 19 civilian professors and 16 military professors.

The number of EN MS graduates during FY 96 was 175. The number of LA MS graduates during FY 96 was 65. The number of EN Ph.D. graduates during FY 96 was 29. Figure 2 shows the number of graduates for the last 10 years. All graduating MS students complete a thesis. The thesis effort is judged to be 6 man-months for EN and 4 man-months for LA. All graduating Ph.D. students complete a dissertation. The dissertation effort is judged to be two man-years.

All faculty are expected to carry out research. In EN, the time allotted for research is 50%. In LA, it is 33%. All of the LA and all of the EN faculty except for five are employed on a 12 month basis. Faculty on a 12 month agreement are given one academic quarter per year free of teaching duties for research. In EN, faculty are expected to spend about 1/3 of their time on research during the three teaching quarters (1/3 of 3/4 plus the research quarter = 50%). LA faculty are expected to spend such time on research during the three teaching quarters to achieve 33% research time for the year. Research time includes the supervision of MS and Ph.D. student research. The five EN faculty not on a 12 month contract are employed on a 10 month contract. They are still expected to devote 50% of their time to research during the year, except that two months (salary) must be funded by research grants and contracts. Current plans are to hire all future EN civilian faculty on the 10 month basis.

5. Research Output Metrics

There are three principal categories of research productivity in a university: faculty and student publications, theses and dissertations, and research funding awarded competitively. One hundred and nine peer reviewed journal articles were published by EN faculty and students during FY 96. Other publications (conference papers, invited articles, book chapters) numbered 162. The corresponding numbers for LA faculty and students were 18 reviewed papers and 38 others.

Historical data on number of articles published are shown in Figure 3. The number of MS Theses for FY 96 was 175 for EN and 65 for LA. Historic numbers for Theses will match the number of graduates in Figure 2. The number of Ph.D. (EN only) dissertations was 29 for FY 96. Again, historic numbers will match the number of graduates in Figure 2.

Funded research dollars are included here as an output metric because a faculty's ability to attract outside research funds is a measure of research value and output. Outside funding in the form of funds transfer, grants, and contracts amounted to \$3.4M in FY 97. Historic outside funding is shown in Figure 4. For the majority of AFIT faculty, outside funding cannot be applied to salaries. (The five 10-month contract faculty are the exception.) Outside research funds at AFIT are used for equipment, supplies, contract services, travel and indirect costs of research. AFIT has an indirect rate for research funds computed on the basis of the Office of Management and Budget circular A-21. Since faculty salaries are the larger part of grants to civilian universities, and since AFIT cannot include salaries in research proposals, the AFIT figure of \$3.4M corresponds to more than that when compared to the community of civilian universities.

6. Comments On The Use Of MS Theses as a Research Output Measure

The US Air Force has long regarded the master's degree as the terminal degree for Air Force officers. While a few officers are selected for Ph.D. programs, the majority will stop at the MS degree. One of the primary reasons for this policy is that Ph.D. education consumes too many years out of a typical 20-year officer career, supposedly limiting "pay-back" to the Air Force. Further, the specialization inherent in a post-Ph.D. career is considered by many to be too specialized to be compatible with the "generalist" career pattern expected of officers, especially at the higher ranks.

As a consequence of treating the MS program as terminal education, the AFIT MS degree program has always been a strong program, typically six academic quarters in length in EN and five academic quarters in length in LA with an intensive research problem, carried out with active faculty mentoring, often in a team situation with the faculty, Ph.D. students and post-doctoral fellows. At some other schools, the MS thesis, if there is one, is a report which is graded as pass/fail by the faculty and the execution of the research behind that report involves

minimal faculty interaction. The faculty at those schools spend their time with the Ph.D. students because that is the most productive route to research accomplishment. That has never been the culture at AFIT. The MS students at AFIT are often the hands and arms of the faculty making them an extension of the faculty. Significant research at AFIT is accomplished with the direct involvement of MS students.

Testimony to the importance of the AFIT MS thesis as a research output measure is given by the research sponsors' comments in the Appendices and by their assignment of dollar value to the thesis as summarized in Figures 8,9, and 10.

7. Research Expenditures

Research in a graduate school serves two purposes; it contributes in a major way to student learning, and it produces useful results and new knowledge that have a value in their own right. At AFIT both purposes are important. For this reason, AFIT student salaries are assigned to the learning function. That, is student salaries are considered to be part of the cost of sending an Air Force student to graduate school for 18 months (MS) or 3 years (Ph.D.) Similarly, faculty salaries during the three teaching quarters (but not the research quarter) are assigned to the teaching function.

Research expenditures then consist of:

- 1. Faculty salaries during the non-teaching (research) quarter, excluding academic administrators and ten-month-contract faculty.
- 2. Indirect charges at the OMB A-21 rate for research at AFIT applied to the above salaries. This covers the time by staff, administrators, and support personnel spent in supporting the faculty and students in the research function.
- 3. Capital expenditures for equipment purchased out of AFIT funds for research purposes.
- 4. All outside sponsor money (fund transfers, grants and contracts) directed to specific research projects.

The above four costs have been used by AFIT (EN only) to report to the National Science Foundation's annual Survey of Research and Development Expenditures at Universities and Colleges. The totals reported for the past three years have been:

AFIT EN Research Expenditures: Minimum calculation

	AFIT funds	Sponsor funds	Total	* average	* research \$
	(1.)+(2.)+(3.)	(4.)		enrollment	per student yr.
FY 94	\$4,630,000	\$2,426,000	\$7,056,000	416	\$16,962
FY 95	\$3,731,000	\$2,229,000	\$5,960,000	364	\$16,374
FY 96	\$3,586,000	\$2,291,000	\$5,877,000	330	\$17,809

^{*} not included in the NSF annual submission

An excursion on the above research costs would be to allocate 50% of faculty salaries and salary indirect to research costs rather than 25%. That would include the non-teaching quarter as well as one third of the EN faculty time spent on research during the three teaching quarters. This would parallel practice in those civilian universities where faculty are permitted to charge salary time to outside grants and contracts <u>during the academic year</u>, as well as during the summer term. Using 50% of AFIT faculty salaries results in:

AFIT EN Research Expenditures: Maximum calculation

	AFIT funds 2x(1.)+2x(2.) +(3.)	Sponsor funds (4.)	Total	average enrollment	research \$ per student yr.
FY 94	\$7,939,000	\$2,426,000	\$10,038,000	416	\$24,130
FY 95	\$7,044,000	\$2,229,000	\$9,273,000	364	\$25,475
FY 96	\$6,948,000	\$2,291,000	\$9,239,000	330	\$27,997

Benchmarks for these AFIT/EN research expenditures per student year can be found in both the American Society for Engineering Education's (ASEE) <u>Annual Directory of Engineering</u>

<u>Graduate Studies and Research</u> (1994-95 edition) and from <u>US News and World Report</u>,

"America's Best Graduate Schools," 1996 edition. The ASEE Graduate Studies and Research report lists "Inside the College of Engineering" expenditures and the total graduate student enrollment for 353 engineering schools is shown below. The classification "Inside the College of Engineering" excludes expenditures made in other colleges in the university and excludes expenditures in separately funded, but attached university research institutes.

Total "Inside college" \$	Total Grad. Enrollment	Research \$/Student yr.
\$2,162,574,000	121,219	\$17,840

When all funds are considered, the ASEE report yields the following average:

Total Research \$	Total Grad. Enrollment	Research \$/Student yr.
\$4,711,217,000	121,219	\$38,865

The <u>US News and World Report</u> description of the top 50 engineering graduate schools lists only the total research expenditures (inside the colleges of engineering, in other colleges and in attached research institutes) as:

Total Eng. Research \$	Total Grad. Enrollment	Research \$/Student yr.
\$3,989,500,000	53,700	\$74,292

The <u>US News and World Report</u> data is for the 1995 academic year as reported in 1996. The sources of funds contributing to the total expenditures reported in all three of the above tables were both internal and external to the universities.

8. Research Benefits

AFIT policy is to obtain sponsorship of all theses and dissertations. The actual sponsorship rate for the last seven years is approximately 75% (Figure 5). Sponsorship means that the problem was either suggested by or endorsed by someone in the Air Force or in DoD. More rarely, the topic was suggested by or endorsed by someone in other federal agencies or from the private sector, the latter through Cooperative Research and Development Agreements (CRDAs) under the Technology Transfer laws. The fraction of sponsorship by these groups is shown in Figure 6 for the last two years.

Because of this emphasis on thesis/dissertation sponsorship, metrics involving theses and dissertations may be a better measure of research benefit to the Air Force than archival journal article publication. The former, especially theses, tend to focus on problems of immediate Air

Force interest, while archival journal articles tend to focus on the theory and method developed for the solution of those problems.

The primary tool for the measure of sponsor benefit has been the Research Assessment form which is sent to all sponsors along with a copy of the competed thesis or dissertation (Figure 7). AFIT has collected and analyzed the responses received from sponsors using this form for the last eight years. As can be seen from a selection of the returned assessment forms in the Appendices, most of these theses and dissertations involved active faculty participation as well as student effort. In fact 33% if the responses for FY 97 which included remarks specifically mentioned the efforts of one or more faculty members in addition to those of the student author. Typical comments included:

- a. "Excellent support from the graduate student and each member (Dr. Mykytka, Major Murdock, Major Pohl) of committee."
 - b. "Student/faculty did a great job"
- c. "great program, largely due to the efforts of Don Thompson [student] and Paul King [faculty]."
- d. "hope to continue this work as Capt Whiteley [student] and Maj Roggemann [faculty] continue to investigate multispectral target detection"
 - e. "I enjoyed my interaction/collaboration with AFIT faculty and students"
 - f. "Maj Griggs and the faculty of the ENS Dept were very helpful"

All sponsors of AFIT theses and dissertations are rewarded with a faculty-student team effort. This is why data on theses and dissertations are presented here as a primary measure of AFIT research benefit to the Air Force. The collected research assessment forms yield both a quantitative and a qualitative measure of research benefit. The quantitative measure is the sponsor's estimate of the cost to perform the work either by contract or by using in-house labor. The qualitative assessment lies in the collected comments or remarks that the sponsors make on the assessment forms.

9. Quantitative Research Benefits

During the years 1990-1997, there were a total of 1,783 graduates. Of these 1,336 had sponsors (75%). As it can be seen from Figure 5, the percentage sponsored was higher in the later years than in the earlier years of the time period covered. Of the EN sponsored theses and dissertations, 897 research assessment forms were returned (67%). During these same years the School of Logistics and Acquisition Management had a total of 679 graduates. The total number of forms returned was 341 for an LA return rate of 50%. Figures 8 and 9 show the distribution of responses to the question "If AFIT had not done this work, please estimate what would it have cost your organization to do it?" for EN theses and for dissertations respectively. (Distribution of responses is not available for LA theses.) The data cover all responses received from mid 1990 through the end of FY 1997. As can be seen from the figures, the sponsor's estimate of the average cost to duplicate an EN MS thesis was \$102,500, and the average cost per dissertation was \$181,000. The seven year estimate of the average cost to duplicate an LA theses was \$91,270. The combined average for MS thesis for the two schools was \$99,182. These responses and their average values are estimates or judgments by the sponsors. They do not represent out-of-pocket expenditures by the sponsors.

Figure 10 shows the year-by-year average value of the answer to the question "If AFIT had not done this work, please estimate what would it have cost your organization to do it?" The data in this figure is for both EN and LA (but excludes EN dissertations).

Question two on the Research Assessment form is: "Would you have completed this work if AFIT had not done it?" Typically, the positive responses were over 90% during the first years of this sample (1990-1992), but then positive responses began declining in the subsequent years. Incomplete 1997 returns show only a 56% positive response. At the same time, the responders have been spontaneously offering comments (under this question) such as "Funds have been too tight for us to contract for this work, and our personnel have been too heavily loaded for us to complete the work in-house." Before 1995, AFIT reported average cost values in the annual research report by counting only those dollar responses which had a "yes" answer to the question "Would you have completed this work if AFIT had not done it?" As comments such as the one above became numerous, it was obvious that this question invited misleading answers. The data presented here in Figures 8, 9 and 10 include all dollar responses, regardless of the answer to

question, "would you have done the work?" Because of this re-interpretation, the values presented here do not exactly agree with those published in the annual AFIT research reports.

Data concerning the answers to question "... how would you rate this work" are given in Figure 11. The responses are dominated by "highly significant" and "significant." In rare cases, the significance answer does not correlate well with the dollar value. For instance, "highly significant" was coupled with a cost estimate of \$5000 or "slightly significant" was accompanied by a cost estimate of \$300,000). The practice has been to enter zero for the cost if the responder says the work had no significance, even if the responder gave a non-zero cost.

10. Qualitative Research Benefits

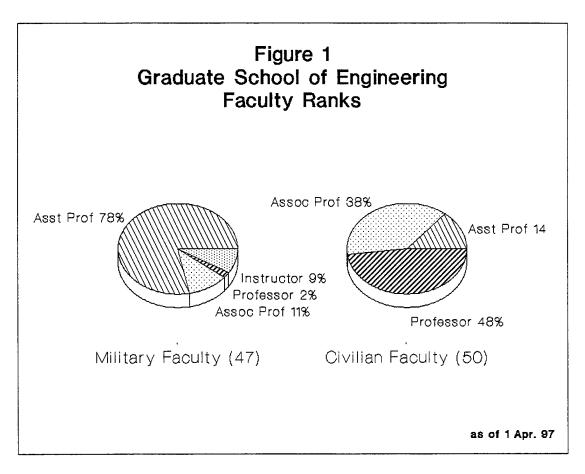

The sponsors' qualitative judgments about the benefit of AFIT research are illustrated by the collected comments in the Appendices. These comments were taken from the Research Assessment forms (Figure 7) after those forms were returned by the sponsors. The individual comments were then pasted onto the report documentation page (Standard Form 298) of the corresponding thesis or dissertation. The original assessment forms are on file in the research offices of the two graduate schools. The full text of the theses and dissertations can be examined in the AFIT library or obtained from the Defense Technical Information Center, 8725 John J. Kingman Rd., Ft Belvoir VA 22060.

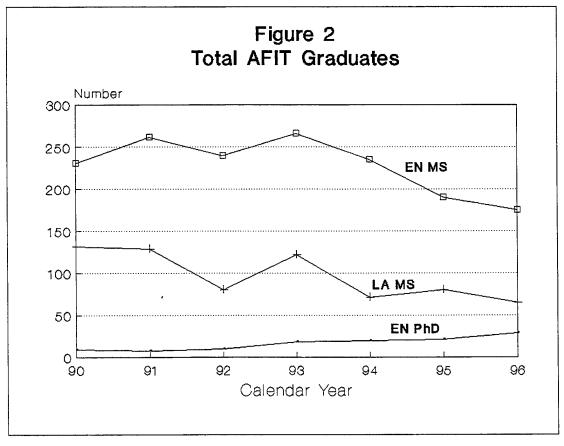

Although they are difficult to summarize, these comments, taken as a whole, may represent a better description of AFIT research benefits than the quantitative numbers presented above.

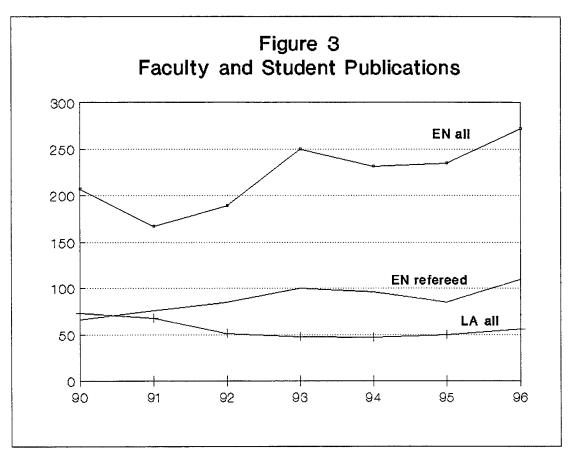

The Appendices are ordered by type of sponsor:

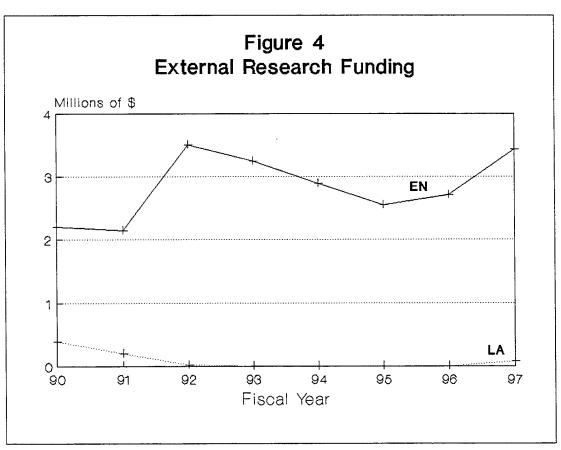

- A. Air Force R&D,
- B. Operational Air Force,
- C. Other DoD,
- D. Other federal agencies and
- E. Private sector (Industry)

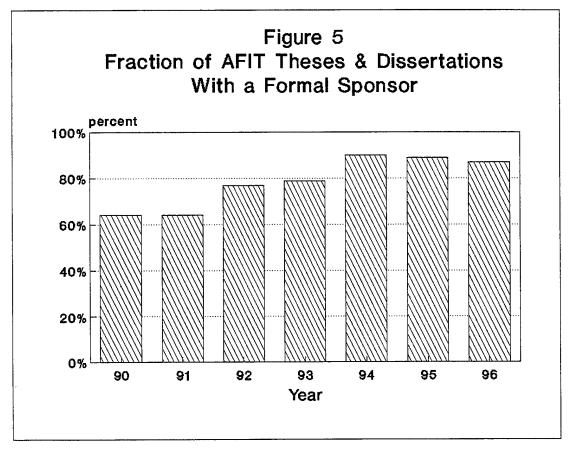

Within each appendix, the comments are organized chronologically (1991 comments first, 1997 comments last).

Perf year of effort has pointed the way to substantially 12 December 1991. Document must be referred to W improve the technical program which will Wright-Patterson AFB undoubtedly lead to additional savings to the USAF. 13. ABSTRACT (Maximum 200 words) Mike's effort is prototypical of the tremendous mutual benefit that AFIT research program affords. The Cross Section and Glint Evaluation System (CAGES) is a Radar Cross Section (RCS) prediction software package written by General Dynamics, Pomona, which provides both time and frequency domain output. This simulation package has potential uses in target identification as well as signature prediction of air targets. CAGES uses primitive targets such as

The Cross Section and Glint Evaluation System (CAGES) is a Radar Cross Section (RCS) prediction software package written by General Dynamics, Pomona, which provides both time and frequency domain output. This simulation package has potential uses in target identification as well as signature prediction of air targets. CAGES uses primitive targets such as flat plates, cylinders and truncated cones to model complicated targets. The electromagnetic theory is based on Physical Optics and Geometrical Optics models. This paper compares the RCS prediction of CAGES primitives to a Uniform Theory of Diffraction (UTD) model and measurement data. Assessments are made on the domain of applicability of CAGES to perform accurate RCS prediction for the target identification role. Also the advantages and disadvantages of modeling and primitives versus modeling with facets and wedges are highlighted. In general, CAGES matches both UTD and measurements in the regions where the specular return is the prominent contributor of the total RCS. The error increases as the aspect angle moves away from the specular return. The main advantage of CAGES over RCS models based on facets and wedges is speed. The greatest disadvantage is the lower resolution available to match primitives to complicated surfaces.

Capt Pernot has made a significant contribution to the understanding and modeling of crack growth behavior of metals thermomechanical fatigue. The concepts developed and demonstrated in his PhD dissertation constitute an important advance in crack growth modeling. The work is of extreme importance to the ML program in that it provides guidance in the evaluation and characterization of new high temperature metals. The work was of the highest technical quality which could only have been accomplished through a contract program by a team of well trained PhDs.

13. ABSTRACT (Maximum 200 words)

In this study, a model is developed to predict crack growth rates in a titanium-aluminide alloy under thermal-mechanical fatigue (TMF). This TMF crack growth rate prediction model, which requires only isothermal data to define its parameters, is distinguished from earlier models which requires only isothermal data to define its parameters, is distinguished from earlier models in two ways. First, it accounts for mechanical-fatigue and environmental crack growth rate contributions while is also considers a retardation mechanism thought to be caused by creep blunting of the crack tip. This is the first study to account for such a retardation mechanism during TMF. The second uniqueness of the model is that its general form can account for cycle-dependent crack growth rate contributions that are temperature dependent. In addition, a series of isothermal-fatigue and hold-time tests are performed to generate the data base required for model parameters, and TMF tests are used to validate the modeling technique. The model predicts in-phase, as well as 180 degree and 270 degree out-of-phase crack growth rates extremely well, and underpredicts the 90 degree out-of-phase crack growth rates by a factor of two. Two other, more complex TMF cycles are studied, and the predicted crack growth rates correlate well with the experimental data.

SPONSORING/MONITORING AGENCY NAME(S) AND ADDRESS(ES) Although similar work on dielectric cure monitoring and control has been going on in MLBC and other Ms. Frances Abrams locations for years, there is still much to be done in the WL/MLBC Wright-Patterson AFB OH 45433-6583 area. The AFIT sensor is unique because of its size an we are hoping to do more development on it. The 11. SUPPLEMENTARY NOTES analysis that Capt Graham did was excellent and we ASSESSMENT will continue to study it. I might add that this effort produced a substantial body of work with almost no ABOVE SPONSOR 12a. DISTRIBUTION AVAILABILITY STATEMENT expenditure of effort on our part. Capt Graham required much less supervision than any contractor or new in-house effort I have ever managed. Approved for public release; distribution unlimited 13. ABSTRACT (Maximum 200 words) The purpose of this study was to design an Interdigitated Gate Electrode Field-Effect Transistor (IGEFET) and evaluate its performance as an in situ resign cure monitor. A commercially available resign was selected for the research, and rheological studies were performed to identify the resign's gelation point during isothermal cures at two selected temperatures. Additional rheological studies were performed to identify the resign's glass transition temperature. The interdigitated gate electrode of the IGEFET was coated with samples of the resign, and electrical measurements were performed while the resigned cured. The chemical changes which occur in the resign as a result of curing were manifested in the interdigitated gate electrode's electrical characteristics. The results reveal that the IGEFET is capable of sensing the electrical impedance changes, and hence the chemical changes, which occur during the resign's cure. In particular, the chemical changes due to gelation are evident in the IGEFET's electrical response data. In addition, the resign which was cured at the higher temperature was close to its glass transition temperature, and hence softer than the resign cured at the lower temperature, and the IGEFET was capable of detecting this difference. 14. DISTRIBUTION AVAILABILITY STATEMENT Approved for public release; distribution unlimited 13. ABSTRACT (Maximum 200 words) The objective of this study was to investigate the material behavior of SCS-6/821-S [0/90] in a thermomechanical fatigue environment. Samples of the SCS-6/221-S composite were subjected to in-phase and out-of-phase cyclic loading. Stress, temperature, and total strain values were acquired during the test sequence and analyzed for indications of possible trends. Experimental results indicated in-phase specimen possessed shorter fatigue lives then their out-of-phase counterparts above the static first ply failure of the matrix. The out-of-phase specimen showed a shorter fatigue life below the first ply failure. The examination of the strain change, modulus change, fractography, and metallography of the in-phase test specimens suggest a fracture mechanism that is fiber dominated. The investigation of these parameters, for the out-of-phase test specimens, indicate the fracture mechanism may be matrix dominated. Additional analysis, using a linear life fracture model and a cumulative damage model, further suggests two parameters govern the fatigue life of SCS-6/B21-S.

ABSTRACT (Maximum 200 words) The purpose of this study was to investigate the use of Artificial Neural Networks to localize sound sources from simulated, human binaural signals. Only sound sources originating from a circle on the horizontal plane were considered. Experiments were performed to examine the ability of the networks to localize using three three different feature sets. The feature sets used were: time-samples of the signals, mean FFT magnitude and cross-correlation data, and auto-correlation and cross-correlation data. The two different types of sound source signals considered were tones and gaussian noise. The feature set which yielded the best results in terms of classification accuracy (over 91%) for both tones and noise was the auto-correlation and cross-correlation data. These results were achieved using 18 classes (20 degrees per class). The other two feature sets did not produce accuracy results as high or as consistent between the two signal types. When using time-samples of the signals as features, it was observed that in order to accurately classify tones of random-frequency, it was necessary to train with random-frequency tones rather than with tones of one, or a few discrete frequencies. 14. adopting commercial style acquisition practices in government acquisitions. Commercial style acquisition practices offer the Government lower costs and faster delivery with no sacrifice of quality. A qualitative analysis of data, collected in telephone interviews of nineteen top level personnel representing twelve domestic aircraft manufacturers, revealed difficulties encountered in selling to the government including: oversight and bureaucracy; payment practices; contract complexity; clause application; and MILSPECs which go beyond FAA certification requirements. Recommendations for acquisition of commercially available aircraft acquisitions included: creating a separate regulation to govern use of commercial practices; using commercial payment practices; requiring cost benefit analysis for MILSPECs and MILSTDs which exceed FAA certifications; removing CAS requirements; establishing a commercial advocate similar to the position of competition advocate; relying on commercial market forces to ensure the manufacturers produce at a low cost and sell at a fair price; and empowering program managers and contracting officers to keep decisions at the lowest possible level and streamline decision making.

SPONSORING/MONITORING AGENCY NAME(S) AND ADDRESS(ES) The research, though of a preliminary nature, is very important for application of VCSELs in optical Capt Chris Keefer processing systems. The issues of optical feedback Rome Lab/OCPA effects on VCSELs in applications requiring Griffiss AFB NY 13441 mutually incoherent laser elements is critical in 11. SUPPLEMENTARY NOTES future high speed interconnect schemes. Possible ASSESSMENT methods of controlling polarization in a VCSEL has applications for differentiating light signals for SPONSOR positive and negative weights in an optical computing architecture. Polarization control also has applications for locking an array of Approved for public release; distribution unlimited VCSELs for a high power laser source. Further research into electrically controlled VCSELs will have important impacts on the use of these devices in 13. ABSTRACT (Maximum 200 words) future optical processing systems. Vertical Cavity Surface Emitting Lasers (VCSELs) are a type of semiconductor laser with a cavity oriented orthogonally to the planes of material growth. These lasers differ from conventional edge emitting lasers in several important ways. They have symmetric output beams and they are easily built into two dimensional arrays, making them very attractive as photonic components. The characteristic of interest in this thesis is polarization. While the asymmetric cavities of edge emitters exhibit a clear preference for light polarized in a particular direction, the cylindrically symmetric cavity of a VCSEL has no clear preference. Therefore, it should be relatively easy to change the polarization of a VCSEL. This thesis examines the polarization switching effects of optical feedback from an external reflector. By feeding back various amounts of cross-polarized light, the switching susceptibility of the VCSEL can be determined. Measurements confirmed that the polarization of a VCSEL can be switched through polarized optical feedback, with the degree of switching depending on the strength of feedback. This switching was a relatively rare behavior, indicating that most VCSELs had some type of preferential polarization. This preference could be due to the VCSEL structure itself or the manner in which it was excited. 14. SUBJECT TERMS 15. 13. ABSTRACT (Maximum 200 words)

ly g y coming era where our forces will be depending heavily on advanced sensor technology to provide "near perfect" knowledge of any adversary. Other areas that this hyperspectral technology could be applied to are optical communications and optical information processing, which future AFIT students could pursue in their thesis research.

This study investigated electrically tunable birefringent optical filters for use as the spectral discriminator in hyperspectral imaging systems. Spectral discrimination requirements for hyperspectral imaging systems were defined using specification from two state-of-the-art hyperspectral imaging systems. The spectral discrimination requirements led to the definition of the ideal tunable optical filter for spectral discrimination purposes. Analytical and computer analysis was performed for known birefringent filters which showed promise of electrical tunability, excluding acousto-optics filters. No perfect match was found to the ideal tunable optical filter for hyperspectral imaging defined in this thesis. Both Lyot and Solc based filters exhibited two drawbacks for hyperspectral imaging application: narrow tuning range with linear bandwidth dependence on center wavelength, or wide tuning range and quadratic bandwidth dependence on center wavelength. The n-tuned Solc filter provided the best compromise between tuning range and bandwidth control; however,, it is not practical due to the excessive number of elements required. This thesis provides the needed background for further research in this area and identifies a number of areas for further worthwhile research. Acousto-optic filters offer another possible avenue for hyperspectral imaging and should be investigated. Birefringent materials should also be studied to determine material limits on the electro-optic effect and spectral transmission characteristics to determine practical capabilities of filters discussed in this thesis.

13. ABSTRACT (Maximum 200 words)			

This thesis describes an efficient method for computer analysis of wedge-shaped finite-by-infinite frequency selective surfaces (FSS). The periodic Green's function for the wedge FSS is not calculated directly. Instead, the Green's function is approximated using image theory and the Geometrical Theory of Diffraction. A method of moments solution for the magnetic scattering currents is obtained using this approximate Green's function. Once the scattering currents have been determined, other parameters of interest, such as radar echo width, are easily calculated.

The method of analysis developed in this thesis has been implemented in a FORTRAN computer program. Comparison of this program's output with measured data from a wedge FSS model indicate that this method of analysis is accurate as well as much faster than a moments method solution using an exact eigenfunction expansion of the Green's function.

The primary intent of this research was to determine the influence of three common degradation mechanisms dark area defects, facet degradation, and contact degradation on the operational lifetime of GaAs edge-emitting semiconductor lasers operating in a continuous fashion at 100C. Inherent to this work was the quantified characterization of the lasers during their operation. This characterization arose as the power function as a function of driving current at room temperature before and after their exposure to 100C. Two more similar characterizations were conducted at the beginning and end of each laser's exposure to 100C. An additional means of examining laser degradation came from measuring the current required over time to maintain a constant power output of 5, 7, or 10mW at the elevated temperature. The research demonstrated that facet degradation and contact degradation were minor contributors to the bulk of the data base's degradation. Dark area defects were the primary degradation mechanism as the data's gradually increasing current necessary to maintain constant output will attest. An HF acid rinse on one laser, reacting aggressively to local crystal defects, highlighted the growth of dark area defects toward the lasing cavity due to continued lasing. As a whole, the lasers performed with higher slope efficiencies at elevated temperature, contrary to previous research. This topic deserves more research.

This is a very good thesis that has both financial and technical support from WL/XPN and US Navy at Pax River. Capt Kehr did a superb job (given constraints of time and finances) to analyze the static vs dynamic RCS of the C-29. I feel that Capt Kehr is just beginning to scratch the surface on the topic. This is a very difficult subject area that WL/XPN would be strongly interested in supporting at a larger level if AFIT students are interested.

13. ABSTRACT (Maximum 200 words)

This thesis characterizes the Radar Cross Section (RCS) of the C-29 aircraft, with the intent of developing a prediction model capable of describing the spatial correlation properties of the aircraft's dynamic RCS. The RCS characterization is accomplished through analysis of RCS data obtained from both static and dynamic RCS measurements. A comparison of both the first and second order moments associated with the aircraft's RCS is accomplished. The correlation properties associated with the static, dynamic, and predicted RCS are all compared and the results discussed.

An enhanced digital radio frequency memory (DRFM) integrated circuit (IC) was designed and fabricated. The DRFM IC consists of a 2K x 6-bit memory array, a finite state machine (FSM) based memory controller, and a digital single-sideband modulator (DSSM). Maximum operational speed of the DRFM IC was increased by improving the speed of the DSSM circuit from 10MHz to 17 MHz. The speed of the DSSM circuit was increased by designing and incorporating faster arithmetic circuits and introducing pipeline latches into the circuit. Other additional features of the DRFM IC included an external processor interface and a DSSM bypass mode. VHSIC Hardware Description Language (VHDL) model designs for two electronic countermeasure (ECM) generation circuits were completed and validated. The ECM generation circuits were designed to be incorporated into the DRFM IC. The two ECM techniques implemented are the range gate pull-off and the head-to-tail algorithm for generating a continuous wave jamming signal. The two ECM technique generation circuits have been laid out in Magic and validated with HSPICE. However, the Magic layouts have not been placed in pad frames, or sent out for fabrication due to time constraints.

ABSTRACT (Maximum 200 words) A periodic "halo" orbit which exists about the interior Lagrange point for the Earth-sun system was decomposed using Floquet theory into modal variables, which are dynamically decoupled subspaces for the six degree of freedom system. Modal control consisted of evaluating the diverging mode and maneuvering to counteract its divergence. In the unperturbed system, this was successful. Control costs were low, and the significance is that the controller did nothing to suppress modes that were oscillatory or converging. The effect of the moon's motion allowed the scheme to operate with reasonable control costs, but the effect of eccentricity caused divergence in spite of the controller.

3. ABSTRACT (Maximum 200 words)		

This study investigated the effects of mechanical aptitude and job experience on the job performance of 204 Air Force Aerospace Group Equipment (AGE) mechanics. Job performance was expressed as productive capacity (PC), which is derived from estimated performance times on job tasks. PC measures were derived for 50 tasks typically performed by airmen in the specialty. Aptitude measures took the form of Mechanical percentile composite scores on the Armed Services Vocational Aptitude Battery (ASVAB). A second-order logistic model was used to regress PC on aptitude and experience at the task level and at the overall job, or aggregate, level. Model R s were generally low. For the tasks, R s ranged from .01 to .13 and for the aggregate model the R was about .16. Generally, experience was a significant predictor but aptitude was not. There was also no indication of an aptitude/experience interaction. These results were verified through forward stepwise regression. There was some evidence that airmen may experience some skill degradation on production-type tasks at around the six year point as they transition to supervisory roles.

13. ABSTRACT (Maximum 200 words)

This research effort characterized VCSEL devices which have applications as optical switches in computing and neural network architectures. These non-linear effects are important for analog systems which need light sources which remain linear over a large dynamic range of output power. Determining the cause of non-linear effects in the VCSEL devices will help with the design and fabrication of devices which either enhance or negate these effects. A current effort is under way at the University of Virginia to develop highly linear devices with respect to input drive current for an analog signal processing application. This effort helped characterize these devices or at least the initial fabrication efforts.

The nonlinear characteristics of optically pumped Vertical Cavity Surface Emitting Lasers (VCSELs) are identified, isolated, and quantified. Three different VCSELs are emulated including two with gain regions of bulk GaAs operating at 875nm and one multi-quantum well (MQW) InGaAs VCSEL operating at 950nm. The nonlinearities evaluated include those due to cavity temperature, carrier injection, and internal lasing field. The VCSELs are pumped by a picosecond/femtosecond Ti:Sapphire laser which is configured to operate in CW, gated CW (minimum gate width was 200ns), picosecond, and gated picosecond modes. A linear relationship is shown between wavelength and substrate temperature, cavity temperature, and injected carriers. It is shown that heating is the dominate nonlinearity in the bulk gain region VCSELs for the pump duty cycles which could be achieved. The MQW VCSEL was dominated by nonlinearities due to carrier population at duty cycles of 10% or less causing the VCSEL to blueshift. A nonlinear relationship is shown between input power and output power and is attributed to the optical Kerr effects in the mirror layers and gain region.

This thesis investigated the change of radome transmission behavior of Frequency Selective Surfaces (FSS), with errors introduced in slots geometric parameters. Three (3) FSS were analyzed. The first is a single thin conducting plane with an array of 35 columns of thin linear slots in free space. The second is composed of two thin conducting planes with an array of 35 columns of thin linear slots per each FSS in free space. The third consists of two thin conducting planes with an array of 21 columns of thin linear slots per each FSS, embedded in dielectric layers. After designing the ideal FSS with the code known as PMM, Gaussian errors are introduced on lengths, widths, locations of the slot columns and z locations of reference slots in each column, and using a "finite by infinite" array code (SFI) the value of the peak transmitted power and the radiation pattern are obtained several times for different generated Gaussian errors. All the results are tabulated and presented in a statistical and graphical way with the purpose of defining tolerance requirements.

The purpose of this research was to develop a cost estimating model which would allow cost estimators the ability to quickly and accurately estimate the acquisition of Air Force Special Air Mission fleet aircraft. The literature review revealed studies, government contracts, and trade publications which served as source data. This information was supplemented by interviews with acquisition specialists and contractors and incorporated into a database. Several estimating techniques were created and used to estimate the various cost elements. The Commercial Aircraft Integrated Cost Estimating Tool (CAICET) model was then developed to incorporate the estimating techniques with the database. This was accomplished by integrating dialog boxes to access the information and estimate the program acquisition. The CAICET model provides the analyst with the ability to estimate an acquisition program based on a few specific parameters concerning the missionization of the aircraft. These parameters include interior configuration, avionics, mission communications, and self-sufficiency items. Once this information is input, the CAICET model provides the analyst with a real-time estimate in standard AF Form 1537 format.

ABSTRACT (Maximum 200 words) This study demonstrated the use of simulation modelling to analyze Granite Sentry system performance. The availability simulation model constructed provides a number of system performance measures as a function of component MTBFs and MTTRs. Analysis of failure data prior to model construction supported the generally accepted use of expoentially distributed failure rates and lognormally distributed repair times. A Microsoft Windows version of SLAMSYSTEM proved to be an efficient modelling tool, especially during early stages of model development. Guidelines for model use in system analysis are explored through a runtime analysis and a response surface model of system downtime as a function of part redundancy. The runtime analysis provides recommendations for appropriate simulation runtime and number of replications to produce reasonably efficient and accurate results. The response surface analysis highlights three system components whose part redundancy significantly affects system downtime. Finally, the analytical availability model developed was an essential validatediovalidation tool in simulation model development. 14. SUBJECT TERMS 15. NUMBER OF PAGES Simulation, Availability 16. This research was to determine to what extent Integrated Maintenance Information System (IMIS) functional requirements could satisfy the maintenance information requirements of the ground-based Theater Air Control System. IMIS is a program sponsored by Armstrong Laboratory at Wright-Patterson Air Force Base, Ohio to automate maintenance information. To date, Armstrong Laboratory has only targeted aircraft maintenance for this automated program. The Theater Air Control System contains powerful military radars connected to a mobile communications and computer network. Theater Air Control System maintenance information requirements were identified through a study of the 728th Air Control Squadron at Eglin Air Force Base, Florida, and the existing aircraft requirements matrix for the Integrated Maintenance Information System was modified to meet Theater Air Control System requirements. The small amount of changes required to modify the aircraft matrix in order to satisfy ground TACS requirements indicate that ground TACS is a prime candidate for IMIS technology.

13. ABSTRACT (Maximum 200 words)

One of the conclusions from the STOL/MTD program was the need for a multivariable method of designing controllers of low order. This research investigated that problem by studying reduced order mixed H-two/H-infinity control theory applied to the STOL landing configuration which employs both thrust vectoring and the use of a canard. Model matching techniques were used to obtain responses that met handling qualities criteria and reduced pilot workload by decoupling pitch rate and velocity commands The time responses were found through nonlinear simulation and showed that the full order designs did match the ideal models very well and had good noise and wind rejection. Singular value analysis showed that the commands were decoupled very well. The reduced order method was mixed H-two/H-infinity optimization. A fourth order controller that had good performance was found by using a performance constraint, and a fourth order controller that provided good margins was found using a robustness constraint. A third order controller was also found with a performance constraint. Recommendations for finding a low order controller with good performance and robustness are given.

Furt Capt Noble demonstrated that promising static to Dissemination only as Directed by WL/XPN, dynamic comparisons are possible. Extending his Wright-Patterson AFB OH 45433 work may allow the Air Force to regularly model the 13. ABSTRACT (Maximum 200 words) differences between static model and dynamic vehicle flight RCS test data. Integrating Capt Noble's techniques with other data, DoD should save DoD T&E funds. This thesis presents an examination of the second order statistical properties of various forms of Radar Cross-Section (RCS). Past research has shown that the probability of radar detection of a target is a function of the autocovariance of the RCS of the target. Given this fact as motivation, this thesis use dynamic and static C-29, 9.2 GHz RCS measurement data to analyze the RCS autocovariance. The RCS is modeled as a random process with independent variables of observation direction and time. Using this breakout of the RCS and a number of underlying assumptions, RCS autocovariance estimates are generated using the static and dynamic data applied to an autocovariance estimator. Autocovariance predictions are generated using theoretical radar target point scatter distribution models applied to the RCS point scatterer theory. The results of the various estimates and predictions are compared to determine the best combination of RCS measurements and predictions required for

creating an accurate characterization of the RCS autocovariance.

In the present research, the flow field associated with the ejection of a crew capsule from the fuselage of a high speed generic aircraft was experimentally investigated by means of the modified gas hydraulic analogy. For this, an existing hydraulic simulator was calibrated and modified to adapt it to the needs of the experiment. The analogy was evaluated for a five-sided capsule alone, and good quantitative agreement with the 2-D shock-expansion theory was obtained. It was found that the size of the model played a key role in the determination of good quantitative data. The analysis of the capsule interacting with a fuselage was made considering it at fixed vertical positions from the fuselage and moving with respect to the fuselage at different constant speeds. A clear difference in water depth ratio distribution on the surfaces of the capsule was found between the static and dynamic conditions and also difference occurred for the various velocities of separation. The agreement between theory and experiment was fair. It was concluded that larger models are needed to get good quantitative agreement between theory and experiment was fair. It was concluded that larger models are needed to get good quantitative agreement between theory and experiment and that any separation study should be made applying a dynamical model.

The primary purpose of this research was to develop a pallet packing program to meet the needs of the sponsor, the Resourc Analysis Group, Aeronautical Systems Center, Wright-Patterson AFB OH. The secondary purpose was to develop an analytical method of solving the two-dimensional packing problem to allow comparisons between the solutions generated by the pallet packing program and the optimal solution. The Interactive Pallet Loading System (IPLS) originally developed by Hodgson was used as the core around which were created the various subroutes that accomplished the data manipulation tasks required to meet the needs of the sponsor to transform a list of spares for a future weapon system into a list of loaded pallets. The two analytical models developed were based on the subregion allocation binary programming model of Benabdallah and Wright. This approach allowed the solution of a hybrid two-dimensional problem where both the deviation in height between the boxes in a layer and the area coverage were combined to find the optimal solution. Further advancements in binary programming techniques are required to allow for the use of these models in statistically validating the optimality of the IPLS generated solutions.

DISTRIBUTION CODE Approved for public release; distribution unlimited 13. ABSTRACT (Maximum 200 words) This study attempted to analyze the effect of calibration on the performance of the SASET computer software cost estimating model. Data used for input into the model were drawn from the most current USAF SMC Software Database (SWDB). Once all the records to be used for analysis were identified, the DBMS/Calibration tool (which is part of SASET) was used to perform regression analysis on the relationship between program size (measured in SLOC) and the effort required to develop the program (measured in man-months). Productivity information reported from this tool was then input into equations used to calculate the Productivity Calibration Constants (PCC) and Software Class Multipliers. A comparison was then made between the model's accuracy before calibration and its accuracy after calibration. This was done using records which were not used in calibration (referred to as validation points). Several measures such as mean, variance, mean magnitude of relative error (MMRE), and the percentage method were used to describe accuracy. The majority of the results agreed with previous studies that calibration does improve a model's prediction performance. However, emphasis is placed on the fact that calibration is most useful when the group of calibration data points are homogenous. 14. This research investigated a heuristic approach to schedule aircraft for the channel cargo system of the United States Air Force's Air Mobility Command (AMC). Given cargo/frequency of visit requirements, a fleet of aircraft, and possible routes, the objective of this research was to develop, implement, and tests an iterative procedure to efficiently schedule and load aircraft in order to maximize the flow of cargo through a channel cargo system. Once a level of flow was established, attempts were made to minimize cost in terms of cumulative weighted time-in-system (CWTIS). A minimum cost flow heuristic, incorporating a successive shortest path algorithm, was coupled with a critical arc schedule improvement heuristic Our procedure iterated between these two heuristics to generate a cargo flow pattern and aircraft schedule. This research demonstrated the usefulness and efficiency of this heuristic in planning airlift for the channel cargo system. The FORTRAN programs which implement the heuristics are compatible with current AMC scheduling/advance planning tools. Given this compatibility, additional testing in conjunction with AMC's current planning tools (STORM, CARGPREP, and CARGOSIM) is warranted. Pending successful testing in this environment, implementation of these methods is recommended.

A two-dimensional, geometrically and materially nonlinear shell theory applicable to arbitrary geometries described by orthogonal curvilinear coordinates and encompassing large displacements, moderate rotations for large strain situations has been developed. Additionally, the theory includes Jacobian transformation matrices, based upon displacement parameters, for the Cauchy-2nd Piola-Kirchhoff stress-state and the Cauchy (Almansi) - Green strain-state transformation, and a layered material approach is included for the elasto-plastic analysis to allow for variation of plasticity through-the-thickness. Doubly curved 20, 28, and 36 degree-of-freedom finite elements are defined based on specialization of the nonlinear problems. Post-collapse nonlinear solutions are found through a displacement-control incrementation scheme. This provides solutions to classical von Karman flat plate and Donnell spherical shell equations, intermediate von Karman flat plate and Donnell spherical shell equations, and large displacement and moderate rotational formulations. For deep shells exhibiting large rotations and displacements over 15-20% of the shell's surface, the Langrangian constitutive relations (Including the Jacobian transformation matrices for the stress- and strain-states) should be included to accurately reflect the variation of the material coordinate system with respect to the structural axis system. For those plates and shells exhibiting large strains, along with large rotations and displacements over 15-18% of the outer surface, plasticity should be included in the model.

A 2K by 8 static random access memory was developed for the Digital Radio Frequency Memory. This research continued previous efforts conducted by the Air Force Institute of Technology in the area of Very Large Scale Integration (VLSI). The circuit was fabricated by MOSIS using an 0.8 micron Complimentary Metal Oxide Semiconductor (CMOS) process. New sense amplifier configurations were investigated along with various architectural changes. Improvements were made in the sense amplifiers and various driver circuits to achieve 100 MHz operation. A phase-locked loop was included to provide a clean internal clock which is synchronized to an external reference clock. Precharging was added to the write operation to improve reliability. Recommendations were made regarding future designs for higher speeds.

Steady-state photolysis experiments were conducted to gain information relevant to the construction of a continuous-wave electronic-to-vibrational pumped infrared laser. An Ar+ laser (λ = 488 nm) was used to produce the electronically excited state Br($^2P_{1/2}$) (Br $^{\bullet}$) via photolysis of molecular bromine. Energy was then transferred to the near-resonant vibrational state CO₂(101) (CO₂†) via the collisional quenching of Br* by CO₂. The dependence of the 2.71 µm Br* and 4.3 μm CO₂† emissions on CO₂ pressure was measured, as well as the dependence of the 4.3 μm emission on pump laser chopping frequency. Unexpected results were obtained in both cases, indicating more detailed modeling of kinetic processes is called for. Additionally, an unexplained long-term decay in the 4.3 µm signal was observed, which may have bearing on the construction of closed-system laser devices. Recommendations are made for further research.

This is an excellent piece of work and begins to answer some very significant questions in compressor design approaches. The following comments are recommendations on future research topics: A. Blade loading levels need to be higher, effect moving hubs would have on these types of stators... Effects of the moving wall are minimal if clearance levels are small. Is this conclusion universal with higher loadings. Crenulations may be of interest in the future...another topic of interest related to transonic rotors in Shock-Tij Vortex interaction...potential AFIT involvement?

13. ABSTRACT (Maximum 200 words)

This experiment involved the design, construction, validation and testing of a new facility for the investigation of vortices generated by compressor rotor blade tip clearance with a moving endwall. A five-tube pressure take placed downstream of the trailing edge of a cascade of blades measured the pressure field for flow coefficients ranging from 20 to 1.66 and tips clearances of 0.33, 1.0, 1.7, and 2.4 percent chord. Contour plots of mass averaged pressure loss coefficient appear to show the no-flow tip vortex becomes entrained and diffused by the moving wall boundary layer. The high loss region near the moving wall contracts toward and extends toward the pressure side of the adjacent blade. This contraction results in a reduction in overall blockage in the passage with a corresponding reduction in passage losses, toward an apparent steady-stat value, for increasing end wall speed and decreasing tip clearance.

13. ABSTRACT (Maximum 200 words)

This thesis is a continuation of a previous effort which developed a finite element solution of Schrödinger's Equation. Identification of laser transition rates can be obtained by solving Schrödinger's Equation for diatomic molecules using the finite elements method. Experimental vibrational eigenvalues for a given electronic state are used to determine the molecular potential surface which yields the closest numerical result. A non-linear minimization routine is used to hunt for this surface by adjusting parameters of energy functions such as the Harmonic, Morse, Lennard-Jones, and Mie potentials. The eigenvalues from these solutions are then compared to the experimental values. Through this iterative process, the best potential surface is isolated. Franck-Condon factors are then computed with the numerical eigenfunctions from two different potential surfaces found in this way. This numerical technique was able to isolate potential surfaces whose eigenvalue solutions had relative errors better than 10⁻³ and 10⁻⁶ percent when compared to the analytical solutions of the Harmonic and Morse oscillators, respectively. Comparisons of the wavefunctions also vielded excellent agreement. Initial work with H_2 (X $^1\Sigma_g^+$) verifies the lower eigenstates can be approximated by the Morse potential with an anharmonicity term of 1.0912 inverse a.u. and a dissociation energy of 0.177 Hartrees.

13. ABSTRACT (Maximum 200 words)			

Barium and strontium release experiments were conducted throughout 1991 from the Combined Release and Radiation Effects Satellite (CRRES) to study both natural and man-made disturbances in the earth's ionosphere. A mass spectrometer on the spacecraft counted the Ba and Sr ions as the cloud expanded. In this study, data from the G-1 (in sunlight) and G-11b (in darkness) releases were modeled to understand the source of the ion signals. The model reproduced the Ba sun data well assuming photoionization (= 28 s) was the primary ionization mechanism. However, it was not able to account for the remaining ion data: (a) Sr has a very long phtoionization time constant (= 1920 s) and model/data comparisons showed that the Sr ionization rate must be 60 times greater than the phtoionization rate to account for the observed signals, (b) The charge transfer ionization process between Sr/Ba and ambient O was not sufficient to reproduce the ionization rates for Sr sun data and Sr/Ba dark data. Processes potentially responsible for the CRRES data include charge stripping and critical velocity ionization (CIV). Split peaks in the ion data were also investigated and found to be due to either an instrument sensitivity feature or a two-process mechanism.

DISTRIBUTION AVAILABILITY STATEMENT Approved for public release; distribution unlimited 13. ABSTRACT (Maximum 200 words) Automatic detection of time-critical mobile targets using spectral-only infrared radiance data is explored. A quantification of the probability of detection, false alarm rate, and total error rate associated with this detection process is provided. A set of classification features is developed for the spectral data, and these features are utilized in a Bayesian classifier. The results of this processing are presented and sensitivity of the class separability to target set, target configuration, diurnal variations, normalization of classification features, in which feature values are normalized using an estimate of the ambient temperature assets reveal a total error rate near 5% with a 95% probability of detection and a concurrent false alarm rate of 4% when a

mean contrast, and ambient temperature estimation errors is explored. This work introduces the concept of atmospheric surrounding the target. Classification testing of spectral field measurements made on an array of US and foreign military single classification feature is employed. Sensitivity analysis indicates that the probability of detection is reduced to 70-75%in the hours preceding daylight, and that for the total error rate to be less than 10%, the target-to-background mean contrast must be greater than 0.1. Analysis of the atmospheric normalization technique reveals that in order to keep the total error rate less than 10%, the ambient temperature must be estimated with less than 3K absolute accuracy.

analysis and experiments and hopefully we can build on this work by exploring Some of the theories

13. ABSTRACT (Maximum 200 words)

This study investigates the role base cavity depth plays in altering the overall subsonic aerodynamic forces on a free spinning axisymmetric body with wrap-around fins. Wind tunnel usage allowed the forces to be monitored for varying base cavity depths and angles of attack. A base cavity depth analysis was also performed on a non-spinning axisymmetric body for comparison. Oil flow visualizations were conducted on the non-spinning configuration to further describe airflow patters around the body and within the cavity. Results revealed that the aerodynamic forces, mostly drag, changed with increasing cavity depth but not to the extent previously believed. The force results, in conjunction with the flow visualizations, suggested that base cavities have very similar effects on spinning and non-spinning missile configurations.

in greater detail.

This study investigated the flame holding properties of recessed cavities in supersonic flow using numerical analysis techniques. A simplified analytical model indicated that an important property for flame holding was the lower residence time. Several chemical kinetics rate models for hydrogen and hydrocarbon combustion were compared. The perfectly stirred reactor model also indicated that trace species diffusion should increase flame spreading rate, and that heat loss reduces flame holding limits. After nonreacting calibration, two-dimensional simulations confirmed the perfectly stirred reactor results for blowout limits. Also, the effect of trace species diffusion on flame spreading was shown to be negligible, and the reduced flammability with heat loss was confirmed. Lowering the temperature of the inflow boundary layer was shown to reduce the flammability limits. Three-dimensional cavities were shown to generate axial vorticity and slightly enhance flame spreading. The methodology developed in this research provides a design guide for the size of cavity required to provide flame holding for scramjet combustor. Also, reduction of heat losses was shown to be a method to improve flame holding performance without increasing the cavity size.

A total Lagrangian finite element scheme for arbitrarily large displacements and rotations is applied to a wide range of shell geometries. The Jaumann stress and strain measures, which are resolved along the axes of an orthogonal triad rigidly rotated and translated with the deforming structure, are employed in the algorithm. Layer-wise higher-order shear warping and thickness stretch effects are included in the model. Two finite elements are employed in the analyses: an eight-noded, 36 degree-of-freedom (DOF) element, and a four-noded, C1 continuous, 44 DOF element. The 36 DOF element proves adequate for moderate rotation problems, but fails in modeling very large rotation problems. The use of the 44 DOF element provides dramatically improved results the the large rotation problem. Isotropic and anisotropic beams, plates, arches, and shells are analyzed. An aircraft tire is also analyzed using the model with regard to deformations resulting from the inflation pressure, and the flexibility of static contact analysis is also demonstrated.

ABSTRACT (Maximum 200 words) A DSP application of interest to the Air Force is high-speed avionics processing. The real-time computing requirements of avionics processing exceed the capabilities of current single-chip DSP processors, and parallelization of multiple DSP processors is a solution to handle such requirements. Designing and implementing a parallel DSP algorithm has been a lengthy process often requiring different design tools and extensive programming experience. Through the use of integrated software development tools, rapid prototyping becomes possible by simulating algorithms, generating code for workstations or DSP micoprocessors, and generating hardware description language code for hardware synthesis. This research examines the use of one such tool, the Signal Processing Work System (SPW) by the Alta Group of Cadence Design Systems, Inc., and hardware implementation. Throughout this process, SPW is evaluated as an aid to the avionics designer to meet design

objectives and evaluate trade-offs to find the best blend of efficiency and effectiveness. SPW is shown to be a viable rapid prototyping solution allowing an avionics designer to focus on design trade-offs instead of implementation details while using parallelization to meet real-time application requirements.

13. ABSTRACT (Maximum 200 words)			

Clustered microcalcifications are one of the earliest indicators of breast cancer, and are detected only by mammography; 30 to 50 percent of nonpalpable cancers are mammographically visible on the basis of microcalcifications alone. Furthermore, for early breast cancers, screening studies suggest that 70 to 90 percent were detected based on microcalcifications alone. This research proposes the following methodology for clustered microcalcification detection. First, preprocess the digitized film mammogram to reduce digitization noise. Second, spatially filter the image with a difference of Gaussians (DoG) kernel. To detect potential microcalcifications, segment the filtered image using global and local thresholding. Next, cluster and index these detections into regions of interest (ROIs). Identify ROIs on the digitized image (or hardcopy printout) for final diagnosis. Finally, to improve detection rates, globally optimize detection parameters using a genetic algorithm (GA), then locally optimize using the simplex method. The data base of 56 digitized (12 bit, 100 mm) full-breast (20x10 cm²) film mammograms contained 63 biopsy-truthed clustered microcalcification ROIs over 28 cases. This technique demonstrated a true positive (TP) case detection rate of 96.4 percent (27/28), and TP ROI (54/63) and TP image (48/56) detection rates of 85.7 percent with 5.75 false positives (FPs) per full-breast image.

13. ABSTRACT (Maximum 200 words) A hybrid method of moments (MM) based numerical model for the electromagnetic scattering from large finite by infinite planar slot arrays is developed. The method incorporates the novel concept of a physical basis function (PBF) to dramatically reduce the number of required unknowns. The model can represent a finite number of slot columns with slots oriented along the infinite axis, surrounded by an arbitrary number of coplanar dielectric slabs. Each slot column can be loaded with a complex impedance, allowing one to tailor the edge currents to provide a desired echo width pattern. The surface equivalence theorem is used to convert the original slotted ground plane geometry to an equivalent unbroken ground plane with magnetic surface currents. An integral equation based on these magnetic scattering currents is solved via the MM. The magnetic currents are approximated by a set of basis functions composed of periodic basis functions representing the edge slot columns and a single PBF representing the interior slot columns. In particular, the PBF captures the behavior of the central portion of the array where the perturbations from the edges have become negligible. Based on Floquet's theorem, the PBF is able to represent an arbitrarily large number of slot columns with just one unknown. The array scanning method (ASM) provides the contributions from the individual edge columns. Finally, a newly developed one-sided Poisson sum formulation provides an efficient means to account for the stratified dielectric media via a spectral domain conversion. The hybrid method is validated using both MM reference codes and measured data. The results clearly demonstrate the method's accuracy as well as its ability to handle array problems too large for traditional MM solutions.

13. ABSTRACT (Maximum 200 words)

Existing sorption models often fail to describe grain scale sorption because of an inability to define the diffusion domain. A proposed improved model required testing to determine model validity. The testing method used a synthetic media of known geometry such that the distribution of sorption sizes was known. Sorption rate data was obtained using batch experiments with the media. Data was used in comparison against model predicted rates. Fitted sorption size distributions were compared to real distributions obtained by controlling sorbent geometries. Comparison determined model performance in fitting known distributions. The focus of this study was to, 1) determine what protocols are necessary to ensure consistent chemical and physical properties of a synthetic media for sorption studies, 2) determine if the proposed model can predict the known shape parameters describing the frequency distribution of sorption sites by using the rate data obtained from sorption studies, and 3) validate the model. Model performance was encouraging for simultaneous fitting of two shape parameters. Simulations resulted in sorption site distributions similar to the known distributions. This model is an improvement over other diffusion models where geometries are assumed to be spherical. Prediction of real soil sorption site distributions may be possible.

ABSTRACT (Maximum 200 words) Future spacecraft technologies require advanced high-temperature thermal control systems. Liquid metal heat pipes are ideally suited for such applications. However, their behavior during microgravity operation is not yet understand. This study investigated liquid metal heat pipe performance in such an environment. Three stainless steel/potassium heat pipes were flown on space shuttle mission STS-77 in May 1996. The objectives of the experiment were characterization of the frozen startup and restart transients, comparison of flight and ground test data, and assessment of three different heat pipe designs. Heat pipe performance was characterized prior to the flight experiment. Predicted performance envelopes for each heat pipe were determined from theoretical calculations. Performance baselines were established from ground thermal vacuum test results. These pre-flight results were compared with those from the flight experiment. Thermal resistances were calculated for each heat pipe design. Microgravity operation did not adversely impact the startup or restart behavior of

were calculated for each heat pipe design. Microgravity operation did not adversely impact the startup of restart behavior of the heat pipes. The heat pipes operated within the predicted performance envelopes. The three designs had distinct startup characteristics yet similar steady-state performance. These results will serve as a benchmark for further liquid metal heat pipe studies and space system applications.

13. ABSTRACT (Maximum 200 words)

Sensor noise is an unavoidable fact of life when it comes to measurements on physical systems, as is the case in feedback control. Therefore, it must be properly addressed during dynamic system identification. In this work, a novel approach is developed toward the treatment of measurement noise in dynamical systems. This approach hinges on proper stochastic modeling, and it can be adapted easily to many different scenarios, where it yields consistently good parameter estimates. The Generalized Minimum Variance algorithm developed and used in this work is based on the theory behind the minimum variance identification process, and the estimate produced is a fixed point of a mapping based on the minimum variance solution. Additionally, the algorithm yields an accurate prediction of the estimation error. This algorithm is applied to many different noise models associated with three basic identification problems. First, continuous-time systems are identified using frequency domain measurements. Next, a discrete-time plant is identified using discrete-time measurements. Finally, the physical parameters of a continuous-time plant are identified using sampled measurements of the continuous-time input and output. Validation of the estimates is performed correctly, and the results are compared with other, more common, identification algorithms. The GMV results are generally better.

This design data provides valuable insight into problems associated with rate limiting and the potential for avoiding the effects with due consideration in the initial steps. This research was an appropriate supplement to investigations into how to predict "pilot-in-the-loop" induced oscillations (PIO), how to specify design features that alleviate the potential for PIO, and how to react once a PIO has incurred.

13. ABSTRACT (Maximum 200 words)

11. SUPPLEMENTARY NOTES

A new control methodology for manual flight control, viz, real-time tracking control, is developed. Amplitude and rate constrained dynamic actuators are considered. Optimal tracking control is made possible by the use of unique reference signal prediction strategies which extrapolate the reference signal over the optimization horizon. A receding horizon, linear-quadratic inner-loop controller is employed in conjunction with an outer-loop nonlinear element. The constraint effects mitigation strategy is to optimally track a modified reference signal which yields feasible actuator commands over the optimization horizon when the pilot demanded reference is too aggressive to be tracked by the inner-loop optimal control law. A discrete-time implementation yields conputationally inexpensive, closed-form solutions which are implementable in real-time and which afford the optimal tracking of an exgenous, unknown a priori reference signal. The developed control algorithm is applied to an open-loop unstable aircraft model, with attention being given to the trade-offs associated with the conflicting objectives of aggressive tracking and saturation avoidance. One-step ahead constraint mitigation is shown to provide substantial improvement in the constrained system response, while slightly more complicated constraint mitigation strategies yield stronger stability properties.

Phillips Laboratory and Air Force Space Command were struggling with the idea of how to integrate small tactical satellites into an infrastructure which was already strained. After defining the parameters of the study and assigning a local point of contact, I essentially backed off from the whole issue and waited to see what a handful of AFIT students could do for practically no money and little if any support from the field. Over the past five years the Air Force has spent in excess of at least nine million dollars wrestling with the key ideas there were fundamental to the thesis proposed by the GSO team. The degree of sophistication in problem definition, systems analysis and synthesis as well as code development was simply outstanding. Such an effort, if I had placed on contract would easily have cost the government over \$500K. The end product was simple, cost effective and extremely useful

13. ABSTRACT (Maximum 200 words)

Current satellite design philosophies concentrate on optimizing and tailoring a particular satellite bus to a specific payload or mission. Today's satellites take a long time to build, checkout, and launch. An alternate approach shifts the design paradigm to one that focuses on access to space, enabling tactical deployment on demand and the capability to put current payload technology into orbit, versus several years by today's standards, by which time the technology is already obsolete. This design study applied systems engineering methods to create a satellite bus architecture that can accommodate a range of remote sensing mission modules. System-level and subsystem-level tradeoffs provided standard components and satellite structures, and an iterative design approach provided candidate designs constructed with those components. A cost and reliability trade study provided initial estimates for satellite performance. Modeling and analysis based upon the sponsor's objectives converged the designs to an optimum solution. Major products of this study include not only a preliminary satellite design to meet the sponsor's needs, but also a software modeling and analysis tool for satellite design, integration, and test. Finally, the report provides an initial implementation scheme and concept for operations for the tactical support of this satellite system.

ABSTRACT (Maximum 200 words) The effects of stepped tip gaps and clearance levels on the performance, flowfield, and stall characteristics of a transonic axial-flow compressor rotor were experimentally and numerically determined. A theory and mechanism for relocation of blockage in the rotor tip region was developed. A two-stage compressor with no inlet guide vanes was tested in the Wright Laboratory's Compressor Research Facility located at Wright-Patterson AFB OH. The first-stage rotor was unswept and was tested for an optimum tip clearance with variations in stepped gaps machined into the casing neat the aft tip region of the rotor. Nine casing geometries were investigated consisting of three step profiles at each of three clearance levels. For small and intermediate clearances, stepped tip gaps were found to improve pressure ratio, efficiency, and flow range for most operating conditions. At 100% design rotor speed, stepped tip gaps produced a doubling of mass flow range with as much as a 2.0% increase in mass flow and a 1.5% improvement in efficiency. The flowfield characteristics associated with performance improvements were experimentally and numerically analyzed. Stepped tip gaps were found to have no significant effect on the stall characteristics of the rotor, the stability characteristics attributable to tip geometry were determined by the clearance over the forward portion of the rotor blade. This study provides guidelines for engineers to improve compressor performance for an existing design by applying an optimum casing profile. 14. SUBJECT TERMS 15. ABSTRACT (Maximum 200 words) This thesis effort focuses on the development of an object-oriented simulation of C-17 personnel airdrop operations and provides a tool for risk assessment of jumper and wingtip vortex interaction. Using the initial modeling efforts of the Wrigh Laboratory, this model expands those efforts to include random aircraft, wind and jumper movement within the simulation using MODSIM III as its language. Once the model was built, verified, and calibrated, it helped perform a preliminary analysis of jumper risk with varying element spacing and no crosswind. The results of the simulation provided 15 data point with which linear and logistic regression provided an estimation of the marginal rate of change of jumper/vortex encounter rate. Using the third order model shows that the encounter rate levels off around 24,000 feet spacing between element leaders at 12%, and stays as high as 11% at 32,000 feet before dropping to 0.4% at 34,000 feet. Further research and mode improvements may bring the encounter rate down at the more distant spacing but that is left for post thesis analysis efforts.

13. ABSTRACT (Maximum 200 words)

This thesis investigates the integration of a three-dimensional (3-D) audio enhanced radar warning receiver (RWR) display. A 3-D enhanced RWR display provides a spatial auditory warning cue enabling the pilot to perceive the direction of the threat without the need to reference a visual display. The goals of this work are to determine the effect of the cockpit environment on auditory localization and demonstrate the potential of a 3-D audio enhanced RWR display. The investigation is conducted with rated military officers, replicated cockpit noise and operational RWR warning signals. The 3-D audio enhanced RWR display includes active noise reduction (ANR) earcups. A comparison of ANR earcups to conventional headphones shows no degradation of localization ability using ANR. An investigation on the effect of aircraft cockpit noise on localization shows no degradation of accuracy. A localization enhancement technique is demonstrated that yields a 2.3 improvement in localization accuracy as well as providing a cue that is perceptually easier to localize. The enhancement technique retains the attention demanding characteristics of auditory warning cues while improving the localization accuracy. In the first air-to-air application of this technology, an airborne demonstration confirms reliable auditory cueing; reduced pilot workload; and increase situational awareness.

ABSTRACT (Maximum 200 words) This research investigated the feasibility of predicting future bits of a given linear pseudorandom binary sequence (PRBS) from past bits by adaptive techniques. An adaptive transversal filter (ATF) modified to operate in the Galois field of prime order 2, designated a GF2ATF, was used to model a linear feedback shift register (LFSR) which generated PRBSs. All tests were conducted in a noise-free environment on maximal-length sequences (MLSs) from 3,4,5,6, and 7 stage LFSRs. Eight weight update algorithms were developed and implemented and performance was established in terms of whether the GF2ATF converged and the time required to achieve convergence. Through the performance surface for the GF2ATF was empirically determined to be flat, one weight update algorithm was developed which resulted in a mean convergence time (MCT) of less than one third of a MLS period. The GF2ATF occasionally failed to converge for some weight update

algorithms because the adaptation entered an endless loop of improper adaptive weight settings.

ASSESSMENT

This thesis explored the use of space-based weapons in a conventional warfare simulation. It answered our request for a way to mathematically model and integrate lethal space-based systems in a conventional combat situation. The investigation was accomplished to give us a better understanding of the complexities and limitations of space-based weapon systems and orbital mechanics. Maj Cozadd's work in this area was exceptional and appreciated.

Maxwell AFB AL

11. SUPPLEMENTARY NOTES

This thesis provides the foundation to expand the newly developed theater level computerized wargame, SABER, at the Air Force Wargaming Center, Maxwell AFB AL to include space conflict at the theater level of simulation. Building upon recently completed SABER, this thesis effort expands the conceptual framework of the model by integrating the dynamics of space warfare into the current theater level model. This expansion forms a new game called SWATTER. This thesis adds the space units required to integrate the land and air patties with the possible interactions from space. This thesis expands the stochastic attrition processes to include interactions between space forces, ground forces, and air forces with the use of unclassified engineering models. The use of these models results in credible interactions throughout SWATTER. The main components of SWATTER include satellite constellation determination, mapboard representation of the satellite constellation, detection and targeting processes, intelligence, command and control processes, laser weapon interactions, and stochastic attrition. The goal is to provide sufficient documentation on the necessary algorithms and related equations for programmers to build a computer simulation with a reasonable run time and credible output.

The simulation model developed by Capt Stephens permits detailed analysis of resource implications Distribution unlimited associated with the provision of obstetrical services, better allocation of scare resources within MTF 13. ABSTRACT (Maximum 200 words) hospitals, and potentially reduced CHAMPUS expenditures. Our office is currently working to further the research and analysis begun by Capt Stephens. The purpose of this research was to develop a decision support tool for users at Air Force Medical Treatment Facility obstetrical (OB) units. The immediate needs of the generalized simulation model contained in this research provide obstetrical wards with the capability to identify unit effectiveness as well as the ability to predict future performance. As a result of this model, decision-makers will now have access to information on system performance as well as insight into the effects of changing conditions. This model was formulated with the flexibility to be adapted to OB wards at regional and local hospitals throughout the Air Force. The generalized approach provides staff the opportunity to explore alternative policy options without detrimental effects on system performance. Options associated with patient arrival, departure, and service conditions can now be fully explored. Possible nurse scheduling options are also afforded through model output. 15. NUMBER OF PAGES 14. As a meaningful alternative to field exercises, we are faced 13. ABSTRACT (Maximum 200 words) with a rapidly growing list of potential customers with various needs, expectations, and capabilities. The Saber wargame is a theater-level air/land battle wargame written in Ada that is being developed for the Air Force Wargaming Center at Maxwell AFB AL. This thesis documents how the user interface and simulation engine were integrated. Integration was accomplished by developing a potable object-oriented database system (OODBMS) interface. The interface was implemented in Ada and tied to an OODBMS also written in Ada. Using the interface, both subsystems were able to work from a consistent database and exchange information. The user interface was enhanced by converting it from the Software Technology for Adaptable Reliable Systems Ada/X Window System bindings to a newer commercial set. Generic components were constructed to allow the rapid development of Motif input forms written in Ada. 15. NUMBER OF PAGES 14. SUBJECT TERMS 159 16. ABSTRACT (Maximum 200 words) This thesis examines the feasibility of using least median of squares (LMS) procedure applied to a reweighted least squares (RLS) autoregression model to identify significant outliers in time series data. The time series were analyzed for data points that were outliers. In order to perform detailed analysis on an outlier, the analyst must be able to determine that an outlier data point is significantly different from normally distributed data. This thesis examines a new method for identifying these outliers. Data from the field were characterized and fit with time series models an autoregressive reweighted least squares routine (ARRLS) derived from the LMS methodology. Various orders of autoregression were applied to the AARLS method to determine an appropriate order for the model; resulting fit coefficients were tests for significance. Regression results from the data taken at five sites are presented. By using an autoregressive order of one (AR(1)) applied to the ARRLS, this method significantly improved outlier detection in the time series data over the recursive removal without regression (RRR) method currently in use. In addition to identifying the outliers found by RRR, the AR(1)-RLS method routinely identified four items as many outliers as AFTAC's RRR method. The AR(1)-RLS method is recommended as a complimentary procedure to the RRR method currently used in identifying significant outliers. After sufficient operational experience is gained, AR(1)-RLS may supplant current schemes. Recommendations for improvements to the AR(1)-RLS method are offered. 15. NUMBER OF PAGES 14. 13. ABSTRACT (Maximum 200 words)

The objective of this research was to develop a framework for a standardized Air Force Contingency Contracting course. This task was undertaken due to the occurrence of a common recommendation calling for specialized training in Contingency Contracting. The recommendation was found in several AFIT theses, as well as, various after action reports generated due to the experience gained during Operation Desert Shield/ Storm and Hurricane Andrew.

This thesis answered the basic questions of need, content, and structure for a future course in Contingency Contracting. Using an exploratory research design, the research team was able to conduct an extensive analysis on completed formalized research in the area of Contingency Contracting.

The outcome of the research is a four-phased, block of instruction with recommended training topics and first hand accounts of contingency contracting. The blocks of instruction can be used alone or as a segment in current DOD Contracting Courses.

For the US Air Force to maintain an accurate and reliable Navigation Reference System (NRS) with Carrier-Phase Global Positioning System (CPGPS) measurements, it must develop an accurate and robust NRS in the face of cycle slips caused by highly dynamic maneuvers. This research investigates the implementation of a double differencing between receivers/satellites scheme to improve the accuracy of current NRS models. The removal of the "perfect Doppler velocity aiding measurements" (a very poor assumption of past research) was completed with stable and accurate results. The double differencing implemented showed improvement in the accuracy of the NRS. An investigation of two Failure Detection, Isolation, and Recovery (FDIR) algorithms for large cycle slip failures is conducted. The two FDIR techniques are the Chi-Square test and a Multiple Model Adaptive Estimator (MMAE). The FDIR results show that a Chi-Square tests as a stand-alone algorithm can work accurately for detection and isolation of failures with an accurate and reliable recovery algorithm. The MMAE algorithm as conjectured seems to be the best FDIR techniques to handle single and multiple cycle slips accurately and reliably.

ABSTRACT (Maximum 200 words) Computer simulation was used to evaluate the impact of a Logistics Control Facility (LCF) with a Total Asset Visibility (TAV) system on the AF logistics system's ability to support a weapon system. For this study, the B-1B was chosen as the weapon system of interest. Two performance measures, expected fully mission capable rates and expected pipeline quantities, were used to evaluate the simulation results. Two-sample t tests were used to compare the current logistics configuration of the B-1B with that same configuration, but with an LCF controlling the movement of assets. The expected FMC rate performance measure showed significant results while the expected pipeline quantity performance measure did not. After determining that the LCF with a TAV system did have an impact on the ability of the AF logistics system to support a weapon system, fourteen different support configurations were evaluated. Variables included mode of transportation, use of buffer stocks, and use of intermediate repair facilities. Analysis of the results was accomplished using a randomized block ANOVA and Least Significant Difference comparison of means. For expected fully mission capable rates, mode of transportation was the most significant factor. For expected pipeline quantities, the use of intermediate repair facilities was the most significant factor. 14. SUBJECT TERMS 15. This research investigate	s the effect of Te	ean Todistics pro	posals on the current

This research investigates the effect of Lean Logistics proposals on the current Air Force reparables pipeline. Lean Logistics proposes reducing reparable asset levels at operating bases, reducing transportation time between bases and depots, and reducing depot repair times. Computer simulation is used as a tool to perform a 3X3X3 full factorial experiment to determine the effects of the Lean Logistics proposals on fully mission capable aircraft and transportation cost. Results indicate that Lean Logistics outperforms the current reparables pipeline in term of fully mission capable aircraft. A cost benefit analysis is performed to determine the trade offs between transportation costs and asset outlays.

ABSTRACT (Maximum 200 Words)

This thesis explores the assumption that cost overruns are related to contract changes. A common assertion in defense ture says that contracts which are relatively stable suffer smaller overruns than those which are highly volatile. The stability or fility of contracts is characterized by their change history. A contract which is modified frequently or by large amounts is more able, or volatile, than one which is not changed either as often or by lesser amounts. This study attempts to find evidence orting this common assertion by examining the relationship between cost growth and baseline stability on over 400 Major nse Acquisition Program contracts over the last 26 years. The results are intriguing because, counter-intuitively, no significant ence is found. Possible explanations and implications of this discovery are provided.

13. ABSTRACT (Maximum 200 words)			

The purpose of this study was to determine if a knowledge-based expert system could be developed for intercontinental ballistic missile (ICBM) maintenance. This study focused on the missile maintenance fault analysis conducted at the operational level. An extensive literature review revealed that a knowledge-based expert system offered capabilities that are compatible with missile maintenance fault analysis. A prototype knowledge-based expert system was built using principles and techniques acquired during the literature review. Five research questions were developed to determine the overall effectiveness of the expert system. Thirty scenarios were tested using both the prototype knowledge-based expert system and the manual method currently in place. Based on these five research questions, several conclusions were reached. First, commercially available software shells can easily be used to develop an appropriate expert system. Second, the necessary missile maintenance knowledge can easily be stored and accessed. Third, priorities and various site modifications can easily be incorporated into an expert system. Finally, the prototype knowledgebased expert system was just as accurate as, yet faster than, the non-computerized system used today.

This research studied the application of cost management competencies in the financial management career field. The purpose was to determine how frequently these competencies are used by the financial analysts and how important they are in the analysts' work environment. To accomplish this research a mail survey was sent to 978 financial analysts across Air Force Materiel Command. Out of the 978 survey instruments sent, 535 were returned with useful data, for a response rate of 54.7%. From these surveys, 24 of the 49 competencies were identified as being valuable to financial analysts. The 24 competencies provide a framework for future education of the financial analysts. Additionally, 19 of the 24 competencies require education to the comprehension level of learning. Only five of the 24 most valuable competencies required achievement of an application level of learning. This result may provide insight for course directors faced with the challenge of appropriately structuring cost analysis courses.

The framework for the evaluation criteria consists of four categories: demographic analysis, impact analysis, integration of demographic analysis and impact analysis, and community involvement. There re a total of 17 criteria within this framework. With respect to reflecting the requirements of EO 12898, AFCEE's draft methodology met ten criteria, was limited in five criteria, and did not meet two of the criteria. When a sample AFCEE application was analyzed, eight of the criteria were met, and nine were not met. This was due, in part, to the fact that the application was analyzed, eight of the criteria were met, and nine were not met. This was due, in part, to the fact that the application was a Base Realignment and Closure Environmental Impact Statement. 115. NUMBER OF PAGES 116. PRICE CODE 117. 13. ABSTRACT (Maximum 200 words)			
The development of increasingly	y accurate new aircraft navigatio	n systems has caused the Air For	rce to develop a new
Navigation Reference System to	test them, called the Submeter	Accuracy Reference System (SA	nseudolite mounted on the
inverted GPS system which con	sists of an array of GPS received	s on the ground and an airborne	on system under test
test aircraft. The SARS will pr	ovide a proof position estimate u	hat is used to check the navigation from high geometric sensitivity	to measurement errors.
Unfortunately, ground based in	- of optimizing the SAPS received	ver array configuration to minim	ize the system's sensitivity
This research tackies the proble	is determines that the proper the	oice of cost function for the optim	mization is the condition
pseudorange errors. The analys	than the commonly used GDOP	Insight into the problem is pro	vided by a graphical
technique for evaluating receive	er array geometry. Moreover, ty	vo receiver array numbered optim	mization programs are
developed. The results of the r	eceiver array optimization show	that the geometric sensitivity to	error in the SARS airspace
can be reduced to acceptable le	vels through proper array design	. Several good receiver array de	esigns are shown. Finally,
technique for further reducing t	he geometric sensitivity of the S.	ARS is discussed.

13. ABSTRACT (Maximum 200 words)			
The purpose of this study is to inv	restigate the effects o	f certain national economic con	nditions and certain Air Force related

The purpose of this study is to investigate the effects of certain national economic conditions and certain Air Force related conditions on officer retention rates and to build, verify, and validate a multivariate linear regression model to be used by Air Force personnel management officials that will predict officer retention rates for rated and non-rated line officers aggregated by Yeargroups and AFSC groups. Previous retention models were reviewed to study possible predictors and methodologies. The logit transformation was used on the logistic regression model for simplification. D. R. Cox gives three assumptions, that were valid in this case, so ordinary least squares was used to estimate the parameters of the logit model. The tournament approach of the Modified Miller's Method was used for variable selection. This new approach was first validated by computer simulation and then used in the model building process for all of the models in this effort. The output of this tournament approach was the model of choice for each AFSC and Yeargroup. Two-way without replication ANOVA was done in order to combine like AFSCs into several groups. There were six groups in all. A separate model was then build for each of the six groups.

13. ABSTRACT (Maximum 200 words)			~ <u>*</u>	

Air Force Global Weather Center's (AFGWC) Relocatable Window Model (RWM) total cloud forecasts were validated using data for selected days in May, June, and July 1996. Forecasts were generated twice daily (00 UTC and 12 UTC) to determine the RWM's ability to accurately forecast total cloud cover during the late spring and early summer. The RWM forecasts were post-processed using the Slingo cloud forecast algorithm and compared against AFGWC's operational real-time nephanalysis (RTNEPH) cloud analysis model. As a minimal-skill baseline comparison to the RWM's total cloud forecast, RTNEPH initial analysis hour was persisted and evaluated against the same RTNEPH analysis as the RWM forecasts. The results of the study suggest RWM total cloud forecasts did not show improved skill, sharpness, accuracy or bias when compared against RTNEPH persistence through the 36-hour forecast period. The results also suggest the Slingo algorithm, as tested, is not appropriate for use in the RWM as an accurate total cloud forecast method for the late spring and early summer months over the North American Window.

13. ABSTRACT (Maximum 200 words)				
The North Warning System (N	WS), a joint program of the US	S Air Force (USAF) and the	Royal Canadian Air Force	
(DCAE) is responsible for the	maintenance of 47 remote rada	r sites across northern Canac	la. NWS's current airlit	
operations, which support the i	radar maintenance activities, co	nsist of both helicopters and	fixed wing aircraft positioned at	
five support denots. This thesi	is considers whether a reconfigu	iration of these support depot	s and the assignment of factal sit	
to them can result in either an	airlift or total cost savings for l	NWS. Mixed integer linear p	rogramming models were	
formulated to address the quest	tions surrounding a configuration	on of the NWS which might g	gain airiin cost savings. Several	
	sidered. The analysis identifies	s mat cost savings may be rea	myon miongh a minioci or	
possible actions.

Reliability analysts are often face	ed with the challenge of charac	terizing the behavior of system components based on lin

Reliability analysts are often faced with the challenge of characterizing the behavior of system components based on limited data. Any insight into which model input data is most significant and how much data is necessary to achieve desired accuracy requirements will improve the efficiency and cost effectiveness of the data collection and data characterization processes. This thesis assesses potential significant factors in the probabilistic characterization of component failure and repair behavior with respect to the effect on system availability estimates. Potential factors were screened for significance utilizing factorial and Plackett-Burman experimental designs for several system models developed using an AFOTEC simulation program entitled RAPTOR. Two input data characterization factors were found to have significant affect on availability estimation accuracy: the size of the structure and the number of data points used for component failure and repair distributional fitting. Estimation error was minimized when the structures analyzed were small and many data points (in this case, 25) were used for the distributional fittings. Assuming constant component failure rates and using empirical repair distributions were found to be equally effective component characterization methods (pertaining to model availability estimation error) compared to using automated software fitting tools (or 'wizards'). The results of this study also indicate that there is no apparent benefit in concentrating on important components for the highest fidelity distributional fittings.

13. ABSTRACT (Maximum 200 words)

Accurate forecasts of contrail occurrence are essential to military aircrews. Although classical forecast methods have been reasonably successful predicting contrails, there is need for improvement at low ambient relative humidity. This thesis examines the performance of the Hanson method, which was developed to provide better contrail forecasts under drier atmospheric conditions. As a secondary objective, the forecast methods of Schumann and Hanson are compared to the algorithm currently in use by the Air Force Global Weather Central. Data used to validate the algorithms were collected at Wright-Patterson AFB OH and Edwards AFB CA. Theoretical contrail forecasts were made for each observation, using the flight level pressure, ambient temperature, and relative humidity. Comparisons were then made between the forecast and actual observation of contrail conditions. Forecast and occurrence data were then statistically analyzed to gauge each method's performance. All methods detected roughly 75 percent of observed contrails under moist atmospheric conditions. However, the Hanson method's performance decreased when drier atmospheric observations were tested. Schumann's method performed as well as the AFGWC algorithm under all atmospheric conditions. Based on this research, the Hanson method is not recommended for operational use.

DISTRIBUTION AVAILABILITY STATEMENT September 1991. As well as play a role in continuing research and analysis on casualty estimation and Distribution Limited to DoD and DoD Contractors On prediction in the US Army. 13. ABSTRACT (Maximum 200 words) The goal of this study was to determine the relationship between battlefield physical insults, levels of protection, and the number and severity of casualties sustained by armored vehicle crews as a result of battlefield physical insults on armored vehicles in the Vietnam conflict. In addition, this study sought to establish the relationship between battlefield physical insults, levels of protection, and vehicle mission vulnerability. An automated database was constructed from paper records in the GRNVEHSEADB database maintained by SURVIAC. This data was analyzed using log-liner modeling, logit modeling, and contingency graphics. The results show that the severity of crew casualties and the impact of those casualties on vehicle mission vulnerability are functions of the vehicle model, threat weapon, and location of weapon impact. Although small sub-sample sizes render the predictive probabilities questionable, the dependence of the relationship is established. Additionally, it was shown that crew casualties were a significant factor in determining vehicle mission vulnerability when hit by a rocket propelled grenade. It was also shown that M113 APC driver casualties to land mines were twenty percent fewer when bolt-on armor was installed. 14. SUBJECT TERMS 15. NUMBER OF PAGES 290 16. 13. ABSTRACT (Maximum 200 words)		

Considerable progress has been made in recent years in the area of standoff minefield detection (SMD). But, techniques currently being developed operate from low altitude airborne platforms making them vulnerable and making the commander's interest in an area obvious to the enemy. SMD from space would address both of these limitations. This research takes a multi-disciplined approach to assessing the potential for SMD from space, considering remote sensing fundamentals, recent SMD experimental results, and space-based issues. The fundamentals of remote sensing limit and enable target detection in terms of resolution, ground penetration, and others. Synthetic aperture radar (SAR) technology at longer microwave wavelengths is theoretically the most promising sensor type. Experimentally, infrared detection technology has shown particular success at low altitudes, with an IR SMD system currently being developed for remotely-piloted vehicle mounting. Once orbital parameters such as the sensor-to-target range, overflight speed, and frequency of coverage are considered, it concluded that a space-based minefield detection system (SBMDS) relying on just one sensor would not be sufficiently capable. A multi-band SAR system would be more promising for SMD from space. Although currently unsuccessful at detecting buried mines, SAR offers high resolution, some ground penetration, and all-weather capability largely independent at range. Augmentation by a multi-spectral visible IR system may prove

ABSTRACT (Maximum 200 words) The purpose of this study was to implement an autonomous face segmentor as the front end to a face recognition system on a Sun SPARCStation2. Face recognition performance criteria, specifically, the capabilities to isolate and resize faces in an image to a consistent scale, were analyzed to determine current practical limitations. Face images were acquired using a S-VHS camcorder. Segmentation was accomplished using motion detection and pre-defined rules. Tests were run to determine the suitable of the autonomous segmentor as the front-end to a face recognition system. The segmentation system developed consistently located faces and rescaled those faces to a normalized scale for subsequent recognition. 15. NUMBER OF PAGES 14. SUBJECT TERMS 125 16. SUPPLEMENTARY NOTES formal specifications of Larch and Z. Further work Assessment shouldbe directed at interfacing the SPECWARE tool as soon as appropriate. The value of the work SPONSOR ABOVE will increase when integrated with our emerging 12a. DISTRIBUTION AVAILABILITY STATEMENT tools. Of secondary importance would be the ability to do static and dynamic analyses of the Approved for public release; distribution unlimited specifications. In the long term however, the types of additional analyses provided will be more beneficial then simply integrating with SPECWARE. 13. ABSTRACT (Maximum 200 words) This research describes the feasibility of developing object-oriented Larch specifications, part of a dual approach for formally extending object-oriented analysis models using Larch and Z. The first phase consisted of two steps: establishing a set of transformation heuristics for algebraically representing object models and implementing a robust Larch parser. The Larch parser produced abstract syntax trees (ASTs) of objects forming the basis for analyzing similarities and differences between Z-based and Larch-based object representations. The second phase used the analysis of Larch and Z to identify fundamental core constructs in the languages and abstract syntax trees. These core constructs consisted of similar syntactic and semantic notions of signatures and axioms for describing a problem domain, thereby forming a canonical framework for formal object representations. This canonical framework provides a front-end for producing design refinement artifacts such as interface languages, theorem proving sentences, and synthesis diagrams. The final phase demonstrated the feasibility of interface language gauge generation by establishing an executable framework. The executable framework mapped Larch into the Software Refinery Programming Environment to rapidly prototype object-oriented Larch specifications. 14. SUBJECT TERMS 15. This thesis describes the development of an air mission planning algorithm for the Joint Staff's Future Theater Level Model (FTLM). The overall problem scope was to develop an algorithm to handle major factors bearing on the combat mission planning problem while providing hook-ups for the FTLM architecture. Other aspects of the problem included finding the appropriate level of detail, developing a fast solving technique, and attempting to use existing data. The problem was handled by using some ideas from existing aircraft allocation algorithms and by adding some new techniques. The proposed air mission planning algorithm supplies the optimum degree of force for campaign objectives by using a linear program (LP) to allocate the optimum number and type of aircraft and munitions against each target. The LP takes advantage of the force multiplying effects of mass and mutual support through its use of strike packages with SEAD and air-to-air escort. Additionally, a decision tree algorithm determines the best plan in light of the uncertainties of weather and weather forecasts. This air mission planning algorithm omits many of the details in the actual aircraft tasking process, but provides fast, nearly optimal solutions which should approximate real world tasking results.

ABSTRACT (Maximum 200 words) This study investigates both the purpose and development of management reserve budget as it pertains to the Cost/Scheduled Control Systems Criteria outlined in DoD Instruction 5000.2. With the Defense Department facing an environment of shrinking budgets, it is becoming increasingly critical for them to manage their acquisition programs as efficient and effective as possible. The objectives of this study were to gain insight, from both a government and commercial perspective, on both the purpose and the development of the contractor's management reserve budget. Contractor system descriptions and interviews of individuals associated with the government acquisition process were used to document and analyze the objectives of the study. The contractor system descriptions and personal interviews both provided detailed information on the purpose of the contractor's management reserve budget. However, neither data source provided a consistent, objective methodology for developing an accurate and comprehensive contractor's management reserve budget. 15. NUMBER OF PAGES 14. This research effort was a qualitative study on the current process of how the DOD provides humanitarian assistance. Currently the process is not well defined and is situation dependent. Historical documents and current guidelines, policies, and regulations were researched for information on what types of humanitarian assistance the DOD provides, how the process is initiated, and who is involved in the process. Agencies outside of the military, both civilian and government were researched to determine the extent of coordination necessary for the military to provide humanitarian assistance. A model was compiled to portray the current process and given to key personnel identified in the research as subject matter experts. Subsequently, their opinion was used to determine the validity of the model and gather additional points of contact for future research. Once the process and key players were defined, additional research can be started to further determine the effectiveness of using the DOD to provide humanitarian aid.

ABSTRACT (Maximum 200 words) Controlling costs in the acquisition of new defense systems is a major challenge in today's environment of declining budgets and rapidly changing technology. One of the challenges faced by program managers and cost analysts is selecting the most appropriate Estimate at Completion (EAC) method for their program. This study compares the performance of the popular index-based EAC methods with several newer nonlinear regression-based EAC methods to determine whether the complex nonlinear methods perform better than the simpler index-based methods. In addition, the sensitivity of the results to stage of contract completion, system type, program phase, contract type, Department of Defense service component, and inflation effects are also investigated. Eighty-eight contracts were examined in this study and it was found that overall the index-based EAC methods performed significantly better than the nonlinear regression-based methods as measured by two criteria, the accuracy and stability of the EACs. In addition, the tip performing method overall was determined to be the index-based method using the Composite Index (0.2SPI_{cum}+0.8CPI_{cum}). The best performing method was, however, sensitive to all of the factors investigated in the sensitivity analysis. 14. SUBJECT TERMS 15. DISTRIBUTION AVAILABILITY STATEMENT Approved for public release; distribution unlimited 13. ABSTRACT (Maximum 200 words) Closed-set speaker recognition systems abound, and the overwhelming majority of research in speaker recognition in the past has been limited to this task. A realistically viable system must be capable of dealing with the open-set task. This effort attacks the open-set task, identifying the best features to use, and proposes the use of a fuzzy classifier followed by hypothesis testing as a model for text-independent, open-set speaker recognition. Using the TIMIT corpus and Rome Laboratory's GREENFLAG tactical communications corpus, this thesis demonstrates that the proposed system succeeded in open-set speaker recognition. Considering the fact that extremely short utterances were used to train the system (compared to other closed-set speaker identification work), this system attained reasonable open-set classification error rates as low as 23% for TIMIT and 26% for GREENFLAG. Feature analysis identified the liftered linear prediction cepstral coefficients with or without the normalized log energy or pitch appended as a robust feature set (based on the 17 feature sets considered), well suited for clean speech and speech degraded by tactical communications channels. Finally, in contrast to previous efforts which have used codebooks consisting of 35-512 codewords, codebook analysis revealed that relatively small codebooks (with as few as 8-10 codewords) are adequate, if not optimal, in terms of classification accuracy and computational complexity for vector quantization-based classification techniques. 15. 13. ABSTRACT (Maximum 200 words)			
Access to communication netwo	rks is increasing rapidly. The is	ncreased access to these network	ks results in delays and at
times loss of data. At times of p	peak traffic or when trunks or ne	odes are down, very important o	customers' communications
requirements are not met. One	way to combat this problem is to	o prioritize the network and pro	vide different levels of grade
of service (GoS) for each priorit	ry. Call preemption provides an	effective method of obtaining of	lifferent levels of GoS. This
research seeks to design the best	circuit switch communications	network preemption model for	the DoD by analyzing
previously developed preemption	n algorithms. Four simulation r	network models are developed.	The grades of service per
priority are obtained as the netw	ork capacity decreases and as the	ne calls generated in node 0 incr	eases. The analysis of
preemption network models are	simulated under the same input	parameters. The analysis show	ed that preemption can
significantly lower the grade of	service for high priority custom	ners in a congested network. The	ne best configuration
preemption models depends on t	he bandwidth flexibility of the r	network and the goals of the cor	nmunications network
organization.	·

ABSTRACT (Maximum 200 words) The presence of an endangered species, the Pacific Pocket Mouse (PPM), in critical Marine Corps training areas aboard Camp Pendleton may adversely affect training activities that are crucial to meeting the Marine Corps' mission. Camp Pendleton must focus limited budgetary assets for live trapping surveys of the PPM in the areas of best habitat suitability and the purpose of this study was to develop a PPM habitat suitability map of Camp Pendleton. Suitability maps were developed by integrating expert opinion with the Camp Pendleton Geographic information System (GIS) database. The seven points scale multicriteria evaluation methodology was implemented to solicit the importance of ground characteristics (criteria) for PPM habitat from field experts. The criteria of interest were coastal proximity, soil type, and vegetation class. The evaluations of the respondents were in agreement. Suitability scores and preference weights were determined from questionnaire responses and input into the ARC/INFO GIS program. Habitat suitabilities were calculated as weighted averages of suitability scores of individual ground characteristics. The criterion and combined suitability maps produced agreed well with known locations of the PPM. This indicated that the evaluations and methodology were valid. Coastal proximity was determined to be eliminated from future research in this area. 15. NUMBER OF PAGES 14. 13. ABSTRACT (Maximum 200 words)

Laser-induced breakdown spectroscopy (LIBS) is a spectroscopic technique where output from a pulsed laser is focused onto a target in order to create an intense plasma. The optical emission is characteristic of the elements in the focal volume and can be used for elemental analysis. Research on the detection of nickel in solution in addition to solvent detection of CCI4, CHC1₄, $C_{\lambda}CL_{4}$, and $C_{\lambda}HC1_{3}$ has been performed. Breakdown was formed at the sample surface via a Q-switched Nd YAG laser. Initially, operation of the laser was at 1064 nm/repetition rate of 5Hz. Experiments were also performed using the third harmonic (355 nm)/repetition rate of 20 Hz. Pulse energy was maintained at 60 mJ. The spark light was spectrally resolved and detected by a time gated photodiode array. A 504s gate width/84s time delay gave detection limits of 56.1 mg/1 for nickel in solution. In the UV, 3 10 µs gate width/3 µs mg/1. Using UV excitation (10 µs gate width/1 µs time delay), saturated solvent solutions as high as 7.71 G/! were not detectable.

13. ABSTRACT (Maximum 200 words)

Capt Taylor's research in development of his thesis contributed directly to the success of on-going efforts by my staff to improve our endgame modeling against low observable vehicles. Our current end game simulation uses a simple stickand-cone fuse model technique which is adequate for conventional platforms. However, low observable platforms need a more complex modeling technique to evaluate the threat system fusing capabilities against our low observable penetrating assets. Capt Taylor's thorough analysis of various near field radar cross section prediction codes helped us select the best code to meet our requirements and contractneeded modeling improvement. His efforts have helped immeasurably in improving our endgame simulation and ensuring USSTRATCOM's mission.

The information of low observable aircraft into the modern battlefield has changed the performance characteristics of many weapon systems, anti-aircraft missiles included. An area of interest to the Air Force now how low observable features applied to an aircraft will affect the ability of anti-aircraft missiles to fuze properly. Current estimates on fuze effectiveness are based on a simple stick-and-cone model where detection of the target is independent of the reflectivity of the target. While this model has been sufficient for conventional targets, a low observable target may have a different response. Present near-exact computational methods can model the electromagnetic scattering from complex objects, like aircraft, but they require too much computational effort for reasonable simulation run times. Approximate methods are available that can obtain faster scattering solutions from simple objects arranged to simulate the target; however, errors can be substantial depending on the complexity of the object being modeled. The purpose of this thesis is to examine near field electromagnetic scattering codes for use in missile endgame simulations. The results of this analysis can be used to select a scattering code that will improve the overall fidelity of missile endgame simulations used by the Air Force.

This thesis describes the develop Laboratory (PNL) regression me conductivity, and two types of d variables from the original mode electrical conductivity than the o	odels are used as base urability. Revised Pl els. The Revised PNI original PNL regression	eline equati NL regress L regression on model.	ons for modeling glass properties on models are developed that eli a model for electrical conductivi	s such as viscosity, electric minate insignificant ty is shown to better predictor for viscosity and the two

PNL regression model in terms of predicting property values for viscosity, PCT-B and MCC-1B. The combined Neural Network/ Revised PNL 2nd order electrical conductivity models are shown to be the best classifiers of nuclear waste glass, i.e., they have the highest probability of classifying a vitrified waste form as glass when it actually did produce glass in the laboratory. Finally, five nonlinear programs are developed with constraints containing 1) the PNL original 1st order models, 2) the PNL original 2nd order models, 3) the Revised PNL 1st order models, 4) the Revised PNL 2nd order models, and 5) the Neural Network/Revised conductivity nonlinear program is shown to minimize the total expected cost of vitrifying nuclear waste glass. This nonlinear program allows DOE to minimize its risk and cost of high-level nuclear waste vitrification.

, '			
This study investigated the feasi	bility of a SAIC proposal to sa	ample New Earth Objects	(NEOs) from an orbiting spacecraft
using a tethered landing device.	The parameters for suitable t	argets were derived from	an analysis of a proposed point
design as applied to current kno	wledge of NEOs. Tether stren	ngth and lifetime for the p	point design were also assessed. First
order modeling of tether dynam	ics showed that deployment an	nd attachment to a NEO a	re feasible. The dynamics of
retrieving a sample via a crawle	r unit which crawls up the tetl	ner requires further explo	ration.

This study used network modeling to evaluate an engineering design process. The design process contained quality control activities which incorporated feedback network branching. The network was analyzed with a stochastic simulation program instead of PERT. Analysis techniques used included pseudo-random number testing for uniformity and independence, and analysis of variance to determine significant activities. A resolution IV experimental design was used to evaluate the improvement of the average project completion for different quality control activity settings. All significant activities identified were quality control activities that contained feedback network branching, and improvements in the project completion time were estimated based on reductions in the probability of feedback branching. A simplified strategic network model was constructed to demonstrate the integration of the detailed tactical model into a decision support system.

	•			
This thosis presents a prelimir	nary design of an ionospheric son	inder to be carried aboar	d one or m	ore of NASA's Mars
Surveyor landers Past Russia	an and American probes have in	dicated the existence of a	n ionosphe	ere, but none of these
missions remotely sensed this	atmospheric layer from the surf	ace. The rationale for ut	ilizing a su	ırface-based Martian
ionospheric sounder is discuss	ed. Based on NASA's choice o	f launch vehicle and pow	er source,	a low-weight, low-powered
Chirpsounder using a horizont	ally-polarized dipole antenna is	recommended for the sou	ınder expe	riment. The sounder
experiment should be conduct	ed for at least one Martian year,	in order to investigate si	ignificant c	hanges in radio propagation
during seasonal transitions. S	pecific data compression technic	ques are suggested in ord	er to reduc	e the quantity of data
transferred from each sounder	. The Appendix presents an over	erview of Earth's ionospl	heric struct	ture and solar cycle effects.
Finally, a Matlab software mo	odel of a hypothetical ionogram	as measured from the Ma	artian surfa	ice is presented.
