## Noether's Theorem

links SYMMETRIES and conservation laws for Euler Lagrange Systems.

What is a conservation law?

Answer: a divergence expression which is zero on solutions of the system.

The heat equation

$$u_t + (-u_x)_x = 0$$

is its own conservation law. Integrating,

$$\frac{\partial}{\partial t} \int_{\Omega} u + (-u_x)]_{\partial \Omega} = 0$$

where we assume u is sufficiently nice that we can interchange  $\partial_t$  and  $\int$ , and we have applied Stokes' Theorem. In words:

Rate of change  $= \frac{\text{Net of comings and goings}}{\text{across the boundary}}$  no sources or sinks

# The usual examples

## Symmetry

## Conserved Quantity

leaves Ldx invariant the quantity behind the  $\frac{D}{Dt}$ 

in the Divergence

$$\begin{cases} t^* = t + c \\ \text{translation in time} \end{cases}$$

$$x_i^* = t + \epsilon$$

 $\begin{cases} x_i^* = t + c \\ \text{translation in space} \end{cases}$ 

$$\mathbf{x}^* = \mathcal{R}\mathbf{x}$$

 $\begin{cases} \mathbf{x}^* = \mathcal{R}\mathbf{x} \\ \text{rotation in space} \end{cases}$ 

$$a^* = \phi(a, b)$$

$$b^* = \psi(a, b)$$

$$\phi_a \psi_b - \phi_b \psi_a \equiv 1$$

 $\begin{cases} a^* = \phi(a,b) \\ b^* = \psi(a,b) \\ \phi_a \psi_b - \phi_b \psi_a \equiv 1 \\ \text{Particle relabelling} \end{cases}$ 

Energy

Linear Momenta

Exactness can be used to find conservation laws for non Euler-Lagrange systems via clever ansatze!

cf Hereman, Sanders, Sayers and Wang, CRM Proceedings; Hydon J. Phys. A

Exactness is proved by the use of so-called homotopy operators  $H_i$ ,

which satisfy

$$(\mathrm{Div}H_1+H_0E)\omega=\omega, \qquad \text{all } \omega\in\Lambda^3$$
 Thus if  $E(\omega)=0$ , then  $\omega=\mathrm{Div}(H_1(\omega))$ .

Idea: solve E(clever ansatz) = 0 for parameters and arbitrary functions. Then you have a conservation law using  $H_1$ .

## More on $\hat{d}$ and $\pi$

#### SMOOTH

$$\begin{split} \hat{\mathbf{d}}(L\mathrm{d}x) &= \hat{\mathbf{d}}\left(\frac{1}{2}\left(u_x^2 + u_{xx}^2\right)\mathrm{d}x\right) \\ &= \left(u_x\mathrm{d}u_x + u_{xx}\mathrm{d}u_{xx}\right)\mathrm{d}x \\ &= \left(-u_{xx}\mathrm{d}u + u_{xxxx}\mathrm{d}u\right)\mathrm{d}x \\ &+ \frac{D}{Dx}\left(u_x\mathrm{d}u - 2u_{xx}\mathrm{d}u_x + \frac{D}{Dx}\left(u_{xx}\mathrm{d}u\right)\right) \\ &= E(L)\mathrm{d}u\mathrm{d}x + \frac{D}{Dx}\eta_L \end{split}$$

General Formula, explicit, exact, symbolic, for  $\eta_L$  known.

 $E = \pi \circ \hat{\mathbf{d}}$ , where  $\pi$  projects out the divergence term.

More than one dependent variable

$$\widehat{\mathrm{d}}L(x,u,v,\ldots)\mathrm{d}x = E^u(L)\mathrm{d}u\mathrm{d}xE^v(L)\mathrm{d}v\mathrm{d}x + \frac{\mathrm{D}}{\mathrm{D}x}\eta_L$$

## More on $\hat{d}$ and $\pi$

#### **DISCRETE**

$$\widehat{d}(Ldx) = \widehat{d}\left(\frac{1}{2}u_n^2 + u_n u_{n+1}\right) \Delta_n$$

$$= (u_n du_n + u_{n+2} du_n + u_n du_{n+2}) \Delta_n$$

$$= (u_n + u_{n+2} + u_{n-2}) du_n \Delta_n$$

$$+ (S - id)(\cdots)$$

$$= E(L_n) du_n \Delta_n + \Delta(\eta_{L_n})$$

General Formula, explicit, exact, symbolic, for  $\eta_{L_n}$  known.

 $E = \pi \circ \hat{d}$ , where  $\pi$  projects out the total difference term.

More than one dependent variable

$$\widehat{d}(L_n \Delta_n) = E^u(L_n) du_n \Delta_n + E^v(L_n) dv_n \Delta_n + \Delta(\eta_{L_n})$$

# Variational Symmetries

Symmetries arise from Lie group actions.

EXAMPLE:  $G = (\mathbb{R}, +)$ 

$$\epsilon \cdot x = x^* = \frac{x}{1 - \epsilon x}, \qquad \epsilon \cdot u = u^*(x^*) = \frac{u(x)}{1 - \epsilon x}$$

Group Action Property

$$\delta \cdot (\epsilon \cdot x) = \delta \cdot \left(\frac{x}{1 - \epsilon x}\right) = \frac{\frac{x}{1 - \epsilon x}}{1 - \delta \frac{x}{1 - \epsilon x}}$$
$$= \frac{x}{1 - (\epsilon + \delta)x} = (\epsilon + \delta) \cdot x$$

and similarly for u(x).

Prolonged Group Action

$$\epsilon \cdot u_x = u_{x^*}^* = \frac{\partial u^*(x^*)}{\partial x} / \frac{\partial x^*}{\partial x} = \frac{u_x}{(1 - \epsilon x)^2}$$

and

$$\delta \cdot (\epsilon \cdot u_x) = \frac{\delta \cdot u_x}{(1 - \epsilon(\delta \cdot x))^2} = \frac{u_x}{(1 - (\delta + \epsilon)x)^2}$$

## Action on Integrals

$$\begin{array}{ll} \epsilon \cdot \int_{\Omega} L(x,u,u_x,\ldots) \, \mathrm{d}x \\ \\ \mathrm{def'n\ of} \\ \epsilon \cdot \end{array} = \int_{\epsilon \cdot \Omega} L(\epsilon \cdot x,\epsilon \cdot u,\epsilon \cdot u_x,\cdots) \, \mathrm{d}\epsilon \cdot x \\ \\ \mathrm{change\ of} \\ \mathrm{variable} \end{array} = \int_{\Omega} L(\epsilon \cdot x,\epsilon \cdot u,\epsilon \cdot u_x,\cdots) \frac{\mathrm{d}\epsilon \cdot x}{\mathrm{d}x} \, \mathrm{d}x \\ \end{array}$$

Use  $L^2$  theory to get that a variational symmetry of a Lagrangian is a group action such that

$$L(x, u, u_x, \ldots) = L(\epsilon \cdot x, \epsilon \cdot u, \epsilon \cdot u_x, \cdots) \frac{\mathsf{d}\epsilon \cdot x}{\mathsf{d}x}$$

## Infinitesimal Action on Integrals

Since the symmetry invariance condition

$$L(x, u, u_x, \ldots) = L(\epsilon \cdot x, \epsilon \cdot u, \epsilon \cdot u_x, \cdots) \frac{\mathsf{d}\epsilon \cdot x}{\mathsf{d}x}$$

is true all  $\epsilon$ , then if everything is sufficiently smooth, applying  $\frac{\mathrm{d}}{\mathrm{d}\epsilon}|_{\epsilon=0}$  to both sides, and noting that when  $\epsilon=0$  we have the identity action,

$$0 = \frac{\partial L}{\partial x} \xi + \frac{\partial L}{\partial u} \phi + \frac{\partial L}{\partial u_x} \phi^x + \dots + L \xi_x$$
$$= \frac{D(L\xi)}{Dx} + \frac{\partial L}{\partial u} Q + \frac{\partial L}{\partial u_x} \frac{DQ}{Dx} + \frac{\partial L}{\partial u_{xx}} \frac{D^2 Q}{Dx^2} + \dots$$

where

$$Q = \phi - u_x \xi, \quad \phi = \frac{d}{d\epsilon}|_{\epsilon=0} \epsilon \cdot u, \quad \xi = \frac{d}{d\epsilon}|_{\epsilon=0} \epsilon \cdot x$$

and  $\frac{D}{Dx}$  is the total derivative operator.

$$0 = \operatorname{Div}(L\xi) + \sum (\mathbf{D}^J Q^{\alpha}) \frac{\partial L}{\partial u_J^{\alpha}}$$

## Almost to the punchline

Let

$$\mathbf{v}_Q = \sum_{\alpha} Q^{\alpha} \frac{\partial}{\partial u^{\alpha}}$$

Then the *prolongation* is defined by

$$\mathrm{pr}\mathbf{v}_Q = \sum_{\alpha,J} \mathrm{D}^J Q^\alpha \frac{\partial}{\partial u_J^\alpha}$$

Note

$$u_J^{\alpha} = \frac{\partial u^{\alpha}}{\partial x_1^{J_1} \cdots \partial x_p^{J_p}} = \mathsf{D}^J u^{\alpha}$$

Then

$$\sum \left( \mathrm{D}^J Q^\alpha \right) \frac{\partial L}{\partial u_J^\alpha} = \mathrm{pr} \mathbf{v}_Q \mathrm{d} \hat{\mathbf{d}} L$$

Recall that  $\hat{d}$  is one of the two operators comprising the Euler Lagrange operator, while the left hand side is a divergence if Q is the characteristic of a symmetry.

## THE PUNCHLINE

$$\begin{split} &Q \cdot E(L) \\ &= \mathbf{v}_Q \lrcorner \hat{\mathbf{d}}(L) + \mathrm{Div}(\mathrm{pr} \mathbf{v}_Q \lrcorner \eta_L) \end{split}$$

If Q is the characteristic of a symmetry, we have that

$$\mathbf{v}_Q \lrcorner \widehat{\mathbf{d}}(L) = \mathrm{Div}(L\xi)$$

and hence that

$$Q \cdot E(L) = Div(something)$$

## Non-trivial example

Semi-geostrophic equations

Group 
$$\begin{cases} a^* = \phi(a,b) & \phi_a \psi_b - \phi_b \psi_a = 1 \\ b^* = \psi(a,b) & \\ h = (x_a y_b - x_b y_a)^{-1} & \\ \partial_x = h(y_b \partial_a - y_a \partial_b) & \\ \partial_y = h(-x_b \partial_a + x_a \partial_b) & \\ D_t x = -\frac{g}{f^2} D_t h_x - \frac{g}{f} h_y & \\ D_t y = -\frac{g}{f^2} D_t h_y + \frac{g}{f} h_x & \end{cases}$$
 Equations

The Lagrangian has 4 arbitary functions which obey two conditions. The conserved quantity is *potential vorticity* 

$$\frac{1}{h}\left(f + \frac{g}{f}(h_{xx} + h_{yy})\frac{g^2}{f^3}(h_{xx}h_{yy} - h_{xy}^2)\right)$$

## **DISCRETE Almost Punchline**

This case is easier than the smooth case.

- Since n cannot vary in a smooth way, the "mesh variables"  $x_n$  are treated as dependent variables.
- The group action commutes with shift:

$$\epsilon \cdot S^j(u_n) = \epsilon \dot{u}_{n+j} = S^j \epsilon \cdot u_n$$

so no prolongation formulae are required.

For example,

$$\epsilon \cdot u_n = \frac{u_n}{1 - \epsilon x_n} \Longrightarrow \epsilon \cdot u_{n+j} = \frac{u_{n+j}}{1 - \epsilon x_{n+j}}$$

The symmetry condition is:

$$L_n(x_n, \dots x_{n+j}, u_n, \dots u_{n+k})$$

$$= L_n(x_n^*, \dots x_{n+j}^*, u_n^*, \dots u_{n+k}^*)$$

where ()\*  $\equiv \epsilon \cdot$  ().

## **Applying**

$$\frac{d}{d\epsilon}\Big|_{\epsilon=0}$$

to both sides of the symmetry condition yields

$$0 = \sum_{k} \frac{\partial L_n}{\partial x_{n+k}} \frac{d}{d\epsilon} \Big|_{\epsilon=0} x_{n+k}^* + \frac{\partial L_n}{\partial u_{n+k}} \frac{d}{d\epsilon} \Big|_{\epsilon=0} u_{n+k}^*$$

Setting

$$Q_n^x = \frac{\mathsf{d}}{\mathsf{d}\epsilon}\Big|_{\epsilon=0} x_n^*, \qquad Q_n^u = \frac{\mathsf{d}}{\mathsf{d}\epsilon}\Big|_{\epsilon=0} u_n^*$$

then since

$$Q_{n+k}^x = S^k(Q_n^x), \qquad Q_{n+k}^u = S^k(Q_n^u)$$

the equation above can be written as

$$0 = X_Q \, | \, \widehat{\mathsf{d}} L_n, \qquad X_Q = \sum_{\alpha, J} S^J(Q_n^\alpha) \frac{\partial}{\partial u_{n+J}^\alpha}$$

## **DISCRETE** Punchline

$$Q \cdot E(L_n) = X_Q \, \lrcorner \, \hat{\mathsf{d}}(L_n) + \Delta(X_Q \, \lrcorner \, \eta_{L_n})$$

Again, we get that if

$$X_Q \lrcorner \widehat{\mathsf{d}}(L_n) = \mathsf{0}$$

then

$$Q \cdot E(L_n) = \Delta(\text{something}),$$

that is, a total difference expression which is zero on solutions of the discrete Euler Lagrange system. Nice example T.D. Lee, Difference Equations and Conservation Laws, J. Stat. Phys., 46 (1987)

A difference model for  $\int (\frac{1}{2}\dot{x}^2 - V(x)) dt$ 

Define

$$\bar{V}(n) = \frac{1}{x_n - x_{n-1}} \int_{x_{n-1}}^{x_n} V(x) dx$$

and take

$$L_n = \left[ \frac{1}{2} \left( \frac{x_n - x_{n-1}}{t_n - t_{n-1}} \right)^2 - \bar{V}(n) \right] (t_n - t_{n-1})$$

The group action is  $t_n^*=t_n+\epsilon$ , with  $x_n$  invariant. The conserved quantity is thus "energy". Now,  $Q_n^t=1$  for all n, and  $Q_n^x=0$ . The equations become

$$0 = E^{t}(L_{n}) = \frac{\partial}{\partial t_{n}} L_{n} + S\left(\frac{\partial}{\partial t_{n-1}} L_{n}\right)$$
$$0 = X_{Q} d(L_{n}) = \frac{\partial}{\partial t_{n}} L_{n} + \frac{\partial}{\partial t_{n-1}} L_{n}$$

as  $L_n$  is a function of  $(t_n - t_{n-1})$ .

It is easy to see in this case that

$$0 = (S - \mathrm{id}) \left( \frac{\partial}{\partial t_n} L_n \right)$$

is implied by the two equations, to yield

$$\frac{1}{2} \left( \frac{x_n - x_{n-1}}{t_n - t_{n-1}} \right)^2 + \bar{V}(n) = c$$

Note that the energy in the smooth case is

$$1/2\dot{x}^2 + V.$$

Can regard the EL eqn for the mesh variables as an equation for a variable mesh.

#### **INTERLUDE**

If we know the group action for a particular conservation law, we can "design in" that conservation law into a discretisation by taking a Lagrangian composed of invariants. These necesarily satisfy  $v_Q(I) = 0$  or  $X_Q(I_n) = 0$ . The Fels and Olver formulation of moving frames is particularly helpful here: a sample theorem is

Discrete rotation invariants in  $\mathbb{Z}^2$ Let  $(x_n,y_n)$ ,  $(x_m,y_m)$  be two points in the plane. Then

 $I_{n,m} = x_n y_n + x_m y_m$ ,  $J_{n,m} = x_n y_m - x_m y_n$  are rotation invariants. Moreover, any disrete rotation invariant is a function of these.

## Made up example

Suppose

$$L_n = \frac{1}{2}J_{n,n+1}^2 = \frac{1}{2}(x_ny_{n+1} - x_{n+1}y_n)^2$$

then

$$\begin{cases} E_n^x = J_{n,n+1}y_{n+1} - J_{n-1,n}y_{n-1} \\ E_n^y = -J_{n,n+1}x_{n+1} + J_{n-1,n}x_{n-1} \end{cases}$$

Now,

$$Q_n = (Q_n^x, Q_x^y) = (-y_n, x_n) = \frac{\mathrm{d}}{\mathrm{d}\theta}\Big|_{\theta=0}(x_n^*, y_n^*)$$
 and thus

$$Q_n \cdot E_n = J_{n,n+1}(-y_n y_{n+1} - x_n x_{n+1})$$

$$+ J_{n-1,n}(y_n y_{n-1} + x_n x_{n-1})$$

$$= -J_{n,n+1}I_{n,n+1} + J_{n-1,n}I_{n-1,n}$$

$$= -(S - id)(J_{n-1,n}I_{n-1,n})$$

gives the conserved quantity.

Note that  $I_{n,m}=I_{m,n}$  and  $J_{n,m}=-J_{m,n}$ 

#### Less easy example

Hereman et al., Densities, Symmetries and Recursion operators for nonlinear DDEs, CRM Proceedings

The Toda lattice in polynomial form is

$$\begin{cases} \dot{u_n} = v_{n-1} - v_n \\ \dot{v_n} = v_n(u_n - u_{n+1}) \end{cases}$$

The scaling symmetry is the basis for the ansatz used to obtain the differential-difference conservation laws, which are of the form

$$\frac{\mathsf{D}}{\mathsf{D}t}\rho_n + (S - \mathsf{id})J_n = 0$$

for example

$$\rho_n = \frac{1}{3}u_n^3 + u_n(v_{n-1} - v_n), J_n = u_{n-1}u_nv_{n-1} + v_{n-1}^2$$

These results use the ansatz plus homotopy operator method outlined earlier.

## Summary of the Pattern

$$Q \cdot E(L) = \left\{ \begin{array}{c} v_Q \\ X_Q \end{array} \right\} \ \, \lrcorner \hat{\mathbf{d}} L + \left\{ \begin{array}{c} \mathrm{Div} \\ \Delta \end{array} \right\} \left\{ \begin{array}{c} v_Q \\ X_Q \end{array} \right\} \ \, \lrcorner \frac{\eta_L}{}$$

- ullet the formula for  $\eta_L$  is explicit, exact, symbolic
- the first summand is a total derivative or difference by the symmetry condition

# OK let's try for a Neother's Theorem for Finite Element!

D. Arnold, Beijing ICM Plenary talk

Given a system of moments and sundry other data, aka degrees of freedom, that yield projection operators such that the diagram commutes:

all relative to some triangulation.

Yields stability!! A Lagrangian is composed of wedge products of 1-, 2- and 3- forms. Choose the discretisation of each to be in the relevant  $\mathcal{F}_i$ . Then commutativity implies conditions for Brezzi's theorem to hold.

In one dimension: with  $e_n=(x_n,x_{n+1})$ ,  $\Pi_0$  to piecewise linear,  $\Pi_1$  to piecewise constant with moment

$$\alpha_n = \int_{x_n}^{x_{n+1}} u(x)\psi_n(x) \, \mathrm{d}x$$

Commutativity of the diagram

$$u \ \stackrel{\mathsf{d}}{\mapsto} \ u_x \mathsf{d} x$$
 
$$\Pi_0 \downarrow \qquad \downarrow \Pi_1$$
 
$$u|_{e_n} = A_n x + B_n \ \mapsto \ A_n = \int_{x_n}^{x_n+1} \, u'(x) \psi_n(x) \, \mathsf{d} x$$
 implies

$$A_{n} = u(x)\psi_{n}(x)]_{x_{n}}^{x_{n+1}} - \int_{x_{n}}^{x_{n+1}} u(x)\psi'_{n}(x) dx$$

Note that

$$\int_{x_n}^{x_{n+1}} \psi_n(x) \, \mathrm{d}x = 1.$$

is required by the projection property.

A finite element Lagrangian is built up of wedge products of forms in  $\mathcal{F}_0$ ,  $\mathcal{F}_1$ ,  $\mathcal{F}_2$ ,  $\mathcal{F}_3$ . Call this resulting space  $\widetilde{\mathcal{F}}_3$ . In each top-dimensional simplex, denoted  $\tau$ , integrate to get

$$L = \sum_{\tau} L_{\tau}(\alpha_{\tau}^{1}, \cdots \alpha_{\tau}^{p})$$

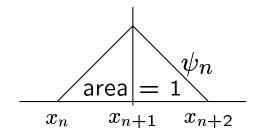

where  $\alpha_{\tau}^{j}$  is the  $j^{\text{th}}$  degree of freedom in  $\tau$ . L can also depend on mesh data.

Can now take  $\hat{\mathbf{d}}$  which is the variation with respect to the  $\alpha_{\tau}^{j}$ .

EXAMPLE In one dimension,

$$\begin{array}{cccc} 0 \to \mathbb{R} & \to \Lambda^0 & \stackrel{d}{\to} & \Lambda^1 \to 0 \\ & \Pi_0 \downarrow & \Pi_1 \downarrow \\ \\ 0 \to \mathbb{R} & \to \mathcal{F}_0 & \stackrel{d}{\to} & \mathcal{F}_1 \to 0 \end{array}$$

 $\Pi_1$  is to piecewise constant functions with moment  $\bar{u}(n) = \int_{x_n}^{x_n+2} u(x) \psi_n(x) \, \mathrm{d}x$  where

on  $(x_n, x_{n+2})$ , while  $\Pi_0$  is to piecewise linear functions with moments

$$\alpha_n = \frac{1}{x_n - x_{n+2}} \int_{x_n}^{x_{n+1}} u(x) \, \mathrm{d}x$$

that is,  $\alpha_n$ ,  $\alpha_{n+1}$  are used in  $(x_n, x_{n+2})$ ;

$$u \mapsto 2\frac{\alpha_{n+1} - \alpha_n}{x_{n+2} - x_n} x + \left(\frac{x_{n+1} + x_{n+2}}{x_{n+2} - x_n}\right) \alpha_n - \left(\frac{x_{n+1} + x_n}{x_{n+2} - x_n}\right) \alpha_{n+1}$$

## Very simple example

 $\int \frac{1}{2}u_x^2 \, \mathrm{d}x$  projects to

$$\sum_{n} \int_{x_{2n}}^{x_{2n+2}} \frac{1}{2} \Pi(u)_{x}^{2} dx = \sum_{n} 2 \left( \frac{(\alpha_{2n} - \alpha_{2n+1})^{2}}{x_{2n+2} - x_{2n}} \right)$$

Then

$$\hat{d}L_{2n} = 4 \frac{\alpha_{2n} - \alpha_{2n+1}}{x_{2n+2} - x_{2n}} (d\alpha_{2n} - d\alpha_{2n+1})$$

$$= 4 \left( \frac{\alpha_{2n} - \alpha_{2n+1}}{x_{2n+2} - x_{2n}} - \frac{\alpha_{2n-1} - \alpha_{2n}}{x_{2n+1} - x_{2n}} \right) d\alpha_{2n}$$

$$+ (S - id)(something)$$

The discrete Euler Lagrange equation is then, after "integration",

$$\frac{\alpha_{2n} - \alpha_{2n+1}}{x_{2n+2} - x_{2n}} = c$$

Look now at the "Noether pattern" for the Finite Element variational complex

$$\begin{array}{ccccc} \rightarrow \tilde{\mathcal{F}}_2 \rightarrow \tilde{\mathcal{F}}_3 & \stackrel{\pi \circ \hat{\mathsf{d}} \circ \int}{\rightarrow} & \tilde{\mathcal{F}}_*^1 \rightarrow \tilde{\mathcal{F}}_*^2 \rightarrow \\ & & & & & & \\ L_\tau & & & & E(L_\tau) + \delta(\eta_L) \\ & & & & = \hat{\mathsf{d}} L_\tau \\ & & & v_{Q_\tau}^{\leftarrow} \ \, & \end{array}$$

where  $\delta$  is the mesh dependent coboundary operator (recall  $\delta(f)(\tau) = f(\partial \tau)$ ).

Step 1: find 
$$\eta_L$$
 Step 2: find  $v_Q$ 

If then  $v_{Q_{\tau}} \dashv \hat{\mathbf{d}}(L_{\tau}) = \delta(\text{something})$  we will have that

$$0 = Q_{\tau} \cdot E(L_{\tau}) + \delta(\text{something}).$$

#### Group actions on moments

The clue is the variational symmetry group action on  $\int_{\Omega} L(x, u, \cdots) dx$ 

Define

$$\epsilon \cdot \int_{\tau} u(x) \psi_{\tau}(x) \, \mathrm{d}x$$

$$= \int_{\tau} \epsilon \cdot u(x) \psi_{\tau}(\epsilon \cdot x) \frac{\mathrm{d} \epsilon \cdot x}{\mathrm{d} x} \, \mathrm{d} x$$

Example Recall the projective action

$$\epsilon \cdot x = \frac{x}{1 - \epsilon x}, \quad \epsilon \cdot u(x) = \frac{u(x)}{1 - \epsilon x}$$

Then the induced action on the moments

$$\alpha_n = \int_{x_n}^{x_{n+1}} \frac{u(x)}{x^3} dx, \quad \beta_n = \int_{x_n}^{x_{n+1}} \frac{u(x)}{x^4} dx$$

is

$$\epsilon \cdot \alpha_n = \alpha_n, \qquad \epsilon \cdot \beta_n = \beta_n - \epsilon \alpha_n$$

In general for this action,

$$\epsilon \cdot \int_{x_n}^{x_{n+1}} x^m u(x) dx$$

$$= \int_{x_n}^{x_{n+1}} \frac{x^m}{(1-\epsilon x)^m} \frac{u(x)}{1-\epsilon x} \frac{dx}{(1-\epsilon x)^2}$$

$$= \int_{x_n}^{x_{n+1}} \frac{x^m u(x)}{(1-\epsilon x)^{m+3}} dx$$

THINK: if you want a coherent scheme which maps to itself under this projective action, and involves only a finite amount of data, then take your moments to be

$$u(x) \mapsto \int_{x_n}^{x_{n+1}} \frac{u(x)}{x^m} dx, \qquad m = 3, 4, \dots N.$$

## **CONCLUSIONS**

- The underlying algebraic pattern of the exact variational complexes provide a framework for generalisations of Noether's Theorem and conservation laws in general.
- Symmetry-adapted moments would appear to be necessary.
- ullet Next: formulae for  $\eta_{L_{ au}}$  where

$$\widehat{\mathsf{d}}(L_{\tau}) = E(L_{\tau}) + \delta(\eta_{L_{\tau}})$$

in terms of the mesh dependent coboundary operator.
