Application for Participating in Facial Recognition Vendor Test 2000

1. Overview

The DoD Counterdrug Technology Development Program Office, the National Institute of Justice (NIJ), the Defense Advanced Research Projects Agency (DARPA), NAVSEA Crane Division and NAVSEA Dahlgren Division are sponsoring an evaluation of commercial off the shelf (COTS) facial recognition products. The purpose of these evaluations is to accurately gauge the capabilities of facial recognition biometric systems that are currently available for purchase. The sponsoring agencies, as well as other government agencies, will use this information as a major factor when determining future procurement or development efforts. Participation in these tests is open to all facial recognition systems on the US commercial market. The U.S. Government will not compensate vendors to participate in these tests.

2. Test Description

Two categories of tests will be conducted: Recognition Performance Tests and Product Usability Tests. For each category, multiple tests will be performed to measure system performance in verification mode and in identification mode. The Recognition Performance Tests will use the FERET test methodology with a new database of images. The Product Usability Tests will evaluate performance in both low and medium security access control scenarios.

2.1 Recognition Performance Test

The Recognition Performance Tests will be very similar to the original FERET tests that were sponsored by the DoD Counterdrug Technology Development Program Office. Since the conclusion of the original FERET program, the data sets and reports have been transferred to the National Institute of Standards and Technology (NIST), who is serving as a technical consultant for these tests. Images used in this test will be a combination of images from the FERET database as well as DARPA's new HumanID database.

2.2 Product Usability Test

The Product Usability Tests will consist of two timed tests and an optional access control system interface test. Each of the timed tests will show the time for the system to make a decision (if it makes a decision) and whether the decision is correct or not. These tests will be performed for both identification and verification, as well as for different lighting conditions. The optional access control system interface tests will test the facial recognition systems' ability to communicate with an access control system using the WIEGAND standard.

3. Required System Description

On the first day of testing, participating vendors will be required to submit a four page (maximum) document that:

- Provides an overview of the submitted system
- Provides a component list for the submitted system
- Provide a detailed cost breakdown of the submitted system

4. Release of Evaluation Results

Results of the evaluations will be documented in a final report and, possibly, several international conference papers. The final report will contain each participating vendor's four page document as well as the results of the government evaluation. All reports and papers will be made available to the public. Testing activities will be recorded using video cameras but the footage will not be released to the public. Portions of the video, however, may be used to provide a quick 5-10 minute overview of the tests.

5. The Facial Recognition Vendor Test 2000 is being conducted for the sole purpose of determining the capability of facial recognition systems and not for fulfilling immediate or long-term mission requirements. The examination and test of these systems will in no way, expressed or implied, obligate the DoD Counterdrug Technology Development Program Office, or any of the test co-sponsors (hereinafter referred to as the "sponsors"), to purchase, rent, or otherwise acquire the systems tested. Manufacture, transportation, maintenance, and company test representatives shall be accomplished without cost to the sponsors. Tests will be conducted by an authorized representative of the vendor furnishing the system, but will be proctored by government personnel. Test sponsors will not endorse the vendor's products after the test conclusion. The test sponsors assumes no cost or obligations, expressed or implied, for damage to, destruction of, or loss of such equipment, or for damages or injuries resulting from the submission to the sponsors of defective items for test.

6. The vendor understands that any data obtained during these evaluations, as well as the four page system description, becomes the property of the DoD Counterdrug Technology Development Program Office and the vendor does not possess a proprietary interest in neither the data nor the system description.

7. The vendor will not file any claim against the sponsors or otherwise seek compensation for any equipment, materials, supplies, information, or vendor services provided.

8. The sponsors are not bound, or obligated, to follow any recommendations of the vendor. The United States Government is not bound, nor is it obligated, in any way to give any special consideration to the vendor on future contracts.

9. If the vendor decides to use results of these evaluations in any form of product literature, it must be accompanied by the following phrase. "Results shown from the Facial Recognition Vendor Test 2000 do not constitute endorsement of any particular system by the Government." It must also be accompanied by a link to the final report that will be generated by the Government.

10. Participating Vendor Information

Company Name	
Product Name	
Point of Contact	
Mailing Address	
(Address Line 2)	
City / State / Zip	
Phone	
Fax	
Email Address	
Web Site Address	
Number of systems to submit for testing	
Number of systems to submit for optional access control system interface test	
If submitting system(s) for optional access control system interface test, please list any weigand interface requirements such as number of wires or number of data bits	

11. Request for Vendor Participation

"With my signature I authorize my company to participate in the Facial Recognition Vendor Test 2000. I have read, and agree to be tested according to, the test description on this form and on the Facial Recognition Vendor Test 2000 website at <http://www.dodcounterdrug.com/facialrecognition>. I understand how the facial recognition systems will be tested and how the results will be used. I understand that only commercially available facial recognition systems will be allowed to participate in these tests. Biometric systems that include facial recognition in cooperation with another biometric type will be allowed to participate, but only the facial recognition algorithm portion of that product will be tested.

"I understand that I must send original signed copies of this form and the Application for Access to NIST Special Database for Facial Recognition form to be allowed to participate in these tests. I must also provide a four page (maximum) document that explains the submitted system. I understand that I must provide a sample similarity file based on the development set of images that is available on the website. Results from the Recognition Performance Test must be written onto a Jaz Disk and given to the government immediately following completion of the test. If I am requesting to have two of my systems tested, I understand that I must provide with this application a written description that shows the difference between the systems so that the government will be able to decide if both will be allowed to participate

"I understand that test activities will be videotaped and that portions of the video may be used for promotional purposes. Any questions that I have had were answered on the FAQ page of the website. I understand that further test details and sample images will be provided in the future on the Facial Recognition Vendor Test 2000 web site. I understand that test details and modifications that are listed on the website supersede any details in the test overview. I understand that the exact testing schedule at NAVSEA Crane will be will be released in the future."

You will receive confirmation note that has your ID and password for access to the restricted area of this web site upon receipt of your completed form.

Application for Access to a Portion of the Development HumanID Data Set and FERET Database

1. Overview

The National Institute of Standards and Technology collects and maintains facial image databases for use by the Government for evaluating human identification technology. The Facial Recognition Vendor Test 2000 is one such evaluation.

2. Database Subsets to be Used

The Facial Recognition Vendor Test 2000 will use portions of the FERET database that was collected as part of the FERET program and the HumanID Data Set.

3. Vendor Access to Facial Recognition Vendor Test 2000 Demonstration Data Set

A small subset (~30 JPG images) will be placed on the restricted portion of the Facial Recognition Vendor Test 2000 website (<http://www.dodcounterdrug.com/facialrecognition>) on March 1. These images are given out as an example of the pictures in the databases and will give the vendor an opportunity to write sample similarity files to verify that they are in the correct format and are readable by the Government's scoring code.

The remainder of the test images, also in JPG format, will be given to the vendor on the day they arrive at NAVSEA Crane to take the test. The images will be given to the vendor on a CD-ROM. Vendors will not be allowed to copy these images onto their hard drive; they must be read directly off the CD-ROM. The vendor must return the CD-ROM to the government at test completion, assure the Government that none of the images are still resident on the test computer, and allow the Government to inspect all disks on the system to verify compliance.

INTRODUCTION

The DoD Counterdrug Technology Development Program Office, the National Institute of Justice (NIJ), the Defense Advanced Research Projects Agency (DARPA), NAVSEA Crane Division and NAVSEA Dahlgren Division are sponsoring an evaluation of commercial off the shelf (COTS) facial recognition products. The purpose of these evaluations is to accurately gauge the capabilities of facial recognition biometric systems that are currently available for purchase. The sponsoring agencies, as well as other government agencies, will use this information as a major factor when determining future procurement or development efforts. Participation in these evaluations is open to all facial recognition systems on the US commercial market. The U.S. Government will not compensate vendors to participate in these evaluations.

Participating vendors will be given access to the restricted area of this web site where they will be able to download important documents - such as the API for the recognition performance tests. The restricted area also has a question/answer forum where all discussion between participating vendors and the Government sponsors will take place. Participating vendors will also be given a set of practice images that are similar to those that they will be tested on.

Two categories of tests will be conducted: [Recognition Performance Tests](#) and [Product Usability Tests](#). For each category, multiple tests will be performed to measure system performance in verification mode and in identification mode. The Recognition Performance Tests will use the FERET test methodology with a new database of images. The Product Usability Tests will evaluate performance in both low and medium security access control scenarios. A more detailed description of the test is provided below.

QUALIFICATIONS

To participate in these evaluations, each vendor must provide commercial facial recognition system(s) that

will be available on the U.S. open market at the time of testing and up to two technicians to run the system through the tests. Vendors will also need to fill out [forms](#) requesting entrance in the test, and submit a four page (maximum) document that:

- Provides an overview of the submitted system
- Provides a component list for the submitted system
- Provide a detailed cost breakdown of the submitted system

Due dates for these requirements vary. Please see the [Upcoming Dates](#).

University and research systems will not be permitted (separate tests for these systems are being developed for the near future). Vendors with multi-biometric types in their systems will be allowed to participate if they have the proper interface to run using only facial recognition. Vendors will be able to pick the components of the system as they see fit keeping in mind that results from these tests, as well as the street price of each system at the time of testing, will be made available to the public.

Each vendor may be allowed to submit up to two systems for testing, but vendors must show that there is a clear difference between the two systems. For example, if a vendor has a high-end/high cost version and a low-end/low cost version they will be allowed to enter both versions. However, if the difference is merely a change of cameras, the second version will not be allowed. Final decision to allow more than one system will be made by the Government. The basis of this decision could be technical or to limit the number of systems to be tested.

TEST RESULTS

Results of the tests will be documented in a final report and, possibly, several international conference papers. The final report will contain each participating vendor's four page document as well as the results of the government test. All reports and papers will be made available to the public. Testing activities will be recorded using video cameras but the footage will not be released to the public. Portions of the video, however, may be used to provide a quick 5-10 minute overview of the tests. General observations of the capabilities within the facial recognition community may be made on this promotional video, but individual vendor's results will not be given.

RESTRICTED AREA INFO

Participating vendors will be given access to the restricted area of this web site where they will be able to download important documents - such as the API for the recognition performance. The restricted area also has a question/answer forum where all discussion between participating vendors and the Government sponsors will take place. A small development set of images will be available for download that will contain images similar to those that will be used for the actual tests.

RECOGNITION PERFORMANCE TESTS

The Recognition Performance Tests will be very similar to the original FERET tests that were sponsored by the DoD Counterdrug Technology Development Program Office. Since the conclusion of the original FERET program, the data sets and reports have been transferred to the National Institute of Standards and Technology (NIST), who is serving as a technical consultant for these tests. Images used in this test will be a combination of images from the FERET database as well as DARPA's new HumanID database.

For more information on the FERET tests, please see the following papers

[The FERET Evaluation Methodology for Face-Recognition Algorithms](#)

[The FERET Verification Testing Protocol for Face Recognition Algorithms](#)

On the day of the Recognition Performance Tests, the vendor will be given a set of test images in JPG format. The vendor may convert the images to another format if necessary, but no extra time will be given for this. The vendor will use their algorithm to compare each image to the others and report the similarity scores in a format that will be provided (in an API document located in the Restricted Area of this web site). The final report will show the results in the form of Receiver Operating Characteristic (ROC) curves for verification tests and Cumulative Match Characteristics (CMC) Curves for identification tests. Other forms of displaying information may also be used.

PRODUCT USABILITY TESTS

The Product Usability Tests will consist of two timed tests and an optional access control system interface test. The timed tests will be used to measure the response time of the overall system for two different operational scenario simulations: the Old Image Database Timed Test and the Enrollment Timed Test. These tests are described below. It is not necessary for a vendor to have an access control product to participate in these tests - these are operational scenarios that were developed to give the public a means of comparing the test results with something they would be familiar with. Each of the timed tests will be performed for both verification and identification and will be performed once with overhead fluorescent lighting and again with the addition of simulated back lighting. Results from the timed tests will be given in a format similar to the chart below.

Subject/Distance	4'	8'	12'
Cooperative	6.73	4.62	9.34
Uncooperative	9.67	7.43	X

Each test will show the time for the system to make a decision (if it makes a decision) and whether the decision is correct or not. The "X" in the chart shows that the system did not reach a decision before the time-out limit occurred. The number that is in red and underlined means that the system reached a decision, but it was the wrong decision.

Old Image Database Timed Test

The operational scenario for the Old Image Database Timed Test is that of a low security access control point

into the lobby of a building. The building's security officers want to improve security into the area but do not want to slow down the flow through the entry area. The security officers also do not want to mandate that the employees take the time to enroll into the new system so they will use their existing digital image database taken from the employee's picture ID badges. The employees may not be aware that they are being checked using a facial recognition system, so they will not be fully cooperative. The security officers would also like to install a facial recognition system in the lobby to automatically identify known bad guys who may be loitering outside the access points.

On the day of the test, the vendor will be given a database of images in JPG format for entry into their system. There will be only one image per subject and it is expected that the quality of these images will be fairly poor, but uniform. The vendor will be shown the low security target region of a hypothetical ROC curve. They will then adjust the sensitivities of the system to meet this goal according to the lighting conditions. The ROC curve location is merely a suggestion for meeting the desired low security level. Vendors may adjust sensitivities as they see fit before beginning the test, but once the test begins, they will not be allowed to adjust the settings. Once the system has been tuned, recognition will be attempted with several live test subjects. The test database will contain one image for each of the test subjects, in addition to other images.

For the verification portion of the test, each subject will stand at a maximum distance from the camera, and an ID number will be entered into the system to simulate a magnetic card swipe. A timer will then be started, and the subject will walk toward the camera. The subject will be looking in the general direction of the camera, but will not be looking at it directly. The timer will be stopped and the subject will stop walking if the system gives a verification result. If the subject reaches the minimum camera distance before the system gives a verification result, he will stop until the time limit is reached. The time required for the system to give a verification result, if any, will then be recorded as well as the distance at which the verification took place. If a verification result is not reached within the time limit or the system gives an incorrect verification result, these facts will be recorded. Each system will be tested using three different subjects. Someone will then attempt verification by holding an 8x10 color photograph of one test subject in front of his face.

For the identification portion of the test, each subject will stand at the maximum camera distance facing away from the camera. The timer will be started and the subject will turn and walk toward the camera as in the verification test. Identification time and distance will be recorded along with the correctness of the result and whether or not results were obtained within the time limit. Each system will again have three test subjects and someone will attempt identification with an 8x10 color photograph.

After both the verification and identification portions of the test have been completed using overhead fluorescent lights, back lighting will be used to simulate conditions in a building with windows. Vendors will be allowed to adjust the system sensitivities for these new lighting conditions, but once the test begins, they will not be allowed to adjust them further. The verification and identification portions of the test will then be repeated using the back lighting.

Enrollment Timed Test

The operational scenario for the Enrollment Timed Test is that of an access control door for a medium security area within the building previously described. In this case, employees will be enrolled in the facial recognition system using the standard procedures recommended by the vendor. The access control system on one door has been setup so that an individual enters his identity with a magnetic stripe card and the system must verify if this is indeed the correct individual. On another door, the system has been setup so that an individual simply walks up to the camera and the door opens if the identity of the individual matches an individual in the database with valid credentials. The employees will be aware that they are being checked using a facial recognition system, but may or may not be cooperative.

This test will be performed after the Old Image Database Timed Test. Vendors will remove the images of the

live test subjects from the database and enroll those subjects using their standard procedures. The vendor will then be shown a medium security target region of a hypothetical ROC curve so that sensitivities can be adjusted to meet this desired security level based on the lighting conditions. Recognition attempts will then be made using the same live test subjects of the previous test.

For the verification portion of the test, each subject will first stand at a maximum camera distance and simulate uncooperative behavior by using head movement without looking directly at the camera. An ID number will be entered into the system to simulate a magnetic card swipe and a timer will be started. If the system makes a verification result, the timer will be stopped and the time will be recorded. If verification results are not reached within the time limit or the system gives an incorrect verification result, these facts will be recorded. The subject will then repeat the test at the same location in a cooperative manner by looking directly at the camera. Each subject will repeat both the uncooperative and cooperative modes at several different camera distances. An 8x10 color photograph of one test subject will then be used for verification attempts at each distance.

For the identification portion of the test, each subject will again stand at several distinct camera distances and behave in both uncooperative and cooperative modes. However, this time they will begin by facing away from the camera and turn toward the camera when the timer is started. Identification times will be recorded in the same manner as the verification times. An 8x10 color photograph of one test subject will then be used for identification attempts at each distance.

After both the verification and identification portions of the test have been completed using overhead fluorescent lights, back lighting will be added and vendors may adjust system sensitivities. The verification and identification portions of the test will then be repeated using the back lighting.

Access Control System Interface Test

This is an optional test meant to determine if the facial recognition system can interface successfully with an access control system. To participate in this optional test, the facial recognition system must have a WIEGAND interface.

The goal is to test the interface rather than the facial recognition algorithm. The vendor will connect the facial recognition system to an access control system via a standard WIEGAND interface and enroll a single test subject that was successfully verified in the Enrollment Timed Test. The subject will present their identity to the access control system and then make three attempts to use the facial recognition system for verification. If the access control system receives a valid signal through the WIEGAND interface upon successful verification, the system will have passed this portion of the test. Vendors must indicate their intent to participate in this optional test. Vendors should also indicate any particular form of the WIEGAND standard required by their system, i.e. number of wires or number of data bits.

27. [When will the results from the Facial Recognition Vendor Test 2000 be released & where can we get them?](#)

1. Who is sponsoring/running these evaluations?

The DoD Counterdrug Technology Development Program Office, the National Institute of Justice (NIJ), the Defense Advanced Research Projects Agency (DARPA), and NAVSEA Crane Division are sponsoring these evaluations. Numerous individuals from NAVSEA-Dahlgren Division volunteered their time to help us make part of the image database. The National Institute of Standards and Technology has been very busy advising us throughout the evaluation development and were instrumental in assembling the various picture databases that will be used for this evaluation (and others). Technical Agents from the DoD Counterdrug Technology Development Office will be administering the evaluation, scoring the results, and writing the final report.

2. Is this evaluation part of the FERET program?

Not really. Although the DoD Counterdrug Technology Development Program also sponsored FERET, Dr. P. Jonathon Phillips (who was the Technical Agent for the FERET program) is actively involved with these tests, and this test uses part of the FERET database and scoring algorithms, this is not considered a part of the FERET program. The FERET program, which began in 1993, consists of three parts:

- Sponsoring research
- Collecting the FERET database
- The FERET evaluations

The goal of the FERET program is to advance the state of the art in facial recognition. The purpose of these evaluations is to measure the current capabilities of facial recognition to determine if it is ready for application or if further development work is still needed.

3. So, this could be the first step of future government activities with facial recognition?

Absolutely, although no specific plans are currently in place. The sponsors, as well as other government agencies that are unable to help sponsor these evaluations, have been studying facial recognition technology for several years and see numerous potential applications. The results of these evaluations will form the basis of our future efforts over the next few years.

4. Who is eligible to participate in these evaluations?

Anyone that has a commercially available system that is available on the United States market is eligible to participate. The government, or a private company that reads the results of the evaluation, must be able to call the vendor and purchase the system that was tested without any development efforts.

5. How do I sign up to participate in these evaluations?

You need to fill out, sign, and mail (original copy) two forms to the government to participate in these evaluations.

6. Where do I send the forms?

Send them to:

Mr. Duane Blackburn
DoD Counterdrug Technology Development Program Office
NSWCDD Code T43

7. What is the purpose of the required forms?

The government needs a record that the vendor has volunteered to participate in these evaluations and understands how the evaluations will be performed and how the results will be released. Additionally, we need a separate record that each vendor has requested and promised to use NIST databases according to the limitations listed on the form.

8. How will the four page writeup be used by the government?

The four page (maximum) writeup will be a section in the final report that will be released to the public. This is your opportunity to describe your system to everyone that reads the report. Please, no salesman language!

9. When will I receive my company's ID and PIN to access the restricted area of this site?

You will be E-mailed your company's ID and PIN to access the restricted area of this site as soon as the government receives the original copies of the two required forms.

10. When will the Image Development Test Set be available?

The Image Development Test Set will be available on the restricted area of this site on March 8.

11. When will the API documentation be available & what is its purpose?

The API documentation will be available on the restricted area of this site on March 8. The Recognition Performance portion of these tests uses the FERET scoring code. In order to use that code, we must have your results in a standard format.

12. If the sample images & API documentation are not available until March 8, why should I sign up for these tests before then?

The restricted area of this web site has a second FAQ page. The FAQ on the public side will answer all general questions. The restricted FAQ page will answer more in-depth questions and allow a forum for Q&A that is not in the public eye.

13. What if my COTS product cannot produce a similarity file?

You will be allowed to modify your COTS system so that it will produce a similarity file. However, this ipatchî must also be available to the general public. A key of any test is the ability for someone else to run the same tests using their images. NIST is currently writing a version of the scoring code that will eventually be made available to the general public.

14. Why do I have to send a similarity file to the government based on the Image Development Test

Set?

We need to verify that we can properly read your similarity file before you arrive for testing.

15. What happens if I do not send the sample similarity file by the required date?

You will not be allowed to participate in these evaluations.

**16. What happens if there is something wrong with my sample similarity file?**

You will be allowed to fix the problem and resend the sample similarity file as many times as needed until the day before you are scheduled to take the tests.

17. When will I receive the actual images that will be used for the evaluation?

You will receive the actual evaluation images on the same day that you take the Recognition Performance portion of these evaluations.

18. Can I keep a copy of these images once I have finished the evaluation?

No. In fact, you will not be allowed to even temporarily copy these images onto your hard drive. You will need to access the images directly off the CD during the evaluation.

**19. When will I need to provide the government the similarity scores for the Recognition Performance Test?**

As soon as you have finished taking the Recognition Performance Test.

20. What media can I use to provide the similarity scores?

Jaz disk.

21. How long will it take me to perform these tests?

It will take two days for each vendor to complete these tests. You will perform the Recognition Performance test on one day and the Product Usability test on the other.

**22. Where and when will the tests take place?**

The tests will begin in April. You will be notified by March 24 the two days that you will be taking the tests. The tests will take place at NAVSEA-Crane Division in Crane, Indiana (approximately 60 miles south of Indianapolis).

23. Can my company request preferred test dates?

Yes. If you've already registered for the tests, just send your preferred dates to Mike Bone, bone_mike@crane.navy.mil. We can't guarantee that your dates will be available, but we'll try to work out any conflicts between you and other vendors that request the same dates. It would be very helpful if you send

alternate dates in case your first choice is unavailable.

24. Will I be compensated for participating in these evaluations?

Unfortunately, no. The government will not be able to fund participating vendors. The added exposure to your product and the benefits of healthy competition with your peers is all we are able to provide.

25. Can my company propose changes to the planned tests?

Absolutely, we are always looking for new ideas on how to compare one system to another. The sponsors, however, have spent considerable time developing the test plan for the Facial Recognition Vendor Test 2000, and have decided that the method given on this web site is how we will be performing these tests. It would be unfair to other test participants to change the tests at this point. We will gladly hold on to all proposed changes and will study them if we should do another series of tests in the future.

26. Can my company enter a facial recognition system based on thermal imaging?

Unfortunately, no. All the images collected for this test were captured using cameras sensitive in the visible spectrum. Testing thermal imaging systems would require us to collect images using thermal sensors. If government agencies show increased interest in these systems, we may consider doing future tests with a separate thermal imaging category.

27. When will the results from the Facial Recognition Vendor Test 2000 be released & where can we get them?

Due to the preferred evaluation dates of the participating vendors, as well as lead-time requirements for some of the non-US based vendors, the evaluation schedule was pushed into the early part of June. Once this is complete it will take a few weeks to analyze the data to ensure its accuracy and then a couple of weeks to finalize the report. We plan to make the results available as soon as possible, but we will make sure that the results are correct before releasing them. The results will be made available at this web site (<http://www.dodcounterdrug.com/facialrecognition>) which will be undergoing a major renovation. Look for these changes soon!

If you are interested in participating in these evaluations, or if you are participating and have specific questions about these tests, please contact:

Mr. Mike Bone

Bone_Mike@crane.navy.mil

Crane Division, Naval Surface Warfare Center

Application for Participating in Facial Recognition Vendor Test 2000

1. Overview

The DoD Counterdrug Technology Development Program Office, the National Institute of Justice (NIJ), the Defense Advanced Research Projects Agency (DARPA), NAVSEA Crane Division and NAVSEA Dahlgren Division are sponsoring an evaluation of commercial off the shelf (COTS) facial recognition products. The purpose of these evaluations is to accurately gauge the capabilities of facial recognition biometric systems that are currently available for purchase. The sponsoring agencies, as well as other government agencies, will use this information as a major factor when determining future procurement or development efforts. Participation in these tests is open to all facial recognition systems on the US commercial market. The U.S. Government will not compensate vendors to participate in these tests.

2. Test Description

Two categories of tests will be conducted: Recognition Performance Tests and Product Usability Tests. For each category, multiple tests will be performed to measure system performance in verification mode and in identification mode. The Recognition Performance Tests will use the FERET test methodology with a new database of images. The Product Usability Tests will evaluate performance in both low and medium security access control scenarios.

2.1 Recognition Performance Test

The Recognition Performance Tests will be very similar to the original FERET tests that were sponsored by the DoD Counterdrug Technology Development Program Office. Since the conclusion of the original FERET program, the data sets and reports have been transferred to the National Institute of Standards and Technology (NIST), who is serving as a technical consultant for these tests. Images used in this test will be a combination of images from the FERET database as well as DARPA's new HumanID database.

2.2 Product Usability Test

The Product Usability Tests will consist of two timed tests and an optional access control system interface test. Each of the timed tests will show the time for the system to make a decision (if it makes a decision) and whether the decision is correct or not. These tests will be performed for both identification and verification, as well as for different lighting conditions. The optional access control system interface tests will test the facial recognition systems' ability to communicate with an access control system using the WIEGAND standard.

3. Required System Description

On the first day of testing, participating vendors will be required to submit a four page (maximum) document that:

- Provides an overview of the submitted system
- Provides a component list for the submitted system
- Provide a detailed cost breakdown of the submitted system

4. Release of Evaluation Results

Results of the evaluations will be documented in a final report and, possibly, several international conference papers. The final report will contain each participating vendor's four page document as well as the results of the government evaluation. All reports and papers will be made available to the public. Testing activities will be recorded using video cameras but the footage will not be released to the public. Portions of the video, however, may be used to provide a quick 5-10 minute overview of the tests.

5. The Facial Recognition Vendor Test 2000 is being conducted for the sole purpose of determining the capability of facial recognition systems and not for fulfilling immediate or long-term mission requirements. The examination and test of these systems will in no way, expressed or implied, obligate the DoD Counterdrug Technology Development Program Office, or any of the test co-sponsors (hereinafter referred to as the "sponsors"), to purchase, rent, or otherwise acquire the systems tested. Manufacture, transportation, maintenance, and company test representatives shall be accomplished without cost to the sponsors. Tests will be conducted by an authorized representative of the vendor furnishing the system, but will be proctored by government personnel. Test sponsors will not endorse the vendor's products after the test conclusion. The test sponsors assumes no cost or obligations, expressed or implied, for damage to, destruction of, or loss of such equipment, or for damages or injuries resulting from the submission to the sponsors of defective items for test.
6. The vendor understands that any data obtained during these evaluations, as well as the four page system description, becomes the property of the DoD Counterdrug Technology Development Program Office and the vendor does not possess a proprietary interest in neither the data nor the system description.
7. The vendor will not file any claim against the sponsors or otherwise seek compensation for any equipment, materials, supplies, information, or vendor services provided.
8. The sponsors are not bound, or obligated, to follow any recommendations of the vendor. The United States Government is not bound, nor is it obligated, in any way to give any special consideration to the vendor on future contracts.
9. If the vendor decides to use results of these evaluations in any form of product literature, it must be accompanied by the following phrase. "Results shown from the Facial Recognition Vendor Test 2000 do not constitute endorsement of any particular system by the Government." It must also be accompanied by a link to the final report that will be generated by the Government.

10. Participating Vendor Information

NOTE: All information is required

Company Name:
Product Name:
Point of Contact: (First Name / Last Name)
Mailing Address:

City, State, & Zip -
Phone:
Fax:
Email:
Web Site Address:

Number of systems to submit for testing:

- One (1) Two (2)

Number of systems to submit for optional Access Control System Interface Test:

- Zero (0) One (1)

If submitting system(s) for optional access control system interface test, please list any weigand interface requirements such as number of wires or number of data bits below:

Please proof the information you entered above to ensure it is correct before submitting.

NOTE: When you press 'Submit Form' (below), a completed form will be displayed. **Your submission is not complete until you print, obtain appropriate signatures, and mail the completed form to Duane Blackburn (address is provided on the form).**

11. Request for Vendor Participation

"With my signature I authorize my company to participate in the Facial Recognition Vendor Test 2000. I have read, and agree to be tested according to, the test description on this form and on the Facial Recognition Vendor Test 2000 website at [http://www.dodcounterdrug.com/facial recognition](http://www.dodcounterdrug.com/facial%20recognition). I understand how the facial recognition systems will be tested and how the results will be used. I understand that only commercially available facial recognition systems will be allowed to participate in these tests. Biometric systems that include facial recognition in cooperation with another biometric type will be allowed to participate, but only the facial recognition algorithm portion of that product will be tested.

"I understand that I must send original signed copies of this form and the Application for Access to NIST Special Database for Facial Recognition form to be allowed to participate in these tests. I must also provide a four page (maximum) document that explains the submitted system. I understand that I must provide a sample similarity file based on the development set of images that is available on the website. Results from the Recognition Performance Test must be written onto a Jaz disk and given to the government immediately following completion of the test. If I am requesting to have two of my systems tested, I understand that I must provide with this application a written description that shows the difference between the systems so that the government will be able to decide if both will be allowed to participate

"I understand that test activities will be videotaped and that portions of the video may be used for promotional purposes. Any questions that I have had were answered on the FAQ page of the website. I understand that further test details and sample images will be provided in the future on the Facial Recognition Vendor Test 2000 web site. I understand that test details and modifications that are listed on the website supersede any details in the test overview. I understand that the exact testing schedule at NAVSEA Crane will be will be released in the future."

If you have a question not currently addressed in the Public or Restricted (for those who have access) FAQ areas, please ask it here by completing the form below. Your question will automatically be Emailed to the appropriate individuals. Answers to questions will be made available in the appropriate FAQ area (Public or Restricted). Due to volume, all questions may not receive individual attention. Please check this site for responses.

Your Question:

Application for Access to a Portion of the Development HumanID Data Set and FERET Database

1. Overview

The National Institute of Standards and Technology collects and maintains facial image databases for use by the Government for evaluating human identification technology. The Facial Recognition Vendor Test 2000 is one such evaluation.

2. Database Subsets to be Used

The Facial Recognition Vendor Test 2000 will use portions of the FERET database that was collected as part of the FERET program and the HumanID Data Set.

3. Vendor Access to Facial Recognition Vendor Test 2000 Demonstration Data Set

A small subset (~30 JPG images) will be placed on the restricted portion of the Facial Recognition Vendor Test 2000 website (<http://www.dodcounterdrug.com/facialrecognition>) on March 1. These images are given out as an example of the pictures in the databases and will give the vendor an opportunity to write sample similarity files to verify that they are in the correct format and are readable by the Government's scoring code.

The remainder of the test images, also in JPG format, will be given to the vendor on the day they arrive at NAVSEA Crane to take the test. The images will be given to the vendor on a CD-ROM. Vendors will not be allowed to copy these images onto their hard drive; they must be read directly off the CD-ROM. The vendor must return the CD-ROM to the government at test completion, assure the Government that none of the images are still resident on the test computer, and allow the Government to inspect all disks on the system to verify compliance.

4. Participating Vendor Information

NOTE: All information is required

Web Site Address:	<input type="text"/>

Number of systems to submit for testing:

- One (1) Two (2)

Number of systems to submit for optional Access Control System Interface Test:

- Zero (0) One (1)

Web Site Address:

Please proof the information you entered above to ensure it is correct before submitting.

NOTE: When you press 'Submit Form' (below), a completed form will be displayed. **Your submission is not complete until you print, obtain appropriate signatures, and mail the completed form to Duane Blackburn (address is provided on the form).**

5. Request for Access to the Facial Recognition Vendor Test 2000 Demonstration Data Test Set

"With my signature I authorize my company to use the NIST Special Database for Facial Recognition, in association with the Facial Recognition Vendor Test 2000, and promise to do so according to the rules and limitations listed on this form."

[Download API \(.pdf\)](#)

1. Overview

This document describes the image data supplied to vendors and the similarity files expected from vendors. The text refers to two data sets: the first, for release in early March 2000 is termed the Development Set; the second is the much larger Test Collection that will be used at the tests in April.

2. Images to Vendors

Development Set

The images provided in the development set are intended to ensure that vendors are capable of handling the images that will be provided in the Recognition Test. There are 17 images in the development set. They are a small subset of those that will be used for the Vendor Recognition Test. They are representative of the images in the larger set. The Test Collection will contain on the order of 10000 images.

Image Formats

The images are all in standard JPEG/JFIF format. They are readable by most image processing and image viewing utilities including the major web browsers. All images may be read using source code from the Independent JPEG Group (<http://www.ijg.org/>) available for download at <ftp://ftp.uu.net/graphics/jpeg/jpegsrc.v6b.tar.gz>.

The images come from various sources and were generally obtained from multiple different devices on different dates. The images do not all have the same width, height nor precision; some are color, some are grayscale; the amount of compression varies.

Naming convention

The files have arbitrary filenames of this form: i00000.jpg ... i00016.jpg. For the larger set containing N images the integer part of the filename will range from 0 to N-1. All filenames contain precisely 10 characters (1+5+1+3).

3. Results from Vendors

Similarity Files

The vendors are required to submit their results as "similarity files", which are described below. This implements the FERET protocol described in "The FERET Evaluation Methodology for Face Recognition Algorithms" published as NIST IR 6264 available here: <http://www.itl.nist.gov/iaui/894.03/pubs.html#face>.

A similarity file contains a numerical similarity match between an image i_x and all other images including i_x itself. For each image provided, vendors must generate and submit a similarity file. The format is described below. For a test collection containing N images, vendors must submit N similarity files, each file containing N lines. Each line must contain an image name and a scalar value indicating the similarity between two images; a large value indicates that two images are closely

matched whereas a small value indicates dissimilarity.

Naming convention

For an image, named for example i00016.jpg, vendors must submit a corresponding similarity file named i00016.sim. Any other file name is illegal.

Format

Similarity files are plain ASCII text files. For a data collection containing N images, a similarity file contains exactly N lines. Each line contains two fields separated by white space ("space Hex 20, or "\t" tab Hex 09). Blank lines are illegal.

First Field

The first field on each line contains the name of one of the images provided to the vendors in the test, e.g. i00016.jpg. Pathnames (for example: /data/results/ or d:\data\results) that precede the file name are illegal. Each file name occurs exactly once in the file.

Second Field

The second item is a floating point value that typically would be generated using the ISO C idioms for printing floating point numbers, namely: "%f", "%e" or "%E" as supplied to fprintf(). While a value may also be a decimal integer it must be readable as a floating point value. Legal examples of similarity values are 3.14159 6.626e-34 2.998e+08 42 Negative numbers are permissible. Large negative numbers indicate very dissimilar images; smaller negative numbers indicate less dissimilarity. Large positive numbers indicated very similar images. Undefined numbers (e.g. NaN and Inf) are illegal.

Files must be sorted

The file must be sorted in numerically decreasing order of the value in the second field; i.e. any given value must be less than or equal to the value on the previous line.

Submission

Vendors will place all similarity files on 2GB Iomega Jaz disks (<http://www.iomega.com>) using as many as are necessary to hold all the files. Partial submissions are ineligible ñ the total number of files submitted must be identically N. All files must end with the ".sim" extension. Files must not be compressed, merged or archived in any way. Zip drives and smaller Jaz drives are not permitted.

The collection of files submitted by a vendor will be screened before scoring to affirm their validity. A vendor will be notified if their submission does not conform to the specifications above.

Submission of the Development Set

The development set must be submitted according to the rules given above. This paragraph is a specific reiteration thereof and is a description of the steps that Vendors must take. There are seventeen images in the development set, so N = 17. Therefore the images are named i00000.jpg through i00016.jpg. Vendors must supply exactly 17 similarity files named i00000.sim through i00016.sim. Further each similarity file must contain exactly 17 lines; each line will contain the name of one of the images, and the similarity of that image to the one for which the file is named. An image name can occur only once in each similarity file. The image for which the file is named will also occur in its own similarity file. The files are sorted.

Caution

As stated above, for a collection containing N images, a vendor must submit N similarity files and each file has N lines. The total volume of similarity data therefore increases quadratically with N. Vendors should be aware that when the number of images is on the order of 10000 the total disk space required for the similarity files may well be in excess of 2 gigabytes. Vendors are advised that this volume of data may fill common hard drive partitions, and should plan proactively.

Example Similarity File: i00005.sim

```
i00006.jpg 96.3  
i00005.jpg 96.0  
i00000.jpg 92.2  
i00002.jpg 90.9  
i00001.jpg 88.5  
i00008.jpg 8.81e+01  
i00007.jpg 84.0  
i00003.jpg 80.04001  
i00009.jpg 77  
i00010.jpg 63.1  
i00004.jpg 50.1111  
i00011.jpg 33.2  
i00012.jpg 33.2  
i00013.jpg 33.0  
i00015.jpg 20  
i00014.jpg 11.03  
i00016.jpg 200.00
```

Note that there are 17 entries and each image is referenced exactly once.

17. [Who do I send the development set similarity files to?](#)
18. [Can we bring two separate systems to the test in order to run the Recognition Performance Test and the Product Usability Tests in parallel?](#)
19. [Why separate performance and usability tests? How can the results be combined and assessed? If I was choosing a system to buy, I'd want to know the recognition performance on real-world images - i.e. those from the usability test. Performance and usability are not separable so it seems scientifically dangerous to test them separately - surely the answers you need are to the question 'Which system works best on real-world images?'](#)

20. Two questions in one really: What proportion of the recognition test set are of very small faces, such as 'i00011'? Our system will not return a similarity score for such images. It is a perfectly reasonable response for a system to 'abstain' when it does not consider the input data to be reliable enough to give an accurate similarity score. How is 'abstention' dealt with in the test?
21. Are the images 24 bit color and 8 bit grayscale only or are some color mapped (i.e. 8 bit color)?
22. What format will the images be in for the Product Usability Test? Where will the images be located?
23. What would happen if I was unable to generate an application in time that would satisfy the Product Usability Test but I do have one that would do the Recognition Performance Test? Could I still take the Recognition Performance Test but not the Product Usability Test?
24. When doing the Enrollment Timed Test, how many images will we be able to enroll per person? Our normal procedure is to enroll more than one.
25. I'd like to ship my system(s) to you in advance. Can you supply monitors for us to use so we can save shipping costs and avoid the risk of damage?
26. Can you provide an uninterruptible power supply for the Recognition Performance Test in case of a power outage during the overnight processing?
27. Can we still submit questions about the test once testing begins?
28. Can we e-mail our sample similarity files instead of mailing a JAZ disk?
29. Can we setup our systems on the day we arrive so we're ready to begin the next day?
30. Where are the targets located relative to the camera?

1. How many images will be used for the Recognition Performance test?

The exact number of images has not been determined since the image are still being processed. However, we expect the database to contain about 10,000 images.

2. What if I have one system that does only live video recognition and one system that does only offline recognition?

As long as both systems use the same recognition engine, both may be tested. The offline system will undergo the Recognition Performance test. The live video system will undergo the Product Usability tests. The product descriptions that you provide should state the intended use of each system as well as the fact that each system is built around the same recognition algorithm.

3. For the Recognition Performance Test, will we be allowed to read the images and make/store a template of the image on our hard disk so that we only have to make a template once? Will I be able to write the similarity files to the hard disk during processing & then copy the files to the Jaz disk?

Yes, this is the preferred method since it is significantly faster. All data and files derived from the images (i.e. templates, similarity files) must be removed at the conclusion of the test. The government must be allowed to ensure this has been completed.

4. You have stated that we will be allowed one day to perform the Recognition Performance Test, but our studies have indicated that it will take XX hours to do these. What will we do?

This question surprised the sponsors of the test since our baseline algorithm was able to perform this test with 10000 images in 6.5 hours (on a standard 1998 400MHz pc) and the longest period required in the FERET program, with significantly slower computers, was two days. We will have to modify our testing procedures slightly. Vendors will be given up to three days to perform the Recognition Performance Test - this includes template generation as well as matching, sorting results, and writing the similarity files. Matching and template

generation must begin with i00000.jpg, continue with i00001.jpg, then i00002.jpg and so forth. Vendors will be allowed to continue testing until the time limit is reached. Test results will be released based only on those images that all vendors provided results. However, if one vendor finishes a small number of the images & all the other vendors complete the entire set, the Government will be forced to make a decision on how to release the results.

5. Will we be able to have the computer make comparisons & write similarity files at night?

Yes. Hours for the test area(s) are 0900-1700 every day. This is the only time that anyone will be allowed in the test area(s). You may setup your computer to run scores during off-hours, but this will be unsupervised by vendor representatives or the Government. The Government suggests that you provide some technique so that if your system crashes during the analysis you will not have to start the process again from the beginning.

6. In some of the images in the Facial Recognition Vendor Test 2000 Demonstration Data Set my algorithm was not able to automatically find the eyes. How will this affect my test results?

This is a problem that was first encountered in the FERET evaluations and is accounted for in the scoring code. This is a system level test, so a failure to acquire on a particular image (which is scored the same as a failure to identify) is a valid measurement of system performance. For a real world example, consider a facial recognition product that is comparing a picture database to images from a surveillance camera. If the facial recognition engine cannot find the eyes on a subject in the surveillance camera it could turn into a significant problem!

7. My company does not have a copy of the FERET development image set (or recently acquired these images) and we are worried that other vendors, who have these images, may have an advantage. How is this being taken care of?

The FERET development image set has been available to anyone that would be eligible to participate in these evaluations. However, only 1/3 of the FERET database has been seen by those outside the government. The other 2/3 has been sequestered for tests such as these. The FERET images used in these evaluations, which will only be a portion of the total images, will be from the previously sequestered images.

8. How long will we be allowed to take the Product Usability Test?

You will be given one full test day (0900-1700)

9. My commercial product does not have a verification mode. How will this affect my participation?

You will be allowed to play with templates & directories so that you can do an "identification" analysis with only the verification test subject in the database as long as you are able to complete the entire test during the test period.

10. The use of live subjects in the Product Usability Test throws some uncertainties in the evaluation. How will this be handled?

The Product Usability Test is more of an operability measure than a performance analysis (which is the Recognition Performance Test). The goal is to show that time is a concern when choosing these systems and that certain parameters such as distance and lighting can change this time. Consistent test subjects are still necessary, however. Two control methods will be in place to help with this. The first is that the test subjects will be required to walk a certain path and look at specific locations. The second is that the test subjects will practice this several times before the first vendor is tested so that they are in a routine before the tests begin.

11. Will the test subjects always be moving?

No. At times they will be standing in a stationary location.

12. Will there be individuals other than the test subjects in the field of view?

No.

13. My product wasn't developed for access control so we don't have a live subject measure. Won't the test using the picture paint an unfair portrait of my product?

The sponsors fully understand this concern and have planned accordingly. Access control was chosen as the scenario for the product usability test. Other scenarios do exist, such as booking stations, where a "live" test would not be needed but would limit the amount of realistic data that we could collect. The Government plans to have text in the test report stating that failure of the "live" test is not a concern for non-access control products (it is for access control products!).

We also invite participating vendors to comment on this in their 4 page system write-up.

14. Approximately how many images will be in the database for the Product Usability Test?

On the order of 150 images.

15. Asking us to set our systems so that they fall in an approximate range on a hypothetical ROC curve seems a bit too vague. Could you narrow this down for us?

Sure, we're not completely inflexible! Instead of a hypothetical ROC curve, we will provide you with a target false acceptance rate to shoot for. These rates will be included in the test plan that will be available on the restricted portion of the Facial Recognition Vendor Test 2000 web site.

16. Will the vendors need to bring their own equipment (computer, camera, etc.) or will the government be providing these?

This is a system test & the Government wants each vendor to provide the components they would normally recommend to someone that has these requirements. The makeup of the system (including computer, camera, etc) and the cost breakdown should be provided in the vendor's four page product description.

17. Who do I send the development set similarity files to?

You need to send these to Mike Bone so that he receives them by March 27.

18. Can we bring two separate systems to the test in order to run the Recognition Performance Test and the Product Usability Tests in parallel?

Absolutely. In fact we encourage you to do so. This will help speed up the testing process and eliminate some of the "down time" while the Recognition Performance Test is processing. The systems must be the same (including recognition algorithm, computer, and miscellaneous components such as processor and memory). Otherwise you are attempting to enter two different systems.

19. Why separate performance and usability tests? How can the results be combined and assessed? If I was choosing a system to buy, I'd want to know the recognition performance on real-world images - i.e. those from the usability test. Performance and usability are not separable so it seems scientifically dangerous to test them separately - surely the answers you need are to the question 'Which system works best on real-world images?'

There are a number of different reasons for conducting an evaluation, and the design of the evaluation is based on the desired purpose. The purposes of the Facial Recognition Vendor Test 2000 are to advance the state-of-the-art, to measure the current state-of-the-art, and to measure the performance of system X at control access to building Y. A more detailed discussion on the subject of evaluating biometric systems can be found in "Introduction to Evaluating Biometrics Systems" in the February 2000 issue of IEEE Computer.

The purpose of the recognition performance part of the Facial Recognition Vendor Test 2000 is assessing the state-of-the-art of commercially available face recognition systems. In terms of the above article, it is a technology test and is designed to assess general ability. This includes the ability to perform identification and verification. This part of the test is designed to evaluate performance on a large dataset.

The purpose of the product usability part is to assess and determine how the systems would function from an operational point of view. Performing two separate, but complimentary, tests allows for a much more detailed understanding of the state-of-the-art. If one were to field or consider a face recognition product for a specific application, we recommend testing candidate face recognition products in that specific application.

20. Two questions in one really: What proportion of the recognition test set are of very small faces, such as 'i00011'? Our system will not return a similarity score for such images. It is a perfectly reasonable response for a system to 'abstain' when it does not consider the input data to be reliable enough to give an accurate similarity score. How is 'abstention' dealt with in the test?

The performance test is intended to assess the state of the art of face recognition "at a distance" - the distance may vary (between 1 meter and maybe 12 meters) as is evident in the Development Set.

The FERET protocol of Sep 96 allows for the scoring of subsets of the images; ie those that belong to certain categories. There will not be one aggregated performance number over all images so if a vendor abstains from certain subsets it will only show in the scoring of those subsets.

One such result of the test will include how state of the art algorithms degrade as the distance increases (or equivalently as resolution decreases). If a vendor abstains from this category of images, it will not affect their performance figures on other subsets (lighting, pose, facial expression etc.)

The vendor should supply a small similarity value in the cases where it abstains. "Small" in this case should be smaller than any value they supplied for the images that they did not abstain on.

21. Are the images 24 bit color and 8 bit grayscale only or are some color mapped (i.e. 8 bit color)?

All images are either 24 bit color or 8 bit grayscale. There are no color mapped images.

22. What format will the images be in for the Product Usability Test? Where will the images be located?

The images will be similar to image i00012.jpg in the Image Development Set. They will be located in a subdirectory of a JAZ disk.

23. What would happen if I was unable to generate an application in time that would satisfy the Product Usability Test but I do have one that would do the Recognition Performance Test? Could I still take the Recognition Performance Test but not the Product Usability Test?

The test report would simply state that your company declined to submit a product for the Product Usability Test. It would be up to you to explain why in your 4-page system description.

24. When doing the Enrollment Timed Test, how many images will we be able to enroll per person? Our normal procedure is to enroll more than one.

You may enroll the live subjects with as many images as your procedure requires. The idea is that you do the things that you would recommend to your customers to achieve the best results. This distinguishes the results of this test from the Old Image Database Timed Test where you must enroll just the images made available to you.

25. I'd like to ship my system(s) to you in advance. Can you supply monitors for us to use so we can save shipping costs and avoid the risk of damage?

We have a few monitors that we can make available to you during the tests. Just send e-mail to Mike Bone stating your requirements and we'll see if any of our monitors fit your needs. Also, be sure to include the monitor you would normally use in your system description and price.

26. Can you provide an uninterruptible power supply for the Recognition Performance Test in case of a power outage during the overnight processing?

Yes, we will provide a small UPS. It won't last through an extended outage, but should handle the unlikely event of a small power glitch.

27. Can we still submit questions about the test once testing begins?

It wouldn't be fair to the vendors who have already been tested if the other vendors are able to get additional information about how the test will be run. We will continue to freely answer questions and post them to the restricted area FAQ until COB April 7. After that, you can still send questions, but we will use our judgement in deciding whether or not to answer them. If we decide that answering your question would give your company an unfair advantage, we will decline to do so.

28. Can we e-mail our sample similarity files instead of mailing a JAZ disk?

Yes. You can e-mail them to Mike Bone at bone_mike@crane.navy.mil, but you must ensure that you are able to read/write to a Jaz disk prior to testing. We will not give you additional time to setup a Jaz drive on your system at the test site.

29. Can we setup our systems on the day we arrive so we're ready to begin the next day?

You can setup your system for the Recognition Performance Test the day you arrive then begin the test the next day if you wish. You can also begin the test on the day you arrive. The current test plan states that the 72 hour time limit includes setup time, but this will be changed in the next revision.

The Product Usability Tests will be run differently, however. The 0900 - 1700 time limit will include setup time. You will not be allowed to setup on your arrival date and start the test the next day. The reason for this is that the amount of time available on the arrival date may vary between vendors. This means that some would gain an advantage by having more time to tune their system to the environment. To be fair to all vendors, we must limit

setup activities to the 0900 - 1700 time limit imposed on the test.

30. Where are the targets located relative to the camera?

The left and right targets are spaced 18 feet apart on a wall located 16.5 feet behind the camera mark. The camera mark is located in the center of these 2 targets. The center target is located at the camera mark and the center of the target is 6 inches above the floor.

The images available for download constitute the Facial Recognition Vendor Test 2000 Demonstration Data Set, which is a subset of the HumanID Data Set. As such, access to these images are controlled. You have been given permission to use these images since you have signed the form "Application for Access to a Portion of the Development HumanID Data Set and FERET Database" on this web site. Do not share these images with anyone outside of your organizational control.

For your convenience, the Data Set is provided in one compressed (.zip) file.

[Download Data Set, FRVTImages.zip \(approximately 1MB\)](#)

A rectangular button with a dark red background and a faint geometric pattern. The word "Logout" is written in a white, sans-serif font on the right side of the button.

Test Plan Document

The following document contains the test plan that will be followed for FRVT 2000. We're still doing trial runs with the test subjects to give them some practice and fine tune the procedures, so there may be some minor modifications to the plan in the following week. However, the basic testing structure will remain the same and no new tests will be added.

Note: The conversion of the test plan to PDF format didn't seem to work very well on the data recording tables in the appendix. Although they don't look right when viewed on screen, they seem to look OK when printed to a PostScript printer.

[Test Plan Document](#) (March 24, 2000)

[Test Plan Document](#) (March 31, 2000)

UPDATE March 31, 2000: The test plan has been modified slightly to clear up a few points of confusion and to incorporate some improvements in the live subject procedures that were identified in the practice sessions. Changes are as follows:

- Test Overview -> GeneralFixed typing error in first paragraph. Updated start time requirements for tests.
- Test Overview -> Test Space -> Room Layout.Reworded Station 2 description to clarify.
- Test Overview -> Test Space -> Floor Marks.Reworded to clarify.
- Test Overview -> Test Space -> Visual Targets.Added more details on the location of targets.
- Test Overview -> Testing Conventions -> Start Location.Changed the way subjects begin identification trials. Rather than beginning with their backs to the camera then turning 180 degrees when the timer is started, we found it was easier for the subjects to begin facing perpendicular to the camera path, but with their heads turned to face away from the camera. This requires subjects to merely turn their bodies 90 degrees when the timer is started.
- Recognition Performance Test -> Test Description -> Time Limits.Updated to allow setup of vendor system before starting 72 hour timer.
- Recognition Performance Test -> Test Procedure -> Test Procedure.Added steps to record start and end times and amended test procedures to state that system settings may not be changed once a particular scenario has started.

Schedule

May 1 - 5 Visionics Corporation

May 8 - 12 Lau Technologies

May 15 - 19 Miros, Inc.

May 22 - 26 C-VIS Computer Vision und Automation GmbH

June 5 - 9 Banque-Tec International Pty. Ltd.

If you haven't already done so, please send e-mail to bone_mike@crane.navy.mil with the names of the representative(s) that will be coming along with arrival and departure dates. This will depend on how long you

expect your system will need to process all images in the Recognition Performance Test and whether or not you bring two systems to run the Product Usability Tests in parallel. Remember that up to 72 hours will be permitted for the Recognition Performance Test and one business day from 0900 - 1700 will be permitted for the Product Usability Tests. All testing must be completed by 1700 on the Friday of your test week.

Travel Information

The test will be held at NAVSEA Crane. Crane is located approximately 70 miles southwest of Indianapolis, IN. The nearest terminal is Indianapolis International Airport, and lodging can be found in Bloomington, IN. See http://www.crane.navy.mil/General/visit_info.htm for directions to Bloomington and NAVSEA Crane from the terminal and a list of Bloomington hotels. The hotels that are closest to the driving route are the Fairfield Inn, Comfort Inn, Day's Inn, Hampton Inn, Holiday Inn, Quality Inn, and Ramada Inn. Directions from the NAVSEA Crane gate to the test space will be provided before testing begins.

Crane, IN is in the GMT -5:00 time zone.

Appendix D – E-mail Announcement

Subject: Facial Recognition Vendor Test 2000

Numerous advances have taken place in the field of facial recognition since the last FERET test was performed in March of 1997. One of the most important of these advancements has been the introduction of facial recognition systems into the commercial marketplace. The competitiveness of the open market has brought forth numerous technological modifications to the algorithms that were available for the FERET program, and has also lowered the cost of the systems significantly. Today there are dozens of facial recognition systems available that have the potential to meet performance requirements for numerous applications. But which of these systems best meet the performance requirements for given applications? This is one of the questions potential users most frequently ask the sponsors and the developers of the FERET program.

Although literature research has uncovered several mentions of recent system tests, none has been both open to the public and of a large enough scale to be completely trusted. This revelation, combined with inquiries from numerous government agencies on the current state of facial recognition technology, has prompted us to establish a new set of evaluations that will be performed in 2Q 2000.

The purpose of these evaluations is to accurately gauge the capabilities of facial recognition biometric systems that are currently available for purchase. The sponsoring agencies, as well as other government agencies, will use this information as a major factor when determining future procurement or development efforts. Participation in these evaluations is open to all facial recognition systems on the US commercial market.

Major sponsors of these evaluations include the DoD Counterdrug Technology Development Program Office, the National Institute of Justice (NIJ), the Defense Advanced Research Projects Agency (DARPA), and Naval Sea Systems Command (NAVSEA). More information about the evaluations, as well as application forms to participate, can be found on the Facial Recognition Vendor Test 2000 web site at <http://www.dodcounterdrug.com/facialrecognition>.

Title: Facial Recognition Vendor Tests 2000

Description: The DoD Counterdrug Technology Development Program Office, the National Institute of Justice (NIJ), the Defense Advanced Research Projects Agency (DARPA), NAVSEA Crane Division, and NAVSEA Dahlgren Division are sponsoring a test of commercial off the shelf (COTS) facial recognition products. The purpose of these tests is to accurately gauge the capabilities of facial recognition biometric systems that are currently available for purchase. The sponsoring agencies, as well as other government agencies, plan on using the results of these tests for both near-time acquisitions and future development efforts.

Participating vendors will run their own tests under direct supervision from the Government. Vendors will be allowed to make any adjustments they would like (while following test guidelines) on their systems prior to (each sub-) test initiation. The test will take place in the spring of 2000 at a location in the continental United States (the final location has yet to be decided).

Two categories of tests will be conducted: Recognition Performance Tests and Product Usability Tests. For each category, multiple tests will be performed to measure system performance in verification mode and in identification mode. The Recognition Performance Tests will use the FERET test methodology with a new database of images. The Product Usability Tests will evaluate performance in both low and medium security access control operational scenarios.

Final reports from these tests will be made available here in mid-2000.

Appendix F – Success Story

Past Success Stories

The DoD Counterdrug Technology Development Program Office (CDTDPO) began the Face Recognition (FERET) program in 1993. Dr. P. Jonathon Phillips was the assigned Technical Agent. At the time, very few individuals believed that facial recognition could become a viable operations support technology. Dr. Phillips and the CDTDPO Program Executive, could foresee the potential benefits of facial recognition technology and decided that those benefits far outweighed the development risk.

The FERET program consisted of three important parts. First was sponsoring research that advanced facial recognition from theory to working laboratory algorithms. Many of the algorithms sponsored by FERET form the foundation of today's commercial systems ([FERET Transition](#)). Second was the collection and distribution of the FERET database, which contains approximately 14000 facial images of 1200 individuals. The DoD Counterdrug Technology Development Program Office still receives requests for access to the FERET database, which is currently maintained at the National Institute of Standards and Technology. Portions of the FERET database have been distributed to over 100 groups outside the original FERET program. The final, and most recognized, part of the FERET program was the FERET evaluations that compared the abilities of facial recognition algorithms using the FERET database. The most recent reports from the FERET program are available for download on the FERET listing in the [Counterdrug Technology Information Network](#).

The test methods used in the FERET evaluations form the foundation of an overall biometric evaluation methodology that was authored by Dr. Phillips, et. al., and published in the February 2000 edition of IEEE Computer. This evaluation methodology has been incorporated into the UK Biometrics Working Group in their "[Best Practices in Testing Performance of Biometrics Devices](#)". As clearly shown, the FERET program continues to have a profound effect on the facial recognition community today.

The biggest change in the facial recognition community since the last FERET evaluation in 1997 has been the introduction of facial recognition products to the commercial market. The competitiveness of the open market has brought forth numerous technological modifications to the algorithms that were available for the FERET program, and has also lowered the cost of the systems significantly. Today there are dozens of facial recognition systems available that have the potential to meet performance requirements for numerous applications. But which of these systems best meet the performance requirements for given applications?

Repeated inquiries from numerous government agencies on the current state of facial recognition technology have prompted the DoD Counterdrug Technology Development Program Office to establish a new set of evaluations. The [Facial Recognition Vendor Test 2000 \(FRVT 2000\)](#), is co-sponsored by the DoD Counterdrug Technology Development Program Office, the National Institute of Justice, and the Defense Advanced Research Projects Agency (DARPA). The FRVT 2000 will be administered in April-May 2000 and will assess the capabilities of facial recognition systems that are currently available for purchase on the U.S. market. Results from the FRVT 2000 will be made available to the public. This evaluation will provide the counterdrug community and Government agencies with information that will assist their efforts of determining where facial recognition technology could best be used in the field. The results will also provide a blueprint of needed development efforts for the government and the vendor community.

Dr. Phillips also continues to be very active in the facial recognition and biometric community, as he has been named the Program Manager for DARPA's new [HumanID](#) program. Dr. Phillips was also an advisor in the development of the Facial Recognition Vendor Test 2000, and views this evaluation as one of the major transitions from FERET to HumanID. The HumanID program is a four year \$50 million effort that aims to significantly improve the recognition capabilities of numerous types of biometric systems. By funding high-risk high-reward development efforts, HumanID will move biometric technology to its next logical step - the recognition of non-cooperative subjects with high accuracy. The DoD Counterdrug Technology Development Program Office is serving as a strategic partner for the HumanID program.

The FERET program was a highly successful effort that provided direction and credibility to the facial recognition community. We are just now beginning to uncover how important the program was during the infancy of facial recognition technology. As FERET nears the end of its transition from active program to a historical program, the DoD Counterdrug Technology Development Program takes great pride on the imprint it has left on the biometrics community, and even greater pride that the FERET ideals and evaluation methods are being used by current programs both inside the Program Office and by other Government agencies.

Appendix G – Data Collection Process

FRVT 2000 Image Collection

1. Introduction

This document describes the imagery used in the Facial Recognition Vendor Test 2000. It details the acquisition, processing and use of the images in the evaluation. The corpus is a heterogeneous set of still images taken under visible light. Each piece of imagery is accompanied by a ground truth attribute list describing its acquisition and properties. The imagery was taken using analog-still, digital-still and digital video cameras at a variety of resolutions. Hundreds of subjects wearing varying facial expressions were taken under several different lighting conditions and at different azimuthal head angles. In addition, some of the imagery is derived from other raw data to allow the effect of image quality on recognition to be quantified. The collection was conducted over a period of several years at different sites. All the annotation information is maintained in ground truth files to allow for the controlled evaluation and development of human face recognition systems.

2. FRVT 2000 Image Corpus

The FRVT 2000 imagery was gathered during dedicated collection sessions lasting a few days. There are 13872 images of 1462 individuals. The imagery was obtained from two distinct sources. The first part, containing 5416 images from 1201 subjects, was taken from the data corpus produced under the FERET program¹. A further 4726 images from 262 subjects were extracted from the Human ID database². Finally some 3730 images were derived synthetically from the FERET images.

The subjects appearing in the images are all unpaid volunteers who had been briefed on the purpose of their participation and who had positively consented to the study. For privacy reasons the data was gathered anonymously; a volunteer's name is not recorded and is instead replaced by an integer ID that is used to label all the imagery ever taken of that individual. The mechanism for maintaining persistent and unique IDs for subjects is a non-trivial task for corpuses obtained at many sites over many months. It is a known problem in maintaining biometric databases and the details of how we attain robust database integrity are beyond the scope of this document.

¹ The FERET program ran from 1994 through 1997 and gathered a very large number of images. It was used to quantify recognition performance using a set of 3816 images; see P. J. Phillips, H. Moon, P. J. Rauss, S. Rizvi, "The FERET Evaluation Methodology for Face Recognition Algorithms," *IEEE Trans Pattern Analysis and Machine Intelligence*, Vol 22, No 11, pp. 1090-1104, 2000.

² The imagery for Human ID database is currently being gathered by a number of organizations funded under DARPA's Human Identification at a Distance program. The small subset of Human ID used in the FRVT 2000 was gathered mostly by NIST in the period 1998 to 2000.

Although the imagery is taken from a diverse population it has not been compared with the U.S. ethnic and demographic composition, which itself has likely changed during the period in which the images were gathered. The conclusion is that the collection is not considered to be a bias-free data set. Nevertheless, the testing imagery is held to be the largest set used to independently quantify the state of the art in human facial recognition.

3. New Image Acquisition

The acquisition of the FERET partition of the FRVT 2000 data collection has been described elsewhere³. The remaining data was gathered at NIST in Gaithersburg MD, and at NAVSEA Dahlgren Division in Dahlgren VA. Consenting volunteers appeared alone in each piece of imagery. The imagery was gathered at imaging stations; a station is defined by a fixed set of cameras attended by one photographer.

3.1 Indoor Still Image Station

The imagery gathered at the indoor still image station was obtained using off-the-shelf consumer grade analog and digital CCD cameras configured in auto-focus mode, using standard film and floppy disks. The photographic set up followed a mugshot geometry⁴ shown in Figure 1.

Specifically, each still image was captured using an 18% gray background and three studio lights. The 18% gray background used was a high quality seamless paper 1.21 meters (4 feet) in height and 1.21 meters in width that was hung on the wall. The subject stood .91 meters (3 feet) on center in front of the gray background and the camera was placed 2.73 meters (9 feet) on center from the background, at a height of 1.75 meters.

Three floodlights provided uniform studio lighting. Each floodlight was mounted on a light stand 1.82 meters above the floor. Two floodlights were positioned 1.21 meters (2 feet) off center from the background. The distance from each floodlight to the background was 2.42 meters (8 feet). Another floodlight was positioned directly in back of the camera at a distance of 3.33 meters (11 feet) from the gray background. The studio lighting was arranged so that the subject's shadow was not visible in the background of the captured image and facial/eyeglass reflection of the lighting was minimized or not visible.

Digital still images were captured on a 3.5inch diskette using an off-the-shelf Sony Mavica digital camera. Each image was captured in portrait mode of operation and generated images 768 by 1024 pixels in width and height. Analog stills were captured using a 35-mm camera with a 49-mm lens using Kodak Royal Gold 400 ASA colored film. Both cameras ran in auto-focus mode.

⁴ See "Best Practice Recommendation for the Capture of Mugshots", Version 2.0, Mugshot and Facial Image Workshop, NIST, Gaithersburg, MD, September 1997. www.itl.nist.gov/iad/894.03/face/bpr_mug3.html.

Figure 1 - Still Image Capture Set

Six different frontal images of each subject were taken using both the analog and digital CCD cameras. In most cases the camera operator took the analog and digital CCD camera pictures simultaneously. The six pictures were obtained in pairs under each of three lighting conditions:

Mugshot lighting set up as described above.

FERET lighting (the above lighting minus the floodlight behind the camera)

No floodlights, just the fluorescent overhead room lighting

In each lighting case the two images taken are referred to as FA and FB

FA is obtained after the subject has been asked to wear a regular or neutral facial expression.

FB is obtained after FA and after the subject has been instructed to wear an alternative expression. In the majority of cases this can be classified as a smile, but in a significant fraction other expressions were presented.

3.2 Outdoor Still Image Station

The still imagery taken outdoors is characterized by changing background and illumination, and often by directional illumination as most images were taken in sunshine with cloud cover. Each

subject posed for two still shots taken at a distance of about 2 meters. The images were obtained using an off-the-shelf Sony Mavica digital CCD camera in auto-focus mode. The first pose was taken with the subject facing the camera. A second was taken with the subject turning their body either left or right such that they were facing approximately 45 degrees to the line of sight. In both cases subjects were asked for a neutral facial expression.

3.3 Indoor and Outdoor Video Image Stations

The indoor and outdoor video sequences were obtained using a high-end consumer grade digital video camera, the Canon XL1, running in auto-focus mode. The subjects walked a 10 meter course directly toward the camera. The illumination was overhead lighting (indoor) or directional sunlight (outdoor). The lighting conditions outdoors were sometimes overcast, but never in rain or other precipitation. The ground truth annotation only records that the image was taken outdoors and does not refine the categorization.

3.4 Badging Station

The images collected at the badging station were acquired using a standard access control badging system developed and maintained by NAVSEA Crane. The system is made up of the following components:

EBACS MK3 MOD4 badging software (developed by NAVSEA Crane)

Integral Technologies FlashPoint 3075 PCI vide frame grabber

Imaging Technology Corporation CCD 1000 video camera

Lowel iLIGHT portrait lighting system consisting of a single 100W, 3200K lamp

Images were collected using overhead fluorescent lighting in addition to the system lamp. Subjects stood one foot in front of a wall. The camera was located eight feet from the subject at a height of 5'-6". Images were captured with a resolution of 380x425 and saved as 24-bit jpeg files with a quality setting of 90%.

3.5 Dahlgren98 Image Collection Station

The data collection at Dahlgren in 1998 was uncontrolled and took place inside a building atrium. The background varied for each image, as did the lighting conditions due to the variation in subject location. Digital still images were collected using a digital video camera and computer-based image capture card. The manufacturer and model number for the video camera and image capture card are not known.

3.6 Summary of Cameras Used

	Canon XL1 Video Camera	Canon XL1 Video Camera	Sony Digital Model 91	Sony Digital Mavica	Minolta X-700 35mm	Olympia 35mm
station used	outdoor video sequence	indoor video sequence	indoor digital still	outdoor digital still	indoor analog still	indoor analog still
site(s) used	Dahlgren, VA (99)	Dahlgren, VA (99)	Dahlgren, VA (99)	Dahlgren, VA (99)	Dahlgren, VA (99)	
	NIST, MD (00)	NIST, MD (00)	NIST, MD (00)	NIST, MD (00)		NIST, MD (00)

4. Derived Imagery

Some subsets of the imagery used were derived from the "raw" images previously gathered.

A series of uncompressed images were compressed by applying the JPEG compression necessary to achieve compression ratios of 10, 20, 30, and 40 to 1. The uncompressed images were included by application of the highest quality JPEG. This allows a quantification of the effect of compression on recognition.

A series of images for which the inter-eye distance in pixels had been manually determined was used to produce low resolution versions of the same image. The images were scaled such that the inter-eye distance was reduced to 60, 45, 30 and 15 pixels, while preserving aspect ratio. This allows a study of the effect of resolution on recognition.

Some of the images used in FRVT 2000 were frames extracted from video sequences. The subjects were walking toward the camera from a range of about 10 meters through 1.5 meters. The frames were taken from fixed points along that trajectory. Inter-eye distances are low as 5 pixels.

5. Ground Truth

The imagery recorded during the collections was subsequently enrolled in a database. Each piece of imagery was accompanied by a set of ground truth attributes. This annotation of the data supplies information on the date, location, cameras, lighting, and on the expression, orientation (angle subject was facing relative to camera), and sex of the participating subject. Subjects were asked to wear either "regular" or "alternative" facial expressions, and these were recorded. This attribute allows evaluation of algorithms' sensitivity to facial expression. In most cases the subject faced the camera, though in specific image sets the azimuthal angle of the head was recorded. This allows the effect of pose on recognition to be estimated. Subjects were asked to remove eyewear, but on some occasions the eyewear was retained and this information was noted. Subject's age, hair and eye color, presence of facial hair, and jewelry were not recorded.

6. Image Distribution

All imagery was prepared in JPEG⁵ format, either natively from the camera or via conversion steps from the respective output of the camera. The video frames were extracted⁶ from compressed AVI⁷ video files. The analog film images were scanned from film by Kodak and converted from their pcd⁸ format to JPEG. Varying amounts of compression were inherent in this process and only those files for which compression was controlled is the amount of compression known.

⁵ JPEG is the ubiquitous Joint Photographic Experts Group image format. All images are compressed in a lossy manner according to a DCT quantization. A full description can be found in J.L. Mitchell, W. B. Pennebaker, "JPEG Still Image Compression Standard", Van Nostrand Reinhold, New York, NY, 1993

⁶ Many camcorders stream information to tape at 25Mbps/s in Sony's real time compressed DV format. Imagery is recovered from tape via a Firewire IEEE 1394 interface to a computer containing suitable hardware. The resulting file can be broken into frames written as 2D raster images. See http://www.manifest-tech.com/pc_video/dv_tech/dv_tech.htm. The DV format is a lightly compressed constant rate stream intended for real time compression and decompression in tape based camcorders

⁷ AVI encapsulates a large variety of proprietary compression codecs that require a dynamically linked library for the input and output. See http://microsoft.com/directx/dxm/help/ds/filtdev/DV_Data_AVI_File_Format.htm.

⁸ See <http://www.kodak.com/US/en/digital/products/photoCD.shtml>.

Appendix H – FRVT 2000 Test Plan

Introduction

This document describes the procedures that will be followed for Facial Recognition Vendor Test 2000. The result of each vendor test will be a set of similarity files that will be processed to generate graphs of recognition performance, data recorded for timed tests, a vendor supplied document describing the tested system and associated costs, and video records of all testing activities. At the conclusion of all tests, a final report will be written describing the results.

Test Overview

General

The test is made up of 2 parts: the Recognition Performance Test and the Product Usability Test. Both are described in detail below. Vendors will supply and operate their own equipment. Government personnel will direct test activities and record data. Vendors may bring 2 separate but identical systems to the test so the Recognition Performance Test and Product Usability Tests can be run in parallel. The Recognition Performance Test will be initiated first, either on the day the vendor arrives or the following morning. The Product Usability Tests will begin the morning after the vendor arrival date if 2 systems are available. Otherwise it will begin the morning following completion of the Recognition Performance Test.

Personnel

Test Agent

Test agent refers to the government representative administering the test and recording results, and possibly and assistant.

Vendor

Vendor refers to the representative(s) of the company whose product is being tested.

Subjects

There will be 3 live test subjects that will take part in the timed tests. They will be referred to specifically as subject 1, subject 2, and subject 3, or generically as subjects. There will be one female subject and two male subjects. One male subject will be wearing glasses. An 8" x 10" color photograph of one subject will be used in some trials. It will be held in front of one subject's face during these trials. For clothing uniformity, all subjects will be wearing lab coats of the same color. All subjects will practice the trials before the first vendor test in order to establish a consistent routine.

Test Space

The following diagram shows the approximate layout of the testing area.

Room Layout

All tests will be held in a single room. There will be 3 stations setup in the testing room, each near a 120 volt standard US power outlet. The stations are assigned as follows:

Station 1 will be used for the Recognition Performance Test. It consists of a table to hold the vendor system, and chairs.

Station 2 will be used for the timed tests. It consists of 2 tables with chairs, markings on the floor to direct subject position, and visual targets to focus subjects' attention during non-cooperative behavior modes. One table with adjustable height will be dedicated to the vendor system. If the vendor system includes camera and lighting supports, they may be placed on the table or on the floor in front of the table. The other table will be used by the test agent when recording data and to hold a timer.

Station 3 will be used for the Access Control System Interface Test. It consists of a table for the vendor system and the access control system to which it will be interfaced.

Floor Marks

Marks have been taped to the floor in front of station 2 as follows:

A camera mark designates the location at which the front of the system camera lens should be aligned. All other floor marks are assigned distances relative to the camera mark in the direction of the subject. The camera mark is labelled "CAMERA".

Marks have been placed at one foot intervals starting one foot in front of the camera mark and ending 12 feet from the camera mark. These marks are used to determine where subjects start the trials, where they stop if the system has not achieved identification or verification, and to determine the final distance between the subject and the camera. Each mark is labelled with its distance from the camera mark and is referred to as a distance mark. The mark placed one foot from the camera mark is also labelled "STOP" and is referred to as the stop mark. The marks at 4 feet, 8 feet, and 12 feet are also labeled "START" and are referred to as start marks.

Visual Targets

Two visual targets printed on 8-1/2" x 11" paper have been posted on the walls behind the vendor system table for subjects to focus their attention during the non-cooperative behavior modes of the timed tests. The center of each target is 6' above the floor, spaced 18' apart on a wall located 16.5' behind the camera mark. These targets are referred to as the left target and right target. A third target, referred to as the center target, has been placed in a vertical position with its center 6" above the floor at the camera mark. The system camera will serve as the visual target for cooperative behavior modes.

Room Lighting

The test room is illuminated with overhead fluorescent lights. The room also has outside windows that will be completely covered by opaque material for the duration of the tests.

Back Lighting

Back lighting will be used for some trials in the timed tests. This is meant to simulate the presence of an outside window behind the subject in a controlled manner. To accomplish this, a custom lighting device has been built consisting of a track lighting system with fixtures arranged in a 4 x 4 grid.

The lights are mounted inside a box facing toward the camera. The front side of the box, which faces the camera, has approximate dimensions of 4' x 4' and is covered by a translucent diffusing material.

Testing Conventions

Start Location

When the subject is to begin a timed test by facing the camera, (s)he will stand with toes behind the designated start mark. When the subject is to begin by facing away from the camera, (s)he will stand with body facing perpendicular to the camera path, head turned away from the camera, and feet behind the designated start mark.

Time Measurement

For each trial of the timed tests, the time will be recorded to the nearest 1/10 second.

Behavior Mode

Two behavior modes will be employed by subjects during the timed tests: cooperative and non-cooperative.

In the cooperative mode, subjects will look directly at the camera with very little head movement while walking or standing.

In the non-cooperative mode, subjects will begin a trial looking at the right target. Once the timer is started, the subject will turn his/her head slowly, moving visual focus on a triangular path from the right target to the left target, down to the center target, then back up to the right target. This will be done using a cadence that allows 2 complete cycles in 10 seconds. This will be done for both standing and walking trials.

Distance Measurement

The final distance from subject to camera in the timed tests will be recorded as the label of the last distance mark that the subject's toes have reached.

Video Recording

All testing activities will be recorded with video cameras to ensure accurate records. One camera will be used to record the activities at station 1 during the Recognition Performance Test. The camera will be placed so that the screen of the vendor system and any operator activity will be in the field of view. The camera will be recording for the duration of the test but only when the testing room is occupied.

Another camera will be placed behind station 2 so that the vendor system and the subjects will be in the field of view. This camera will be recording during system setup and during all trials of the timed tests. This camera will also be used to record all activities of the Access Control System Interface Test at station 3.

Recognition Performance Test

Test Description

Overview

The Recognition Performance Test will be very similar to the original FERET tests that were sponsored by the DoD Counterdrug Technology Development Program Office. Since the conclusion of the original FERET program, the data sets and reports have been transferred to the National Institute of Standards and Technology (NIST), who is serving as a technical consultant for these tests. Images used in this test will be a combination of images from the FERET database as well as DARPA's new HumanID database.

On the day of the Recognition Performance Test, the vendor will be given a set of test images in JPG format. The vendor may convert the images to another format if necessary, but no extra time will be given for this. The vendor will use their algorithm to compare each image to the others and report the similarity scores in the format defined in the API document.

Time Limits

Once the system is setup, vendors will be allowed 72 continuous hours to process the test images. Vendors should process test images in filename order so that if time runs out before processing is complete, a common set of similarity scores can be identified among all vendors. Vendors will only be allowed access to the test space between the hours of 0900 and 1700. The system may continue to process test images outside these hours during the 72 hour time period, but in the event of an overnight system crash, vendors will not be allowed to restart the system until 0900 the following day. Vendors are encouraged to implement their system in a manner that allows restarting from the point where a system crash occurred rather than restarting from the beginning.

Data Recording

Vendors will generate a similarity file for each test image. All similarity files will be stored on one or more 2GB Jaz disks and submitted to the test agent at test completion. The final report will show the results in the form of Receiver Operating Characteristic (ROC) curves for verification tests and Cumulative Match Characteristics (CMC) Curves for identification tests. Other forms of displaying information may also be used.

Test Procedure

Preparation

1. Test agent records available space on system hard disk.
2. Test agent releases Jaz disk containing image database to vendor.

Test Procedure

1. Test agent records start time.
2. Vendor inserts Jaz disk into system and initiates test sequence.
3. Test ends when all images have been processed or 72 hours has elapsed.
4. Test Agent records end time.
5. Test agent collects Jaz disk containing similarity files from vendor.
6. Vendor deletes any remaining templates and similarity files from system hard disk.
7. Test agent records available space on hard disk.
8. Test agent wipes free space on hard disk.

Product Usability Tests

Test Description

Overview

The Product Usability Tests will consist of two timed tests and an optional interface test. The timed tests will be used to measure the response time of the overall system for two different operational scenario simulations: the Old Image Database Timed Test and the Enrollment Timed Test. Optionally, the Access Control System Interface Test will be used to determine if the system can communicate with an access control system. It is not necessary for a vendor to have an access control product to participate in these tests - these are operational scenarios that were developed to give the public a means of comparing the test results with something they would be familiar with.

The operational scenario for the Old Image Database Timed Test is that of a low security access control point into the lobby of a building. The building's security officers want to improve security into the area but do not want to slow down the flow through the entry area. The security officers also do not want to mandate that the employees take the time to enroll into the new system so they will use their existing digital image database taken from the employee's picture ID badges. Some employees may not be aware that they are being checked using a facial recognition system, so they will not always be fully cooperative.

The operational scenario for the Enrollment Timed Test is that of an access control door for a medium/high security area within the building previously described. In this case, employees will be enrolled in the facial recognition system using the standard procedures recommended by the vendor. The access control system on one door has been setup so that an individual enters his identity and the system must verify if this is indeed the correct individual. On another door, the system has been setup so that an individual simply walks up to the camera and the door opens if the identity of the individual matches an individual in the database with valid credentials. The employees will be aware that they are being checked using a facial recognition system, but may or may not be cooperative.

Each of the timed tests will be performed for both verification and identification and will be performed once with overhead fluorescent lighting and again with the addition of simulated back lighting.

The Access Control System Interface Test is an optional test meant to determine if the facial recognition system can interface successfully with an access control system. To participate in this optional test, the facial recognition system must have a WIEGAND interface. The goal is to test the interface rather than the facial recognition algorithm.

Time Limits

One full business day, between the hours of 0900 and 1700, will be allowed for running all Product Usability Tests, including setup. Each trial for the timed tests will be limited to 10 seconds. Based on our trials, we expect the test to take about 6 hours, not including setup time or the optional Access Control System Interface Test.

Data Recording

Results of the timed tests will be recorded on the tables in Appendix A. The distance between the subject and the camera at the end of each trial will be recorded in the Final Distance column to the nearest 1 foot increment. This column will not be used for trials where the subject stands in place. If the system acquires a match for the subject, the time to make the match will be recorded in the Acquire Time column to the nearest 1/10 second. If the correct match was acquired, the word "yes" will be recorded in the Correct Match column. If a match was not acquired or was incorrect, the word "no" will be recorded in the Correct Match column. These tables will be published in the final report as recorded without any analysis.

Old Image Database Timed Test Procedure

Preparation

1. Vendor sets up system at station 2. Front of camera lens is aligned with camera mark.
2. Test agent releases access control image database to vendor on Jaz disk.
3. Vendor enrolls database images from Jaz disk (~150 images, one image per subject).
4. Vendor adjusts system for the suggested low security false alarm (false positive) rate of 0.4%. Settings may not be changed until backlighting is added. This includes camera zoom, unless the system controls the camera automatically while attempting recognition.

Verification Test

Steps 1 - 6 are repeated with <start distance> = 12', 8', and 4'

1. Subject 1 stands facing camera at <start distance> mark.
2. Vendor enters subject 1 ID into system.
3. Test agent vocally counts to 3. On "3", test agent starts timer while vendor simultaneously presses key to begin verification.
4. Subject 1 walks toward camera using cooperative behavior mode.
5. Subject 1 stops walking if vendor and test agent acknowledge match, time expires, or stop mark is reached. If stop mark is reached before time expires, subject 1 stands at stop mark until vendor and test agent acknowledge match or time expires.
6. If vendor and test agent acknowledge match, test agent records time, distance, and correctness of match. If match does not occur before time expires, test agent records that fact.

Steps 7 - 12 are repeated with <start distance> = 12', 8', and 4'

7. Subject 1 stands facing camera at <start distance> mark.
8. Vendor enters subject 1 ID into system.
9. Test agent vocally counts to 3. On "3", test agent starts timer while vendor simultaneously presses key to begin verification.
10. Subject 1 walks toward camera using non-cooperative behavior mode.
11. Subject 1 stops walking if vendor and test agent acknowledge match, time expires, or stop mark is reached. If stop mark is reached before time expires, subject 1 stands at stop mark until vendor and test agent acknowledge match or time expires.
12. If vendor and test agent acknowledge match, test agent records time, distance, and correctness of match. If match does not occur before time expires, test agent records that fact.

13. Repeat steps 1 – 12 with subject 2 for each value of <start distance>.
14. Repeat steps 1 – 12 with subject 3 for each value of <start distance>.
15. Repeat steps 1 – 6 (8) times with subject 3 for <start distance> = 12' to test variability.
16. Repeat steps 1 – 6 with subject holding photograph for each value of <start distance>.

Identification Test

Steps 1 - 5 are repeated with <start distance> = 12', 8', and 4'.

1. Subject 1 stands facing away from camera at <start distance> mark.
2. Test agent starts timer.
3. Subject 1 turns then walks toward camera using cooperative behavior mode.
4. Subject 1 stops walking when vendor and test agent acknowledge match, time expires, or stop mark is reached. If stop mark is reached before time expires, subject 1 stands at stop mark until vendor and test agent acknowledge match or time expires.
5. If vendor and test agent acknowledge match, test agent records time, distance, and correctness of match. If match does not occur before time expires, test agent records that fact.

Steps 6 - 10 are repeated with <start distance> = 12', 8', and 4'.

6. Subject 1 stands facing away from camera at <start distance> mark.
 7. Test agent starts timer.
 8. Subject 1 turns then walks toward camera using non-cooperative behavior mode.
 9. Subject 1 stops walking when vendor and test agent acknowledge match, time expires, or stop mark is reached. If stop mark is reached before time expires, subject 1 stands at stop mark until vendor and test agent acknowledge match or time expires.
 10. If vendor and test agent acknowledge match, test agent records time, distance, and correctness of match. If match does not occur before time expires, test agent records that fact
11. Repeat steps 1 – 10 with subject 2 for each value of <start distance>.
 12. Repeat steps 1 – 10 with subject 3 for each value of <start distance>.
 13. Repeat steps 1 – 5 (8) times with subject 3 for <start distance> = 12' to test variability.
 14. Repeat steps 1 – 5 with subject holding photograph for each value of <start distance>.

Backlighting Test

1. Test agent adds backlighting behind subject.
2. Vendor may adjust settings if necessary. Settings may not be changed until backlighting is removed. This includes camera zoom, unless the system controls the camera automatically while attempting recognition.
3. Repeat steps 1 – 16 of the Verification Test with Subjects 1, 2, 3, variability test, and photograph.

4. Repeat steps 1 ñ 14 of the Identification Test with Subjects 1, 2, 3, variability test, and photograph.
5. Test agent removes backlighting.

Enrollment Timed Test Procedure

Preparation

1. Vendor deletes enrolled templates of 3 test subjects.
2. Vendor adjusts system for the medium/high security false alarm (false positive) rate of 0.1%. Settings may not be changed until backlighting is added. This includes camera zoom, unless the system controls the camera automatically while attempting recognition.
3. Vendor enrolls 3 test subjects using their standard enrollment procedure.

Verification Test

Steps 1 – 6 are repeated with <start distance> = 12', 8', and 4'.

1. Subject 1 stands facing camera at <start distance> mark.
2. Vendor enters subject 1 ID into system.
3. Test agent vocally counts to 3. On "3", test agent starts timer while vendor simultaneously presses key to begin verification.
4. Subject 1 continues standing using cooperative behavior mode during recognition attempt.
5. Trial ends when vendor and test agent acknowledge match or time expires.
6. If vendor and test agent acknowledge match, test agent records time and correctness of match. If match does not occur before time expires, test agent records that fact.

Steps 7 – 12 are repeated with <start distance> = 12', 8', and 4'.

7. Subject 1 stands facing camera at <start distance> mark.
8. Vendor enters subject 1 ID into system.
9. Test agent vocally counts to 3. On "3", test agent starts timer while vendor simultaneously presses key to begin verification.
10. Subject 1 continues standing using non-cooperative behavior mode during recognition attempt.
11. Trial ends when vendor and test agent acknowledge match or time expires.
12. If vendor and test agent acknowledge match, test agent records time and correctness of match. If match does not occur before time expires, test agent records that fact.
13. Repeat steps 1 – 12 with subject 2 for each value of <start distance>.
14. Repeat steps 1 – 12 with subject 3 for each value of <start distance>.
15. Repeat steps 1 – 6 (8) times with subject 3 for <start distance> = 12' to test variability.
16. Repeat steps 1 – 6 with subject holding photograph for each value of <start distance>.

Identification Test

Steps 1 – 5 are repeated with <start distance> = 12', 8', and 4'.

1. Subject 1 stands facing away from camera at <start distance> mark.
2. Test agent starts timer.
3. Subject 1 turns to face camera then stands using cooperative behavior mode during recognition attempt.
4. Trial ends when vendor and test agent acknowledge match or time expires.
5. If vendor and test agent acknowledge match, test agent records time and correctness of match. If match does not occur before time expires, test agent records that fact.

Steps 6 – 10 are repeated with <start distance> = 12', 8', and 4'.

6. Subject 1 stands facing away from camera at <start distance> mark.
7. Test agent starts timer.
8. Subject 1 turns to face camera then stands using non-cooperative behavior mode during recognition attempt.
9. Trial ends when vendor and test agent acknowledge match or time expires.
10. If vendor and test agent acknowledge match, test agent records time and correctness of match. If match does not occur before time expires, test agent records that fact.
11. Repeat steps 1 – 10 with subject 2 for each value of <start distance>.
12. Repeat steps 1 – 10 with subject 3 for each value of <start distance>.
13. Repeat steps 1 – 5 (8) times with subject 3 for <start distance> = 12' to test variability.
14. Repeat steps 1 – 5 with subject holding photograph for each value of <start distance>.

Backlighting Test

1. Test agent adds backlighting behind subject.
2. Vendor may adjust settings if necessary. Settings may not be changed until backlighting is removed. This includes camera zoom, unless the system controls the camera automatically while attempting recognition.
3. Repeat steps 1 – 16 of the Verification Test with Subjects 1, 2, 3, variability test, and photograph.
4. Repeat steps 1 – 14 of the Identification Test with Subjects 1, 2, 3, variability test, and photograph.
5. Test agent removes backlighting.

Access Control System Interface Test Procedure

Preparation

1. Vendor sets up system at Station 3.
2. Vendor connects system to WIEGAND interface of supplied access control system.
3. Vendor enrolls subject 1 in recognition system and assigns WIEGAND format ID.
4. Test agent enrolls subject 1 in access control system using the same WIEGAND format ID.

Test Procedure

1. Vendor enters subject 1 ID into recognition system.
2. Subject 1 stands in front of camera and cooperates to try to achieve successful verification.
3. If successful verification occurs and access control system receives the correct WIEGAND format ID, test agent records successful completion of test. Otherwise, vendor will be given 2 more attempts at successful completion. If successful completion does not occur in 3 total attempts, test agent will record that fact.

Data Recording Tables

The following information is to be completed for each vendor. By signing below, the vendor agrees that the data recorded in the following tables is accurate. Signatures are for the records of the FRVT 2000 sponsors only and will not appear in the test report.

Appendix I – Case Study: A Participant Withdraws

What follows is an excerpt of communications between one of the vendors and the FRVT 2000 sponsors regarding the methodology chosen for the test. Our intent in providing this information is not to judge this particular individual or his company's views. Rather, this is an interesting case study for anyone that wishes to perform any future evaluations because it provided some idea of the issues they should expect to encounter. We believe this shows that differing views do exist in the biometrics community and, by including this alternate view, we will spark further discussions about evaluation methodologies that will improve all future biometric technology evaluations.

The vendor was the first to sign up to participate in FRVT 2000 only two (weekend) days after it was announced to the public. The day after signing up, the vendor wrote in a message distributed via the Biometric Consortium's listserv that they were "provisionally entering the FRVT 2000 facial recognition vendor test, subject to our acceptance that the test is hard enough." In the same forum they said they "regard the previous FERET test with enormous skepticism. The problem is that the test protocol was *too easy*."

A few weeks passed before the vendor expressed concern that some of the vendors who had participated in previous FERET tests would have an unfair advantage since they have seen some of the images. The sponsors did not feel this was an issue because the FERET program did not involve any vendors in the FERET evaluations, the FERET images used for FRVT 2000 had not been made available to anyone, and a representative of this vendor had previously been given the FERET development database, which was available to all the other vendors. (This is question 7 in the restricted area FAQ.) The sponsors did not anticipate this complaint from this representative because previously he had stated that the FERET evaluations were too easy. He also claimed that the live tests would be unfair because the live images of the subjects would not be exactly the same for each vendor and proposed that we use prerecorded video clips instead. (This is question 10 in the restricted area FAQ.)

Approximately one week later, the vendor submitted a signed request to participate in the evaluation and was given their ID and password to access the restricted area of the FRVT 2000 web site, and hence, the Image Development Set and API documentation. The next day the vendor asked "what proportion of the recognition test set are of very small faces, such as 'i00011'? Our system will not return a similarity score for such images. It is a perfectly reasonable response for a system to 'abstain' when it does not consider the input data to be reliable enough to give an accurate similarity score." (This is question 20 in the restricted area FAQ.) He also asked, "Why separate performance and usability tests? How can the results be combined and assessed? If I were choosing a system to buy, I'd want to know the recognition performance on real-world images - that is, those from the usability test. Performance and usability are not separable so it seems scientifically dangerous to test them separately." (This is question 19 in the restricted area FAQ.) The answers to these inquiries were provided to all vendors the next day.

The following week, which was one week before the detailed Test Plan was released to all participants, the vendor sent a letter withdrawing from the FRVT 2000 evaluations. The primary cause cited for requesting the withdrawal was a disagreement with the evaluation methodology used for the FRVT 2000, which is explained in Section 3 of the Executive Overview of this report. The vendor requested a more narrow evaluation that concisely ranked the vendor systems. The sponsors rejected this approach as it would significantly limit the usefulness of the evaluation to only those with a planned usage that exactly matched the narrow evaluation methodology.

Appendix J – Vendor Product Descriptions

Summary Description of FRVT System Banque-Tec International

Overview of System

The system constructed for FRVT consists of both hardware and software components. The hardware is essentially a PC equipped with a frame grabber and a video camera. Two software programs were provided to cover the FRVT 2000 requirements *RPTprog* for the *Recognition Performance Test* and *Eidolon* for the *Product Useability Test*. Both make extensive use of CSIRO's SQIS API. Each component is discussed in more detail below.

Hardware

The hardware used in the FRVT 2000 is listed in Table 1. Considerable computer power was required due to the nature of the tests and the more modest requirements of our commercial system are shown for comparison.

	FRVT	Commercial
Computer	Dell Precision 420 dual 600 MHz Pentium III	Minimum 266 MHz dual Pentium II
Memory (Ram)	512 Mb	Minimum 128 Mb
Frame Grabber	Matrox Meteor	Matrox Meteor II
Camera	Sony SSC-DC50AP	Any PAL CCD camera
Lens	Avenir SLO8551	Customer choice

Table 1: Hardware configuration

It is readily apparent that the requirements of the commercial system are somewhat less critical than those of the test system. The primary reason for this is that a real door access system is not required to capture faces over the range 4i to 12i so the additional computer power required for face location at longer ranges is not required.

A full costing of the system used in FRVT is as follows:

1. Dell Precision 420 Workstation with 512 Mb Ram: AUS\$8816.00
2. Matrox Meteor II frame grabber: AUS\$1420 (Meteor: AUS\$1086)
3. Sony SSC-DC50AP : AUS\$1629
4. Avenir SLO8551 Lens: AUS\$480

Software

SQIS API

The SQIS API has face detection; identification and verification capabilities designed in an object-oriented fashion and implemented using industry standard C++. Although the SQIS API is currently only available for the PC platform it has been designed to be readily ported to most other hardware. Figure (1) illustrates the basic functionality of the API. The Face Locator module (FLM) provides functions to locate a potential human face in a video stream or a still frame and to then locate the eyes of any found faces. The Face Verification module (FVM) provides the core functions for comparing one face against another and the functions required for enrolling Operators into the system. The Database module (DM) provides a convenient mechanism for dealing with face databases and comparisons against multiple faces. Routines are provided to convert a facial image into a representation suitable for comparison against other faces. This process is known as *encoding*.

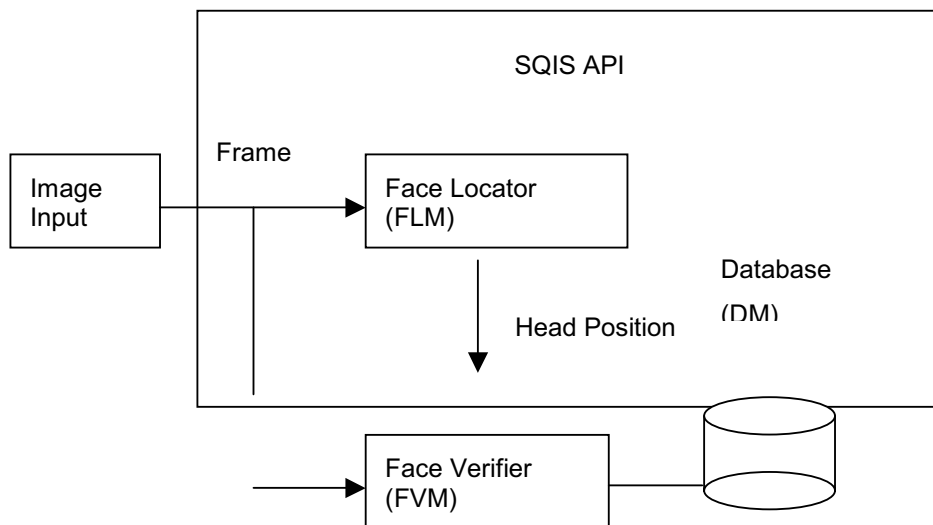

Figure 1: Block diagram for SQIS API

RPTprog

The *RPTprog* program is designed to read all JPEG images in a designated directory and perform one-to-one comparison between each image. The output is in the form of SIM files as specified in the FRVT 2000 documentation. It is hardened against system crashes and can be restarted at any point. The basic operation is as follows. All images in the designated directory are read, eye-located and encoded. The encoded images are then stored in the database. Test images are then read, eye-located, encoded and compared against the database. Finally, the output SIM file is written.

Telephone: +44 (0) 181 263 2770 Facsimile: +44 (0) 181 263 2701

Eidolon

The *Eidolon* program is a GUI based face recognition application designed to process incoming video streams at near frame rate. Such performance is possible through the use of multi-threaded programming techniques that make optimal use of the two system processors. Control of the program is through interaction with various dialogue boxes that allow certain system parameters to be set and modified on the fly. Success or failure of the system to complete a match is indicated visually. The operation of *Eidolon* may be broken up into three parts:

1. Enrolment; which may be further divided into two subcategories
 - (a) Enrolment from a set of still images in which images are read in, eye-located, encoded and stored in a database, and
 - (b) Enrolment from a live video stream in which the system operator selects asks the subject to stand in front of the camera and the captured video frames are eye-located, encoded and stored in a database. The enrolled face images are then presented to the operator who can carry out a manual quality check, deleting those images that are deemed to be below standard.

2. Verification (one-on-one comparison) is the mode of operation normally used in an access control system. A person desiring entry presents an identifying credential to the system which then checks the person's identity based on data derived from that credential. In the case of *Eidolon* the derived data is the enrolled Operators encoded face. The verification process proceeds as follows:

Operator modifies system parameters from defaults if required

Operator selects subject to be verified from database list

Operator starts verification process

Verification stops when a match with the subject is obtained, a preset number of frames have been tried or an operator set time limit is reached. In either of the latter cases a non-match is recorded.

3. Identification (one-on-many comparison, ie, database search) is similar to verification except that the only credentials presented to the system are captured images of the subject's face. The *Eidolon* system then checks whether that Operator has previously been enrolled in the system by performing a search over all enrolled Operators. The basic operation is as follows:

Operator modifies system parameters from defaults if required

Operator starts identification process

Identification stops when a match with the subject is obtained, a preset number of frames have been tried or an operator set time limit is reached. In either of the latter cases a non-match is recorded

FaceSnap Recorder – General Overview

The FaceSnap recorder digitizes standard video sources and performs real-time pattern recognition on the captured images. The FaceSnap recorder detects human faces in the video stream and stores a user-adjustable image region around each face. A powerful image database facilitates easy navigation and search on large numbers of stored images. For analyzing the face image database, interactive and automatic search functions are provided. As an option, the FaceSnap recorder can perform real-time face recognition (requires two product units). The FaceSnap recorder is a revolutionary solution for person-oriented video surveillance, access monitoring and other applications requiring face image recording and face recognition.

There are several modes of operation:

1. Standard recording mode

The FaceSnap recorder screen shows the live camera image and a number of most recently recorded persons. The user can switch between a number of different video inputs. The captured face images are displayed in a normalized format and can be stored in real-time on the local disk.

2. Replay mode

In replay mode, the user can easily navigate through a large amount of image data. Images are time stamped and can be directly accessed through their time keys or the graphical event histogram that provides an overview of the temporal distribution of recorded images.

3. Search mode

In search mode, the user can define image groups as a general purpose tool for data management. In addition, image groups are used to define training sets for face identification. Automatic functions for image pattern recognition are provided to search the face image database and support content-based data management.

4. Training mode

The FaceSnap recorder can be trained to recognize faces based sample images collected by the user. In training mode, an image group can be imported to establish or extend a training set for a particular person. There are two hyper classes of persons: a) the class of all persons known to the FaceSnap recorder and b) the class of all persons the FaceSnap recorder is supposed to look for.

5. Selective recording mode

Face images captured by a FaceSnap recorder operating in recording mode can be sent to a second FaceSnap recorder over a high-speed 100BaseTX network connection in real-time. The second system, which has to be put in the selective recording mode, receives the stream of face images and tries to identify all persons belonging to the hyper class of "active/interesting" people. Only those images for which the similarity value exceeds a user-defined threshold are displayed and optionally stored in the database.

Technology

The most important technology built into the FaceSnap recorder is the automatic selection of human faces in an image. The underlying technical problem is to detect and localize face-like patterns in a digitized image of an arbitrary scene. Moreover, the computer has to complete this search within fractions of a second since the person may not look straight toward the camera much longer than that. An additional requirement FaceSnap was designed to meet is the independence of object cues like motion or color. FaceSnap looks for face patterns in an image, not for regions showing a certain color range or being in motion relative to the image background. FaceSnap solves these problems by using a fuzzy abstract face model in combination with a neural net classifier. The outcome of the face finding stage are face image windows which are ranked according to a faceness value indicating how much the selected image portion resembles a human face

The face detection (face spotting) of the FaceSnap recorder works uses the FaceSnap technology as described above. The model-based pattern recognition has a processing rate of up to 25 images per second, depending on CPU type and size of the source image. Frontal views of human faces are preferred with a rotational tolerance of ca. +/- 15 degrees. Tolerance to deviations of the frontal face pose can be adjusted.

The face identification of the FaceSnap recorder uses the FaceCheck technology. The pattern recognition for face identification is based on user-provided training sets. The facial feature extraction is designed for frontal face views. Compensation of image rotation works up to +/- 15 degrees. Based on the location of prominent facial features, the face images are first geometrically normalized and then normalized with respect to the gray level distribution. From the normalized images, feature vectors are produced and then used for classification.

Screenshots of standard recording mode (left) and replay mode (right).

Screenshots of search mode (left) and training mode (right).

The submitted system consists of the following components:

Pos.	Quantity	Component	Price in Euro (total)
1.	2	FaceSnap recorder standard unit	10.123,60
2.	2	CD-Writer, incl. SCSI adapter	562,40
3.	1	High resolution camera (XC-8500), option package	1.508,30
4.	1	FaceCheck real-time option	1.789,50

The individual components are described in the attached price list.

Submission: TrueFace API 4.0 SDK
Test Date: May 15-19, 2000

TrueFace Overview

The eTrue (formerly Miros) TrueFace API version 4.0 Software Development Kit (SDK) represents the latest face recognition technology from eTrue. It offers image acquisition and manipulation from Video-for-Windows (VFW) compatible video sources as well as reading standard image file formats. TrueFace is the only face recognition product certified by the International Computer Security Association (ICSA).

The TrueFace SDK gives applications the ability to find faces in images and to perform facial verification and identification. The software runs on Windows 9x, NT, and 2000. To speed development, the software includes several working sample applications written in Microsoft Visual C++ and Visual Basic along with source code.

The TrueFace SDK can be purchased with one of three different licenses:

1. **Locate** – For applications that only want to find faces in images.
2. **Verify** – For applications that want to verify a user's face against a claimed identity. Includes the Locate functionality.
3. **Identify** – For applications that want to identify a user's face within a database of users. Includes both the Locate and Verify functionalities. The Identify licensing is priced based on the desired number of users in the database.

The hardware requirements for the TrueFace SDK are as follows:

1. A PC running Windows 95, 98, NT or 2000.
2. The preferred processor is an Intel Pentium III or higher. The Intel Pentium II and the Celeron family also will work as well as all comparable AMD processors.
3. At least 32 MB of RAM.
4. A Video-For-Windows (VFW) compatible camera and driver. This includes all USB, parallel-port, and frame-grabber acquisition sources that have VFW drivers.

An overview of the face finding and matching capabilities of the TrueFace SDK is given in the following sections.

Face Finding

When processing an image, TrueFace first finds the face using a combination of very efficient neural networks. The image can be either color or black-and-white in any standard image format

and of any size. When processing a video stream, TrueFace tracks the movement of the faces in the field of view, thereby increasing system throughput. After finding the face and locating the eyes, TrueFace generates a binary face template that can range from 500 to 2000 bytes in size, depending upon the accuracy desired.

Face Matching

The matching algorithm in the 4.0 version of the TrueFace API is based on an adaptive matching technique using neural networks. Matching times between two face templates range from under 0.1 ms to 4 ms on a Pentium III 800 MHz PC, depending on the template size. All of the face templates for a single person can be aggregated together into a person template. A person template allows the common properties of the individual face templates to be used to speed up the matching process further. In addition, person templates can reduce the time needed to update the enrollment database when upgrading to a new TrueFace version.

Face Recognition Vendor Test 2000

For the FRVT2000, the core face recognition engine in the TrueFace SDK was used for both the Recognition Performance Test and the Product Usability Test. However, the test application software used to access the TrueFace SDK was different between the two tests because of the requirements for the two tests. For both tests, the test application software is described in more detail in their respective sections below. For both tests, full-size face templates were used for the highest accuracy.

The PC platforms used in both tests were not identical but were very comparable. Both PCs used the same processor (Pentium III at 800 MHz), had a 133 MHz front-side bus (FSB), and had 256 MB of RAM. However, the type of RAM differed between the two machines (SDRAM vs. RDRAM). They both used a 20 GB Ultra ATA-66 (7200 RPM) hard drive and ran Windows NT 4.0 Workstation with Service Pack 5. On sample runs for the Recognition Performance Test, both PCs performed nearly the same.

Recognition Performance Test

The test application for this test was a custom console-based (command line) Win32 application written in C++. It first generated face templates for all the images in the test set. Then, it performed the matching between the face templates and collated the match output scores according the FRVT2000 specification for this test. Finally, it generated the required output similarity files.

The component list for the system submitted for this test is given in the following table:

COMPONENT	DESCRIPTION	COST
Software	eTrue TrueFace API v. 4.0 Software Development Kit with an Identify engine with a database limit of 100,000 users. Driven by a custom command-line program.	See pricing note below
Computer	Dell Dimension XPS B800R, 800 MHz Pentium III, 133 MHz FSB, 256 MB 266 MHz RDRAM, 20 GB ATA-66 7200 RPM hard disk, 17 inch monitor, WinNT 4.0 SP5.	\$2750

Product Usability Test

The test application for this test was TrueFace ID version 2.5.

The test scenario is an access control application. TrueFace ID is intended for use as a tool to identify people under suspicion, usually in public settings, and to notify security personnel if a possible match has been found. Because fraud by photograph is typically not a problem in public settings, TrueFace ID has no photograph detection capability. A "Verify" mode allows for verification in addition to identification.

Enrolling images into TrueFace ID is easy. It can accept images in files (any standard format) or previously captured video images. It also can be used to enroll cooperative subjects in a controlled setting and uncooperative subjects under surveillance. For a cooperative subject, the person simply needs to look at the camera for a few seconds while the software captures 8 images of the person. For an uncooperative subject under surveillance, TrueFace ID stores the last 20 faces found, any of which can be enrolled into a person's database record.

When identifying faces in a stream of video images, TrueFace ID scans the input images and attempts to continuously identify the best faces found. Visually, the software displays the whole image, the cropped-out facial image, and the list of possible matches from the database, sorted in order of decreasing match score. All matches above a low threshold are displayed. Any matches above a high threshold can generate an audible alert for notifying security personnel. Furthermore, all matches above either the high or low threshold can be saved to a database event log for later review.

The hardware requirements for running TrueFace ID are the same as for the TrueFace SDK. However, the minimum amount of memory for TrueFace ID is 128 MB of RAM. For a database size larger than 1,000 people, additional RAM is recommended.

The component list for the system submitted for this test is given in the following table:

COMPONENT	DESCRIPTION	COST
Software	eTrue TrueFace ID v. 2.5 (uses TrueFace API v. 4.0 with an Identify engine) with a database limit of 100,000 users.	See pricing note below
Computer	Micron Millennia MAX GS133, 800 MHz Pentium III, 133 MHz FSB, 256 MB 133 MHz SDRAM, 20 GB ATA-66 7200 RPM hard disk, 17 inch monitor, WinNT 4.0 SP5.	\$2300
Video Capture	Coreco Bandit frame grabber and display card with camera cable.	\$870
Camera	Hitachi VCC-151 color camera.	\$625
Lens	Computar T6Z5710-CS 5.7-34.2 mm 1:1.0 zoom lens or Fujinon-TV CF12.5A 12.5 mm 1:1.4 fixed focal length lens (CS-mount).	\$205

Pricing Note

eTrue was asked to supply the price of its TrueFace software for this report. Unfortunately, we were unable to comply with this request for the following reasons: The price of the TrueFace software varies considerably depending on which application it will be used for, which country we sell it to, what support we provide with the product, how many units are ordered, and other considerations we negotiate with our customers. The price can fluctuate dramatically over a short time frame in this competitive market place, especially during a period of quickly changing market demand that we are in today. To be fair with all our corporate customers, we provide our price on an individual customer basis. However, our aim is to be the least expensive provider of face recognition, with our range of performance, in the entire industry.

Overview of HUNTER™

A Facial Recognition Surveillance System

LAU Technologies
30 Porter Road
Littleton, MA 01460

This document contains proprietary information to LAU Technologies and is Copyright © protected. Unauthorized copying, duplication and use in part or whole without express written approval of LAU is not permitted.

1.0 Lau Technologies Core Facial Recognition Technology

The facial recognition technology developed at the Massachusetts Institute of Technology (MIT) and exclusively used by LAU Technologies employs “Eigen faces”, which are characteristics of a person’s face, and maps the facial image into a multi-dimensional face space. Using special techniques developed by LAU the Eigen faces are used to provide high speed facial matching to one or many candidate faces in a database.

Figure 1.1: Eigen Faces

The multidimensional Eigen space itself is determined through a separate process at Lau Technologies that is typically done only once. This process begins with a large diverse population of thousands of facial images. For each of these images, the head and eyes are located; the image is standardized, and then masked. The resulting ensemble of localized, standardized and masked images are then processed with a mathematical technique called Principal Components Analysis. The result of Principal Components Analysis is a set of face-like images called Eigen faces. Each Eigen face is mathematically independent/orthogonal to all others, and is an independent degree of freedom for describing faces. In other words, these face-like images are the most efficient set of building blocks needed to build any face. Figure 1.1 shows the first five Eigen faces that result when Principal Components Analysis is performed on a large sample of face images.

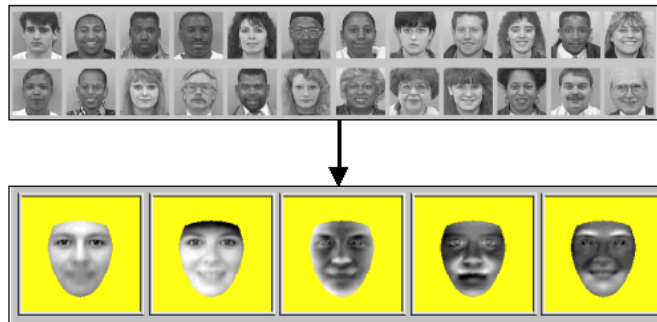

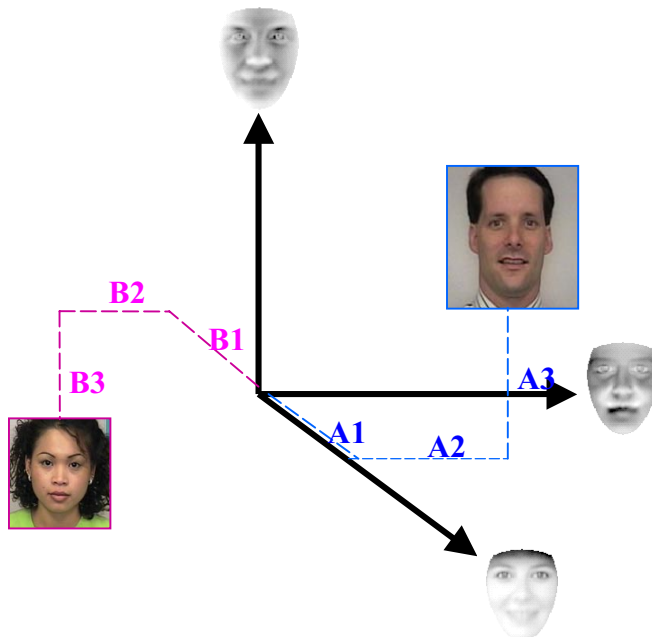

Figure 1.2: Face Space

After standardization and masking, the image is projected into the multidimensional Eigen space of facial recognition as shown in Figure 1.2. The result of this projection of the facial image onto the Eigen face templates is a set of Eigen coefficients, which together form an Eigen vector. The multidimensional Eigen space is constructed of 128 mathematically orthogonal coordinates and each coordinate is representative of a single characteristic Eigen face.

The first coefficient of the image being enrolled is calculated through the projection of that image onto the primary Eigen space coordinate, which is also referred to as the average Eigen face. Once determined, the first coordinate projection is subtracted from the original image in order to produce a residual image. This residual image is then

projected onto the second designated Eigen space coordinate and thus the second coefficient is obtained. Then the second projection is subtracted from the previous residual image in order to produce a new residual image. Successively, each new residual image is projected onto the next coordinate. Each projection subtracted produces a further deconstructed residual image.

This process of projecting the resulting residual image onto each coordinate produces a total of 128 characteristic Eigen coefficients. Together this set of characteristic coefficients represents a complete vector projection in the facial recognition Eigen space. The combination of these 128 coefficients with respect to their corresponding Eigen face images produces a reconstructed masked image that can be viewed and verified as being visually very similar to the original masked image.

The captured or scanned digital image is converted to Eigen coefficients (simply described as facial features) and submitted to the Facial Recognition Search Engine, which returns results in real-time to the requesting client. These results comprise the closest matches found for the individual. They are ranked in order with the closest match shown first.

2.0 Product Usability Test

Figure 2.1 shows a block diagram of a Facial Recognition Access Control system, operating in verification (1 to 1 matching) mode. The user is prompted for his or her ID number in the Access Control Entry Screen. Although this example shows a screen where an ID number is typed on a keypad, alternative means of asserting identity include magnetic strip card, or RF proximity badge. Once the ID is asserted, the system continuously searches for heads and eyes for a fixed time period. Each time that a face is found, it is standardized and converted to a set of Eigen face coefficients, and compared to the database of one or more reference images corresponding to that ID number. If the captured face matches one or more reference images with a degree of confidence, which exceeds a customer-defined threshold, then a GO decision is made, and access is granted. Otherwise, face images will continue to be captured until the timeout period. If no match is found before the timeout period, then a NO GO decision is made, and access is denied. In either case, an entry is stored in a log file for immediate or subsequent review by a system administrator. For each transaction, the log file stores a pair of images showing both the enrollment image used for the match, and the live capture image. This information can serve as a valuable audit trail to understand events where unauthorized access was attempted.

Facial Recognition Access Control System

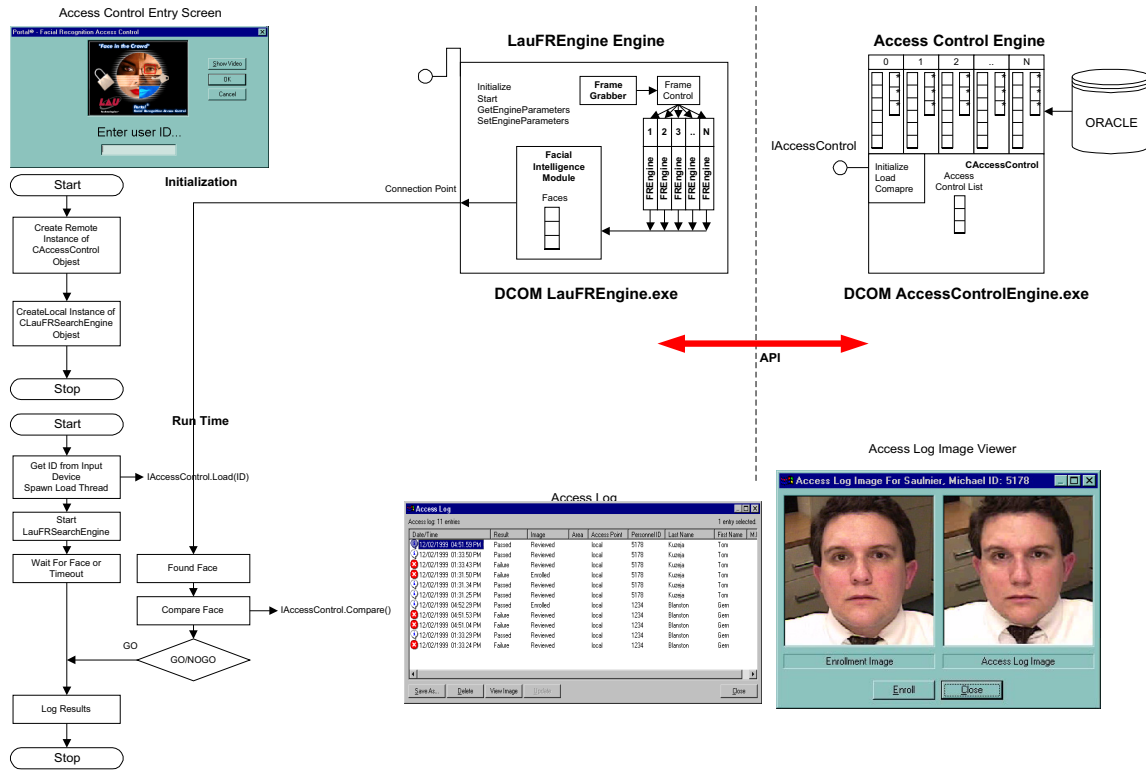

Figure 2.1 Access Control Flow Diagram

3.0 Hunter Surveillance Product

The Hunter system automatically acquires (finds the face) and recognizes subjects in real time. The surveillance application continuously searches the camera's field of view for heads. When a head is found the eye locations are calculated, and the face is converted to an Eigen vector. For each successful acquisition the subject's face is displayed in the top half of the GUI. If a face is captured that is sufficiently close to a face on the watch list (pre-enrolled subjects), then the potential match is display for consideration by the operator.

The facial biometric data stored will include Eigen coefficients, compressed standardized images and eye locations of the original image. Since each coefficient is 2 Bytes in size, a set of Eigen coefficients for a single face is a total of 256 Bytes. These characteristic coefficients are used solely for the purpose of facial recognition searches and verifications. The eye locations and standardized images are used for review and future enhancement purposes, but they are no longer required for the performance a facial biometric match. This biometric data can be stored with relational links to corresponding demographic data. This demographic data can be utilized to enhance or modify facial search results

4.0 Products and Pricing

Hunter Surveillance System

The entry level Hunter software product is designed to operate as a stand alone surveillance system. The product is shipped on a CD with a decoding software dongle. The price of Hunter in this configuration is \$1000 U.S.

Hunter runs on a PC running Windows NT platform, and uses COTS video hardware. Lau will be pleased to make hardware recommendations for frame grabbers, cameras and computers.

Cost of system components used in FRVT2000.

FaceIt® Technology used in Facial Recognition Vendor Test 2000

All Visionics Corporation's products are derived from the algorithms in the Facelt® Identification Software Developers Kit (SDK).

Recognition Performance Test

The system used for the Recognition Performance Test was comprised of an application written with the Facelt® Identification SDK and a computer running the Windows NT operating system. The Facelt® application performs one-to-many and many-to-many facial matches on stored images. It is a high-speed, high-accuracy engine designed for checking the integrity of databases and for prevention of identity fraud.

The application used for the Recognition Performance Test includes algorithms for automatic face segmentation from an image (face finding and alignment), facial template creation, and template-to-template matching. This functionality is provided to developers using the SDK in two COM objects: FaceItLocate and FaceItRecognize. The console application built with these objects consists of four simple modules that thinly wrap the SDK objects. The first module does not actually rely on the SDK, but is used to read images from a directory and create a text database with links to each image location, as required for the Facial Recognition Vendor Test 2000. The next module uses the FaceItLocate object to find faces in the images and pinpoint the location of the eyes. The remaining modules use the FaceItRecognize object. The third module creates facial templates, the biometric FacePrints. The fourth and final module performs matching operations and generates the similarity files. The code for this application is available with purchase of the Identification SDK.

Face Finding and Template Creation

On a single 500MHz Pentium III computer, up to 60 images can be pre-processed (face finding, alignment and template creation) per minute; very complex images may require more pre-processing time. Visionics face finding technology is able to find heads at a very wide range of sizes and in complex, real-world scenes.

FaceIt® technology employs **Local Feature Analysis** (LFA) to represent facial images in terms of local, statistically derived building blocks. Identity is determined not only by which elements are characteristic of a particular face, but also by the manner in which they are geometrically combined (i.e. their relative positions). LFA is a mathematical technique that enables high accuracy facial matching and is robust with respect to variations in lighting, facial expression, hairstyle and pose.

Facial Matching Speed

LFA operates in two modalities: Vector, which uses a very compact representation of the face, and Intensive, which uses a more rich representation. Search speed using the Vector modality is 47,000,000 matches per minutes on a single 500 MHz Pentium III computer. Search speed using the Intensive modality is 10,000 matches per minutes on the same CPU. The accuracy of the two modes is equally high, except when image quality is poor. In this case, the Intensive mode of LFA may provide superior performance.

For large database searching applications where some images are poor quality, we recommend use of a two-pass search strategy in order to optimize both speed and accuracy. First, a rapid pass is performed over all records using the Vector mode. Results are sorted in order of the confidence that the comparison was a match. Then a second pass is performed using the Intensive mode to search some fraction of images that yielded the highest confidence of a match in the first pass. The fraction used in the second pass is a tuning parameter that enables one to trade-off between speed and accuracy when image quality is sub-optimal. We utilized this technique in the Recognition Performance Test, specifying that the top 15% of the images from the first pass be searched again in the second pass.

Component List

- Application built from FaceIt® Identification Software Developers Kit
- Dell PowerEdge 6300 computer (only a 400 MHz single processor required)

Cost Breakdown

The total cost of the system used for the Recognition Performance Test was \$26,660* in April, 2000. This figure includes the cost of the SDK used to create the facial recognition application.

The cost of the FaceIt® Identification SDK from Visionics is \$9,995.

The computer used was a Dell PowerEdge 6300 with four Pentium Xeon 550 MHz CPUs, 512 Cache, 1GB RAM, an 18GB SCSI Hard Drive, CD-ROM drive, 15 inch monitor and a 2GB Iomega Jaz Drive. This system was priced at \$16,665 from Dell's website. *Note that while we chose to use a relatively high-end computer for the purpose of performing nearly 200,000,000 matches in 28 hours, the Recognition Performance Test can be run on any Pentium class computer. Typically we recommend a single Pentium III 400 MHz processor as the best compromise between speed and price. However, FaceIt® technology is fully scalable as shown by our ability to run our many-to-many engine on a quad processor.

Product Usability Test

The system used for the Product Usability Test was comprised of an application called **FaceIt® Surveillance**, a computer running the Windows NT operating system and a Video for Windows compatible video capture system. FaceIt® Surveillance utilizes the same core algorithms contained in the Identification SDK, but is a product designed for real-time face finding in video and automatic searching for facial matches in a watch list. This application is available for purchase from Visionics Corporation.

FaceIt® Surveillance includes algorithms for automatic face segmentation from a video image (face finding and alignment), facial template creation, and template-to-template matching. FaceIt® Surveillance is an intelligent software solution that is designed to compliment and enhance existing CCTV systems by automating and improving the routine and arduous surveillance tasks performed by a human operator. FaceIt® Surveillance accepts as input either live or recorded (archived) video and performs one-to-many searches for the purpose of identification and to alert operators as to potential matches with members of a watch list.

Face Finding and Template Creation and Facial Matching Speed

Please refer to information above, in description for system used in Recognition Performance test.

In order to perform the Verification portion of the Product Usability test, we created a facial database containing one or more images of a single person. However, FaceIt® Surveillance was not designed for the purpose of one-to-one matching. Also, because this application is designed for automated surveillance, rather than access control, it does not include the **Liveness Testing** mechanisms that are employed by Visionics' technology for computer information security. These proprietary mechanisms enable FaceIt® to distinguish real faces from photographs of faces in access control verification scenarios.

Component List

- FaceIt® Surveillance
- Dell Precision 210 Workstation
- Canon VC-C3 camera
- Winnov Videum capture card

Cost Breakdown

The total cost of the system used for the Product Usability Test is \$14,675.

The cost of FaceIt® Surveillance from Visionics is \$9,995 - \$24,995, depending on database size. A similar product, FaceIt® Sentinel, allows search "on-demand" (click on face of interest to initiate search for a match) and is available for \$4,995 - \$9,500, depending on database size. The most economical versions of Surveillance and Sentinel handle up to 1000 records each.

The computer used was a Dell Precision 210 with two Pentium III 600 MHz CPUs, 512 Cache, 384 MB RAM, an 18GB IDE Hard Drive, a CD-ROM drive and a monitor. A comparable machine, the Precision Workstation 220, is currently priced at \$3131 from Dell's website. FaceIt® Surveillance was designed to run on a dual processor.

The camera used was Canon VC-C3 Communication Camera, which costs \$1400.

The Winnov Videum VO PCI capture card costs \$149.

Appendix K – Sample Images

The following images were taken from the database used for FRVT 2000. They are shown here as a representative sample of the different methods used to capture images for the test. There were three basic variables in the image collection process: expression, lighting and media.

Subjects posing for the images were asked to use two different facial expressions. A normal expression, called *fa*, was used for some images. Another expression of the subject's choosing, called *fb*, was used for other images. The *fb* expression could be a smile, frown, grimace or other expression.

There were five types of lighting used for image collection. In the mugshot style, three flood lamps were used to illuminate the subject. In the FERET style, two flood lamps were used. A single flood lamp was used for the badge system lighting. Overhead fluorescent lighting was used for some images, while other images were taken outdoors using available daylight.

Images were collected using several types of media, including a digital still camera, a 35mm film camera, and a DV video camera. The 35mm film was later scanned to obtain digital images. Footage from the DV video camera was transferred digitally to a computer and still frames were selected for the database. For the badge system, the camera's analog video signal was captured using a computer with an installed frame-grabber card.

The techniques used to collect images are discussed in more detail in Appendix G.

Appendix N – Glossary

Biometric signature (biometric template)	A digital representation of the user's distinct characteristics. Exact definition depends on the type of biometric system used.
Cooperative subject	A subject that actively assists the biometric system.
Cumulative match characteristic (CMC)	A set of data points that describes the identification performance of a biometric system when the system returns the top n matches, where n is a user-defined number. See Section 7.1.2 in this document for an in-depth description of a CMC curve.
Duplicate	A probe image of a person whose corresponding gallery image was taken from a different image set. Usually, a duplicate is taken on a different day than the corresponding gallery image.
Duplicate I probes	Set of duplicate probes for a gallery used in the FERET evaluations.
Duplicate II probes	Set of duplicate probes in the FERET program where there is at least one year between the acquisition of the corresponding probe and gallery images.
Enrollment	The process of observing an individual's chosen characteristic, normalizing it and storing it in the biometric system's database.
Equal error rate	The operating point in a biometric system where the false acceptance rate and false reject rate are equal.
False acceptance (alarm) rate (FAR)	The percentage of imposters whose identity claims are incorrectly accepted.
False reject rate (FRR)	The percentage of valid users wrongly rejected.
FERET	The FacE REcognition Technology program sponsored by the DoD Counterdrug Technology Development Program Office from 1993 through 1998. Detailed information about the FERET program can be found at http://www.dodcounterdrug.com/facialrecognition .
Fully automatic algorithm	An algorithm that can locate a face in an image and recognize the face. All algorithms tested in FRVT 2000 were fully automatic.
Gallery set	The collection of images of individuals known to the algorithm. A gallery set always has only one image per person. See <i>probe set</i> .
Identification mode	The biometric system compares the given individual's biometric signature to all biometric signatures in its database and returns the top n matches.

Indifferent subject	A subject that does not actively help or hinder the biometric system.
Noncooperative subject	See <i>uncooperative subject</i> .
Operational evaluation	The third in a sequence of three evaluations outlined in “An Introduction to Evaluating Biometric Systems,” by P. J. Phillips, A. Martin, C. L. Wilson and M. Przybocki in <i>IEEE Computer</i> , February 2000, p. 56-63, 2000. The primary goal of an operational evaluation is to determine if a biometric system meets the requirements of a specific application. See <i>technology evaluation</i> and <i>scenario evaluation</i> .
Partially automatic algorithm	An algorithm that requires that the centers of the eyes be provided prior to recognizing a face. Most of the results cited in the FERET reports are from partially automatic algorithms.
Probe set	A set of images containing the face of an unknown individual that is presented to an algorithm to be recognized. Probe can also refer to the identity of the person in a probe image. A probe set may contain more than one image of an individual. See <i>gallery set</i> .
Recognition	A generic term used in the description of biometric systems. Recognition does not inherently mean either identification or verification but is sometimes used as such.
Receiver operating characteristic (ROC)	A collection of data points that describe a biometric system’s numerous FAR/FRR associations. See Section 7.1.2 in this document for an in-depth description of a ROC curve.
Scenario evaluation	The second in a sequence of three evaluations outlined in “An Introduction to Evaluating Biometric Systems,” by P. J. Phillips, A. Martin, C. L. Wilson and M. Przybocki in <i>IEEE Computer</i> , February 2000, p. 56-63, 2000. The primary goal of a scenario evaluation is to determine whether a biometric technology is sufficiently mature to meet performance requirements for a class of applications. See <i>technology evaluation</i> and <i>operational evaluation</i> .
Scoring software	A software package that uses similarity files and experiment definitions as input, and then returns output that can be displayed graphically by a ROC or CMC curve.
Similarity score	A numerical description returned by a facial recognition algorithm that describes that algorithm’s confidence that the probe and gallery image were of the same individual.

Similarity file	A predefined file structure used in the FERET program and the FRVT 2000 evaluation that documented the similarity scores from numerous image comparisons.
Technology evaluation	The first in a sequence of three evaluations outlined in “An Introduction to Evaluating Biometric Systems,” by P. J. Phillips, A. Martin, C. L. Wilson and M. Przybocki in <i>IEEE Computer</i> , February 2000, p. 56-63, 2000. The primary goal of a technology evaluation is to measure the state of the art, to determine technological progress, and to identify the most promising approaches. See <i>scenario evaluation</i> and <i>operational evaluation</i> .
Uncooperative subject	A subject that attempts to actively hinder the biometric system. Sometimes referred to as noncooperative.
Verification mode	The biometric system compares the given individual with who that individual says they are and gives a go/no-go decision.

Appendix 0 – Participant's Comments on the FRVT 2000 Evaluation Report

The sponsors of the FRVT 2000 sent a copy of the Evaluation Report to the participating vendors on February 8, 2001. The sponsors were given the option to prepare and submit a position paper to be included in this appendix. The deadline for including their position papers was 9 A.M. EST on February 16, 2001.

The submitted position papers are included in this appendix without modification. Furthermore, the sponsors have decided not to comment on these papers except to correct one misconception. In the lighting section on page one of the Lau Technologies position paper, Mr. Cusak states, "An option was made available to participants to make use of auxiliary lighting equipment in the manner they saw fit. Most participants enthusiastically embraced this offer." Surprisingly, this was not the case because none of the participating vendors used auxiliary lighting equipment.

Comments from C-VIS on the Facial Recognition Vendor Test 2000

The FRVT 2000 was the first independent, truly open, and published evaluation of commercial facial recognition systems. However, the preconditions for participation excluded research projects and implicitly required a number of advanced technical capabilities that are not found in all commercial systems on the market. We believe that the FRVT 2000 is an important milestone in the evolution of facial recognition technology and for the development of markets for its applications. As the sponsors correctly point out, the FRVT 2000 report cannot be used as a "buyer's guide for facial recognition". It does, however, give valuable insights on both the relative strengths and weaknesses of the tested systems and on the state of the art in general.

Our comments on the Facial Recognition Vendor Test 2000 focus on three questions:

1. Which results of the test are most significant for practical applications?
2. What do the results tell us about our product FaceSnap RECORDER?
3. What should be additional issues in future facial recognition tests?

Feasibility of Practical Applications

There are numerous existing and potential applications of facial recognition. We do not attempt to rank them according to some criteria of importance. However, there are two fundamentally different situations for which customers may want to have a facial recognition system: In the one category (A), both the reference image(s) (gallery set) and the probe set are taken from the same image source. This is typical for biometric computer login programs, for example. In the other category (B), a gallery set consists of images taken with different cameras and at different locations than the images of the probe set. In the FRVT 2000 report, one example for this situation is cited as a "mugshot vs. subsequent video surveillance scenario".

There is another fundamental distinction across all applications of facial recognition: Do we need a human supervisor or not? That is, does the customer need an interactive facial recognition system for assistance to a human operator, or is there a compelling need for a fully automatic system?

The FRVT 2000 results of the "Enrollment Time Test" and a number of experiments in the "Recognition Performance Test" clearly show that with current technology both interactive and automatic systems are feasible for viable commercial solutions to be operated in a category A situation.

If we look at automatic systems to be operated in a category B situation, the FRVT 2000 results clearly suggest that viable commercial solutions are not feasible today. This must be concluded from the results of the "Old Image Database Timed Test" and the "Distance Experiments" (D1-D3). As an example, a false alarm rate of 10% with only a ca. 50% chance of correct verification (average from the best system / Figure 22) is certainly not acceptable in most professional applications (just imagine an industrial inspection system with those error rates!).

If we look at interactive systems, the identification performance and the false alarm rate are much less critical in practice. In fact, a human operator searching a database does not gain significant convenience or time saving when presented with only 20 identification hits instead of 50, for example. That is, for category B situations other features and capabilities of a facial recognition product may be more important in practical applications than what has been tested in the Recognition Performance Test.

FaceSnap RECORDER

C-VIS submitted its product FaceSnap RECORDER to the Facial Recognition Vendor Test 2000. We felt that the addition of the Product Usability Test to the FERET style evaluations targeted products like the FaceSnap RECORDER. However, the FaceSnap RECORDER was not designed for access control and it is neither specialized on automatic database searches. The FaceSnap RECORDER is a digital video recorder with built-in real-time face capturing. The FaceCheck subsystem for face image search usually

requires several sample images of each reference face. For the FRVT Recognition Performance Test it had to run in an atypical operational mode in which a direct comparison of just two face images is possible. Actually, this requirement of the FRVT 2000 initiated the development of a new software generation that has eventually become operational only in the beginning of 2001.

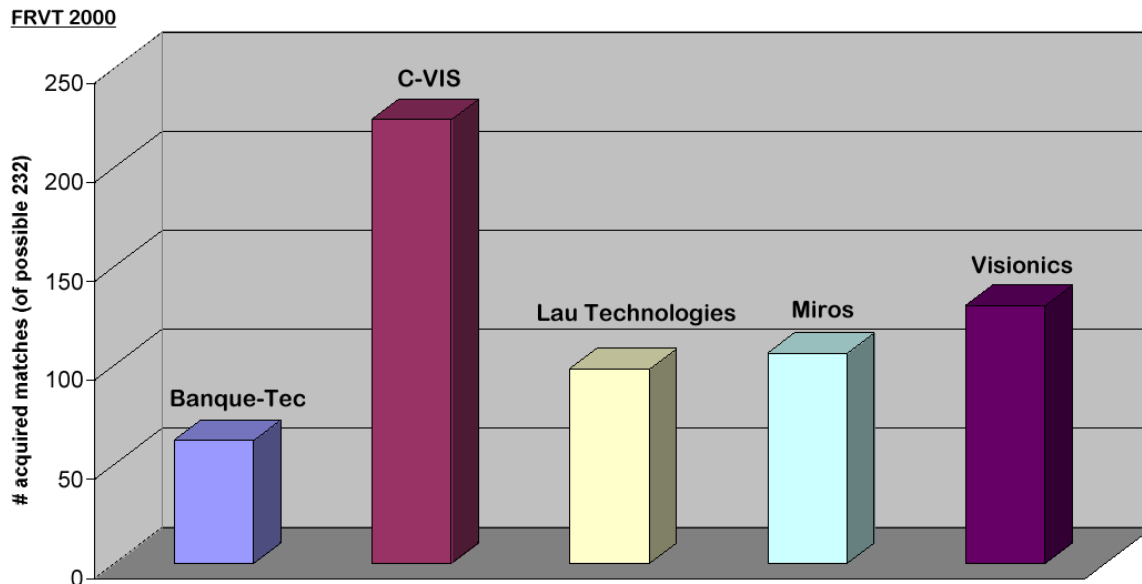

The FaceSnap RECORDER is being used for video surveillance, access monitoring, post-event analysis and a number of applications in law enforcement. The product philosophy is based on the realistic assessment that in most surveillance applications reliable automatic facial identification is not feasible given the current state of the art in facial recognition. Instead, the FaceSnap RECORDER delivers reliable real-time performance on the detection and recording of face images. Using this capability, police officers can find persons in time-lapse video recordings within minutes, as opposed to hours it takes them without a FaceSnap RECORDER.

In the FRVT 2000, the superior real-time performance of the FaceSnap RECORDER has become visible only in the results of the Product Usability Test. The report contains many comprehensive charts for the results of the Recognition Performance Test. Unfortunately, the reader of the report is left with the raw result data (tables 10 to 29) when it comes to the Product Usability Test. For this reason, we produced two charts that visualize the overall performance of the participating vendors in the Product Usability Test. The data were taken from the tables number 10 to number 29 on pages 46 to 55.

The first chart given below shows the total number of acquired matches in all experiments of the Product Usability Test. This number is an indicator of the reactivity of the systems in the face capturing phase. In the FRVT 2000 experiments, the FaceSnap RECORDER was set up to always capture at least three face images before a recognition decision was made. We believe that the FaceSnap RECORDER is currently the best system for face image recording. Although the FRVT 2000 lacks any separate test for face finding, the results of the Product Usability Test suggest a superior performance of the FaceSnap RECORDER.

Number of Acquired Matches within the Time Limit

(total number of "non-X" results in the "Old Image Database Timed Test" and the "Enrollment Timed Test" as reported in tables 10 to 29)

The Old Image Database Timed Test and the Enrollment Timed Test gave significant different results for all vendors. Again, the report contains the raw data from the experiments only, no charts. Below we show a chart that summarizes the total numbers of correct matches in the Old Image Database Timed Test and

the Enrollment Timed Test. For this chart, the trials in the Photo Test were not included because some vendors treated faces on photos as normal recognition objects and others tried to check for liveness.

In a typical application of the identification mode of the FaceSnap RECORDER many face images of visitors are routinely collected by a stationary surveillance camera at some point in a building. From these images a selection of 3 to 20 images of the same person is used to train the system. After that, the user can choose to record only images that have similarities with "known" persons or he can choose to record all images that do not look alike any of the "known" persons. In any case, the identification mode of the FaceSnap RECORDER is currently restricted to operate in category A situations only (see above).

Suggestions for future facial recognition tests

The FRVT 2000 appears to focus primarily on the "Recognition Performance Test" which is an attempt to evaluate a technology by a set of "designed test data". In our opinion, this approach has to be accompanied with an evaluation of an extensive set of application scenarios. In a real application scenario, the success or failure of a particular system may not depend primarily on the performance of a single "core technology". Instead, the quality of interaction of all system components and the suitability of the system design for a particular purpose becomes crucial. For an access control scenario, like the one in the Product Usability Test, a number of additional test issues should be added, e.g.:

- Rejection of Imposters (Is there an active decision of the system on imposters, or does the system just "don't recognize"? What is the FRR in what reaction time?)
- Does the system recognize the case that more than one person is present and imposters may walk in together with an authorized person?
- Does the system recognize other attempts to fool it? (e.g. by a photo, does it recognize the fact that there is photo or just don't recognize the face?)

There are a number of important real world applications for which customers seek a complete and viable solution. A commercial system should be tested against its claims with respect to particular applications. For future tests, it would be desirable to exactly identify the most important applications of facial recognition and to tailor test procedures to them.

Response to the FRVT 2000 Report

In reading the Face Recognition Vendor Test 2000 report, it is clear that a lot of effort and resources were applied to the preparation, collection, testing, analysis, evaluation and reporting of commercial face recognition technology. Overall, we appreciate the thoroughness and rigor of the approach (given the assumptions that were made) and reporting of the results. Unfortunately, the results that are reported do not show the complete state of the accuracy of face recognition technology today.

The test team made certain assumptions in preparing the test which were intuitive prior to the test, but which led to some unexpected surprises during the test. Using a homegrown face recognition algorithm as a guide, the team estimated the number of images that a commercial face recognition solution should be expected to process in a few days of testing. Providing some buffer beyond what their home grown solution performed, the test team decided on a base number of a little less than 200,000,000 face pair comparisons, with several hundred to thousand subset test pairs for the analysis.

By the definition of this type of test, it eliminated commercial face algorithms that could not perform 200,000,000 face pair comparisons in a few days to a week, but which may have been more accurate. Our company has no idea how accurately our face recognition algorithm performed on this test, because we have not been told and because the results of our participation in the major accuracy portion of the test are not reported.

When we asked the test team about reporting partial results (eTrue completed about a third of the test), they responded that the number of sample test points were too small (tens instead of hundreds) for a comparison between full results and partial results to be meaningful. It is unfortunate that based on the decision to use a homegrown algorithm as a guide and the subsequent choice of 200,000,000 face pair comparisons, this test mostly shows the accuracy of fast algorithms. Furthermore, this level of speed is simply irrelevant in one-to-one face verifications which represent a majority of real world applications. Many of these applications just need to complete one face pair comparison in under 1 second.

If there was an algorithm available (not necessarily ours) that could only do 1,000,000 face image pair comparisons in a few days but had 10X lower false accept errors and 10X lower false reject errors than the results report, this test would never show it. The government test team could have taken guidance from other third party organizations that have done tests in which both the accuracy and speed of face recognition technology were quickly and cheaply determined. It's too bad that the public or private sector will not have the opportunity to decide between faster versus potentially more accurate face recognition in a government sponsored test with the FRVT 2000 report, because potentially more accurate face recognition results were simply ignored.

Sincerely,

Michael Kuperstein, Ph.D.

Dear FRVT2000 Sponsors:

Thank you for providing Lau Technologies with the opportunity to participate in this important test program. Our team on site found the administrators to be very helpful, cooperative and sincerely committed to conducting the test by the most proper and objective means possible.

Please find attached, in PDF format, our response to the FRVT2000 test program. In our response, we included plots that were created from tabular data within your report. We would like to suggest, outside of the scope of the formal response, that perhaps you also see the benefit of presenting this data in plot format and consider appending your final release.

On behalf of Lau Technologies, I thank you for your professionalism. I have been involved first hand in a number of facial recognition tests over the last few years, ranging from Heathrow airport to the deserts of the occupied West Bank. From my experience, the testers and the tested always learn important lessons from intense efforts like this one. We look forward to working together with you to collectively move this emerging field forward, and bringing facial recognition a step closer to meeting the challenge of the most demanding real world applications.

Congratulations on a test program very well done.

Sincerely,

Francis J. Cusack Jr.

Lau Technologies

Lau Technologies' Position Paper

Introduction

Lau Technologies was pleased to participate in this important test effort. We share in the hope of the test creators and administrators that objective and professional third party test data will be invaluable to potential consumers in this emerging field. We point out here some of our insights into the test results, and suggestions for future testing presented very much in the spirit of furthering the development of facial recognition products that will be of practical value to industry and government.

Lighting

An option was made available to participants to make use of auxiliary lighting equipment in the manner they saw fit. Most participants enthusiastically embraced this offer. While lighting has historically been a fundamental limitation to robust recognition performance, Lau made a conscious decision to not conduct any of our tests with any supplemental lights of any kind. This decision reflects our commitment to build, and submit for test, products that are practical and robust. We have put a high priority on developing and fielding algorithms that actively mitigate the effects of real world lighting variations, and while there is still much room for improvement, have realized what we believe to be a unique and highly effective solution.

Surveillance

Many of the most compelling real world facial recognition applications are those that require automatic subject acquisition and recognition. Biometric surveillance systems that can acquire, identify and track subjects autonomously are now well within the realm of what can be successfully deployed, as we demonstrated at Super Bowl Thirty Five in Tampa this year. For many of the applications we discuss with partners and customers, this automatic real time video recognition is central. Furthermore, as this capability is developed and refined, new applications will present themselves. In light of these trends, and the intrinsic advantage facial recognition has in this area over other biometrics, we would like to see more third party testing with a strong emphasis on recorded digital video sequences. This will allow repeatable, reliable experiments testing recognition for a variety of conditions and scenarios typical of real world requirements for biometric surveillance systems.

Lau Technologies

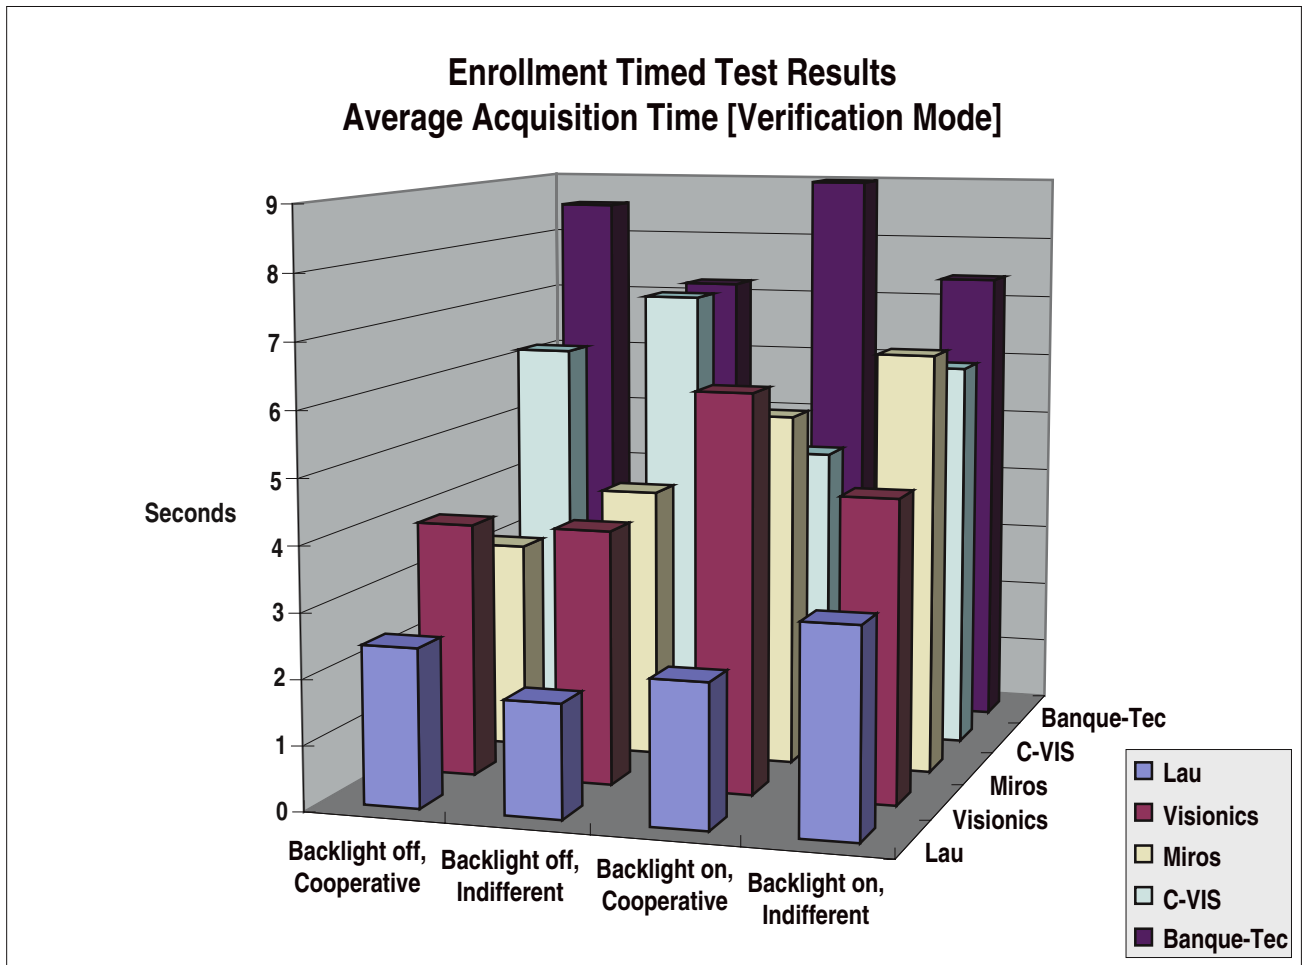

Speed

Lau has placed a high priority on developing technologies and systems to specifically meet challenging surveillance applications. This is evidenced by our results in the distance experiment featuring color images at a variety of distances with overhead and outdoor lighting, and the enrolled usability test. The recognition response time is also of particular importance in surveillance, as the probability of capturing suitable images from uncooperative subjects is proportional to the rate at which the video can be processed. Again, Lau's understanding of these dynamics, rooted in real world products and experiences, is evidenced by the relevant data in this report.

A comparative chart was constructed for all participants in the Enrollment Timed Test. Since the maximum allowed was 10 seconds, failures to acquire and acquisitions with wrong identities were counted as taking 10 seconds for the purpose of computing these averages. It may be of interest to readers to note that the Lau Technologies software ran on a single processor Pentium III at 866 MHz, while other participants chose to run quad Xeon processor platforms for some of the testing.

Executive Summary

The Facial Recognition Vendor Test 2000 (FRVT2000) was a state-of-the-art evaluation of facial recognition solution providers for the year 2000. It was divided into two categories: the Recognition Performance Tests and the Access Control Product Usability Tests. Overall both categories paint an extremely strong technology picture for Visionics, which ranked number one in 6 out of 7 of the Recognition Performance tests categories, as well as in most of the access control Product Usability tests. In most cases, Visionics significantly outperformed the nearest competitor.

The single Recognition Performance study in which Visionics did not rank first as well as some of the non-optimal timing results in the Product Usability test, can be explained by a primary constraint imposed by the test protocol. Namely, each of the tests had to be performed using a *single off-the-shelf implementation of our technology*. Because of this constraint, we chose products that had the closest compatibility with the most test evaluation criteria, but the choice could not be perfect. In the real world, a product implementation that is optimized for a specific task at hand would be supplied, unlike in these tests, where a single compromise had to be made to cover all tasks. Therefore, as we explain in this response document, these results should be viewed as anomalies and do not indicate a failure of our technology.

It is important to note that there were a number of vendors that participated in the FRVT2000 but whose technology failed to complete the tests on time and that there were others that chose not to take the test at all or pulled out after criticizing it. Our position from the beginning has been to promote honest communication and assessment of our technology, so we have embraced this test and its objectives. We have also encouraged many partners to test and validate our technology in their specific applications and environments.

The list of real world applications in which FaceItÆ has already been adopted is a testament to the fact that it is a serious commercial technology that continues to be the state of the art. Our in-house research team is tasked with the continued advancement of the technology and its maintenance ahead of the competition. Our record shows that we have released significant enhancements of the technology at the rate of once every one or two quarters.

It is worth noting that among all the vendors that participated in the FRVT2000, Visionics is the only vendor that was selected to participate in DARPA's Human ID at a Distance program. Our goal in this program is to develop complete systems for identification up to 200 feet. This has already resulted in major advancements in our capabilities.

Recognition Performance Test Paradigm Comments

The FRVT2000 recognition test as a whole does not correspond to a test of face recognition as it would be used in a particular market implementation, such as duplicate searching or surveillance. Instead, FRVT2000 is an attempt to test the boundaries of the technology and meaningfully differentiate between vendors—which is very valuable to the industry as a whole and to the adopters of technology. It sets apart what is genuine from what is marketing hype. As such, equal error rates quoted for each test are meaningful between vendors but do not indicate the typical performance of a particular product.

Both the Recognition Performance and the Product Usability tests measured a combination of two different technologies: face finding and face recognition. This is the correct approach because for almost all uses of face recognition, automatic face finding is required as a necessity (large scale database searching) or as something extremely useful (access control). In many cases, failure to acquire can be the limiting factor in the performance of the product. This point was not made explicitly in the FRVT2000 evaluation report.

Interpreting Results - Recognition Performance Tests

Introduction

Visionics technology performed extremely well in the Recognition Performance test. A brief summary of results is shown in the table below.

Test	Visionics	Lau	C-VIS	Miros	Banque-Tec
Expression	1	2	3	X	X
Illumination	1	2	3	X	X
Pose	1	2	3	X	X
Media	1	2	3	X	X
Distance	2	1	3	X	X
Temporal	1	2	3	X	X
Resolution	1	2	3	X	X

Table 1: Recognition Tests results shown as rank order where 1 is best. (X) indicates unable to complete entire test.

Table 1 shows the order of results for each category of test. 1 indicates the best performance and 3 indicates the worst. To be concrete, the rank order can be determined by comparing the top match results in the identification experiments for each category, and averaging over different experiments. However, the rank order is basically independent of all good measures used to determine it. For example, ordering the equal error rates for each experiment (with the lowest EER indicating the best performance) will yield the same results. The "X" indicates that the vendor was not able to complete the entire test. Overall, one can see from this table that Visionics performed exceptionally well in recognition performance.

A quick way to analytically gauge performance is to average the ROC curves for all trials together for each test and present the results:

At FAR = 10 ⁻³ (1 in 1,000) the probability of verification (1-FRR) is...					
Test	Visionics	Lau	C-Vis	%Gain over Lau	%Gain over C-Vis
Expression	.925	.72	.21	+28%	+340%
Illumination	.71	.55	.11	+29%	+545%
Pose	<u>.12</u>	.02	.02	+500%	+500%
Media	.965	.88	.335	+10%	+188%
Distance	<u>.12</u>	.12	.01	0%	+1100%
Temporal	<u>.32</u>	.22	.02	+45%	+1500%
Resolution	.905	.67	.17	+35%	+432%

Table 2: Averages of the probability of verification at FAR 1 in 1,000

The **bold** values are where we clearly outperformed the competition. The ***bold, underlined, italic*** values indicate areas in which we did as well (distance) or, in other cases (pose and temporal), better than the competition, but feel that we could have performed better. These latter areas are discussed in the sections below.

Pose Experiments

It is important to note that in this test the two images to be compared were frontal and at pose 40 degrees. While we far outperformed the competition, the technology provided for this particular test was not designed to perform well matching at poses differing by this degree. It is important to note, however, that we do provide better performance when matching fixed pose against the same fixed pose. Also the technology that was tested did not provide for pose compensation through morphing which is now a technological element that we offer.

Distance Experiments

The distance experiment results are different than all of the other experiments in that Visionics did not outperform all other vendors. We believe that the fundamental reason is that the test software used for this experiment was a poor fit to the task at hand. In fact, we believe that the experiment itself does not fit into a product category.

The software used by Visionics for the recognition performance testing was based on our Identification SDK. This SDK is designed for database searching applications. This was the appropriate choice for most of the recognition tests, as one is comparing many images against many images (a many-to-many identification search).

For the distance experiment, however, this software was not the right choice. According to the sponsors themselves, the Distance study, "...may be thought of as mimicking a low-end video surveillance scenario...". However, the design of the Distance study was not the most appropriate one for testing technology geared toward the task of video surveillance.

As discussed above, the Recognition Performance test can be thought of as a combination of two different tests: a face finding test and a face recognition test. The critical point is this: for surveillance, we perform face finding quite differently than we do for ID systems. For surveillance, we find multiple faces in the video frame (multi-face), and allow for the possibility that some faces found, particularly small faces, may be artifacts of the poor image quality. (These faces are never recognized, of course.) In ID systems, we only attempt to recognize one face, assuming that the one real face in the image has a much stronger signal than any artifacts.

Our analysis of the distance results indicates that the face artifacts generated by the poor image quality were in many cases those being matched against the gallery database. This explains the roughly linear ROC curves in experiments D2-D7, as this linearity is a signal that many of the scores are random in nature. It also explains why Visionics performed so well on the resolution experiments R1-R4; there were not artifacts in these images. If the multi-face technology that is used today in our surveillance products was used in tests D1-D7, we are confident we would have found the real faces and hence the results would have been significantly better.

There is an additional reason that we believe this study was not a real test of surveillance. In surveillance, image processing time is a crucial factor, as video is being fed into the system. In many cases it is better to be able to process multiple frames quickly rather than process a single frame thoroughly as one gets many chances to identify a different image of the person this way. One can also combine information between frames to improve the face finding and face recognition accuracy.

Motion detection is a very good pre-filter that can straightforwardly reduce the face artifacts input into the search system. The ability to perform motion detection requires video input, which was not provided in this test.

In the future, we would recommend that static images not be used to test surveillance. Instead, sequences of pre-recorded video would offer a more realistic testing scenario and allow the most accurate assessment of technology that has been explicitly designed to take advantage of video input.

Temporal Experiments

In a real world application such as access control, we recommend enrolling multiple (5) images/templates of the same person and design our systems to work in that manner. This dramatically decreases the FRR. Obviously, the Recognition Performance test did not allow us to take advantage of this real world systems engineering technique.

In addition, we recommend that the application perform a dynamic update of the templates. Dynamic update enables the facial recognition system to ile arnî the changes in a face that occur over time.

Nonetheless, we managed to outperform the competition in this study.

Additional Caveats

We would like to stress that the test did not really measure performance in real time. Vendors were not penalized for taking longer (unless they could not finish within three days). For the record we finished the test in two days; leaving more than 24 hours unused. The software was set on a fast setting which uses the least computing time. Had we set the software to

"intensive" mode, we could have done even better than we did. However, had we done so, we would have used up the additional 24 hours which was allowed by the test. We erred on the side of finishing early since we wanted an extra day in case of unforeseen problems occurred or in case the test consisted of more images than expected. (The number of images was not set to a fixed number prior to the test.)

Since the time of the test, new and improved face finding and face recognition algorithms have been developed. At that time, the new code was not yet mature. In addition, performance in the pose tests would have benefited significantly from our latest technology that finds faces at arbitrary pose.

Interpreting Results- Product Usability Tests

The second half of the FRVT2000 testing was a simulation of a hands-off access control system.

The system used by Visionics however, was not intended for access control applications. This caused two problems to occur in the testing. Firstly, in the simulation of the access control scenario where a single image is loaded into the surveillance system, there is a few-second startup time that comes from the surveillance software design. This time lag appears as a constant added to each acquire time because we had to re-start the surveillance application for each trial. This led to artificially large face acquire times in tables 14, 19, 24, and 29. This startup time lag would be negligible in a properly designed access control system using Visionics technology.

Secondly, the surveillance product used for the test has no "liveness" (photo test) technology. The surveillance product was not designed to include a mechanism for distinguishing between a live subject and a photograph, because in real world surveillance scenarios, there is no expectation that a person would attempt to be identified using a photograph. (Note that Visionics has advanced "liveness" technology that has been used in IT security products for a number of years.)

There were several problems with both the test design and with our performance. For instance, the tests are not repeatable nor do they accurately reflect the results. In most tests the subject walked towards the camera and the distance from the camera was used as a measure of how the recognition works. Due to the use of our surveillance product, the subject was typically at the close limit (1 foot) by the time the first image (12 foot) was recognized. So we are on record as recognizing the person at 1 foot even though the recognition was from a picture of the subject acquired 12 feet away. Because of the height difference in the subjects (5'5" - 6'2") we could not even see their faces at 1 foot away from the camera. Therefore, the results are misleading.

Nevertheless, one can roughly summarize the test results by counting the number of correct match results obtained in the Old Image Database Timed Tests and the Enrollment Timed Tests. We have excluded the photo test for the reason given above. This analysis is shown in Table 3.

Correct Matches for the Timed Tests					
	Visionics	Lau	C-Vis	Miros	Banque-Tec
Old Image Database Timed Test					
Verification	33	0	0	20	0
Identification	16	0	0	0	0
Enrollment Timed Test					
Verification	<u>45</u>	49	41	40	13
Identification	<u>30</u>	49	48	41	13
Total	124	98	89	81	26

Table 3: Timed Test Correct matches

The **bold** values are where we clearly outperformed the competition. The ***bold, underlined, italic*** values indicate unexpected performance. Both are discussed in the sections below.

Old Image Database Timed Test

The old image timed test was the more difficult of the two timed tests, because the enrollment was not performed in-situ. While the enrollment procedure was far from optimal, it is clear from Table 3 that Visionics far outperformed all other vendors. In a real-world access control application, we believe that this performance difference would increase because some, if not most, of the non-matches were due to a time lag attributable to the design of the surveillance software.

Enrollment Timed Test

Overall, most groups performed well on this test because of its relative ease -- the recognition of users occurred directly after the enrollment procedure. Failure of Visionics to score well on the Enrollment/Identification test was due *solely* to the time-lag in the surveillance software used and does not reflect the true performance of Visionics technology in the context of access control.
