Approved for public release; distribution is unlimited
The Deployable Navigation System (DeNS) is a prototype system designed to facilitate Command and Control during over the horizon small boat operations. It is designed to allow small boats to deploy from their host ships with a Bluetooth GPS (Global Positioning System) receiver and PDA (Personal Digital Assistant) running the appropriate software which provides a real time navigational picture in terms of position and relation to a predetermined track. This same data is shipped immediately back to the control ship via a wireless network and displayed on a laptop computer to allow the mission commander to monitor the small boat’s progress and position, also in real time. The small boat’s relation to the track is compared on every received fix and appropriate indicators are displayed to inform both users if a predetermined distance from track (track tolerance) has been exceeded. It utilizes jpg formatted maps that are derived directly from the Digital Nautical Chart (DNC) library overlaid with track information. Positions received from the GPS are converted to pixel coordinates that correspond to their original positions on the jpg chart and plotted, providing an electronic display that is very similar in appearance to the traditional plot maintained on paper charts.
DEPLOYABLE COMMAND AND CONTROL SYSTEM FOR OVER THE HORIZON SMALL BOAT OPERATIONS

ACKNOWLEDGMENTS

I would like to thank my thesis advisors, Professors Craig Martell and Gurminder Singh, for the immense amount of help and guidance that they provided in throughout the thesis process. Without their academic support, insight, and clarity of focus this project would not have been possible.

I would also like to thank the Information Professional community for allowing me to attend NPS and pursue work in the area of Computer Science. In addition, I would like to recognize all of my prior commands for providing me with the background and insight necessary to identify this body of work and develop a viable solution to the problems of navigation and Command and Control involved with small boat operations.

Finally, and most importantly, I would like to thank my family: my parents who have always provided me with love, encouragement, and support for all my endeavors, and my wife, Jenny, and children, David and Audrey, without whose patience, sacrifice, and support I could not be successful. Thank you all for everything you have given me.
I. INTRODUCTION

A. OVERVIEW

Upon US Naval Surface Vessels, small boats are an invaluable asset. They function in a multitude of capacities, including operation as lead lifeboats, man overboard recovery, certain mooring evolutions, Search and Rescue (SAR) operations, Maritime Interdiction Operations (MIO) and other boarding evolutions, just to name a few. The importance of the small boat to shipboard life is evidenced by its inclusion on the list of daily reports submitted to the ship’s Commanding Officer (CO) for review; a report that details the status and condition of the boat and its assigned crew each day.

Typical uses of the small boat by naval vessels involve those operations which can be accomplished while maintaining visual contact between the boat and its parent vessel. Command and Control (C2) and other communication are typically provided by standard Very High Frequency (VHF) radio or other similar means. These communications are sent in the clear (i.e., not encrypted) and are subject to easy interception due to the widespread use VHF maritime radio in all seagoing vessels. Rules of the Road mandate their use on these vessels, and by placing the radio in scan mode, multiple frequencies can easily be monitored.

Navigation on the small boat is carried out by seaman’s eye, steering by instruction passed through the VHF radio, and/or the use of a magnetic compass. Paper charts can provide some assistance to the boat crew through the use of estimation techniques such as dead-reckoning (DR) to help identify aids to navigation and or pass general area coordinates, but they are cumbersome to use and highly subject to weather conditions, sea spray, high winds due to the boats movement through the water, etc.

While some naval vessels have developed “home grown” solutions to provide a better capability for C2 and general communication with the small boat, no standard solution is available—none that can be easily implemented, is portable across platforms, is both accurate and extendable to ranges that would
facilitate over the horizon (OTH) operations, and that utilizes naval standards by leveraging current technology in terms of devices, architectures, and systems. The Deployable Navigation System (DeNS) prototype system is a first attempt to do just those things.

B. PROBLEM SPACE

With the emergence and increasing popularity of mobile device technology and the increasing acceptance of wireless network standards and architecture, the US Navy should look for ways to leverage these advancements in order to improve its everyday operations. The DeNS prototype system concentrates on a way of achieving this goal in regards to C2 of small boat OTH operations. By utilizing mobile devices—such as the Personal Data Assistant (PDA) and laptop computer, as well network architectures as defined by the Institute of Electrical and Electronic Engineers (IEEE) standards 802.11 (WiFi), 802.16 (WiMax), and 802.15.1 (Bluetooth) in conjunction with the Global Positioning System (GPS) and Digital Nautical Chart library (DNC)—the DeNS is able to provide a viable, easily obtainable, and highly deployable C2 system for use in this arena.

To date, the DNC provides the only digital cartography product that has been authorized for use in the navigation of US Naval vessels by the Chief Navigator of the Navy. While its use in shipboard systems is currently being implemented, there are no efforts being made to port this powerful geospatial database onto a PDA. The DeNS prototype system makes in-roads into this endeavor by allowing the user to create accurately scaled jpg formatted digital images, similar in appearance to paper charts, which are derived directly from the DNC. These images can then be transferred to the PDA for use with the DeNS prototype system. While this is not the optimal application of DNC data on the PDA (further work as will be discussed in Chapter V will explore full DNC implementation on the PDA device,) it does provide the first step towards its implementation.
While GPS systems currently exist and are commercially available that can provide the small boat with accurate positional information, they neither implement the DNC, nor allow for communication and data relay between the small boat and its parent vessel. These aspects of a deployable system are crucial to establishing the C2 functions necessary to enable a CO to comfortably authorize extended OTH operations. Further discussion of this aspect of these systems, as well as descriptions of “home grown” systems will take place in Chapter II, Section E.

Of primary importance in the development of the DeNS prototype system was the ability to provide a means of two way communication for both GPS positional data, as well as other supplemental information such as the issuance of orders and compliance with those orders, deviations from a designated track determined prior to mission start-time, and the possibility to transmit other data packets such as photographs or scanned documents. While not all of these were implemented in the prototype due to time constraints, those which were omitted can be easily added in future iterations of the system due to the built in flexibility provided by the design of the server/client model that was implemented. By creating new packet types, the client and server applications can easily be made to handle new types of data in the appropriate manner.

C. OBJECTIVE

DeNS is a prototype system designed to facilitate C2 during OTH small boat operations. It is designed to allow small boats to deploy from their host ships with a GPS receiver and PDA running the appropriate software which provides a real time navigational picture in terms of position and relation to a predetermined track. This same data is shipped immediately back to the control ship and displayed to allow the mission commander to monitor the small boat’s progress and position, also in real time. The small boat’s relation to the track is compared on every received fix and appropriate indicators are displayed to inform both users (in the small boat and onboard the control ship) if a predetermined distance from track (track tolerance) has been exceeded.
As described above, the objective of this project was to build a proof of concept system which implemented the DNC, GPS, and a wireless network with ranges sufficient to facilitate C2 and a common operation picture (COP) that is shared between the small boat and its parent vessel. Of primary importance in this phase of the project was the implementation of the DNC data on a PDA platform, and proper rendering and plotting of positional data. Both of these objectives were met, as will be demonstrated in the remainder of this paper.

Our main concern during the inception of the DeNS Prototype system thesis was: Can the DNC be exported to a windows based pocket personal computer (PC) in manageable pieces to allow for OTH small boat operations and two way data update in a manner that doesn’t impede operator mission success? The answer to this question was a resounding “yes.” As with most questions of this overarching nature, many subsequent, more pointed questions resulted. These included such items as process automation, ease of use, the best user interface and network architectures to implement, etc. The remainder of this paper will address these concerns, with results summarized in Chapter V.

D. SCOPE

The DeNS prototype system is a proof of concept system as described earlier in this chapter. Specifically, development included the implementation of applications on both the PDA and the control ship to facilitate the display of jpg images derived from the DNC with applicable track overlays, GPS data display, and addressed the communication of such information over a portable protocol that will work across network topologies. The proof of concept presented here focused on the use of an 802.11 wireless Local Area Network (LAN), but should be expanded to a more able network implementation in the fielded system, as discussed in greater detail in Chapters II and V. Additionally, while the focus for the proof of concept is the sharing of a navigational track and related information, we will present recommendations for future expansion in Chapter V.
As with any proof-of-concept constraints on the operation of the DeNS prototype system were also necessary. Most of these limitations to scope are discussed in Chapter IV, sections B.4 and C.2.d. They include network implementation on 802.11 vice 802.16, and the operational constraints in terms of latitude and longitude to the inclusive degrees of 360 N and 1210 W. Further, at this point only positional data and message data transmissions are implemented, and only in one direction (small boat to control ship), though this can easily be expanded.

E. THESIS ORGANIZATION

This thesis consists of five chapters and three appendices. Chapter II will provide foundational background information on which this thesis was based, along with a brief discussion of existing related works focusing on both Commercial Off the Shelf (COTS) products, and US Navy “home grown” solutions. Readers not interested in detailed descriptions of development environments and device specifications can safely skip Chapter II, Section C. Chapter III will provide an architectural description of the various components that comprise the DeNS prototype system. Chapter IV will provide insight into the implementation and usability of the system, along with its known bugs and limitations. Finally, Chapter V will provide conclusions, recommendations for future works, and a summarization of the project.

Appendix I and II both provide a listing of the MobileDeNS and DeNS C# code, respectively, along with applicable comments. Throughout this thesis certain conventions are used when referring to the DeNS system. The DeNS prototype system is comprised primarily of two applications, one designed to run as a client on the PDA, which will be referred to as MobileDeNS, and one designed to run on a laptop or desktop computer, referred to as DeNS. For clarity, any reference to “the DeNS”, “the DeNS system”, or “the DeNS prototype system” refers to the DeNS system as an overarching entity comprised of all of its various components. Reference to “DeNS” simply refers to the server portion of the system that is designed to run on the laptop.
II. BACKGROUND AND RELATED WORK

A. OVERVIEW

While much work has been done in the civilian sector to develop and market handheld navigation devices to recreational boaters and professional mariners, they do not address certain requirements for the US Navy. Specifically, they use charting tools other than the DNC Library, which is the only digital media authorized for navigational use by the Navigator of the Navy (USN, GIN 002, GIN 003, GIN 004). Additionally, they do not address the need for C2 of the small boat by the boat’s parent vessel, nor do they allow for a COP.

In this chapter, we will discuss the choices made in the development of the DeNS and the different device components used in the prototype and their specifications. Also covered will be the aspect of content repurposing that was required to implement the DNC on a handheld device, exactly what the DNC is and how it works. Finally, we present an overview of related work within the US Navy in the fielding of various systems intended for a similar purpose as that of the DeNS.

B. NETWORK CAPABILITIES

When considering network capabilities, it is important to note the immediate differences between the various types of networks as a whole. Networks can range in size from the small Personal Area Network (PAN) that has a range of a few meters, to the much larger Metropolitan Area Network (MAN) and Wide Area Network (WAN) that can span cities and even states, respectively (Antonello).

The PAN is implemented using technologies such as Bluetooth to create a short-range network through which Bluetooth enabled devices can communicate. This is most common in the cell phone and PDA arena, where devices utilize the Bluetooth connection for connectivity between accessories such as headsets, or for synchronization purposes between devices such as PDA’s, cell phones, and
desktop computers. It is also expanding to include peripheral devices such as printers, scanners, and similar devices to allow wireless transmission of data between said devices. DeNS uses a PAN via Bluetooth to facilitate communication between the PDA running MobileDeNS and a Bluetooth enabled GPS receiver, both of which are detailed below.

The MAN is typically a collection of nodes within a metropolitan area that fall under the same corporate control; possibly a telecommunications company or an ISP. The wireless medium used most often in this area of networking is the IEEE 802.16 standard (Antonello). Table 1 presents a quick comparison of the 802.16 standard with the WLAN standard, 802.11. Speed and area of coverage, both of major concern for the DeNS implementation, is shown to be superior for 802.16 in standard installations. Particularly important to DeNS is the range of coverage. Assuming the standard visible horizon for a naval vessel is 10 Nautical Miles (NM) (this is a rule of thumb as the actual horizon distance will vary based on height of eye), it is clear that 802.11 will not achieve the ranges needed for a major goal of the DeNS, C2 for OTH operations. As shown, 802.16 can achieve ranges up to 30 miles with adequate antennae height and transmitter power. The aspect of included bands is not addressed in this paper beyond what is shown, as both are capable of utilizing unlicensed bands, which is the desired state for DeNS.

<td>2-30 Miles</td>
</tr>
</tbody>
</table>

Table 1. Quick Technology Comparison after (Airespace Technologies).
1. Development Medium

Having acknowledged the requirement of 802.16, or a similarly positioned network standard, the decision was made to implement the prototype for DeNS on an 802.11 network. The primary reasons for this decision were the availability of an already existing 802.11 network, the cost and time constraints that would have been associated with planning and implementing an 802.16 network solely for the development of this prototype, and the fact that despite the differences cited, both standards are equally operable with the Transmission Control Protocol/Internet Protocol (TCP/IP) which is the basis of communication for the DeNS.

2. Implementation Medium

As discussed above, any further development of the DeNS and/or fielding of the DeNS should be done with an 802.16 implementation in order to ensure the OTH ranges are achieved. The speed advantage of 802.16, while not paramount in the prototype which is sending relatively simple, small packets across the network connections, could become a much more important factor if the system were expanded to allow for more complex traffic such as photographs, scanned documents, or streaming video.

C. ENVIRONMENT / DEVICE SPECIFICATIONS

The DeNS was developed using the equipment, software, and Integrated Development Environment (IDE) listed as follows, detailed below:

- Development PC: Toshiba Tecra M4-S435
- PDA: HP iPAQ hx4700
- GPS: HP iPAQ Navigation System
- Master Station: Toshiba Tecra M4-S435
- Third Party Software: MultiIE v3.1-d59
1. Development Environment Specifications

All coding requirements for the DeNS were implemented using a Toshiba Tecra M4-S435 as detailed in Table 2. DeNS and MobileDeNS code (found in Appendix I and II, respectively) were written in C# using the Microsoft Visual Studio .NET 2003 Enterprise Architect Edition IDE.

Table 2. Development PC (Toshiba Tecra M4-S435) Specification.

2. DeNS Device Specifications

The DeNS is primarily comprised of three devices: a PDA; a GPS receiver; and a laptop or desktop computer, hereafter referred to the master station. All three device specifications used in the prototype are as follows:

a. PDA

MobileDeNS runs on the PDA using a GPS receiver which is discussed below. The PDA used for implementation of the prototype system is
an HP iPAQ hx4700 as detailed in Table 3. This PDA was appealing for the prototype primarily for its full video graphics array (VGA) display capability, vs. the more common quarter video graphics display (QVGA) on competing PDA’s. For actual fielding of the system, a ruggedized solution should be implemented to ensure the PDA device is protected from factors existent in the small boat environment, such as inclement weather, sea-spray, and rough treatment of the device. This could be accomplished through the use of either a ruggedized PDA, or a ruggedized case, both of which are readily available on the commercial market.

Table 3. PDA (HP iPAQ hx4700) Specification.

b. **GPS Receiver**

The GPS receiver used was the unit which comes with the HP iPAQ Navigation System bundle. There is no programmable Application Programming Interface (API), nor otherwise accessible methods to communicate with the unit as packaged, nor does HP provide any additional support for this functionality. The GPS unit uses Bluetooth technology to communicate with the PDA, however, so third party software can be purchased to allow access to the
GPS receiver and its data. The software used in this prototype was GPSAccess, which is discussed at more length below.

c. Master Station

The master station used for prototype development was the same Toshiba Tecra M4 tablet PC that was used for development. DeNS runs on this platform as a C# windows application, so it should run on any Windows platform with the .NET framework installed.

3. Third Party Software Specifications

Four pieces of third party, commercially available, software were used in the development and implementation of DeNS: MultiIE for browser functionality; GPSAccess for Bluetooth connection with, and data extraction from, the GPS receiver; ArcGIS Suite for chart creation; and ArcIMS to facilitate web sharing of charts created using ArcGIS. Further details are as follows:

a. MultiIE v3.1-d59

MultiIE is a browser plug-in built specifically for mobile devices by Southway Mobile Applications. Considering the limitations inherent in mobile devices, many software applications are stripped of features which are not considered necessary for mainstream use (Yao). This is true of Microsoft Internet Explorer (MSIE) 4.01 which is the browser included in the Microsoft Windows Mobile2003 Second edition OS. Of particular interest to the DeNS system MSIE 4.01 does not allow images (.bmp, .jpeg, etc…) browsed to be saved on the mobile device on which it is installed (the “Save picture as...” option that is accessible by right clicking an image in the browser). This is the primary means to load the chart images from the ArcIMS server, which will be detailed below. To add this functionality back into the browser, MultiIE was used, as it includes this feature as well as many others.
b. GPSAccess v1.0.0

As was mentioned earlier, GPSAccess is a third party solution created by High Point Software which comes complete with a C# library to allow customized programs to access Bluetooth enabled GPS devices. GPSAccess primarily consists of two components, the library mentioned above, and GPSLink, an application that runs on the device with which you wish to connect to the GPS receiver, in our case the PDA (Highpoint Software).

The included library integrates the .NET Compact Framework v2.0 with the Widcomm Bluetooth stack v1.6 and later. The integration of the Widcomm is of primary significance here, because it allows a seamless user interface without requiring the specification of ports or the need to choose a device from a list of all possible devices. It connects directly to the GPS receiver without prompting. Additionally, the library allows the DeNS to access data directly without the need to parse the National Maritime Electronics Association (NMEA) formatted string for all information needed, and allows direct control and monitoring of GPS receiver status (Highpoint Software).

The second component, GPSLink is the application that manages the connection to the GPS receiver for the PDA. Using this tool, not only do you connect to the GPS receiver, but you can also monitor its status, readings, and control it manually through a variety of settings (Highpoint Software).

c. ArcGIS v9.1

ArcGIS by ESRI provides the method through which the DNC can be viewed and manipulated to build the nautical charts required by the DeNS. It is a Geographic Information System (GIS) product that reads a variety of file and database formats, though we are only interested in its ability to render Vector Product Format (VPF) based files, as this is the standard format used by the Department of Defense (DoD) to create digital maps and charts (ESRI GIS an Mapping Software). It consists of several parts, but of primary use in the DeNS are the ArcCatalog and ArcMap applications, as well as the Military Analyst
extension. While details of each of these products, and their respective use in DeNS will be detailed in section D, part 2, of this chapter, a brief explanation of each product is given below.

ArcCatalog is the application included in the ArcGIS suite that organizes and manages all GIS data including maps, charts, and metadata. With ArcCatalog the user can browse geospatial data, manipulate metadata, and create, define, and export and import geospatial databases (ESRI GIS and Mapping Software). This is the starting point for building DNC charts for use with DeNS.

ArcMap is the central application included in the ArcGIS suite. It allows map analysis and editing of maps; as well as export functionality in a variety of formats, including jpg formatted images (ESRI GIS and Mapping Software). This tool is used to build and edit the charts for use with DeNS.

By applying the Military Analyst extension within both ArcCatalog and ArcMap, both products are able to read, understand and render the VPF data contained in the DNC. By default, ArcGIS does not support this format. VPF is a standard that was created specifically for DoD use in digital geospatial products (USN, Interface Standard for Vector Product Format). As such, it is not the industry standard; however, since ESRI played a large part in the creation of the VPF standard, they have developed the Military Analyst to ensure compatibility with their products (ESRI GIS and Mapping Software).

d.  ArcIMS v9.1

ArcIMS is a web based GIS Server that delivers GIS data in a format that can be accessed through a network, be it the World Wide Web, or a local intranet. It is completely compatible with other ArcGIS products and can read and render GIS data created with ArcGIS or images based on said data (ESRI GIS and Mapping Software). DeNS currently uses this product as the
delivery tool for image based charts to be deployed to the PDA, though the possibility exists to extend its functionality, as will be discussed in Chapter V, section C.

D. CONTENT REPURPOSING

Most of today’s online content is built to be viewed on a conventional desktop PC. While this meets the needs of a large majority of online users, it can often fall short of optimal, or sometimes even usable, parameters when accessed by users of mobile devices such as PDA’s. This is due to the inherent differences between the two platforms in general (Singh, Content Repurposing).

Table 4 offers a generic comparison of the desktop platform vs. the mobile device. As can be seen, some consideration must be taken in planning to deliver content of any kind to both desktop PC’s and mobile devices. This consideration is known as content repurposing. In the DeNS implementation this becomes important in the handling of the DNC chart information.

</tr>
</tbody>
</table>

Table 4. Typical Desktop vs. PDA Quick Comparison.
Content repurposing as whole can be implemented in a variety of methods (Singh, Device Independence-II):

- **Post-processing** – Content repurposing is conducted dynamically at the time it is requested.

- **Pre-processing** – Content repurposing is conducted before requests are processed, and mechanisms are in place to help facilitate the correct objects being utilized.

- **Server-side processing** – All content repurposing is conducted at the server, freeing the client resources for other work.

- **Client-side processing** – All content repurposing is conducted by the client, freeing server resources for other work.

- **Proxy based processing** – Client requests content from a proxy which retrieves the content and repackages it as necessary for delivery. This frees resources on both the client and server side.

While each method listed above has its advantages and disadvantages, most often they are implemented in a hybrid manner. That is, one or more of the above techniques are used in conjunction to try to achieve optimal retrieval while freeing resources wherever possible. The DeNS utilizes such a hybrid scheme, implementing a pre-processing, server-side implementation for chart retrieval by the PDA. This approach provides less taxing of the more limited PDA, while requiring slightly more code in the ArcIMS server. The pre-processing portion of the DeNS content repurposing scheme refers to the fact that the charts are prepared and placed in the server before any request is ever made for them in both .axl format (for web display using ArcIMS) and .jpg format for DeNS and MobileDeNS.

1. **Digital Nautical Chart Library**

The DNC is a vector-based digital database library providing coverage of over 5,000 nautical charts intended to provide world wide coverage between the
latitudes of 84° N and 81° S (USA, Performance Specification: Digital Nautical Charts). It uses the VPF format, as mentioned above, which was developed in cooperation with ERSI, the manufacturer of the Arc line of GIS products, and has the distinction of being the only digital chart media authorized for navigation by the Chief Navigator of the Navy (USN, GIN 002, GIN 003, GIN 004).

The DNC itself consists of 29 CD-ROM libraries, each providing non-overlapping coverage of a specific area of the globe as shown in Figure 1. Libraries are organized using the World Geographic Reference System (GEOREF); a system that divides the surface of the earth into quadrangles, each with sides that are specific lengths of arc of latitude and longitude as appropriate, and identified by a systematic letter code to provide positive identification. Each quadrangle can be considered a tile, and further divided into smaller tiles. The DNC consists of four levels of tiles, based on the original paper chart scale and type, as shown in Table 5 (USA, Performance Specification: Digital Nautical Charts).

Figure 1. DNC Library Coverage from (USA, Performance Specification: Digital Nautical Charts)

</tr>
</tbody>
</table>

Table 5. DNC Tile Sizes from (USA, Performance Specification: Digital Nautical Charts).

Data stored in the DNC is divided into libraries based on the chart types as shown in Table 5 on the individual CD-ROM’s. The GOEREF identifier is used as the directory name that contains all primitives related to that particular tile, and the tiles for each chart scale band reside in different libraries allowing unique identification through their path name (i.e., DNC03\GEN03\MKNN is a general library, while DNC03\COA03\MKNN is a coastal library, each a 3° tile in the DNC03 database) (USA, Performance Specification: Digital Nautical Charts).

Considering the shear amount of data which must therefore be contained on each CD-ROM, and the corresponding small area being utilized for small boat operations, it becomes obvious that some type of content repurposing is necessary to prevent overburdening the PDA device, the limitations of which have already been discussed. As previously stated, DeNS utilizes a pre-processing, server-side repurposing scheme along with VPF to JPG conversion to properly implement the DNC based charts that it uses as a basis for navigation.

2. Creating Extents with ArcMap

An extent is simply the portion of the GIS product that is currently being used in the ArcGIS suite. While the DNC is not technically a GIS product, with the use of the Military Analyst extension discussed in section C.3.c. of this chapter, we can use the DNC in the same manner as a GIS product. Before this
can be done, however, there are some preliminary steps that must be completed (ESRI GIS Mapping and Software).

Obviously, the ArcGIS suite must be properly installed and functioning, and specifically, both the ArcCatalog and ArcMap products must be components of that install. Additionally, the ArcToolbox should be installed, and the Military Analyst extension needs to be activated in both ArcCatalog and ArcMap (ESRI GIS Mapping and Software). Once this is complete, the process of creating an extent can begin:

1. In ArcCatalog a new personal geodatabase must be created. This is accomplished by simply right clicking in the explorer window in the appropriate directory in which you wish the database to reside, and choosing the “New>Personal Geodatabase” option from the resulting menu. Name the database as desired.

2. Load DNC data into the geodatabase just created.
   a. Before this step can be accomplished, it may be necessary to copy the actual database contents from the CD-ROM to your hard drive. This was necessary in the development of the DeNS prototype, though whether this was due to hardware limitations or ArcGIS inherent limitations remains unclear, even after contact with ESRI support facilities.
   b. After the DNC is copied to the local machine, you can proceed to add it to the geodatabase. This is accomplished by right clicking the geodatabase in the explorer window and selecting “New>MA Catalog”. This will open a dialog window in which you will specify the name of catalog to be created, the location of the data to be added, and the format of the files to be added. The location should be the top level directory copied from the DNC CD-ROM, and the file type should be VPF Catalog.

   At this point there should be a working MA Catalog with the applicable DNC data added to it. We can now proceed to ArcMap to begin defining the extent we will use in the DeNS.
1. Open ArcMap and click the “Add MA data” button on the Military Analyst toolbar. By default this will reside in the bottom right-hand part of your screen as shown in Figure 2. This will open a dialog box asking for the name and type of catalog to be added. Specify the type to be “MA VPF Catalogs” and Browse to the MA catalog in the geodatabase created previously. Click Add.

![Add MA Data button (black plus over green tile).](image)

Figure 2. Add MA Data button (black plus over green tile).

2. The wireframe representing the GOEREF tiles will be displayed initially. In the explorer window, right click on the top level layer just added, and choose properties.

3. In the VPF layers tab under VPF Display Options, check “Display VPF Data for Selected VPF Products”. In the VPF Layer Selection window on the right, we can browse and choose those layers we wish to view in our extent. Click OK.

With the DNC data made available for viewing, we can now zoom to the applicable area in which small boat operations will be conducted. ArcMap allows complete customization of the chart display including color and/or patterns used to display features, turning features on or off as needed, and rearranging the drawing order of said features to ensure important items are visible and not overlooked. This is an exercise left to the discretion of the user, as it will be
somewhat operationally dependent, and the details of ArcMap use beyond what has already been given is beyond the scope of this paper.

3. Exporting Extents for use with DeNS

Once the extent that will be used has been created, it is a relatively simple task to export it. Simply choose the Export option from the file menu and it will allow you to produce a .jpg image of the extent currently being viewed. This same extent should be saved for later use with ArcIMS as will be detailed in Chapter 3. Also of note, the extreme latitudes and longitudes of the current extent should be recorded by hand as there is currently no automation involved to export/import them into either DeNS or MobileDeNS. They will, however be required for both applications to properly plot the GPS coordinates on the jpg representation of the DNC based chart. Also required will be the pixel height and width of the resulting jpg.

E. RELATED WORK

1. Overview

Related works in the area of interest, specifically network-enabled navigation systems, will be covered in this section. To illuminate various sectors of products and research, this section will provide a broad overview of COTS products available for similar purposes, United States Navy (USN) specific products intended for small boat C2, and finally research currently underway to facilitate networking at the desired ranges for OTH operations.

2. COTS Products

The commercial sector provides many options for both mounted and handheld GPS navigation at sea. Manufacturers such as Garmin, Magellan, and Cobra all provide solutions ranging in price from $100 to $1,000+ that are intended primarily for recreational boaters, or mariners operating independently. These products can be easily purchased from a local marine store or the internet,
but most of these low cost, easily available products do not provide any networking features that would allow for a COP between units, nor do they utilize the DNC, both of which are necessities for a naval vessel conducting small boat OTH operations.

The network tracking aspect of the navigation system can be obtained through the implementation of either a commercially managed navigation tracking system, or by the purchase of a much more elaborate self managed system. Both of these solutions are routinely utilized by commercial fishing fleets, merchant marines, cruise lines, etc. However, in both types of systems, price can be prohibitive, as subscription rates, equipment costs and the cost of satellite communications can reach figures which preclude this option based on the relative time it would be utilized by a naval vessel and its respective small boat. Further, the scalability of these solutions, from fleet-size implementations to a 2-3 vessel implementation at most, makes them impractical for consideration as viable solutions for individual naval units, and again, they do not utilize the DNC.

3. USN Products

In 1999, Electronic Technicians (ET’s) onboard USS FLETCHER developed a system referred to as NavTrack in order to aid in conducting MIO’s in the Northern Arabian Gulf. This system is the only system of its kind discovered during research for the DeNS project. It was designed for the same purpose, namely small boat C2, but was limited to a range of 5 NM, which would not allow for the small boat to be deployed OTH. Additionally, visual display was available only onboard FLETCHER, not in the small boats themselves, and even onboard FLETCHER the electronic chart representation was achieved through commercial products, rather than the DNC (Earhart).

NavTrack utilized Ross DSC 500 P radios, Furuno GPS units, and a wireless LAN known as RIBNET which was capable of transmitting digital imagery, scanned text files, sound and video at speeds up to 1.54 MB per
second at distances up to 5 NM. The Ross radios interfaced with the GPS receivers to display ownship’s position and fly to points on a dot matrix display, as well as allowing for polling and display of other ships positions equipped with similar radios. In the FLETCHER implementation, each Rigid Hull Inflatable Boat (RHIB) and the FLETCHER pilot house was equipped with such a unit (Gombert).

In order to display the positions received at the pilot house, Hi-plot software developed by West Marine of Hawaii was used on a standard laptop to control the radio and plot the received polling data on an electronic chart. Hi-plot controls the Ross radios via an RS232 cable to a combiner used to multiplex radio in, radio out, and NMEA data sent to and from the laptop’s serial port. Multiple RHIB data could be displayed along with ownship’s positional data, but the program was designed to only work with the Ross radios and the MS Windows XP Operating System exclusively. Issues were noted when trying to install the software to any other OS, including other versions of MS Windows (Gombert).

4. **Wireless Networking**

As has been discussed repeatedly, the networking aspect of the DeNS is crucial. It allows for a COP between parent vessel and small boat, as well as the passing of other mission critical information such as imagery, orders, and interrogative messages. As was discussed in section B above, the IEEE 802.11 standard was used to implement the networking portion of the DeNS. While this medium models the necessary networking ability of the system well, it is not appropriate for fielding the actual DeNS due to range limitations. For this reason another medium must be implemented when fielding this system.

IEEE 802.16 has been recommended as it closely resembles the development medium to the end applications. The 802.16 implementation could be achieved in a variety of ways. One possible implementation would be through the use of antennas mounted on the highest mast of the ship and in the small
boat itself, and/or the use of small Unmanned Arial Vehicles (UAV’s) to act as relay stations between the two communicating end points. In practice however, any medium which is capable of transmitting the TCP/IP packets and achieving the appropriate ranges could be used in its place. This could include satellite communications, Iridium phones, or any other medium over which the master station and PDA could be connected.

Beyond this, the question of networking in the field is beyond the scope of this thesis, though it will be touched on again in Chapter V as future work.

F. SUMMARY

In Chapter II we have focused on the background, development, and existing works related to the DeNS. Networking was shown to be a crucial aspect of the systems as it is required for not only communication between the GPS device and the PDA, but also to facilitate the sharing of that data with the master station onboard the parent vessel. Further, ranges of up to 15NM were established as the minimum requirement for such a system in order to allow OTH operations, and IEEE 802.16 was recommended as the medium of choice.

Specifications were provided for the DeNS devices as well as the environment used to create the prototype system. Third party software were also discussed in terms of their respective fit and functionality in the system, and a brief description of the DNC was provided for insight into it’s operation, functionality, and the role that content repurposing plays in its implementation. Finally, a brief overview of related works was provides which focused on naval applicability and the sole existing system discovered during the research phase of this project.

Before discussing actual usage and implementation of the DeNS, we will look further into the architectural details of the system in Chapter III. This will provide diagrams and data flows to help better understand what is happening in the system as various functionalities are discussed in the Chapter IV.
III. ARCHITECTURE DESCRIPTION

A. OVERVIEW

Chapter III is intended to provide a better understanding of the specific architectural elements of the DeNS and the interaction between those various elements. In order to better illustrate the prototype system’s architecture, we will first discuss the overall architecture, followed by a more in-depth look at the architectural elements in both MobileDeNS and DeNS, complete with data flow descriptions and diagrams.

B. OVERALL ARCHITECTURE

The overall prototype system architecture of the DeNS is shown in figure 3 below. As shown, there are six primary elements of the prototype system: 1) the Master Station; 2) the DNC database; 3) Web/GIS Server; 4) PDA and GPS receiver; 5) GPS constellation; and 6) the Surplusdedicate 802.11 network. Of the six elements, two will not be discussed at depth as they either exist external to the scope of the DeNS, or are being used to facilitate prototype testing only. The two elements in question are the GPS Constellation and the Surplusdedicate wireless network.

The GPS Constellation is a fully functional satellite network that is already in place and managed by government agencies. While it is an integral part of the DeNS’ functionality, it is an external element and as such is beyond the scope of this project. It is shown to complete the diagram, but only the data gathered by the receiver may be manipulated by the system, therefore, no further discussion will be addressed to this aspect of the DeNS prototype.

The second element of the diagram which will not warrant further discussion is the Surplusdedicate wireless network. This is an IEEE 802.11 network (SSID Surplusdedicate) located on the Naval Postgraduate School (NPS) campus that is managed and ran by the Information Technology and Computer Services office of NPS, which operates and/or maintains all school
ADP equipment. As has been discussed at length in Chapter II, 802.16 is recommended for fielding of the DeNS system.

![DeNS Architecture](image)

The remaining four elements can be divided into two distinct groups, MobileDeNS and DeNS, the distinction being all MobileDeNS equipment is deployable on the small boat, while all DeNS equipment is maintained onboard the parent vessel.

C. MobileDeNS

MobileDeNS is that portion of the system that is deployable to the small boat, i.e., the GPS receiver and the PDA. Figure 4, below, provides an overview of the architecture that comprises this portion of the DeNS prototype system. The blow up of the PDA shows the software interaction as well as input and output that is required or produced, respectively. Before detailing the MobileDeNS application, third party applications will be discussed.
1. **Third Party Extensions / Applications Used**

There are three third party applications utilized by MobileDeNS: 1) MSIE 4.01; 2) MultiIE; and 3) GPSAccess. The first two will be discussed together, as they function as one program after being installed. The final COTS product will be discussed separately at more length, since it plays a much more central role to the DeNS as a whole.

a. **MSIE 4.01 / MultiIE**

MSIE 4.01 is the browser that ships with Microsoft Pocket PC 2003 (refer to Table 3 for PDA specifications.) Since Pocket PC and the Compact Framework are both designed specifically to run on a PDA, which is shown to be a limited platform as discussed in Chapter II and demonstrated in Table 4, it follows that many of the features that were not considered critical to functionality were removed in order to improve performance. Likewise, redundant features
(those with multiple paths of execution) were reduced to a single implementation. The result is that many of the features one could expect to readily find on a desktop PC is either not available on a Pocket PC, or if so, they may require some amount of effort on the users part to find. It follows then that the same circumstance would directly apply to MSIE 4.01.

This is the case with a key feature used by MobileDeNS to import the DNC based JPG images that are created through ArcMAP: the ability to save a browsed image to the device. Natively, MSIE 4.01 Pocket PC edition does not support this functionality, thus the MultiIE extension adds it and many others back in with no noticeable degradation in performance. While it is certainly possible to transfer the file via other means such as file synchronization or beaming the file via the IR port, the ability to save the image from a web server was considered less time consuming and more flexible for future work on the prototype system, as will be discussed in more depth in Chapter V.

Beyond the stated ability to save the image to the device, no modification was necessary to either MSIE 4.01 or MultiIE. Since this is the case, further in-depth study of either program is not required. The method of saving the browsed image to the device will be covered in Chapter IV.

b. **GPSAccess**

GPSAccess is a COTS application that allows the PDA to connect with the Bluetooth GPS receiver and extract NMEA data from it via the provided API. The latest version works only with the Compact Framework V1.0, which requires it be implemented in 2 separate components, GPSLink.exe and GPSAccess.dll. A newer version of the GPSAccess package is currently being developed which will work with the Compact Framework v2.0 which will eliminate the need for GPSLink.exe, but at present, it has not been released (Highpoint Software).

GPSLink.exe is a standalone program which runs on the PDA and works with GPSAccess.dll to provide threading for the GPS connections and data
collections. Additionally, it allows easy monitoring of the connection and its status outside of MobileDeNS if troubleshooting is required in regards to the GPS connection (Highpoint Software). For the DeNS, it should be started prior to launching MobileDeNS. This ensures the proper handling of the GPS connection when the program is launched.

GPSAccess.dll was built on High Point Software’s BTAccess library, which is a leading software development kit (SDK) for Bluetooth communications with all Pocket PC devices using the Widcomm/Broadcom Bluetooth stack. GPSAccess utilizes the BTAccess.dll to transparently search for and connect to Bluetooth enabled GPS receivers. It then opens an appropriate COM port, and starts collecting data from the receiver. As such, GPSAccess has the distinction of being the world’s only Bluetooth-integrated GPS library for the Widcomm stack, and eliminates many of the otherwise prevalent Widcomm popup screens requiring user interaction. GPSAccess.dll is used by both GPSLink.exe and MobileDeNS via a class called GPS that offers all of the properties and methods that make up GPSAccess, including GPS methods such as GPS.Start() and GPS.Stop(), which starts and stop data collection, respectively, as well as the GPSData class, which is used to extract all GPS data available (Highpoint Software).

2. **Architecture Details**

MobileDeNS is the PDA application that handles mapping, plotting and transmission of GPS positions as well as other data between the PDA and the Master Station. This section provides detailed architectural insight into how MobileDeNS works and the classes and forms that provide its functionality. Figure 5 provides a block diagram containing all classes and forms used by MobileDeNS. Arrows indicate calling forms and classes, i.e., Form1.cs can call FormMapInfoLat.cs, GPSHandler.cs, and FormMapDetailsTest.cs. Dotted lines are provided strictly for visual guidance, as the structure was manipulated to provide a more efficient fit into this paper.
Pocket PCs use forms to interact with the user, whether that interaction is getting information into the program, displaying information already in the program, or calling other classes to perform certain functionalities within the program. As such, there is typically no main class within a mobile device application. Rather, a distinction is made between form types: a form is either classified as a dialog box, which can be considered a temporary form to get or display information; or a form is considered a main form which serves as the home page throughout the user's navigation of the application (Yao).

It follows, then, that Form1.cs as seen in Figure 5 is a main form. It contains the logic to keep the program running, drawing on all other resources of the application either directly or indirectly to do so. The other five forms shown
are considered dialog boxes, as they are temporary windows that either receive information from, or display information for, the user. Additionally there are three helper classes that handle specific functionalities within the application. Discussion of these components will be accomplished by grouping them into two distinct groups, dialog boxes and classes.

To aid in the logical grouping of all components, Form1.cs will be included in the discussion of the classes, while the remaining forms will be discussed as dialog boxes. The brief descriptions that follow are intended to give a sense of what the various components of MobileDeNS do, not to provide an in-depth understanding of exactly how these functions are carried out. For more clarification on exactly what is taking place within the program, please refer to the appropriate section of Appendix I.

a. **Dialog Boxes**

(1) FormMapInfoLat.cs. This form allows the user to enter the upper and lower latitude bounds into the system for the map to be displayed. Latitude is entered in degrees, minutes, and seconds (seconds to the nearest hundredth) followed by the one letter designator N or S (North or South, respectively.) The Monterey Bay test map values for all parameters are displayed by default. This form receives the MapHandler instance by reference and writes all values directly to its variables when the OK button is clicked. It is the first in a series of four forms called when loading a new map into MobileDeNS or changing map parameters on a currently loaded map.

(2) FormMapInfoLong.cs. This form allows the user to enter the left and right longitude bounds into the system for the map to be displayed. Longitude is entered in degrees, minutes, and seconds (seconds to the nearest hundredth) followed by the one letter designator E or W (East or West, respectively.) The Monterey Bay test map values for all parameters are displayed by default. This form receives the MapHandler instance by reference and writes all values directly to its variables when the OK button is clicked. It is
the second in a series of four forms called when loading a new map into MobileDeNS or changing map parameters on a currently loaded map.

(3) FormMapInfoPix.cs. This form allows the user to enter the pixel size into the system for the JPG map to be displayed. Pixel size is entered as integers, and can be obtained by viewing the jpg's properties. The Monterey Bay test map values for all parameters are displayed by default. This form receives the MapHandler instance by reference and writes all values directly to its variables when the OK button is clicked. It is the third in a series of four forms called when loading a new map into MobileDeNS or changing map parameters on a currently loaded map.

(4) FormMapConfirmation.cs. This form allows the user to review all the information entered previously (latitude, longitude and pixel size) and then either accept these changes or go back and revise them. This form receives the MapHandler instance by reference and reads all values directly from its variables. This is the last in a series of four forms called when loading a new map into MobileDeNS or changing map parameters on a currently loaded map.

(5) FormMapDetailsTest.cs. This form allows the user to view the latitude and longitude differences currently being used by the application to calculate the pixel position of the position indicator to be drawn on the JPG map. The application uses a series of functions to convert geospatial positions into pixel coordinates for accurate plotting. The latitude and longitude differences being shown are the result of these functions, representing how much arc of both latitude and longitude relates to one pixel on the screen.

b. Classes

(1) Form1.cs. As previously stated, this is the main form that acts as the director for the rest of the application. When this form is running, the application is running as well; likewise, when it has been properly exited (via the exit option on the File menu) the application is terminated. User interaction with the form occurs primarily through the menu system provided along the bottom of the screen, consisting of three main menus: File; GPS; and Map. Each
menu has one or more options that can be selected to drive the program as required by the user. These options will be further discussed in Chapter IV, Section B.

More to the point for the discussion at hand is the functionality taking place that is transparent to the user. When the application is started, immediately after the form is created, it: 1) loads the default map: a DNC based JPG of Monterey Bay, along with all of its parameters; 2) sets the viewport to orient itself over the upper left-most corner of the underlying JPG (due to screen limitations on the PDA, only 256 x 224 pixels are visible at a time leaving the rest of the JPG off-screen; ) 3) an instance of GPSHandler is instantiated; 4) it recognizes that no position yet exists to try to display; 5) it immediately tries to connect to the Master Station server which should be listening on port 5000; and 6) loads the waypoint data from an external file named “waypoints.txt”. Action 5 requires that the Master Station be running at the time that MobileDeNS is started for successful completion, as indicated above.

GPS data collection is managed through the use of a timer that polls the GPS receiver for new data every five seconds. If the resulting position is not located on the map as defined by the latitude and longitude bounds entered at the map’s load, then that position will not be plotted and the user will be informed that they are not currently in a viewable position. Otherwise, Form1 will use calls to its instance of GPSHandler and subsequent calls from GPSHandler to GPSPacket and MapHandler to calculate the latest position and plot it if it is currently within the viewport. Further, the position will be tested for its proximity to the designated track, as defined by the waypoints. If it is within tolerance (50 yards for the prototype, though this should be a user assigned distance in the fielded system) it will be plotted using a green positional cursor. Otherwise, it will be plotted using a red cursor to serve as a visual indicator to the PDA user and flags will be sent to the Master Station to indicate that the position has exceeded tolerance.
(2) GPSHandler.cs. This class is responsible for GPS receiver interface and management, as well as interaction with the MapHandler and GPSPacket classes on behalf of Form1. Upon instantiation, this class, in turn, creates an instance of MapHandler and an array to store 2,000 GPSPacket instances. Utilizing these instantiations, GPSHandler can get positional fix details; Parse NMEA data received as strings, and retrieve the pixel X and Y coordinates for a given position. In terms of GPS management, GPSHandler can start or stop the GPS receiver connection, poll the receiver for live data, and determine if the connection still alive. This is also the class that calculates the positions relation to the designated track tolerance mentioned above.

(3) GPSPacket.cs. GPSPacket is instantiated through the use of strings created based on data taken from the NMEA strings received from the GPS receiver. When it is passed the string from GPSHandler, it stores the string as several smaller substrings, and parses numbers appropriately for latter calculations within the application. GPSPacket basically acts as a storage vessel for GPSHandler to use as required to organize positional data for later retrieval. All of its methods are either get- or set-type methods.

(4) MapHandler.cs. While MapHandler does not interact with the DNC based JPG map in any way, it is the class which holds all of the map’s parameters for use in calculations. It stores all of the latitudinal and longitudinal boundary information as floats, as well as the latitude and longitude per pixel. JPG pixel height and width is stored in integer form. It is the responsibility of the MapHandler class to calculate the X and Y pixel coordinates of a given latitude and longitude, as well as to determine whether a given coordinate is valid within the bounds of the loaded map.

3. Data Flows

The data flow diagram shown in Figure 6 provides a visual representation of the data flow between those components of MobileDeNS previously discussed. Note that this does not specify control, or how it is passed among the various components. As can be seen, Form1 interacts solely with the Master
Station via the 802.11 network and GPSHandler, which handles the bulk of data flow management. This is achieved through the dialog boxes because as they are spawned by Form1, the instance of GPSHandler created in Form1 is passed by reference to the forms, allowing them to directly update or retrieve the parameters in GPSHandler's instance of MapHandler. FormMapConfirmation.cs, for example, retrieves its information directly from the current values of MapHandler allowing for review of the current parameters at the time it is spawned.

![Image of Data Flow Diagram]

**Figure 6. MobileDeNS Data Flow Diagram**

As has already been discussed, GPSHandler instantiates MapHandler as well as the GPSPacket instances that are stored in the array, so access to these instantiations is solely available through GPSHandler. Similarly, since
GPSHandler manages the connection to the GPS receiver, it follows that data retrieved from the GPS receiver should be solely available through GPSHandler and its management of the GPSPacket array, as is the case. The DNC based JPG will reside on the PDA device and be made available through the use of Open File dialog boxes; it is considered an external source in Figure 6. Similarly, the waypoint text file must also reside on the PDA, though it is accessed transparently to the user.

D. DeNS

DeNS, as discussed here, is that portion of the system that is intended to remain aboard the parent vessel. It consists primarily of three parts, excluding the Surplusdedicate network which will not discussed further for reasons noted above: 1) the DNC database; 2) the Web/GIS Server; and 3) the Master Station. Figure 7, below, provides an overview of the architecture that comprises this portion of the DeNS prototype system. The blow up of the Master Station, as with the PDA shown in Figure 4, shows the software interaction as well as input and output that is required or produced, respectively. As can be seen, there is no interaction with the GPS which results in a much simpler architecture at the Master Station than was required on the PDA.

The DNC database, having already been discussed in Chapter II will warrant no further direct discussion here. It is, however, important to note the meaning of the lines depicted in Figure 7 connecting the DNC to both the Master Station and the Web/GIS Server. In the case of the Master Station, the solid lines indicate that the DNC data is directly imported and manipulated on the Master Station. The dashed lines between the DNC database and the Web/GIS Server indicate that while the database itself is not necessarily accessible from the server, its use (on the Master Station to create the map file) is a prerequisite to the map product’s display by the ArcIMS software.

While the Web/GIS Server plays a small role in the current prototype of the DeNS system, it could potentially take on a much larger, more central role as
will be discussed in Chapter V. Visual Studio .NET 2003 is mainly used on the server to facilitate the editing of web pages at this time. Though this function could just as easily be accomplished through other software that performs the same function, Visual Studio was chosen because of its prior implementation in the construction of MobileDeNS and its potential use in future work as will be discussed in Chapter V. Additionally, IIS, the web server implemented in the solution, can natively interface with Visual Studio, further increasing compatibility throughout the project.

Though ArcIMS can be used with other web server suites, such as Apache Tomcat, IIS was selected due to its integration with Windows and ease of installation. Likewise, the servlet engine, New Atlanta’s ServletExec, was selected for its availability; it is provided on the ArcIMS CD. ArcIMS itself consists of three major components: 1) ArcIMS Author; 2) ArcIMS Administrator; and 3) ArcIMS Designer. These components are briefly discussed below in terms of interoperability and function, while more thorough descriptions of their installation and use can be found by consulting the applicable reference (ESRI, Getting Started with ArcIMS).

ArcIMS Author is the first step in the ArcIMS process to enable maps created in ArcMAP to be delivered via the web. ArcIMS displays files using a configuration file (.axl file) based on an existing shapefile (created in ArcMAP) (ESRI, Getting Started with ArcIMS). Specific guidance on this process can be found in the ArcIMS documentation cited. It is important to note that prior to saving your final .axl file, it is a good idea to review the layer ordering and symbology representation, such as shape, color and pattern to ensure they are still acceptable for proper web display.

Once the .axl file is created, the next step involves ArcAdministrator. This component of the ArcIMS suite allows ArcIMS services to be created and started in order to serve the .axl files previously created (ESRI, Getting Started with ArcIMS). Once this is accomplished, ArcIMS Designer can be used to build the web site which uses the service to deliver the .axl files (ESRI, Getting Started
with ArcIMS). ArcIMS Designer does this through a series of simple wizard-like screens which require the site’s creator to provide minimal information, after which it builds the site automatically. Again further details can be found on these processes in the applicable reference (ESRI, Getting Started with ArcIMS).

![DeNS Architecture Diagram](image)

**Figure 7. DeNS Architecture**

After this entire process is complete, there exists a web site that is accessible via the internet and capable of displaying vector products in the form of .axl files. Unfortunately, the current implementation of the prototype system does not use these .axl files, though that would be desirable and will be further discussed in Chapter V. In order to mitigate this issue, content repurposing was implemented in the web site via Visual Studio. By checking browser versions when a user tries to access the file, the web site can determine if the user may be coming from a PDA (MSIE 4.01) vs. more capable desktop computer (MSIE 4.01).
Based on this observation, it can redirect the PDA user to a site from which they are presented a list of available DNC based JPG maps that can be downloaded to the PDA itself using the MultiIE extension discussed earlier. User's coming from desktop systems running more advanced browsers can choose to view the web presentation of .axl files and/or use FTP in order to download the same JPG files as the PDA user.

1. Architecture Details

DeNS operates on the desktop using the same logic as MobileDeNS with a few exceptions. The positional information that is being plotted comes across the 802.11 network from the PDA, vice a Bluetooth connection to the GPS receiver in the case of MobileDeNS. After the positional data is received, it is handled in the same manner as the GPS data after it is parsed in MobileDeNS. Additionally, DeNS acts as the server for communication, while MobileDeNS acts as the client. This means that when DeNS is started, it immediately starts listening on port 5000 for incoming connection requests from the PDA. Figure 8 provides a block diagram containing all classes and forms used by DeNS. Solid arrows indicate calling forms and classes, while dashed arrows indicate that a class is accessed by reference as will be discussed in Section D.2, below.

As DeNS was ported to the desktop based upon the work completed in MobileDeNS (intended for use on a PDA), much of its functionality is common, though names have changed. There still exists a distinction between main forms, dialog boxes, and classes, and therefore the discussion will follow the same format as that of MobileDeNS above.

Form1.cs is still the main form, containing the logic to keep the program running, drawing on all other resources of the application either directly or indirectly to do so. Due to considerable differences in screen size between the desktop and the PDA, the number of dialog boxes has been reduced from five to two; one for entering map parameters, and one for reviewing map parameters. While the number of forms has decreased, the number of helper classes has
increased primarily due to the addition of the DeNSServer class. This has also resulted in some of the functionality be moved from one class to another, though the logic involved has remained the same.

![DeNS Architectural Detail](image)

Figure 8. DeNS Architectural Detail

a. **Dialog Boxes**

1. FormNewMapProp.cs. In contrast to MobileDeNS, Dens allows the user to enter all required map parameters in one screen. In MobileDeNS, screen size prohibited this ability, which is obviously not an issue with larger 14+ inch screens available for the Master Station on which DeNS runs. Another noticeable difference is the elimination of the requirement to enter the jpg pixel size, which can be gathered automatically by the program through the jpg's properties. Default values for Monterey Bay are provided when the form is instantiated.

2. FormMapProp.cs. This form allows the user to review the current map parameters, including the latitude and longitude per pixel currently being used by DeNS to calculate the position cursor placement on the DNC based JPG map currently loaded in DeNS. This screen is read only and therefore doesn't allow parameters to be changed.
b. Classes

(1) Form1.cs. As previously stated, this is the main form that acts as the director for the rest of the application. Unlike its MobileDeNS counterpart, Form1.cs when implemented in DeNS can be exited either through the File menu by selecting Exit, or by using the “X” in the upper right-hand corner of the program’s main window. The difference is due to the different way that mobile devices handle what is typically considered the close command on a standard desktop computer. The “X” in the upper right-hand corner of a PDA application typically only minimizes a window, but leaves the application running, utilized primarily because of screen limitations in an effort to provide the user the opportunity to use more than one program at a time. User interaction with the program occurs primarily through the menu system provided along the top of the screen, consisting of three main menus: File; Map; and Connect. Each menu has one or more options that can be selected to drive the program as required by the user. These options will be further discussed in Chapter IV, Section C.

As with MobileDeNS, there is certain functionality that takes place transparent to the user. When the application is started, immediately after the form is created: 1) it creates an instance of MapHandler and DeNSServer; and 2) The instantiations of MapHandler and DeNSServer are passed by reference to create an instance of Plotter, which can now access the same information and threads that Form1 uses.

As stated previously, DeNS does not interface directly with the GPS receiver, so all data collection takes place via the 802.11 network by way of the DeNSServer instantiation. Positions are plotted when the plotting function is turned on through the Map menu. When activated, a timer is used to request new information from the DeNSServer every five seconds which is then displayed on the DNC based JPG to represent the small boat’s position. Waypoint data is not required by DeNS as all calculations associated with track tolerance take place on MobileDeNS, with indicators being received via the Surplusdedicate network and processed upon receipt.
(2) DeNSServer.cs. This class is the counterpart of GPSHandler found in MobileDeNS. It is responsible for: the management of the 802.11 connection, packet transmission between DeNS and MobileDeNS; the proper handling of transmissions sent and received; storage and retrieval of packets received via the network connection; and proper handling of track tolerance indicator data. Upon instantiation, DeNSServer creates two ArrayLists; one to store position packets, and one to store message packets. It also starts listening on port 5000 for incoming connection requests from MobileDeNS clients.

(3) MapHandler.cs. The MapHandler class in DeNS, as with MobileDeNS, does not interact with the DNC based JPG in any way. It simply acts as a method to load the map, and a vessel in which to store the parameters entered for that map. Unlike its MobileDeNS counterpart, however, MapHandler in DeNS does not perform any calculations nor determine validity of positions, as this functionality has been moved to other methods contained in DeNS.

(4) Plotter.cs. The Plotter class is the class that is responsible for calculating the x and y screen positions for a given latitude and longitude. As such, it is necessary that it can access the DeNSServer for position packet retrieval, and MapHandler for access to the currently loaded map’s parameters. To achieve this end, both instantiations are passed by reference to the plotter class at the time of its own instantiation, allowing it to access the most current information when needed. This class is also the class that instantiates PktHandler when a new position is to be plotted for display.

(5) PktHandler.cs. PktHandler is the class which is responsible for all parsing of the position based packets received by DeNSServer. As such, it is also the class which retrieves data from the packets for use in calculations, and user-information oriented display.
2. Data Flows

The data flow diagram shown in Figure 9 provides a visual representation of the data flow between those components of DeNS previously discussed. As with Figure 6, this does not specify control, or how it is passed among the various components. Unlike MobileDeNS, data flow in DeNS indicates a much more dispersed architecture. As previously stated, the logic, (i.e., processes, mathematical equations and data formats) remain consistent between the two applications. This ensures that the same manipulations are taking place on each end system, providing consistency between the two.

What is different is where these manipulations take place, which fundamentally stem from inherent differences between the .NET Framework and the Compact Framework on which Microsoft’s C# language is based. As was previously discussed, much of the redundant or superfluous functionality of the full .NET Framework was removed from the Compact Framework in order to reduce it’s size from a 40 MB footprint with approximately 86 libraries and 20+ supported languages down to a 2 MB footprint with only 18 libraries and 2 supported languages that would be more compatible with mobile devices (Yao).

After these fundamental differences shaped the architectural changes between the two end applications, other logical structural changes followed. For example, the replacement of the GPSHandler class with the DeNSServer class resulted in the data store for packets existing within the DeNSServer class, forcing the Plotter class to retrieve information as needed and create a PktHandler instance with which to manipulate it.
Figure 9. DeNS Data Flow Diagram

E. SUMMARY

Chapter III has provided an in-depth look at the architecture used in the construction of the DeNS prototype system. Beginning with an overall view of the system as a whole and how the various components interact with one another, we then moved to a more detailed view of MobileDeNS and DeNS, respectively. In these more detailed descriptions, we again began with an overall view of the components of the system in question, moving finally to a discussion of programming structure and data flow descriptions. More detailed programming insight can be gleaned from Appendices I and II by reviewing the actual code and the inline comments provided.

In the next chapter, we will discuss the usability issues, functions, and features associated with the DeNS. Also provided will be a discussion of the specific limitations of, and known bugs that exist in the DeNS prototype.
IV. IMPLEMENTATION

A. OVERVIEW
Chapter III discussed the DeNS implementation from an architectural/programming perspective. While Chapter IV also discusses implementation, it approaches the subject from a program usability aspect. In this chapter, both MobileDeNS and DeNS will be examined in terms of usage, features, implemented error handling, and prototype limitations and existing bugs which have been identified but not addressed due to time constraints. The wireless network architecture, setup, and implementation will not be discussed as they are beyond the scope of this thesis.

B. MobileDeNS
As was the case in the previous chapter, MobileDeNS will be discussed first and applies to the application intended for deployment to the small boat, i.e., it will deal with the MobileDeNS application that runs on the PDA. While the GPS receiver is also deployed on the small boat, all of the access and control mechanisms are implemented within the PDA application.

1. Usage
This section will focus on basic functionality and usage of the MobileDeNS program. Discussion will be limited to Installation, proper start-up and shut-down, actions required to begin the navigation process, and basic usage. Specific features implemented in the prototype application will be covered in the next section.

   a. Installation
The Installation process of MobileDeNS involves the setup and installation of four distinct pieces of the DeNS system: 1) Wireless setup and
connectivity; 2) MultiIE; 3) GPSAccess; and finally 4) the MobileDeNS application. The installation of all of these components takes place on the PDA.

(1) Wireless setup. As stated above, wireless network connectivity will not be covered except to say that it will be assumed that prior to installation the PDA’s networking capability has been established with regards to connectivity to the network medium of choice for DeNS installation (the Surplusdedicate network in the case of the prototype.) Additionally, it is assumed that the Bluetooth capability on the PDA has been activated and is capable of detecting and connecting to Bluetooth enabled devices within the area of the PAN.

(2) MultiIE. With the PDA resting in its docking cradle, run the MultiIE DesktopInstall.exe application. This will Install MultiIE to the desktop computer and subsequently, allow it to be chosen for installation to the PDA via the “Add/Remove Programs…” option available on the Tools menu of Microsoft Activesync if the PDA installation does not start automatically. After installation of MultiIE is complete on the PDA, it must be registered. Without registration, MultiIE is only available for a 15 day trial period, after which its functionality is locked until registration is complete. To register the software, a registration code must be purchased from Southway Software for $15. Upon receipt of the registration code, it and the registering email address must be entered by clicking the register button available from the “About” tab located on the “MultiIE Options…” menu accessible by choosing the MultiIE icon shown in the MSIE window, as per Figure 10.

Figure 10. “MultiIE Options…” will provide access to the registration option.
(3) GPSAccess. The zip file acquired from Highpoint Software contains a number of files the must be extracted to the hard drive of the computer prior to installation. After all files have been extracted, the installation process consists of simply copying a selected few of them into the \windows directory on the mobile device. The easiest way to accomplish this is to browse to My Computer\Mobile Device which will be accessible if the device was left properly cradled as indicated above, otherwise the PDA will have to be cradled before progressing with the installation.

There are two BTAccess dll files that were extracted as a result of unzipping the file above, each used to address different versions of the Bluetooth widcomm stack that could be used by the Bluetooth device in question. For the DeNS prototype, we will be using BTAccess4700.dll. To install the GPSAccess application, simply copy BTAccesss4700.dll, GPSAccess.dll, and GPSLink.exe to the same directory as the MobileDeNS application will be installed to (the Program Files directory under its own folder named DeNS is recommended.) Once this is accomplished, rename BTAccess4700.dll to BTAccess.dll. This completes the GPSAccess installation. Further information on the installation process is available in the GPSAccess User’s Guide (Highpoint Software), and the readme.txt file extracted from the original zip file.

(4) MobileDeNS. To install MobileDeNS, simply copy the MobileDeNS.exe file, created from the source code located in Appendix I, to the PDA. This can be copied anywhere on the PDA, though for standardization purposes it is recommended that it be placed in the Program Files directory under its own folder named DeNS. The GPSAccess files mentioned above must be located in this same directory.

Before using MobileDeNS, a map will have to be made accessible to it on the PDA. This can be done by downloading a map from the ArcIMS server, detailed later, or by transferring a map using Microsoft Activesynch, beaming, or any other appropriate method. It should be noted that for development reasons, the MobileDeNS prototype attempts to load the MontereyBay.jpg map at startup. If this map is not located in the “My
b. Start-up

Once the DeNS installation is complete (consisting of both DeNS and MobileDeNS), MobileDeNS is ready to be started up as follows and can then be expected to function within its normal parameters. MobileDeNS startup is a two part process consisting of activating GPSLink.exe followed by MobileDeNS.exe. As previously discussed, GPSLink is the tool through which MobileDeNS is able to access the GPS data made available from the GPS receiver. As such, it is necessary to have established a connection with the receiver prior to trying to read any data.

Activation of both GPSLink.exe and MobileDeNS is accomplished, as with any other PDA application, by tapping its icon on the PDA screen from the directory location of installation. The use of shortcuts to facilitate easier access to both GPSLink.exe and MobileDeNS may be used. These shortcuts can easily be placed on the start menu for quick access. Additionally, as mentioned above, the MontereyBay.jpg file is required to be in the appropriate directory for the prototype to start-up error-free, as is the waypoints.txt file.

c. GPS Activation

In order to connect to the GPS receiver, simply choose connect from the GPS menu from within MobileDeNS. This will begin the position
collection and display process which will repeat every five seconds in the prototype system, though the fielded system should provide a mechanism to change the timer setting. If the GPS receiver is not currently connected, GPSLink has not been started, or the positions read as the default positions (i.e., 0.0 N by 0.0W) MobileDeNS notifies the user that synchronization has not yet taken place.

While GPSLink is not required to ensure that MobileDeNS will properly start-up, i.e. will not shut down with errors, it must be activated before attempting to connect with the GPS or otherwise a satellite synchronization notification will appear at every GPStimer tick as indicated above. When testing the prototype system, it proved helpful to start GPSLink.exe and monitor the connection status on the PDA, starting MobileDeNS only after the first legitimate position is obtained. The reason for this is that the error control for the GPS connection is based both on GPS connection status and the positional information that would indicate that the initial 3-4 minute wait for GPS positional calculation and synchronization are past. While the GPS receiver is connected but awaiting it’s first valid positions from the constellation, a default value of 0.000\(^0\) is used for both latitude and longitude. The act of monitoring the status of the GPS connection via GPSLink proved to eliminate the frustration of getting synchronization messages while waiting for the initial position to be obtained. Once the status in GPSLink shows connected and latitude and longitude positions vary from the default position, the GPS receiver has synchronized and is ready for use.

d. Usage

Basic usage of the MobileDeNS application is simple, assuming the prerequisites for running MobileDeNS have been met: maps have been created; a network is established and available; GPSLink is running and providing valid GPS data; and DeNS is running on the Master Station to act as the server side of the system. After the MobileDeNS prototype application has been started, the default map is automatically loaded, and the network connection is established
with DeNS. At this point MobileDeNS is ready to start collecting and displaying GPS positions from the GPS Bluetooth receiver. This is accomplished by selecting “Connect” from the GPS menu within MobileDeNS which starts the GPSTimer that manages the GPS data collection and display process. Once this has been done, the collection and display process, as well as shipping the data back to the Master Station for remote display and monitoring, takes place with no user intervention. Stopping this process is equally simple: choose the “Disconnect” option from the GPS menu within MobileDeNS (formerly the “Connect” option) and the collection, display and relay functions will be stopped.

A more in-depth look at some of the features available to the user will be provided in the next section of this chapter.

**e. Shut-down**

As has been previously discussed, the MobileDeNS application is only properly exited through the use of the “Exit” option on its File menu. Due to the differences in mobile devices and desktop computers, using the “X” in the upper right hand corner simply minimizes the form and leaves the application running, using valuable resources on the PDA, perhaps unintentionally. Using this minimize feature for switching to other applications, such as GPSLink to verify or monitor the GPS receiver connection, is particularly handy when troubleshooting. It is also possible that future fielded versions of DeNS will have the capability to send and receive other file types, such as image files, documents, video etc. If this is the case, the minimize feature will prove its worth in allowing access to other programs to import/export, edit, and/or otherwise manipulate these file types.

**2. Features**

In the last section general usability of the MobileDeNS application was provided. This section elaborates on the usability of the application by providing insight into the various features and functionality that it contains. All menus will be discussed first, along with the various features accessible through them.
Following the menu discussions, access methods and discussions of each feature available through other means will be given. Any associations to limitations and known bugs will be provided for reference in both instances, though specifics of said limitations or bugs will be discussed in the appropriate section of this chapter.

**a. File Menu**

The file menu in the prototype system consists of only one available option, Exit. As this option has already been discussed above, no further discussion is necessary in this section. It should be noted that while the File menu in the prototype system only contains one option, the File menu in the fielded system will probably contain more. As with the other menus to be discussed, those options envisioned for the fielded system will be visible but disabled. This ensures that the vision of the system at inception will be considered and either carried out or discarded in the final product.

**b. GPS Menu**

Like the File menu, the GPS menu in the prototype system has only one available option, Connect. This option allows the MobileDeNS application to connect to the GPS receiver via the Bluetooth connection and GPSAccess.dll. Additionally, it changes this particular menu item’s text to “Disconnect”, and uses the state of the displayed option’s text to determine what logic to implement; connection logic, or disconnect logic.

Based on the option’s text at selection, the menu item will call the start or stop function of the GPSAccess.dll, change the text display to either connect or disconnect as will be appropriate for the next selection of this menu item, and either enable or disable the GPSTimer to manage the collection, display, and relay of GPS data in the appropriate fashion.
c. Map Menu

The Map menu in the prototype system is where most of the available menu options reside. It consists of four available options: 1) Clear Map; 2) **Test**; 3) New Map; and 4) Properties. Each of these available options will be discussed in more depth below.

(1) Clear Map. This option allows the current position to be erased from the map’s display, but does not alter the internal mechanisms used to store either the said position, or the currently loaded map parameters. It is intended as a method to clear the map of positional displays, which is admittedly not of substantial use in the prototype, but will be of much greater use in a fielded system which should be capable of displaying track histories.

This will become apparent if, for example, a small boat is deployed along a predetermined track and ordered to linger in one area for a prolonged period. If old positions are being maintained within the DeNS, then multiple positional displays will begin to overwrite one another, potentially causing a great amount of confusion in sorting out which is which. In this case, the ability to clear the map of positional data, while maintaining the program’s integrity in regards to track history becomes paramount. This feature allows the map to be cleared as described above, but continue tracking the small boat’s progress unimpeded. One note: as the prototype was designed to only display one position at a given time, logic will have to be built in to allow multiple positions to be cleared. This can easily be accomplished through the use of an appropriate data structure and the logic to loop through that data structure setting all or some of the positions properties to not visible.

(2) **Test**. This option was used primarily for many different troubleshooting tasks during the prototype design, hence the lack of an otherwise descriptive handle. Its final use, however, was for the display of latitude and longitude per pixel; a feature that proved invaluable in verifying proper plotting of GPS positional data received. As such the decision was made to leave this feature in the prototype system as a reference for further development in the fielded system. It is not anticipated that this information
would prove useful to the average user of a fielded system, so it should be considered for removal prior to fielding the system, though if sufficient justification is present, it may included. Fields displayed are read only, so no changes to internal parameters are possible through this display.

(3) New Map. This feature allows the user to load a new map and change the map parameters to conform to said map. Upon selection, this option will open a file dialog box that will allow the user to browse to a specific directory from which to load a new map file. As has been previously stated, certain limitations exist on PDA devices that do not exist on desktop computers. One such limitation is the depth to which a user can browse through an open dialog box. On a desktop computer, the user can browse to an unlimited depth, however, through a mobile device (running the Pocket PC OS), that depth is limited. To alleviate this issue, the decision was made to place map files in the My Pictures directory of My Documents, a second level directory that is both reachable and readily familiar to typical PC or Pocket PC users.

Based on the above decision, the initial directory for the open file dialog box is the “\My Pictures” directory on the PDA, since the PDA is intended in the DeNS system for exclusive use within the system. This, of course, can be changed in the fielded system if desired but it is recommended that an equally high level directory be used to skirt the issues associated with lower level directories in terms of browsing. In any case, once the file has been chosen through use of the dialog box, it will be loaded into the viewport for display, and the sequence of specifying the map’s parameters via the forms detailed in Chapter 3.C.2.a will begin. It should be noted here, that if the user chooses the “OK” button on FormMapConfirmation.cs, all parameters will remain loaded and the map will be ready for use. If, however, the user spots an error made in entering the data, choosing the “Change” button will allow them to go back to the beginning of the parameter specification process and enter the correct information.

(4) Properties. The Properties option allows the user to review all map parameters previously entered for the current map, and either
accept them or change them as outlined directly above. Choosing this option places the user on the FormMapConfirmation.cs form; the end of the map parameter form cycle. From this point they can choose to either accept the displayed parameters, or revise them as described above. This option is intended to allow review and correction to the currently loaded map parameters at any time.

d. View Fix Details

Certain details of any given fix can be viewed when desired by tapping on the fixes positional cursor displayed on the current map. Each fix cursor is actually an active button. The action of clicking on a given fix calls the button’s action listener and will result in a message box with the fix’s time, latitude and longitude. Currently there is a formatting bug in this portion of the code that results in a somewhat garbled, confusing display as will be discussed at more length in Section 4 below.

e. Auto-scroll

At the time of design, it was decided that an “auto-scroll” feature that automatically scrolled the viewport in order to center the current position would be a desirable feature to implement. This would allow the user to watch the orientation of the viewport as their current position was plotted by allowing smooth transitions to the current position. This feature is automatic and cannot be turned off. For reasons discussed in section B.4 of this chapter, however, this same feature is listed as a bug in the prototype system.

f. Fix Distance from Track

This feature compares each GPS fix position to a designated track as defined by the waypoints.txt file. In the prototype system only two waypoints were used to create and test this feature, though the fielded system should allow for multiple waypoints, thus enabling multiple legs of a single track to be
traversed with tolerance indicators provided. Figure 11 provides a graphical depiction of the triangle used to determine whether the fix position is within the allotted track tolerance. Distance in the DeNS system is determined using trigonometry to derive the height of the tolerance triangle, represented in Figure 11 by the line segment CD.

In order to determine the length of segment CD, the length of the triangle’s side, a, b, and c must be known. This information is derived using features provided by GPSAccess, specifically the GetVector method that is available by enabling Geo-fencing within the application. This method uses two latitude and longitude coordinate pairs, or simply put two positions. By using both waypoint coordinates for the track and the GPS fix in question (annotated as A, B, and C respectively in Figure 11), three GPSvectors are returned from corresponding calls to the GetVector method. Each of these GPSvectors represents one side of the triangle, depending on the parameter combinations that were passed, and each instance of this class contains a property for the vectors length.

![Track Tolerance Triangle](image)

Figure 11. Track Tolerance Triangle
Once the lengths are made accessible, they are used mathematically to determine the cosine of angle a (represented by “ang a” in Figure 11) using the Law of Cosines provided in Figure 12. Since all three sides of the triangle are known at this point, the equation is manipulated algebraically, as shown, so that it can be used to derive the cosine of “ang a”. This manipulation allows all known measurements to be applied in order to produce the cosine of “ang a” to which the arc cosine can then be applied to produce the actual measurement of “ang a”.

\[ a^2 = b^2 + c^2 - 2bc \cdot \cos(\text{ang} \ a) \]

\[ \frac{a^2 - b^2 - c^2}{-2bc} = \cos(\text{ang} \ a) \]

Figure 12. Law of Cosines Restated

After the measurement of “ang a” has been determined, the triangle shown in figure 11 can be reduced to the smaller triangle ACD for the remainder of the calculation. This results in the hypotenuse of the new triangle being the line segment CA, while the opposite side from “ang a” becomes line segment CD. Since the measurement of the angle has already been derived, the trigonometry function stated in Figure 13 can be manipulated as shown to solve for the distance of the fix for the track.

\[ \sin(\text{ang} \ a) = \frac{|CD|}{|CA|} \]

\[ |CD| = |CA| \cdot \sin(\text{ang} \ a) \]

Figure 13. Sine Function Restated
Once the length of line segment CD is known it is compared to the track tolerance being used by the program to determine if the fix has exceeded the tolerance. If it has not, then the position will be plotted in green, otherwise, the position will be plotted in red. Either way, a packet is sent back to the master station along with the position to signify to DeNS if the position is within tolerance so that it too can process the position accordingly. Finally, if the new fix has exceeded tolerance a message packet will also be sent to the Master Station for display to the user informing them of the deviation from track.

3. Error Handling

It is important to note that the DeNS, as has already been stated numerous times, is a prototype system. As such, much more attention has been placed on proper operation and handling of valid data, than on ensuring data entered is valid. It was assumed in the creation of the prototype that all users would enter information that was correct, with very little validation taking place. The majority of prototype data validation and error handling occurred in the areas that were beyond the limits of programming control, i.e. the TCP/IP connection via the implemented wireless network and the GPS connection and data. Of course, when fielding the system this will not be the case. In a fielded system, extensive validation and error handling would have to be implemented to ensure the safety of the boat and its crew. Below are the validation and error handling methods that were implemented in the Prototype system.

a. Socket Loss to Master Station

The user of the DeNS system is expected to have specific knowledge in setting up and establishing the network medium of choice for implementation. Proper setup of the network will negate half of the potential error messages a user will encounter, as these messages will either be of the nature of network resources not being available, or even in the event of proper setup and implementation, an interruption in service resulting in loss of the established connection.
The former, network resources not available, is typically a result of improper setup in routing and/or port forwarding or port triggering if an internal router is being used. This can also result if the DeNS application is improperly shut down and still has an instance running in the background unbeknownst to the user. In this case accessing the Task Manager in the Master Station and the Running Programs window on the PDA will allow the rogue instances of the program to be stopped, and the resources consumed to be released for reuse. As previously stated, it is assumed that the user has an intimate knowledge of setting up network services, and as this endeavor is beyond the scope of this thesis, due to the innumerable network configurations available and the prototype nature of the project at this time, the former will not be discussed further.

While the later instance, a previously successful connection that has subsequently failed, has not happened in testing of the prototype system, it is possible given power fluctuations, variations in visibility of the network, etc. If this occurs, there is currently no way to successfully recover in the prototype system, though a message box will be displayed informing the user that an error reading the server data has occurred. In this case, the prototype system should be shut down along with the master station and restarted. The fielded system should implement a graceful way in which to reestablish the connection without requiring shutdown.

b. GPS Connection Interruption

If, during the operation of the MobileDeNS application, the GPS connection fails it can attributed to one or both of two reasons, either the Bluetooth connection is no longer valid, or the position reads 0.000° latitude by 0.000° longitude (the default reading). The former can occur if the connection has been lost, which occurred in testing, due to failure of the GPS device due to insufficient battery to sustain the connection, or if entering a GPS-denied coverage area, i.e. connection to the GPS constellation was not accessible due to occlusion, or both.
As has been previously discussed, either occurrence will result in “Waiting for Satellite Synchronization” messages. While the issue of constellation occlusion can occur at any time for a myriad of reasons, it is not expected to occur at great periodicity at sea where the system is expected to be fielded, as access to satellite coverage should be unimpeded as long as the PDA and GPS units remain under open sky. On the contrary, the default reading of 0.000° latitude by 0.000° longitude occur whenever the GPS receiver is trying to synch up with the GPS constellation and obtain an initial position. This is the fundamental reason for starting GPSlink.exe, and monitoring the progress of said link, prior to starting the MobileDeNS prototype. In the fielded system, there should be a mechanism in place to monitor the connection from the application, ensuring adequate synchronization before the boat is deployed.

c.  **Position Location Outside of Map Parameters**
As has been established, the prototype system was designed to operate within a specific map (Monterey Bay) and its associated parameters at any given time. As such, logic was implemented which would result in any GPS position that was either above the upper latitude or the left longitude limits, and/or below the lower latitude or right longitude limits, be flagged as an invalid position; the user would be notified that they were no longer within the limits of the map currently loaded, and the position would not be plotted. That said, the limits of the map currently being displayed are the responsibility of the user, and accuracy and attention to detail in entering said limits is paramount to the accurate operation of the DeNS. In the fielded system, these same logic operations should be applied universally to current map parameters, regardless of the map’s coverage area.

d.  **Unreliable GPS data**
According to NMEA standards, reliable GPS data is annotated by the 38th character in the NMEA string. It should be noted that as with any string in the C# programming language, the first character is considered to be the 0th
character, thus the fix quality character in the NMEA string would be accessed by specifying the 37th character. This character can range from 0 – 8 inclusive, with associated meanings as defined in Table 6 below.

<table>
<thead>
<tr>
<th>Designator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Fix not available</td>

<tr>
<td>7</td>
<td>Manual input mode</td>
</tr>
<tr>
<td>8</td>
<td>Simulation mode</td>
</tr>
</tbody>
</table>

Table 6. NMEA Fix Quality Indicator Definitions.

From these definitions, it is obvious that we are only interested in those NMEA strings with a designator of one; a GPS fix. Therefore any NMEA string with a designator other than 1 is discarded by the GPSHandler class. The user is then notified that a bad packet was received, and the plotting, display, and relay of said packet does not occur.

4. Limitations and Known Bugs

As with most prototype systems, the DeNS components were built within certain pre-conceived parameters. These parameters imposed limitations on the functionality and effective areas of operation of the prototype system. Additionally, certain known bugs exist within the program that were not able to be
corrected due to time limitations. This section lists both limitations and bugs that are known to exist within the prototype system along with the justification of why the limitations were imposed or the suspected cause of the bug as applicable.

a. **Prototype Operation Limited to 36° N and 121° W**

The DeNS prototype was developed as a proof of concept prototype for C2 during over the horizon small boat operations at NPS in Monterey California. In order to speed development by simplifying the coding logic, the decision was made to limit the effective area to the degrees of latitude and longitude above. The result of this design decision is that only minutes and seconds are used to calculate fix positions on the screen. This does not present a problem for the prototype system, as all map files implemented are constrained to the same coordinate areas, with no overlap to the next higher or lower degrees allowed. As has been discussed previously this is included in the assumption of accurate user-provided data for the system to operate with. Naturally a fielded system would have to expand to be operable at all possible latitudes and longitudes with potential overlaps in order to be considered a viable solution, as the US Navy conducts operations around the world.

b. **Prototype Operation Limited to NW Hemisphere**

It follows from the discussion of latitude and longitude constraints above that the DeNS will only operate in the NW hemisphere of the globe. It is important to note, however, that aside from the necessary calculations for overlapping degrees of latitude and longitude within the same hemisphere, considerations must be made when applying the same calculations in different hemispheres, and still other considerations exist when the area of coverage requires that hemisphere boundaries be crossed.

In the case of areas of coverage within the same hemisphere (i.e. both upper and lower boundaries of coverage are either North or South, and both left and right boundaries are either East or West) It is a simple case to determine
how to properly perform the mathematic application of the spatial differences and the upper and left boundaries in order to properly calculate the pixel position of the fix for display to the screen. Noting that the upper left corner of the map is always pixel position (0, 0), while the same corner represents an arbitrary latitude and longitude which will either be greater than or less than the lower right corner depending on the hemisphere, one can readily see how it will be necessary to apply the spatial difference in order to calculate the pixel position of a given GPS fix. For example, in the Northern hemisphere the spatial difference must be subtracted from the upper bound because a valid GPS fix for the given map parameters will always be less than the upper bound. That difference is then converted into the appropriate number of pixels to be plotted on the screen. The reverse is true for the Southern hemisphere, however, in which case the valid GPS fix will always be greater than the map parameters upper bound, necessitating that the upper bound be subtracted from the fix position in order to generate the difference for pixel conversion and subsequent plotting. The same is true for the Eastern and Western hemisphere.

The case of overlapping hemispheres creates a new problem; the GPS fix position's hemisphere must first be determined with relation to the upper and left boundaries of the map parameters. If the position lies in the same hemisphere as the boundary, the calculation can take place as described above. If, however, the position lies across the boundary of the hemisphere then two calculations must take place, one to determine the spatial difference between the hemisphere boundary and the map parameter boundary in question, and another to determine the spatial difference between the GPS fix position and the hemisphere boundary. The resulting two differences are then added together to obtain the total spatial difference of the GPS fix position from the map parameter boundary in question, either upper or left. That difference is then converted to pixel coordinates for screen display.
c. **DeNS Application on the Master Station Must be Running**

As previously mentioned, DeNS performs all server functions from the Master Station. In the prototype system, the TCP/IP socket connection was programmed for automatic connection at startup. While this sped up development of the prototype system, it requires that DeNS be running and awaiting incoming connection requests before MobileDeNS is launched in order to prevent Mobile DeNS from shutting down due to an unsuccessful connection. In the fielded system it is recommended that this feature be replaced by the option to start the connection on both sides of the system when the user desires, which will eliminate this problem and expand the functionality of the PDA application to areas beyond the scope of small boat C2, as will be further discussed in Chapter IV.

d. **GPSLink on PDA Must be Running**

As previously stated, this is a requirement imposed by the GPSAccess.dll. While a new version of GPSAccess is in progress that will alleviate this requirement and allow connection to the GPS receiver directly from within MobileDeNS, it has not yet been released.

e. **Default Map Required**

As was discussed earlier in both this chapter as well as Chapter 1, the MobileDeNS prototype was designed with the constraint of operability within the Monterey Bay area exclusively. As such, in order to speed development and testing, the decision was made to automatically load the Monterey Bay DNC based JPG map file on application start-up. This necessitates the map file be located in the appropriate directory as discussed in the installation section of this chapter. In the fielded system, this requirement should be removed by loading a map file at the users request rather than automatically doing so at start-up.
f. **Waypoint File Required**

This limitation has also already been discussed. The waypoint file is required by the prototype system at application start up in order to read in track information for processing. It is a simple text file that provides latitude and longitude coordinates in the form DDMMSS.SSDDDMMSS.SS where D is degrees, M is Minutes, and S is seconds using decimal notation with two significant decimal digits, and Latitude precedes longitude. As mentioned earlier, only two waypoints can be used in the prototype, but the fielded system should allow for waypoint exclusion or multiple waypoints to be used.

g. **Fix Details Display**

The feature described in section B.2.d above, allows the user to view details of the fix by tapping the fixes positional cursor on screen which is actually a small button that is moved as new positions are read in and displayed. As was discussed, there is currently a bug in the display code which results in a garbled display. While the labels of time, latitude, and longitude are displayed, the data following the labels is not always correctly presented, presumably due to the way that the data is accessed based on the status of the GPS receiver. This is considered to be a minor bug, as the prototype system only displays one position at a time, always the latest one received. As a result, the decision was made to focus on other, more important features of the prototype. In the fielded system, this bug should be eliminated.

h. **Auto-scroll**

The auto-scroll feature was initially added to the system as a user-enhancement to improve the user perception of bearings and placement on the currently loaded map file when the fix position moved off screen. In the initial version of MobileDeNS, when new fixes were plotted that were off screen, the application would simply jump to a view in which that position was centered. This resulted in a fair amount of user confusion and the decision to make the program
gracefully scroll to the new fix position to allow the user to follow along and avoid any momentary disorientation during use. This feature is automatic and cannot be turned off.

In implementing this feature, however, cascading issues have changed the picture somewhat. What was initially implemented as a user-enhancement, created a situation that in most cases frustrated the user by implementing a slow moving perspective, which at close interval fix times, could take multiple fixes to correctly orient the map. Further issues arose after the auto-scroll feature was added with regards to allowing the user to scroll the map at will, as it would immediately begin to try to reorient itself after the current position was no longer displayable on the screen. Additionally, while the program is performing auto-scroll, it is inaccessible to user interaction.

Based on these results it is recommended that the fielded system either have a method for activating and deactivating the auto-scroll feature, or that it is removed from the system entirely. Alternative methods to avoid the disorientation that precipitated the addition of this feature should be explored, such as the possibility of using lines to connect current positions with their predecessors to indicate the direction of movement on the map along with the area of the map previously visited. Similarly, the GPS information can be used to determine direction and speed, and DR symbology could be used to indicate where the next fix is expected to appear.

C. DeNS

Having discussed MobileDeNS in terms of usage, features, error handling, and limitation and known bugs, we will now do the same with DeNS: that portion of the prototype system the resides on the small boat’s parent vessel. As discussed in Chapter III, this portion of the system consists primarily of four separate components: 1) the DNC database; 2) the Surplusdedicate network; 3) the ArcIMS Server; and 4) the Master Station. For the same reason given in Chapter III, the DNC database and the Surplusdedicate network will not be
discussed at any further length, leaving the remainder of this chapter to focus on the ArcIMS server and the Master Station.

1. ArcIMS

The first of these components, the ArcIMS server, will be discussed in a cursory manner, as most of the technical information is available in the applicable reference (ESRI, ArcIMS9: Getting Started with ArcIMS). This document covers basic installation, features, usage, and other technical aspects of the program at great length. What will be discussed here are the different roles, and the methodologies of implementation of said roles, of the ArcIMS server.

a. Map File Server

The primary use of the ArcIMS sever is to facilitate the downloading of the previously prepared DNC based JPG map files to both the MobileDeNS PDA application and DeNS running on the Master Station. For the PDA, downloading is accomplished via the content repurposing strategy previously discussed. Since the PDA browser is not capable of handling the Dynamic Hypertext Markup Language (DHTML) code used by the ArcIMS server, a home page was implemented that checks the browser version and directs requests from MSIE 4.01 to an alternate site from which the appropriate map file can be downloaded. Figure 11 shows the redirection that takes place based on browser version where the black lines indicate the actual redirection, while the blue line indicates the reason for said redirection.

The Master Station can download the same DNC based JPG files from the same directory as the PDA by browsing to it and saving the file from the browser, or alternatively using an FTP site to accomplish this same purpose. Similarly, a link to the applicable directory could be easily added to the home page to ease the facilitation of this process. The link from the home page, shown in Figure 11, will direct the Master Station to a web-based viewer that displays the web-version of the map file created in ArcMap as described below.
b. Web-based DNC Access

From the Master Station, following the link on the home page places the browser at a web-based viewer that uses the .axl files created in ArcAuthor which retain the underlying DNC database structure. This allows resizing, zooming, panning, and similar functions to be accessed through the browser, as well as selection of specific objects represented on the chart in order to view their underlying characteristics. For example, an object that represents a buoy can be selected and thereby enable the type, color, name, etc, of the buoy to be viewed. Further, from this web-based viewer, zooming in on the map results in its natural de-cluttering as objects are linked to their spatial grid reference not a pixel location. This can be invaluable in helping the small boat, which doesn’t have this capability, gain general orientation and also confirmation of those objects which they have depicted on their jpg representation of the chart. Further discussion and application of this aspect of ArcIMS viewer will be discussed in the Future Works section of Chapter V.

2. Master Station

As with MobileDeNS, full explanations for usage, features, error handling, and limitation and known bugs will be provided for DeNS which runs on the
Master Station. As was demonstrated in Chapter III, DeNS is a much simpler implementation, architecturally speaking, than is MobileDeNS. As such, the discussion that follows does not have as many components as did MobileDeNS, though since DeNS was created based on the functionality of MobileDeNS, many of the same issues are likely to exist and will be discussed here as they relate to the Master Station.

a. Usage

This section will focus on basic functionality and usage of the DeNS program on the Master Station. Discussion will be limited to Installation, proper start-up and shut-down, actions required to begin the navigation process, and basic usage. Specific features implemented in the prototype application will be covered in the next section.

(1) Installation. The Installation process of DeNS on the Master Station involves the setup and installation of only two distinct pieces of the DeNS system, as opposed to the four required for MobileDeNS: a) Wireless setup and connectivity; and b) the DeNS application.

a) Wireless setup. As with MobileDeNS, wireless network connectivity will not be covered except to say that it will be assumed that prior to installation, the Master Station’s networking capability has been established with regards to connectivity to the network medium of choice for the DeNS installation, the Surplusdedicate network in the case of the prototype.

b) DeNS. To install DeNS, copy the DeNS.exe file (created from the source code located in Appendix II) to the Master Station. This can be copied anywhere on the Master Station, though for standardization purposes it is recommended that it be placed in the Program Files directory under its own folder named DeNS. Unlike MobileDeNS, DeNS doesn’t attempt to load a map at startup. This negates the requirement to have a map available before its first use, as was the case with MobileDeNS on the PDA.
(2) Start-up. While MobileDeNS required both itself and DeNS to be installed with DeNS running prior to start-up, DeNS does not have such a requirement. As DeNS implements the server side of the system, it can be started independent of MobileDeNS, and will immediately begin listening for incoming connection requests on port 5000. While DeNS is listening for incoming requests, it is capable of loading maps along with the associated map parameters. This is recommended before starting MobileDeNS in order to ensure that the application is ready to begin receiving and processing GPS data from MobileDeNS, and in any case is necessary before the GPS connection within MobileDeNS is activated.

Activation of DeNS is accomplished, as with any other desktop application, by double clicking its icon on the screen from the directory location of installation. The use of shortcuts to facilitate easier access may be used as the user desires. Once DeNS is running, it is ready to establish the TCP/IP socket connection and begin processing GPS data received from said connection. Additionally, as mentioned above, a map file is necessary to facilitate proper handling of GPS data received, and should be identical to the map and parameters being used in MobileDeNS.

(3) Usage. Basic usage of the DeNS application is simple, assuming the prerequisites for running it have been met: i.e. maps have been created and are available and coordinated between DeNS and MobileDeNS; a network is established and available; and MobileDeNS has been installed and is ready for use. As described above, after the DeNS prototype application has been started, it will immediately begin listening for connection requests from the MobileDeNS client application and allow the user to load appropriate map data. After the map data has been loaded, and the connection is established, the application will begin processing incoming GPS data after the user selects the Start Plotter option from the Map menu. This will continue to plot positions received in accordance with the plotTimer which is set to activate every five seconds. If no new position exists at that time, the user will be alerted, and offered the option to either continue with or stop the plotter's operation.
It is recommended that the plotter be started in conjunction with the GPS Connect function of MobileDens to ensure that fix position plotting on both ends are being synchronized between the two applications. While time constraints prohibited its implementation in the prototype system, it is recommended that the fielded system automate the start plotter function whenever a new position is received from MobileDeNS, or an alert of some type is implemented that alerts the Master Station that new positional data has been received so the plotter can be started manually.

(4) Shut-down. Unlike its MobileDeNS counterpart, DeNS can be properly exited through the use of the “Exit” option on its File menu, as well as by using the “X” in the upper right hand corner of the application window. As previously discussed, mobile devices and desktop computers utilize the “X” in different manners.

b. Features

In the last section general usability of the DeNS application was reviewed. This section elaborates on the usability of the application by providing insight into the various features and functionality that it contains. Unlike the MobileDeNS discussion above, this section will focus solely on menu driven features. This is because in DeNS there are no features that are available outside of the provided menus. The auto-scroll feature was not added due to issues already cited, and the Fix details feature was similarly excluded due to the faulty logic that resulted in the garbled appearance of intended data. As before, any associations to limitations and known bugs will be provided for reference in both instances, though specifics of said limitations will be discussed in the appropriate section of this chapter.

(1) File Menu. The available file menu in DeNS is identical to that of MobileDeNS, consisting of only one option, Exit. This option operates in an identical fashion to the corresponding option in MobileDeNS, and as this option has already been discussed above, no further discussion is necessary in this section. It should be noted, however, that while the File menu
in the prototype system only contains one option, the File menu in the fielded system will probably contain more. As with the other menus to be discussed, those options envisioned for the fielded system will be visible but disabled. This ensures that the vision of the system at inception will be considered and either carried out or discarded in the final product.

(2) Map Menu. The Map menu in the prototype system is where most of the available menu options reside. It consists of four available options: a) Clear Map; b) Start Plotter; c) New Map; and d) Properties. Each of these available options will be discussed in more depth below.

a) Clear Map. This option allows the current position to be erased from the maps display, but does not alter the internal mechanisms used to store either the said position, or the currently loaded map parameters. It is intended as a method to clear the map of positional displays, which is admittedly not of substantial use in the prototype, but will be of much greater use in a fielded system which should be capable of displaying track histories, as discussed in MobileDeNS above.

b) Start Plotter. This option is used to manually start and stop the plotter function of DeNS on the Master Station. When selected it changes the displayed text of this option to either “Stop Plotter” or “Start Plotter” and either starts or stops the plotTimer, as is applicable. PlotTimer is the counterpart of GPSTimer in the MobileDeNS application and manages the plotting function of all received GPS positions when enabled. When disabled, GPS positions are still received and stored, but are not plotted until the plotter is enabled.

c) New Map. This feature allows the user to load a new map, and change the map parameters to conform to said map. Upon selection, this option will open a file dialog box that will allow the user to browse to a specific directory from which to load a new map file. The browsing limitations which affect the open file dialog box on the PDA do not impede the same dialog box on the Master Station. Similarly, on the desktop it is possible to
automatically retrieve the map file height and width so these parameters are not required from the user when loading the map. Remaining parameters are entered through a single dialog box which is editable so review can take place at the same time as data entry.

d) Properties. The Properties option allows the user to view all map parameters currently entered for the map being displayed. This is a read-only form and does not provide a mechanism to change incorrect parameters. To do this, the user must reload the map using the New Map option from the Map menu.

(3) Connect Menu. The Connect menu provides two available options: a) Test Server; and b) Start Server. In the prototype system, both of these options were used strictly for troubleshooting and testing functionality as described below.

a) Test Server. This option was used early in the development process to ensure that plotting functions were operating correctly. It does not interact with the TCP/IP socket connection in any way, but instead simulates it by storing three NMEA strings in the ArrayList to be used by the plotter. This option is now obsolete and marked for deletion.

b) Start Server. This option does not initiate the server class to begin listening for a TCP/IP connection as the name would imply. Rather, it was used in testing the GPS data retrieval and plotting function of DeNS as a precursor to implementing the plotTimer. It was used after the Test Server option above. This option is also marked for deletion.

(4) Distance from Track. This feature is simplified as compared with the case of MobileDeNS. This is because all of the calculations take place within MobileDeNS, with indicator packets being sent to DeNS to signify whether the latest fix has exceeded the allowable track tolerance. Once the comparison has been made within MobileDeNS, a packet containing either a “W” (within tolerance) or an “X” (exceeded tolerance) is sent to the Master Station. Upon receipt the Master Station then sets a flag to indicate what the fix
cursor color should be for the next fix plotted. Additionally, if the fix has exceeded track, a message indicating such is sent to the Master Station for display to inform the monitoring user of the deviation from track. The prototype implementation of this feature resulted in the possibility of misrepresentation of data as will be discussed in section d below.

c. Error Handling

As was stated when discussing error handling in MobileDeNS, the DeNS is a prototype system and operates under a number of assumptions. As these assumptions have already been listed in the section address error handling for MobileDeNS they will not restated here. The removal of the GPS interface in the Master Station (which receives its data via the 802.11 network) in turn simplified the error handling that was implemented, resulting in error handling primarily concerned with the TCP/IP socket connection. Again, when fielding the system this will not be the case. In a fielded system, extensive validation and error handling will have to be implemented to ensure the safety of the boat and its crew. Below are the validation and error handling methods that were implemented in the Prototype system.

1. Socket Loss to MobileDeNS. As has been stated previously, the user of the DeNS system is expected to have specific knowledge in setting up and establishing the network medium of choice for implementation. Proper setup of the network will negate half of the potential error messages a user will encounter, as these messages will either be of the nature of the network resources not being available, or even in the event of proper setup and implementation, an interruption in service resulting in loss of the established connection. Both of these cases have been covered under the MobileDeNS section of this chapter, and apply equally to the Master Station.

2. Position Location Outside of Map Parameters. This error should not occur on the Master Station, since positions outside of the MobileDeNS map parameters are not processed, nor, therefore, relayed to the Master Station. It is implemented in order to bring to light erroneous map
parameters existing between the two end systems. Proper setup of the map and its associated parameters, as well proper coordination between the two applications in regards to the correct data entry for parameters will ensure that this error is mitigated on the Master Station. If it occurs, the map parameters on both applications should be compared and corrected.

d. Limitations and Known Bugs

As with MobileDens, the scope and parameters of the overall project imposed limitations on the functionality and effective areas of operation of the prototype system. Additionally, certain known bugs exist within the program that were not able to be corrected due to time limitations. This section lists both limitations and bugs that are known to exist within the prototype system along with the justification of why the limitations were imposed or the suspected cause of the bug as applicable.

(1) Prototype Operation Limited to 36° N and 121° W. This limitation of the DeNS prototype system applies universally to all components thereof. As such the causes and discussion provided in Section B.4.a of this chapter have not changed and apply here as well. Please refer said section for review of this limitation.

(2) Prototype Operation Limited to NW Hemisphere. As with item 1) above, this limitation of the DeNS prototype system applies universally to all components thereof. As such the causes and discussion provided in Section B.4.b of this chapter have not changed and apply here as well. Please refer said section for review of this limitation.

(3) Coordination Between Plotter and GPS Connect. As mentioned briefly in the section c.4 above, it is imperative that the plotter in DeNS and GPS connect in MobileDeNS be started together. Otherwise lag time could result in misrepresentation of the fixes relation to track when received. For example, if more than an entire fix interval is skipped between the two functions start times, the boat could deviate from track and correct, but the Master Station would see the fix that exceeded tolerance as valid while it was alerted that the fix within tolerance had exceeded it. This compounds as more fix intervals are
skipped. In the fielded system it is recommended that either the synchronization be automated by automatically starting the plotter when fix data arrives, or by adding the tolerance information to the fix packet that is sent to DeNS to ensure it is processed along with the fix to which it applies.

D. SUMMARY

Chapter IV took the architectural information provided in Chapter III, and added to it in terms of program implementation and installation, usability, features, error handling, and limitations and known bugs for each component of the DeNS. While initially focused on those components implemented on the PDA and deployed to the small boat, discussion then moved to components implemented on the parent vessel. The first component reviewed on the parent vessel was the Web/GIS Server providing a very brief discussion with applicable references noted for further in-depth study. Discussion then focused on the Master Station implementation following the same format as that used for discussion of the PDA implementation.

Chapter V will conclude discussion of the DeNS prototype system. It will provide information concerning project conclusions, performance, and test results, and provide suggestions for future works involving the system with the ultimate goal of a fielded system.
THIS PAGE INTENTIONALLY LEFT BLANK
V. DISCUSSION

A. OVERVIEW

Chapters I through IV have provided thorough discussion of the problem addressed by the DeNS prototype system, related background information, and detailed aspects of its implementation in terms of both architecture and usability. In Chapter V, conclusions will be drawn based on the observed results of the DeNS prototype and recommendations for future work and expansion of the system will be given. Finally, the DeNS project will be summarized in terms of functionality, applicability, and performance.

B. CONCLUSIONS

As has been previously stated, the DeNS prototype system was designed to function in the vicinity of the Naval Postgraduate School campus, i.e., in latitude and longitude ranges contained within $36^\circ$ N and $121^\circ$ W. This worked well in the development and testing of the system because the network infrastructure was already in place to facilitate the TCP/IP-based communication between the various components, and the close proximity to the Pacific Ocean. Additionally, the DNC, as with paper charts, provides some coverage of terrestrial areas as well navigable waters. This resulted in the entire campus and surrounding area being available for testing purposes. It should be noted that all testing of the prototype system has taken place on land, rather than in the maritime environment in which it is intended to operate. This should pose no issue, however, in its operation in such an environment, since all charting was derived directly from the same source as would have been used in a maritime environment covering the same area (Monterey Bay.)

The geographic coordinate to pixel coordinate conversion that takes place is considered sound due to the fact that the chart jpg files preserve the scaling factor used by the DNC. Therefore, any given jpg will cover an area represented by a given range of latitude and longitude coordinates without distortion, thus
allowing a pixel to represent a precise amount of latitudinal and longitudinal area. That said, the amount of latitudinal and longitudinal area covered by a pixel was hard-coded into the DeNS applications for use with the test map, just as the degrees for both coordinates and the hemisphere were disregarded, since it was given that it would be contained on the chart and the chart would fall within the same degree ranges. This allowed more rapid development of the prototype system than would otherwise have been possible, though it severely limits usage outside of the designated area defined above.

An additional limiting factor which affected testing was somewhat spotty coverage of the Surplusdedicate network available in an outdoor situation which was necessary for the GPS receiver to maintain satellite connectivity. In testing MobileDeNS as a standalone product, this was mitigated, and proper functionality of the plotting procedure was verified using various landmarks provided on the DNC based jpg image. Likewise, by developing a client tool which allowed positional and message data to be entered and passed to the Master Station in the same format as used by MobileDeNS, it was possible to verify the same GPS and landmark positions, thus proving proper plotting functionality in DeNS, as well as the proper handling of messages.

Once independent verification of both applications was completed satisfactorily, a test path was determined on which all connectivity was possible (Surplusdedicate in an outdoor environment, Bluetooth connectivity between the GPS receiver and the PDA, and GPS satellite connectivity.) Using this path as a test track, both applications were tested and positional data was verified as having been correctly plotted and displayed correctly in regards to track tolerance. As has been previously stated, when testing the applications together in this manner, care had to be taken to coordinate the GPS Connection function on MobileDeNS with the Start Plotter function on DeNS in order to ensure that the track tolerance information displayed was relevant to the current position being displayed. Proper synchronization in this manner allowed verification of the proper functioning of the DeNS prototype system as a whole.
Performance of the system was as expected, i.e., real time information was displayed on MobileDeNS and immediately passed back to DeNS where identical information was displayed for remote monitoring, also in real time. No unexpected issues such as system failure, unknown bugs, or program crashes occurred during at any time during testing of the final prototype system. As such, performance of the DeNS prototype can be characterized as outstanding within the specifications in which it was designed to function.

C. FUTURE WORK

The DeNS prototype system offers an in-road into C2 of small boat operations that has yet to surface in the US Navy. Through future work and expansion of the DeNS project, a myriad of possibilities exist that would not only allow OTH operations at a level previously unattained in terms of safety and precision, but could also extend the use of the MobileDeNS application to other endeavors outside the realm of small boat operations. This section will delineate several ideas for future expansion and use of the system, though it is not meant to be an exhaustive list.

1. Full DNC Implementation

As it currently exists, the DeNS prototype system utilizes jpg based images that are derived from the DNC. While this provides the required minimum level of navigational information to allow the system to operate, it does not exceed that standard. Additionally, it can be a somewhat daunting task to create the charts to be used by system to an average user. In lieu of using the jpg images, work should be conducted to implement the DNC directly on the PDA.

By implementing the DNC on the PDA, it would enable tracks to be updated “on the fly” by the Master Station to allow for dynamically changing missions, or conversely by the small boat based on situational awareness that the Master Station may not be privy to. Additionally, PDA implementation of the
DNC would allow the small boat to query the DNC directly to determine what chart symbology means when required. This could in the form of pulling navaid characteristics for positional verification, or viewing safety warning for specifically charted areas, without requiring messages or voice communications with the Master Station and/or control vessel.

A more flexible display would also result from full DNC implementation, since charts would not be designed with specific boundaries. Instead, charts would be both scrollable and scalable. In the first case, small boat operations would not be constrained by the predetermined jpg image, in which the edge represents a boundary beyond which operations cannot proceed with the DeNS system. When the edge is reached on a DNC implementation, the map would simply scroll to reveal the new area. In the second case, the DNC would allow a scalable image which can be freely zoomed in or out on to provide the necessary view for the situation. Additionally, unlike jpg or bitmap files, when the DNC is zoomed in or out on, it naturally de-clutters because the symbology is not tied to pixel location, but rather a reference location. This allows the area covered to change, while the symbology remains at a constant scale.

In light of all this, it is evident that DNC usage on the PDA is a desirable feature. One potential method of implementation of this feature would be the expanded integration of the ArcGIS line of software into the DeNS prototype system. ESRI, the makers of ArcGIS, also make a PDA application called ArcPAD. ArcPAD is a mobile GIS solution that integrates database access, mapping, and GPS functionality with a multilayer support environment. It supports file formats which include jpg, bitmap, ESRI shapefiles created by ArcMAP, and ArcIMS image Services as was discussed in Chapter IV. Use of this solution could enable both the Master Station and PDA to share a picture being maintained by the ArcIMS server that is already being used for image file access. The entire range of ArcGIS products is customizable and programmable through a C# API extension usable in Microsoft Visual Studio.
2. **Network Architecture**

As has already been discussed numerous times, 802.11 is not an acceptable medium for use in the fielded system, and should be replaced by a more robust architecture. 802.16 has been presented as the alternative of choice in this paper, though testing in the maritime environment at applicable ranges would have to be conducted before it is considered as the replacement standard. Other thesis projects are currently being conducted on campus into various network architectures on which the DeNS system could be an excellent candidate. One such project is COASTS, being conducted by the Operations Research department. It is an 802.16 based network that has achieved ranges out to 30NM.

3. **Program Expansion**

The DeNS prototype system lends itself to expansion in many areas. Some of these have already been discussed, such as the ability to start and stop the client/server communication channel and the ability to automatically synchronize the GPS connect and Plotter Start functions. Others are hinted at by currently disabled menu options, such as the ability to send a message packet, load a saved track file, turn on or off tracking features that would display all fixes obtained thus far, find a given fix or set of coordinates, and mark a given position on the display.

Other expansion could also be desirable, such as the ability to send a file along with the coordinates at which it was sent. This could enable, for example, a picture of jettisoned contraband and its position to be saved for later retrieval of said contraband. Similarly, other packet types could be implemented to provide proper handling of data transmitted, such as pictures, scanned documents, and even new map files. Additionally, the infrastructure is already in place to allow text messaging between the MobileDens and DeNS applications, only the user interface is required to enable this feature.
Further expansion is possible when considering applications of the system in operations outside of the small boat arena. Consider the navigation detail in which it is standard practice to issue paper “chartlets,” typically a photocopy of the chart on which navigation is taking place for visual aid to the cognizant people in the navigation detail. Rather than providing a cumbersome stack of paper that must be flipped through by the Conning Officer, MobileDeNS could be issued in a standalone version that would display the GPS position and update the display accordingly, providing real-time information regarding the ship’s position in a channel.

D. SUMMARY

The DeNS prototype system is a viable solution that can be used in a myriad of ways and can be applied to any navigational evolution that takes place aboard a naval vessel. The C2 capability and real-time positional display it provides, coupled with its small footprint and use of use mark it as a much needed asset to the ship’s company. Further development resulting in fleet wide implementation would provide a much needed tool to any platform on which it is used.
APPENDIX I

A. OVERVIEW

Appendix I is intended to provide code listing for forms and classes used in the implementation of the MobileDeNS client of the DeNS prototype system. Each form or class will be detailed separately, with comments provided in-line. All code was programmed in the Microsoft C# language constrained by the Microsoft .NET Compact Framework, and designed to run on a windows based PDA platform utilizing the .NET Compact Framework.

APPENDIX II

A. OVERVIEW

Appendix II is intended to provide code listing for forms and classes used in the implementation of the DeNS server side of the DeNS prototype system. Each form or class will be detailed separately, with comments provided in-line. All code was programmed in the Microsoft C# language constrained by the Microsoft .NET Framework, and designed to run on a windows based PC platform utilizing the .NET Framework.

1. Form1.cs

```csharp
using System;
using System.Drawing;
using System.Collections;
using System.ComponentModel;
using System.Windows.Forms;
using System.Data;
namespace DeNS
{
    /// <summary>
    /// Main form for DeNS desktop application. It instantiates the DeNSServer, MapHandler, and Plotter classes and contains all menus and the plotTimer that manages the drawing functions for DeNS.
    /// </summary>
    public class Form1 : System.Windows.Forms.Form
    {
        private System.Windows.Forms.MainMenu mainMenu1;
        private System.Windows.Forms.PictureBox viewPort;
        private System.Windows.Forms.MenuItem fileMenu;
        private System.Windows.Forms.MenuItem mapMenu;
        private System.Windows.Forms.MenuItem connectMenu;
        private System.Windows.Forms.MenuItem fileMenuExit;
