13. SUPPLEMENTARY NOTES

14. ABSTRACT

The NF2 product, Merlin, has recently been shown to inhibit p21-activated kinases (Paks), enzymes known to activate cell cycle progression and to induce changes in the actin cytoskeleton. These findings suggest that loss of Pak function might inhibit the abnormal growth and/or movement of cells lacking Merlin. We had proposed two aims: to test if loss of all Pak function affects signaling in NF2-/- cells and to test if Paks are required for tumorigenesis in an NF2 mouse model system. In the third year of this project, we published a manuscript describing the first selective small molecule inhibitor of group A Paks; completed crossing NF2 and Pak1-/- mice into a C3H genetic background; used a retroviral vector to express an enhanced Pak inhibitor (the Pak2 inhibitor domain) in normal and NF2 BBA (dominant negative) mutant mouse fibroblasts, and showed that loss of Pak function impedes NF2-driven cell proliferation and abnormal morphology; and used the same approach in xenograft experiments to show that loss of Pak function reduces NF2-induced tumor formation. With these advances, we have matched and in some cases exceeded our timetable for year three.

INTRODUCTION:

The goal of this project is to determine if group A p21-activated kinases (Paks) are important elements in signaling in neurofibromatosis type II (NF2). Our hypothesis is that inactivation of the *NF2* gene disrupts a signaling pathway emanating from the small GTPase Rac and its effector, p21-activated kinase (Pak). We propose that stimulation of the Rac/Pak signaling axis in cells lacking Merlin leads to changes in transcriptional activity and cytoskeletal dynamics, ultimately resulting in enhanced cell proliferation and motility, which are hallmarks of tumorigenesis. If this hypothesis is correct, then inhibition of Pak signaling should disable the growth advantages of cells lacking Merlin. We intend to test this theory using Pak loss-of-function cells and animals.

BODY: We set ourselves two specific tasks. These were:

Task 1. To determine if Pak function is required for mitogenic or morphogenic signaling in fibroblasts and Schwann cells lacking Merlin (Months 1-24):

a. Analyze the expression level and activity of group A Paks in fibroblasts and Schwann cells (Months 1-6).
b. Analyze effects of loss of Pak function on mitogenic and morphogenic signaling in mouse embryo fibroblasts lacking Merlin (Months 6-18).
c. Analyze effects of loss of Pak function on mitogenic and morphogenic signaling in mouse Schwann cells lacking Merlin (Months 18-24).

Task 2. To investigate the influence of Pak on the formation of tumors in transgenic mice expressing a dominant negative form of Merlin (SchΔ(39-121), by determining if crossing such mice with a) transgenic mice expressing a Pak inhibitor (PID), or b) *Pak1*$^{-/-}$ mice affects their predisposition to the tumors typically seen in NF2 (Months 6-48):

a. Generate PID transgenic cells (Months 6-12).
b. Generate and analyze PID transgenic mice (Months 12-24)
c. Mate P0-SchΔ(39-121) mice with the PID transgenics and *Pak1*$^{-/-}$ mice and analyze crosses (Months 24-48).

Progress

We have met, and in some cases, exceeded, our goals for the third year, as detailed below.

Task 1

a) Analyze the expression level and activity of group A Paks in fibroblasts and Schwann cells. This was accomplished in the first year when we showed that Pak1 is the predominant group A Pak expressed in both fibroblasts and Schwann cells but that Pak2 is also expressed at reasonably high levels. These results

confirmed our strategy to focus on these two isoforms of Pak in our genetic and biochemical experiments.

b) Analyze effects of loss of Pak function on mitogenic and morphogenic signaling in mouse embryo fibroblasts lacking Merlin. As described in our previous progress report, we created both retroviral and adenoviral expression vectors encoding the Pak1 inhibitor domain (PID). These were altered to avoid binding of the PID region to the Fragile X (FGX) protein. We have found that the newly constructed PID vectors do not bind FGX or interfere with normal cell cycle progression, while retaining the ability to inhibit group A Paks. Thus, these reconfigured reagents are suitable for evaluating the role of Pak in NF2. Rather than use $NF2^{-/-}$ MEFs, we instead carried out our analysis in mouse fibroblasts transformed with the NF2 BBA mutant (1). The results of these studies are summarized in Task 2b, below.

In addition, as described previously, we developed a small molecule inhibitor of Pak, termed IPA3. This compound inhibits Pak1 at a K_i of 2.4 μM in fibroblasts and is also a potent inhibitor of the other two group A Paks, Pak2 and Pak3. IPA3 does not inhibit the three group B Paks at 10 μM concentrations. Remarkably, when tested against a panel of ~240 protein kinases, we found that the specificity of IPA3 is comparable to that of some of the best protein kinase inhibitors known, such as the Abl inhibitor Imatinib (Gleevac) and the Rho kinase inhibitor Y-27632 (2). IPA3 thus represents an additional reagent for testing the role of group A Pak function in NF2-deficient cells. In cell-based experiments, IPA3 blocks Pak activation and subsequent downstream activation of ERK, as well as preventing ruffling of the plasma membrane. We are currently testing the effects of IPA3 on $NF2^{-/-}$ cells as well as in fibroblasts expressing the NF2 BBA dominant mutant.

c) As planned, we have left the Schwann cell experiments for last, as these cells are relatively difficult to isolate and manipulate. We plan to analyze Pak function in these cells this year.

Task 2

a) As described in previous progress reports, we altered the order of experiments to reflect certain logistical realities; namely, that we already had available $Pak1^{-/-}$ and $Pak2^{flox/flox}$ mice, whereas we are still in the process of generating transgenic mice expressing the PID. For these reasons we focused our initial efforts on task 2c: to cross mice transgenic expressing dominant negative NF2 in Schwann cells (P0-SchΔ(39-121))(3) with $Pak1^{-/-}$ mice. We completed one version of this experiment. We studied two groups of approximately 30 mice each: P0-SchΔ(39-121) $Pak1^{+/+}$ and P0-SchΔ(39-121) $Pak1^{-/-}$. Over a two-year period, we watched these cohorts for the development of Schwannomas and other malignancies. We found that 6/30 P0-SchΔ(39-121) $Pak1^{+/+}$ mice developed NF2-related pathologies (schwannomatosis, nerve sheath tumors, sarcomas), whereas 2/34 P0-SchΔ(39-121) $Pak1^{-/-}$ mice developed NF2-related pathologies. These data suggest that our main hypothesis is correct: Pak1 is required for the efficient

development of NF2-related pathologies, and also support the corollary idea that Pak inhibitors might be useful in the treatment of NF2.

Although these experiments were very encouraging, we were disappointed the control group of mice (P0-SchΔ(39-121) *Pak1*$^{+/+}$) did not develop disease more frequently, making it difficult to get statistically meaningful data from the crosses to Pak1$^{-/-}$ mice. As explained in last year's progress report, during the course of this experiment, we learned that the mixed C57 Bl6/C129 background is not ideal for studying the effects of the NF2 transgene (P0-SchΔ(39-121). This is because disease is slow to develop in this mixed strain background, making the experiments difficult to complete in a reasonable timeframe. The creator of the P0-SchΔ(39-121) transgenic mice, Marco Giovannini, has found that the C3H background is much more favorable for analysis (M.G., personal communication), as schwannomatosis develops in all the transgenic mice by three months of age. We have therefore crossed P0-SchΔ(39-121) mice and *Pak1*$^{-/-}$ mice into the C3H background and are in the middle of repeating the studies listed above. We expect the complete results to be available by the end of 2009.

b) As reported previously, we added a new task to those originally specified in the grant proposal. We transduced mouse fibroblasts with a dominant negative form of NF2 (the NF2 BBA mutant (1)) and characterized these for growth properties. As expected, expression of this NF2 mutant altered the morphology and growth properties of the fibroblasts (**Figs. 1 and 2**). These cells were then transduced with empty virus, a virus encoding the Pak1 PID, or a virus encoding an inactive form of the Pak1 PID (PID L107F). Expression of the PID, but not the mutant PID, normalized the morphology and slowed the growth of the NF2 BBA expressing cells (**Figs. 1 and 2**). We then performed xenografts using these cells. Cells expressing NF2 BBA were highly tumorigenic, forming palpable tumors within 1 week of injection. In contrast, cells co-expressing NF2 BBA plus the Pak1 PID showed fewer and smaller tumors, whereas those co-expressing NF2 BBA plus Pak1 PID L107F showed even more and larger tumors (**Fig. 3**). Interestingly, tumors that formed in the BBA/PID xenografted animals consistently showed elevated expression of NF2 BBA. We interpret this result to mean that escape from PID expression requires upregulation of the tumorigenic stimulus (i.e, NF2 BBA). These experiments are consistent with recent findings based in shRNA suppression from the Kissel lab (4) and support the idea that group A Paks are required for transformation in NF2.

KEY RESEARCH ACCOMPLISHMENTS: Bulleted list of key research accomplishments emanating from this research.

- Published a small molecule inhibitor of group A Paks.
- Completed initial study of crosses between NF2 with *Pak1*$^{-/-}$ mice.
- Completed crosses of NF2 and *Pak1*$^{-/-}$ mice into C3H genetic background and initiated study of Pak1 effects in this genetic background.

- Carried out cell-based and xenograft models to evaluate the role of group A Paks in NF2.

REPORTABLE OUTCOMES:

A manuscript on the development of IPA3, a small molecule inhibitor of group A Paks, was published Chemical Biology (Deacon et al, An isoform-selective, small-molecule inhibitor targets the autoregulatory mechanism of p21-activated kinase, Chem Biol. 15:322, 2008.). This manuscript describes the first specific inhibitor of group A Paks.

CONCLUSION:

We have completed portions of this project in line with our overall plans. There are two new approaches that we have added: i) the use of a small molecule Pak inhibitor to supplement our cell-based studies and ii) xenograft studies as a quick readout of Pak's role in NF2-related tumorigenesis. We have made significant progress on both these fronts.

SUMMARY

Autoregulatory domains found within kinases may provide more unique targets for chemical inhibitors than the conserved ATP-binding pocket targeted by most inhibitors. The kinase Pak1 contains an autoinhibitory domain that suppresses the catalytic activity of its kinase domain. Pak1 activators relieve this autoinhibition and initiate conformational rearrangements and autophosphorylation events leading to kinase activation. We developed a screen for allosteric *i*nhibitors targeting *P*ak1 *a*ctivation and identified the inhibitor IPA-3. Remarkably, preactivated Pak1 is resistant to IPA-3. IPA-3 also inhibits activation of related Pak isoforms regulated by autoinhibition, but not more distantly related Paks, nor >200 other kinases tested. Pak1 inhibition by IPA-3 in live cells supports a critical role for Pak in PDGF-stimulated Erk activation. These studies illustrate an alternative strategy for kinase inhibition and introduce a highly selective, cell-permeable chemical inhibitor of Pak.

INTRODUCTION

Protein kinases are important therapeutic targets and are considered highly druggable owing to their conserved ATP-binding pocket that can accommodate small molecules. However, because of the evolutionary conservation of this pocket across kinases, ATP-competitive inhibitors can inhibit large numbers of other kinases in addition to their intended targets (Bain et al., 2007; Karaman et al., 2008). Recently, it was demonstrated that ATP-competitive inhibitors such as imatinib (Gleevec) can achieve unusually high kinase selectivity by binding a less conserved region adjacent to the ATP-binding pocket (Nagar et al., 2002; Schindler et al., 2000), thus underscoring the idea that inhibitor interactions with less conserved regions of a kinase can provide opportunities for greater kinase selectivity. Indeed, many kinases contain nonconserved sequence elements outside the kinase domain that mediate important facets of their function such as localization, substrate recruitment, or the regulation of catalytic activity. Several kinases contain autoinhibitory domains that bind and inhibit the activity of the catalytic domain (Cheetham, 2004). We, and others, have proposed that proteins regulated by autoinhibition may be susceptible to inhibition by small molecules that perturb the conformational changes that accompany relief of autoinhibition (Cheetham, 2004; Liu and Gray, 2006; Peterson et al., 2004; Peterson and Golemis, 2004). The additional domains and conformational changes that mediate kinase autoregulation may, therefore, provide novel opportunities for more specific small-molecule inhibition than ATP-competitive compounds.

Members of the *p*21-*a*ctivated *k*inases (Paks) are one such family that is subject to autoregulation. Group I Paks (Paks 1–3) are regulated by autoinhibition that is relieved by binding to the 21 kDa GTP-binding proteins Rac and Cdc42. This distinct regulatory mechanism is not observed, however, in the more distantly related group II Paks (Paks 4–6). However, Pak5 may undergo autoinhibition mediated by an unrelated domain (Ching et al., 2003). Autoinhibition of Pak1 is mediated by the formation of an inactive homodimer in which the autoregulatory region of one monomer binds and inhibits the catalytic domain of its partner and vice versa (Lei et al., 2000; Parrini et al., 2002). One critical element of the autoregulatory region is the kinase-inhibitory segment, which binds in the active site cleft and sequesters the kinase activation loop in an inactive conformation (Lei et al., 2000). Pak1 activation involves the local unfolding of the autoinhibitory domain caused by binding of Rac/Cdc42 to a partially overlapping region, resulting in Pak1 monomer dissociation and displacement of the inhibitory segment. Subsequent autophosphorylation events at multiple sites along Pak1 stabilize the catalytically competent, monomeric conformation (Chong et al., 2001; Lei et al., 2000; Parrini et al., 2002). This multistep activation cascade may offer additional opportunities for small-molecule binding that could selectively inhibit group I Paks.

Increasing data implicate Pak1 in tumorigenesis and metastasis (reviewed in Kumar et al., 2006). Thus, inhibitors of Pak1 have been suggested as a novel oncologic therapy (Kumar et al., 2006; Nheu et al., 2002). Although no highly selective inhibitors of Pak1 have been reported, several compounds originally identified for their ability to target other kinases also inhibit Pak family members (Eswaran et al., 2007; Nheu et al., 2002; Porchia et al., 2007). Here we report the identification and characterization of a highly selective, non-ATP-competitive inhibitor that targets the

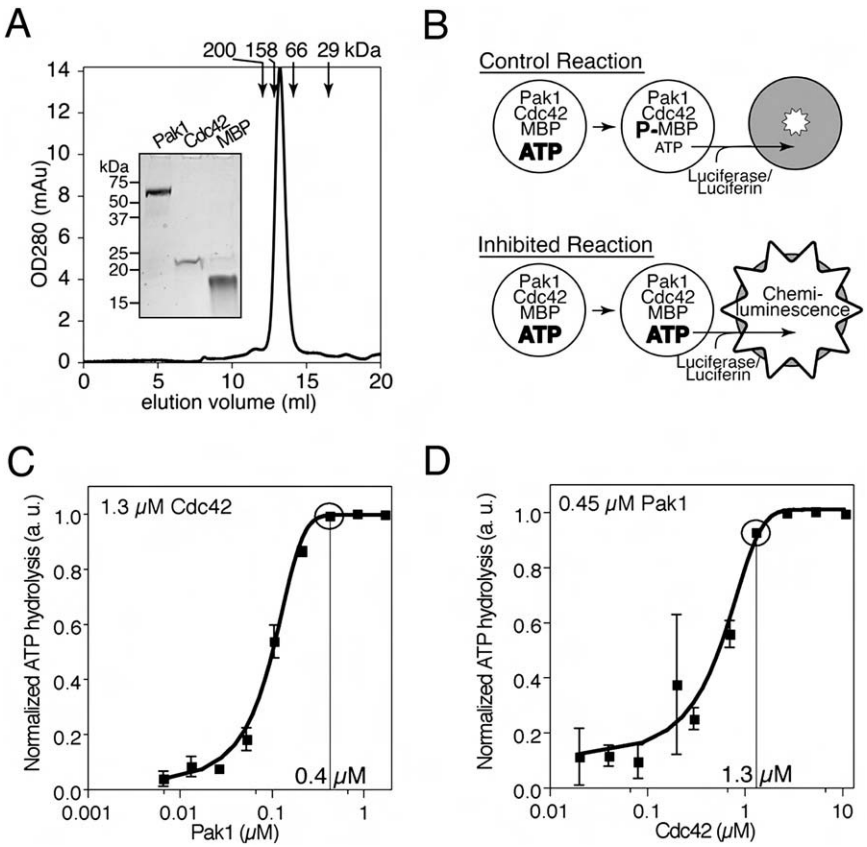

Figure 1. An ATP Depletion Assay Reports Cdc42-Dependent Pak1 Activation

(A) Recombinant Pak1 is a homodimer. The gel-filtration elution profile of Pak1 is shown. Elution volumes of standards are indicated. Inset: Coomassie-stained SDS-PAGE analysis of Pak1 and other proteins used in the screen.

(B) Pak1 assay scheme. Pak1 is incubated with its activator, GTPγS-charged Cdc42, and a substrate, myelin basic protein (MBP), in the presence of 10 μM ATP. Control kinase reactions (top) hydrolyze a substantial fraction of the starting ATP resulting in low final ATP concentrations, whereas inhibited reactions (bottom) do not. Residual ATP is enzymatically converted to chemiluminescence proportional to residual ATP.

(C) ATP hydrolysis is strictly Pak1-dependent. Cdc42 was incubated with MBP, ATP, and the indicated concentrations of Pak1. Residual ATP levels were measured as in (B). Results are expressed as ATP hydrolyzed in arbitrary units (normalized to the maximum ATP hydrolyzed) as a function of Pak1 concentration. Data points and error bars show mean and SEM of triplicate wells. Circled point indicates Pak1 concentration used in the screen.

(D) ATP hydrolysis by Pak1 is Cdc42-dependent. ATP depletion was monitored in reactions as in (C) except that the indicated concentrations of Cdc42 were used. Circled point indicates Cdc42 concentration used in the screen.

autoregulatory mechanism of group I Paks. This work illustrates how conformational rearrangements accompanying kinase activation can be exploited by compounds to achieve greater target specificity, and introduces a selective reagent for Pak inhibition.

RESULTS

A Chemical Screen Identifies IPA-3 as an Inhibitor of Pak1

To identify inhibitors of Pak1 activation, we developed a high-throughput assay measuring ATP hydrolysis as an indicator of Pak1 catalytic activity. Recombinant, full-length Pak1 exhibited an apparent molecular weight of ~130 kDa by gel-filtration chromatography (Figure 1A). SDS-PAGE analysis demonstrated the appropriate monomer molecular weight of ~60 kDa (Figure 1A, inset), as expected for the inactive Pak1 homodimer (Lei et al., 2000). Pak1 was incubated with individual compounds followed by addition of recombinant Cdc42-GTPγS (hereafter simply Cdc42) and myelin basic protein (MBP) as substrate (Figure 1A, inset) in the presence of 10 μM ATP (Figure 1B). Following incubation, nonhydrolyzed ATP was quantified using Kinase-Glo (Koresawa and Okabe, 2004). Titrations of both Pak1 (Figure 1C) and Cdc42 (Figure 1D) demonstrated that ATP hydrolysis was strictly dependent on both Pak1 and Cdc42. These results demonstrate that ATP hydrolysis measured in this assay is due to Pak1 kinase activity and confirm that the recombinant Pak1 utilized in the screen is autoinhibited yet activatable by Cdc42 as expected.

This assay was used to screen 33,000 structurally diverse small molecules in duplicate. Compounds inhibiting ATP hydrolysis by greater than three standard deviations below the mean of control reactions in both replicates were considered for further analysis. Approximately 1% of the compounds tested met this criterion. A secondary screen was then conducted on active compounds to identify those that were potentially non-ATP competitive. Individual compounds (10 μM) were incubated with Pak1, Cdc42, and MBP in the presence of [γ-^{32}P]ATP and were assayed for their ability to inhibit incorporation of [^{32}P]phosphate into MBP. To reduce the detection of undesired ATP-competitive inhibitors, reactions were conducted in the presence of 1 mM unlabeled ATP. Of the 342 compounds identified in the primary screen, 32 compounds continued to exhibit robust inhibition at 1 mM ATP. These compounds were ranked according to their relative potency and reproducibility of inhibition in subsequent assays, as well as their commercial availability. The cumulative results of these secondary assays led us to focus on one particular compound, 2,2′-dihydroxy-1,1′-dinaphthyldisulfide (Figure 2A; hereafter called IPA-3), that at 10 μM inhibited Pak1 activity by 95% ± 3%.

IPA-3 Is a Direct, Noncompetitive Inhibitor of Pak1

To determine the protein target of IPA-3, we performed Pak1 kinase assays in which MBP was omitted. Pak1 kinase activity was measured by monitoring Pak1 autophosphorylation using phospho-specific antibodies against threonine 423 within the activation loop (Thr423; Zenke et al., 1999). IPA-3 (10 μM) prevented Cdc42-stimulated Pak1 autophosphorylation on

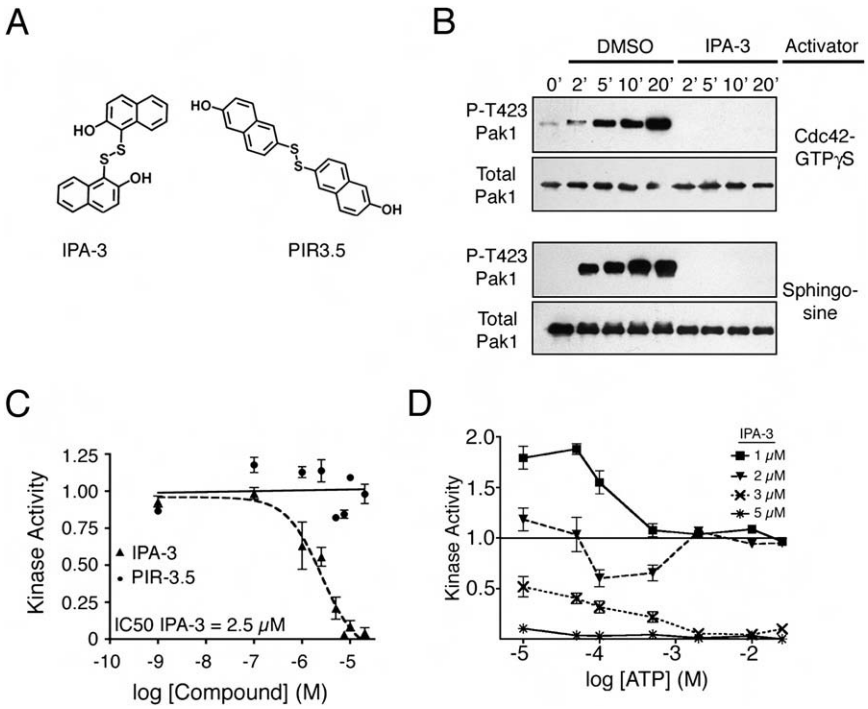

Figure 2. IPA-3 Is a Direct, Non-ATP-Competitive Inhibitor of Pak1

(A) Structure of IPA-3 and an inactive relative, PIR-3.5.

(B) IPA-3 directly inhibits Pak1 autophosphorylation. Pak1 was incubated with ATP and either Cdc42 (top panels) or sphingosine (bottom panels) in the presence of DMSO or 10 μM IPA-3. Samples were probed using phospho-specific antibodies against Pak1 Thr423. Data are representative of three experiments.

(C) IPA-3 inhibits Pak1 kinase activity with low micromolar potency. Pak1 was preincubated with the indicated concentrations of IPA-3 or PIR-3.5. Kinase reactions were started by addition of Cdc42, MBP, and a mixture of 1 mM ATP and [γ-^{32}P]ATP. Kinase activity is reported as phosphate incorporation onto MBP expressed as a ratio to MBP phosphorylated in reactions in the presence of solvent alone (1% DMSO). Data are represented as the mean ± SEM. n ≥ 3.

(D) IPA-3 is noncompetitive with ATP. Kinase assays were performed as in (C) at the indicated concentrations of ATP and IPA-3. n = 3.

Thr423 (Figure 2B, top), demonstrating that IPA-3 must target either Cdc42 or Pak1. We next substituted Cdc42 with a distinct Pak1 activator, the sphingolipid sphingosine (Bokoch et al., 1998). IPA-3 also prevented sphingosine-dependent Pak1 autophosphorylation (Figure 2B, bottom panel). Together, these assays demonstrate that Pak1 is the protein target of IPA-3. Furthermore, the inhibition of Thr423 phosphorylation, which is required for full activation of Pak1 (Zenke et al., 1999), indicates that IPA-3 may inhibit a step in the Pak1 activation process.

To confirm the chemical identity of the active compound, we developed a novel chemical synthesis of IPA-3 (see Figure S1 in the Supplemental Data available with this article online). The inhibitory activity of resynthesized IPA-3 was confirmed using in vitro kinase assays (data not shown), demonstrating that 2,2′-dihydroxy-1,1′-dinaphthyldisulfide was indeed the agent responsible for inhibition of Pak1 activity.

To determine the potency of IPA-3, kinase assays were performed at a range of compound concentrations, yielding an IC_{50} for IPA-3 of 2.5 μM (Figure 2C). A number of structurally related compounds were also tested (Figure S2), yet none inhibited Pak1 kinase activity as potently as IPA-3. A structural isomer of IPA-3, 2-naphthalenol-6,6′-dithiobis (Figure 2A, right), termed PIR-3.5 (*P*ak1 *i*nhibitor-*r*elated 3.5), displayed no inhibitory activity toward Pak1 (Figure 2C), and was therefore chosen as a negative-control compound for subsequent analyses.

The ability of IPA-3 to inhibit Pak1 activity at 1 mM ATP (Figure 2C) suggested that this compound might be noncompetitive with ATP. Indeed, when tested at a range of ATP concentrations, the inhibitory activity of IPA-3 was not decreased by increasing concentrations of ATP (Figure 2D). These results clearly demonstrate that Pak1 inhibition by IPA-3 is not competitive with ATP.

IPA-3 Does Not Target Exposed Cysteine Residues on Pak1

Cysteine-modifying agents that form mixed disulfides with protein targets have been shown to perturb the biological activity of proteins (Rice et al., 1995). Therefore, initial experiments to determine the mechanism of Pak1 inhibition by IPA-3 focused on the role of the disulfide bond in IPA-3 (Figure 2A). We found that IPA-3 inhibitory activity was dramatically reduced in the presence of >1 mM of the reducing agent dithiothreitol (DTT) (Figure 3A). We also found that addition of DTT could relieve inhibition of Pak1 when added after IPA-3 (Figure 3B). Thus, IPA-3 inhibition of Pak1 could be both prevented and reversed by 1 mM DTT.

The sensitivity of IPA-3 inhibition to DTT could be a result of reduction of IPA-3 itself or the reduction of an IPA-3-Pak1 adduct. We first considered the possibility that IPA-3 formed mixed disulfides with Pak1. Pak1 contains five cysteine residues, all of which are found in the kinase domain. Computational analysis of crystal structures of Pak1 kinase domain in both active (Lei et al., 2005) and autoinhibited conformations (Lei et al., 2000) using UCSF Chimera demonstrated that only two of those residues, Cys360 and Cys411, are surface exposed. To determine whether inhibition by IPA-3 could be a result of the formation of mixed disulfides with these cysteines, we mutated both residues to serine. Like wild-type Pak1, the mutated Pak1 (Pak1-CS) exhibited a basal level of kinase activity that was stimulated by addition of Cdc42 (Figure 3C). Importantly, Pak1-CS was similarly inhibited by 10 μM IPA-3 compared to wild-type Pak1 (Figure 3C), demonstrating that the mechanism of IPA-3 inhibition is not through the formation of mixed disulfides with Cys360 or Cys411. In addition, Pak1 migration in nonreducing SDS-PAGE and size-exclusion chromatography was not affected by IPA-3, ruling out IPA-3-mediated formation of Pak1 multimers or aggregates (not shown).

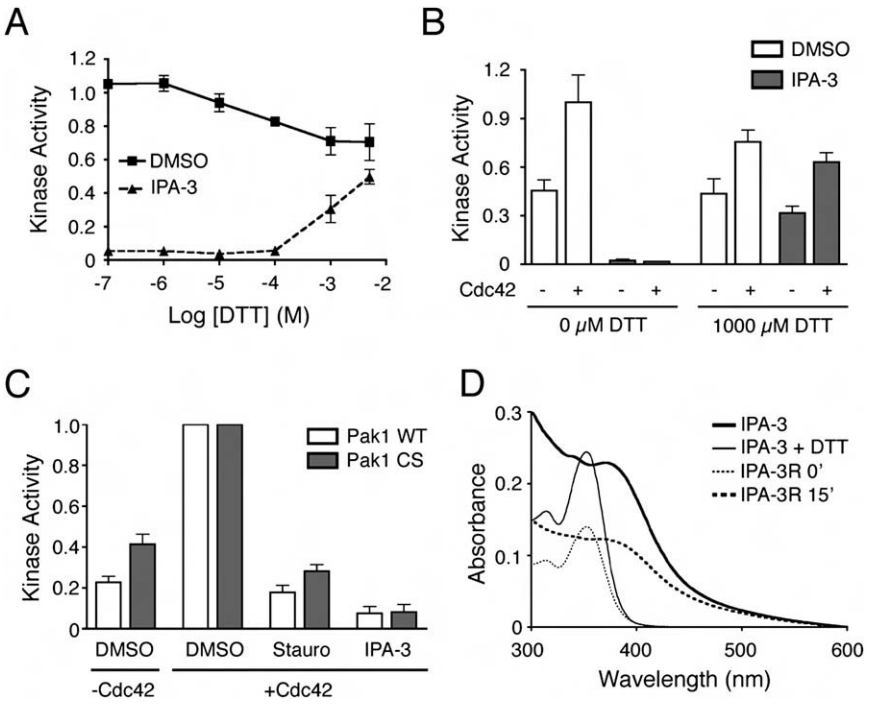

Figure 3. The Role of Disulfides in IPA-3-Mediated Pak1 Inhibition

(A) IPA-3 activity is diminished in the presence of the reducing agent DTT. IPA-3 (10 μM) was incubated with the indicated concentrations of DTT, followed by the addition of Pak1. Kinase activity was determined as in Figure 2. n = 6.

(B) DTT relieves IPA-3-dependent inhibition of Pak1 and restores Cdc42-mediated activation. Pak1 was incubated with IPA-3 and divided into vessels containing 0 or 1000 μM DTT, followed by addition of Cdc42 where indicated. Samples were subjected to kinase assays as in Figure 2. Data are represented as the mean ± SEM. n = 3.

(C) Mutation of solvent-accessible cysteine residues in Pak1 to serine does not prevent inhibition by IPA-3. Pak1-CS (Cys360 mutated to serine, Cys411 mutated to serine) and wild-type Pak1 were preincubated with either DMSO or the indicated compound. Kinase activity was determined as in Figure 2, and was normalized to the maximum activity in the presence of solvent alone (1% DMSO) and Cdc42. n = 5.

(D) Absorption spectroscopy suggests that the disulfide bond in IPA-3 is sensitive to reduction by DTT. Absorption spectra were recorded for 20 μM IPA-3 in the presence of 0 (thick trace) or 1000 μM (thin trace) DTT. A freshly prepared solution (20 μM) of the reduced form of IPA-3, IPA-3R (1-mercapto-2-hydroxynaphthalene), was also analyzed either immediately (thin dotted trace) or following a 15 min incubation on the benchtop (thick dotted trace). Data are representative of multiple experiments.

To test whether IPA-3 itself was sensitive to DTT, we analyzed a solution of IPA-3 by absorption spectroscopy in the presence of a range of DTT concentrations. We observed a dramatic change in the absorption spectrum of IPA-3 at ≥1 mM DTT (Figure 3D). Interestingly, chemically synthesized 1-mercapto-2-hydroxynaphthalene (IPA-3R), the expected product of the reduction of the disulfide in IPA-3, exhibited an absorption spectrum indistinguishable from that of IPA-3 in the presence of 1 mM DTT (Figure 3D). Furthermore, IPA-3R rapidly reoxidized into IPA-3 under our buffer conditions (Figure 3D). Thus, the sensitivity of IPA-3 inhibition to DTT is likely due to direct reduction of the IPA-3 disulfide, although we cannot formally rule out the possibility that IPA-3 forms a DTT-sensitive adduct with residues other than surface-exposed cysteines.

IPA-3 Targets the Pak1 Activation Mechanism

Pak1 activation is a multistep process involving the relief of autoinhibitory interactions and autophosphorylation at key residues (Buchwald et al., 2001; Chong et al., 2001; Zenke et al., 1999). IPA-3 inhibition of Thr423 autophosphorylation suggests that IPA-3 may inhibit steps in the Pak1 activation mechanism. To determine the point in Pak1 activation at which IPA-3 may be acting, a series of kinase assays were performed in which the order of addition of reaction components was systematically varied. Consistent with the results of the initial screen, when IPA-3 was added prior to Cdc42 and ATP, it significantly inhibited Pak1 kinase activity (Figure 4A, condition A). When added to Pak1 *after* incubation with Cdc42, but prior to the addition of ATP, IPA-3 similarly inhibited Pak1 (Figure 4A, condition B). Finally, we tested the ability of IPA-3 to inhibit Pak1 when added after both Cdc42 and ATP, when Pak1 is preactivated (Figure 2B, 20′). Strikingly, IPA-3 was much less effective at inhibiting this preactivated Pak1 (Figure 4A, IPA-3, condition C). In contrast, the ATP-competitive inhibitor staurosporine inhibited Pak1 kinase activity equally regardless of when it was added (Figure 4A, Stauro). The requirement that IPA-3 be present prior to Pak1 activation to be effective was also observed for Pak1 activated by sphingosine (data not shown). These results demonstrate that IPA-3 is ineffective at inhibiting preactivated Pak1. Moreover, the ability of IPA-3 to dramatically inhibit Pak1 only when added prior to Pak1 autophosphorylation suggests that IPA-3 inhibits a step in the Pak1 activation process.

The Conformation of Inhibitor-Bound Pak1

We hypothesized that IPA-3 might inhibit Pak1 activation by stabilizing the autoinhibited Pak1 conformation. Indeed, conformational stabilization of the autoinhibitory domain of N-WASP, which is structurally related to the autoinhibitory domain of Pak1 (Kim et al., 2000; Lei et al., 2000), has been reported for a small-molecule N-WASP inhibitor (Peterson et al., 2004). In addition, the symmetrical dimeric structure of IPA-3 suggests that this compound might contact both Pak1 monomers within the autoinhibited dimer. One important feature of the Pak1 autoinhibited conformation is the folding of the activation loop (residues 408–428) into the catalytic site of the kinase (Lei et al., 2000), thereby masking the activation loop and rendering Thr423

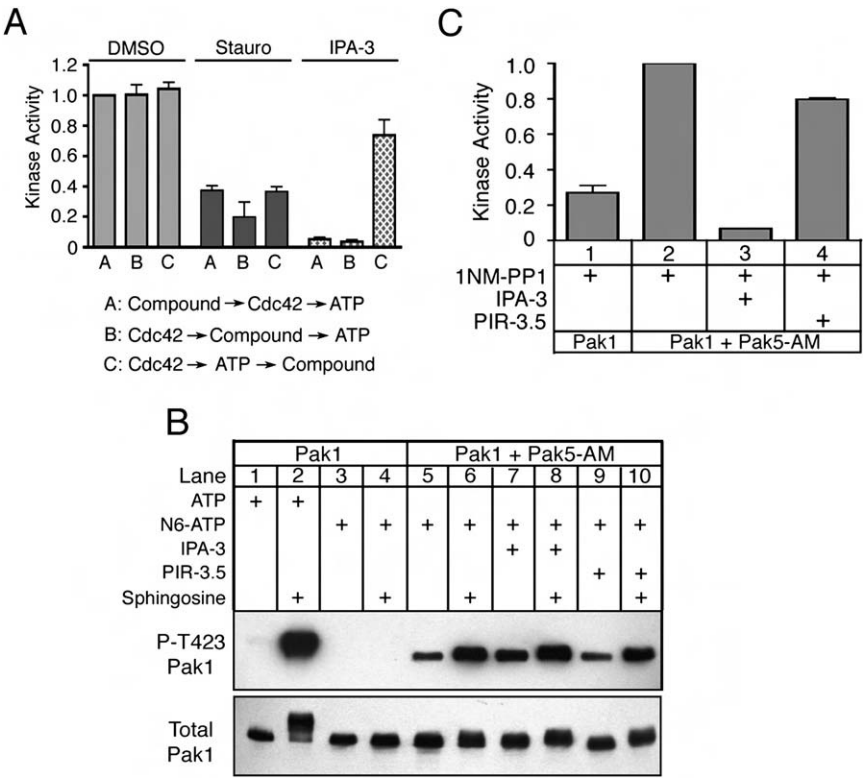

Figure 4. IPA-3 Targets the Pak1 Autoregulatory Mechanism

(A) IPA-3 inhibits Pak1 activation but does not inhibit preactivated Pak1. Pak1 was incubated with components in the following order: condition A: 10 μM compound, Cdc42 and ATP; condition B: Cdc42, compound, ATP; condition C: Cdc42 and ATP, compound. After all incubations, kinase reactions were initiated by addition of MBP and [γ-^{32}P]ATP. Kinase activity is reported as in Figure 2 and was normalized to reactions in the presence of 1% DMSO and Cdc42 under condition A. n ≥ 4.

(B) IPA-3 promotes the accessibility of Thr423 to phosphorylation by exogenous kinases. Pak1 was incubated with the indicated compound followed by addition of the ATP-binding pocket mutant Pak5 (Pak5-AM), sphingosine, and ATP or N^6-benzyl-ATP (N6-ATP). Reactions were analyzed using phospho-specific antibodies against Pak1 Thr423 or total Pak1. Data are representative of three experiments.

(C) Exogenous phosphorylation of Thr423 does not restore the kinase activity of IPA-3-inhibited Pak1. Pak1 was incubated as in (B) in the presence of 125 μM sphingosine and N6-ATP. Postincubation, 2 μM 1NM-PP1 was added to inhibit Pak5-AM, and kinase assays were conducted. Kinase activity is reported as in Figure 2 and normalized to the reaction in lane 2. Data are represented as the mean ± SEM. n = 4.

inaccessible to phosphorylation. On relief of autoinhibition, a large conformational change in the activation loop exposes Thr423 to phosphorylation by other Pak1 monomers as well as other kinases (King et al., 2000; Parrini et al., 2002; Zenke et al., 1999). Thus, accessibility of Thr423 to phosphorylation can be used to reveal whether the activation loop is in the "open" (active) or "closed" (inactive) conformation. We therefore tested the ability of exogenous kinases to phosphorylate Thr423 in the presence of IPA-3. We have found that Pak5 can phosphorylate Thr423 of Pak1 in vitro but is itself insensitive to IPA-3 (see below). For this reason, Pak5 was chosen as the exogenous kinase for this assay.

To ensure that at all Thr423 phosphorylation was mediated by Pak5, we mutated the gatekeeper residue of Pak5 (methionine 523) to glycine according to the strategy pioneered by Shokat and colleagues (Liu et al., 1998). This Pak5 *A*TP-binding pocket *m*utant (Pak5-AM) can utilize the bulky ATP derivative N^6-benzyl-ATP (N6-ATP), whereas wild-type Pak1 cannot (Figure 4B, compare lanes 3 and 5). In vitro kinase assays using N6-ATP revealed that Pak5-AM phosphorylates Pak1 on Thr423, and that these phosphorylation events were enhanced in the presence of sphingosine (Figure 4B, lanes 5 and 6). Importantly, IPA-3 did not prevent Pak1 phosphorylation by Pak5-AM and, indeed, promoted Thr423 phosphorylation in the absence of sphingosine (Figure 4B, compare lanes 5 and 7). Thus, IPA-3 does not stabilize the native autoinhibited conformation of Pak1 but instead promotes a conformation of Pak1 in which Thr423 is exposed. Similar results were obtained using 3-phosphoinositide-dependent kinase 1 (PDK1), another Thr423-directed kinase (King et al., 2000 Figure S3A).

That Thr423 can be phosphorylated by exogenous kinases but not by Pak1 itself in the presence of IPA-3 suggested that phosphorylation of this residue by exogenous kinases might overcome Pak1 inhibition by IPA-3. To test this, we took advantage of the observation that the gatekeeper residue mutation in Pak5-AM renders Pak5-AM sensitive to inhibition by the ATP-competitive inhibitor 1NM-PP1, whereas wild-type Pak1 kinase activity was unaffected (Figure S3B). We first incubated Pak1 with Pak5-AM and N6-ATP in the presence of sphingosine and either DMSO or IPA-3. Next we added 1NM-PP1, MBP, and a mixture of ATP and [γ-^{32}P]ATP to specifically measure Pak1 catalytic activity. Prephosphorylation of Pak1 with Pak5-AM and N6-ATP led to a significant increase in Pak1 catalytic activity (Figure 4C, lane 1 versus 2). However, Pak5-AM phosphorylation of Pak1 did not overcome inhibition by IPA-3 (Figure 4C, lane 3). Inhibition of MBP phosphorylation by IPA-3 is due to direct inhibition of Pak1, as the Pak5-AM phosphorylation of Pak1 was not affected by IPA-3 (Figure 4B, lanes 6 and 8). Together, these results demonstrate that in the presence of IPA-3, Pak1 adopts a conformation in which Thr423 is exposed and therefore must be distinct from the autoinhibited conformation. Nevertheless, this conformation is catalytically inactive and cannot be reactivated by phosphorylation by exogenous kinases. In addition, these results demonstrate that a group II Pak (Pak5) can phosphorylate the activation loop of a group I Pak (Pak1) in vitro, suggesting the possibility of regulatory crosstalk between the two Pak groups.

IPA-3 Targets Group I Paks

The Pak1 autoregulatory strategy is conserved in all group I Paks (Paks 1–3). By contrast, the group II Paks (Paks 4–6) do not contain the inhibitory domain found in group I Paks, and are not thought to undergo autoinhibition by the same mechanism. We

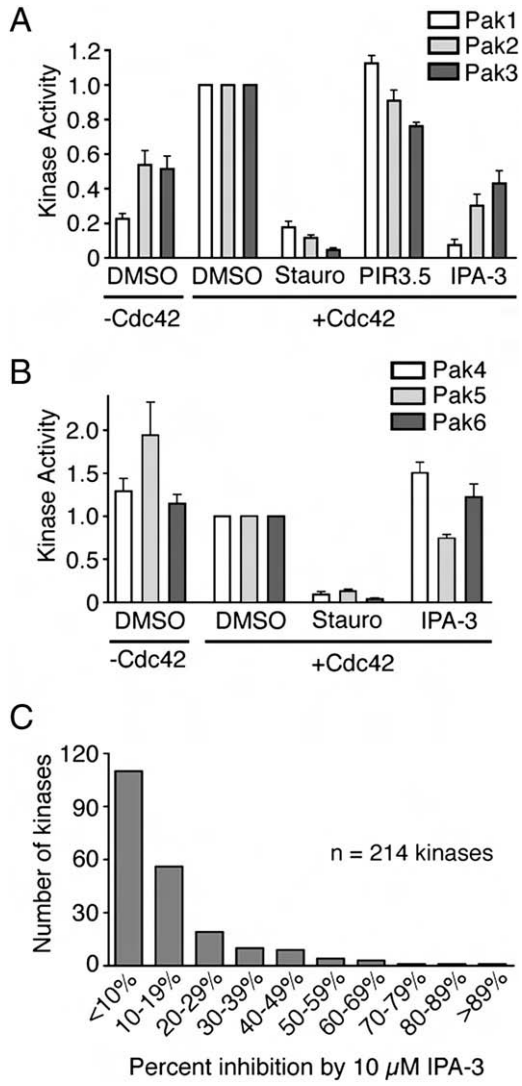

Figure 5. IPA-3 Kinase Selectivity

(A) IPA-3 inhibits all group I Paks. Paks were incubated with 10 μM indicated compound followed by addition of buffer or Cdc42, MBP, and a mixture of 1 mM ATP and [γ-^{32}P]ATP. Kinase activity is reported as in Figure 2. n ≥ 3.

(B) IPA-3 is not an effective inhibitor of group II Paks. Purified Pak4 kinase domain or full-length Pak5 and Pak6 were tested in kinase reactions as described in (A). n ≥ 4.

(C) Distribution of IPA-3 inhibitory activity against recombinant kinases. Full-length human kinases (214) were treated with 10 μM IPA-3 and subjected to kinase assays. The histogram represents the number of kinases that displayed the indicated mean percent inhibition compared to control reactions without inhibitor in two independent experiments. Data are represented as the mean ± SEM.

therefore tested IPA-3 on all members of the Pak family. As expected, full-length Paks 1–3 displayed basal levels of kinase activity that were stimulated by the addition of Cdc42 (Figure 5A). Dramatic inhibition of kinase activity in the presence 10 μM IPA-3 but not PIR-3.5 was observed for all three group I Paks, with the strongest inhibition observed for Pak1 (Figure 5A).

We next tested the ability of IPA-3 to inhibit full-length Pak5 and Pak6 and a catalytic fragment of Pak4. Consistent with reports demonstrating that these kinases do not undergo autoinhibition or Rac/Cdc42-mediated activation (Abo et al., 1998; Cau et al., 2001; Lee et al., 2002), the basal kinase activity of the group II Paks was not stimulated by Cdc42 (Figure 5B). Importantly, the kinase activity of Paks 4–6 was not dramatically inhibited by 10 μM IPA-3 (Figure 5B, IPA-3). Taken together, these results demonstrate that IPA-3 exhibits selectivity for the group I versus group II Paks.

Kinase Specificity of IPA-3

To determine the specificity of IPA-3 across a larger fraction of the kinome, we tested the ability of this compound to inhibit 214 full-length human kinases using an assay that monitors phosphorylation of a peptide substrate (Invitrogen Z′-Lyte). IPA-3 (10 μM) significantly inhibited (≥50% inhibition) only 9 of the kinases tested (4% of total) (Figure 5C; Table S1). By comparison, the broad-spectrum kinase inhibitor staurosporine, the highly selective Bcr-Abl inhibitor imatinib, and the receptor tyrosine kinase inhibitor gefitinib inhibited (by ≥50%) 93%, 12%, and 21% of the kinases tested, respectively (data not shown). Although Pak2 and Pak3 were represented in the collection of kinases tested, they were not significantly inhibited by IPA-3. This can be explained by the fact that the recombinant Paks used in the Z′-Lyte assay are preactivated and no longer responsive to Cdc42 (Figure S4). It should be also be noted that 34 of 214 kinases were tested in the presence of 1 mM DTT (see Table S1), conditions sufficient to reduce the IPA-3 disulfide. Nevertheless, these data demonstrate the remarkable kinase specificity of IPA-3, and further support the notion that this inhibitor acts on the unique regulatory cycle of group I Paks.

IPA-3 Inhibits Pak1-Mediated Signaling In Vivo

Platelet-derived growth factor (PDGF) promotes Pak activation in fibroblasts (Beeser et al., 2005). We therefore tested the ability of IPA-3 to inhibit PDGF-stimulated Pak activation in mouse embryonic fibroblasts. Both basal and PDGF-stimulated Pak activities were impeded by 30 μM IPA-3 as assessed by in-gel kinase assay (Figure 6, upper panel, arrows). In contrast, the activity of an unidentified ~40 kDa kinase was unaffected (upper panel, arrowhead). Western blotting of the same lysates with group I-specific Pak antibodies showed that the increase in Pak apparent molecular weight in control PDGF-stimulated cells, likely due to Pak autophosphorylation, was also inhibited by IPA-3 (Figure 6, Total Pak). The inhibition of Pak's apparent molecular weight increase by IPA-3 in cells was also observed in vitro (Figure 2B, bottom panel), supporting a common inhibitory mechanism. These data show that IPA-3 can inhibit activation of group I Paks in cells. The need for higher concentrations of IPA-3 for Pak inhibition in cells compared to in vitro is likely due to reduction of the IPA-3 disulfide bond in the reducing cytoplasmic environment. This would be expected to be counteracted by the large, exchangeable reservoir of IPA-3 present in the nonreducing cell-culture medium, thus maintaining a sufficient intracellular concentration of active compound.

To assess the effect of IPA-3 on signaling components upstream of Pak, the same cell lysates were analyzed using phospho-specific antibodies against activated forms of the PDGF receptor and Akt. IPA-3 had little effect on these signaling events upstream of Pak. By contrast, Erk activation by PDGF, which

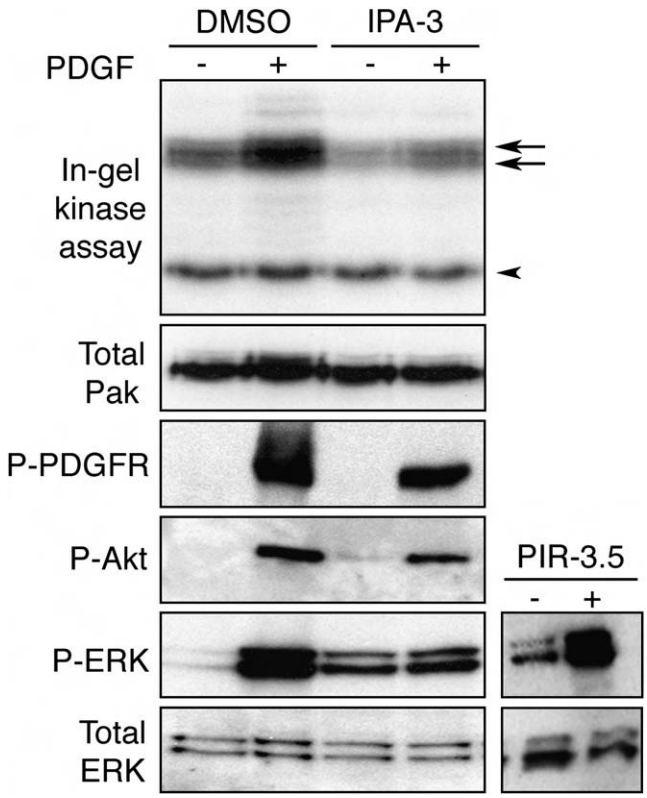

Figure 6. IPA-3 Selectively Inhibits Pak1 Activation in Mammalian Cells

Mouse embryonic fibroblasts were serum starved for 18 hr, followed by treatment with 30 μM IPA-3, PIR-3.5 (right panels), or DMSO for 10 min. Cells were stimulated with 10 μg/ml PDGF-BB for 5 min and lysed. Cell lysates were normalized by protein concentration and probed with antibodies as described in Experimental Procedures. Endogenous Pak kinase activity was observed by in-gel kinase assay.

we and others have shown is dependent on Pak (Beeser et al., 2005; Tang et al., 1997), was strongly inhibited by IPA-3 (Figure 6). Interestingly, IPA-3 caused a slight elevation in basal Erk activity even in the absence of PDGF, although this effect was cell-type-dependent (data not shown). As expected, the control compound PIR-3.5 did not inhibit Erk activation (Figure 6, right panels). Thus, IPA-3 specifically and selectively inhibits signaling events mediated by group I Paks.

DISCUSSION

The work presented here describes the identification of a highly selective inhibitor of group I Pak kinases that achieves this selectivity by targeting the distinct autoregulatory mechanism conserved in group I Paks. That IPA-3 targets this regulatory mechanism and not the kinase active site directly is supported by the following findings. First, the inhibition of Pak1 is noncompetitive with respect to ATP. Second, IPA-3 targets the group I but not group II Pak kinases, which share a highly conserved C-terminal kinase domain but differ in their N-terminal regulatory sequence elements. Third, IPA-3 inhibits activation of Pak1 by diverse activators, but does not inhibit preactivated Pak1. Finally, IPA-3 does not prevent rearrangements of the activation loop that result in phosphorylation by exogenous kinases. One interpretation of these findings is that IPA-3 prevents Pak1 activation by stabilizing an activation intermediate that is semi-open yet catalytically inactive. A precise understanding of the molecular basis of Pak1 inhibition by IPA-3, however, awaits detailed structural studies.

A number of endogenous protein regulators of Pak1 kinase activity have been reported that appear to target the Pak1 autoregulatory strategy. hPIP1 (Xia et al., 2001), CRIPak (Talukder et al., 2006), and the tumor suppressor merlin (Kissil et al., 2003) have all been shown independently to bind the Pak1 autoregulatory region and inhibit kinase activity. CIB1 also binds this region but, like Rac and Cdc42, promotes Pak1 activity rather than inhibiting it (Leisner et al., 2005). These observations suggest that modulation of the Pak1 autoregulatory domain may be a physiologically relevant strategy for regulating catalytic activity. Therefore, it is conceivable that IPA-3 may bind and/or inhibit Pak1 in a manner that mimics endogenous protein inhibitors.

As expected for an allosteric kinase inhibitor, kinase profiling experiments revealed a high degree of kinase selectivity to IPA-3 inhibition (Table S1). The lack of kinase domain sequence similarity or functional overlap in IPA-3 kinase targets is not unexpected for a compound targeting a nonconserved regulatory mechanism. Indeed, specificity profiling of clinical kinase inhibitors has shown that many selective compounds also target seemingly unrelated kinases (Karaman et al., 2008). These observations emphasize the importance of broad kinase profiling experiments in the characterization of kinase inhibitor selectivity. To our knowledge, the profiling studies of IPA-3 reported here (Table S1) describe the first chemical inhibitor of Pak1 that achieves documented specificity comparable to that of the clinically relevant kinase inhibitors imatinib and gefitinib.

Although IPA-3 represents a novel experimental reagent to inhibit Pak kinase activity, other groups have reported the use of small molecules derived from known ATP-competitive kinase inhibitors to target Pak1 (Nheu et al., 2002; Porchia et al., 2007). However, these inhibitors target a number of other kinases, and their broader kinase selectivity has not been reported. An alternative approach to inhibiting Pak kinase activity has been the expression of recombinant fragments such as the Pak inhibitory domain or catalytically inactive mutants of Pak1 that inhibit the activity of endogenous Pak protein, although these may cause unintended Pak-independent side effects (Thullberg et al., 2007). By contrast, we show here that IPA-3 is Pak isoform selective, cell permeable, and rapidly acting. As such, this compound can serve as a distinct tool to elucidate Pak function in cells and may facilitate the validation of Pak inhibitors as a therapeutic strategy.

The screening strategy used to identify IPA-3 relied on the use of full-length Pak1 prepared under conditions that preserve the native autoregulatory mechanism. This is in contrast to the dominant paradigm in kinase-targeted screens of utilizing constitutively active kinase or isolated kinase domains (Sebolt-Leopold and English, 2006). These screens are biased toward inhibitors targeting the active site and are restricted in their ability to exploit sequence differences outside the catalytic domain. The results presented here support the possibility that screens using full-length kinase may provide unexpected opportunities for allosteric inhibition. This strategy need not be restricted to kinases,

however, and could be utilized for other enzymes or noncatalytic proteins that undergo conformational regulation (Peterson and Golemis, 2004). Indeed, for scaffolding proteins, conformational inhibitors of this type may provide the only route to achieving inhibition by small molecules.

SIGNIFICANCE

Lack of target specificity is a major limitation of many widely used kinase inhibitors. This results in part from the high degree of evolutionary conservation in the ATP-binding pocket targeted by these compounds across the human kinome. Nonconserved regulatory elements found in some kinases may offer unique targets for more selective kinase inhibition. Here we test this hypothesis using the p21-activated kinase 1 and report the screening for and identification of a highly selective, cell-permeable inhibitor that targets the Pak1 autoregulatory mechanism. Biochemical studies suggest that IPA-3 may trap a transient intermediate step in Pak activation, because preactivated Pak1 is insensitive to IPA-3. In addition, IPA-3-bound Pak1 exhibits some but not all structural features of the active conformation, and is catalytically inactive. Critically, kinase specificity profiling studies reveal an exceptional degree of kinase selectivity by IPA-3, consistent with its targeting the unique Pak1 regulatory domain. Furthermore, cell-based experiments using IPA-3 provide evidence that Pak promotes mitogen-activated protein kinase activation and illustrate selective inhibition of Pak in live cells. Thus, kinase autoregulatory mechanisms provide an alternative target for kinase inhibition by small molecules. The widespread use of constitutively active, recombinant kinase forms in kinase inhibitor screening programs likely limits the identification of compounds acting by such novel allosteric mechanisms. Our results suggest that screening assays that recapitulate biologically important regulatory mechanisms may reveal additional opportunities for selective kinase inhibition.

EXPERIMENTAL PROCEDURES

Protein Purification and Characterization

The following proteins were purified as described: Cdc42-GTPγS (Peterson et al., 2001), Pak2 (Rennefahrt et al., 2007), Pak4 and Pak5 catalytic domains (Eswaran et al., 2007), and full-length Pak1 (Rennefahrt et al., 2007). Full-length Pak3 (Bagrodia et al., 1995) and Pak5 (Cotteret et al., 2003) were expressed in HEK293 cells and immunopurified (see below). Full-length Pak6 (PV3502) was purchased from Invitrogen. MBP was purchased (Sigma) or purified from bovine brain acetone powder (Sigma) as described (Prowse et al., 2000).

Recombinant Pak1 was characterized by analytical gel-filtration chromatography on a calibrated Superdex 200 10/300 GL column. For the identification of surface-exposed cysteine residues within Pak1, computational analysis of crystal structures of Pak1 kinase domain in both active (Lei et al., 2005) and autoinhibited conformations (Lei et al., 2000) was performed using the MS/MS solvent accessibility module of UCSF Chimera (Pettersen et al., 2004).

Immunopurification of Pak3 and Pak5

HEK293 cells were transfected with 0.5 μg Pak3 or myc-Pak5 DNA using liposome-mediated transfection (Lipofectamine 2000, Invitrogen). Forty-eight hours posttransfection, cells were washed in ice-cold phosphate-buffered saline (PBS) and lysed into lysis buffer (20 mM Tris [pH 7.5], 150 mM NaCl, 1 mM EDTA, 1 mM EGTA, 1% Triton X-100, 1 mM phenylmethylsulfonyl fluoride (PMSF), and 10 μg/ml each of chymostatin, leupeptin, and pepstatin). Insoluble material was removed by centrifugation at 12,000 × g for 10 min at 4°C. Lysates were incubated with protein A agarose (Pierce) and either anti-Pak3 (Cell Signaling Technology) or anti-myc (Santa Cruz Biotechnology) for at least 2 hr at 4°C. Precipitates were washed twice in lysis buffer and once in assay buffer (50 mM HEPES [pH 7.5], 25 mM NaCl, 1.25 mM $MgCl_2$, 1.25 mM $MnCl_2$).

Chemical Compounds

The compound library consisted of 30,000 diverse compounds, largely conforming to Lipinski's rules, obtained from ChemDiv and the Challenge Set, Mechanistic Diversity Set, Natural Products Set, and Structural Diversity Set provided by the Developmental Therapeutic Program (DTP) of the National Cancer Institute. Compounds were stored as 5 mM DMSO stock solutions (except for the Mechanistic Diversity Set compounds, which were stored at 0.5 mM) at −80°C and were thawed immediately prior to use in a dessicator. IPA-3 was resynthesized and characterized as described in the Supplemental Experimental Procedures. PIR (*P*ak *i*nhibitor-*r*elated) compounds were provided as dry powder by the DTP.

High-Throughput Luminescence Assay for Inhibitors of Pak1 Activation

Recombinant Pak1 (8 μl of a 50 μg/ml solution) in assay buffer was aliquotted using a BioTek MicroFill into wells of columns 2–23 of a 384-well plate (Corning). Individual compounds were then added using disposable 384-pin polypropylene pin replicators (Genetix) to transfer ~20 nl from compound stock plates. Reactions were started by the addition of a solution (7 μl per well) containing MBP (0.32 mg/ml), GTPγS-charged Cdc42 (2.9 mg/ml), and ATP (21 μM) in assay buffer. Final reaction composition: 450 nM Pak1, 1.3 μM Cdc42, 0.15 mg/ml MBP, 10 μM ATP, 0.1% DMSO, and library compounds at ~7 μM. Plates were incubated for 2 hr at 30°C. Reactions were stopped by the addition of an equal volume of Kinase-Glo reagent (Promega) and incubated for 10 min at room temperature. Chemiluminescence was measured at 555 nm (20 nm emission slit) using a Cary Eclipse fluorescence spectrophotometer (Varian) equipped with a microplate carrier.

Compound stock plates were organized with library compounds in columns 3–22 (20 μl of a 5 mM solution in DMSO). Column 2 contained three wells of 2 mM staurosporine as positive controls and the remaining wells of column 2 contained DMSO as negative controls. Column 23 was empty and these wells served as a "no-addition" control. All compound plates were screened in duplicate.

Data analysis was conducted on a plate-by-plate basis in Microsoft Excel. Mean and standard deviation of the luminescence intensity of all wells were calculated. Wells containing compounds that resulted in luminescence intensities greater than three standard deviations above the mean of control samples in both replicate plates were considered hits.

In Vitro Kinase Assays

Pak1 (571 nM final) in assay buffer was mixed with DMSO or compound for 5 min at room temperature, followed by addition of 4 μM Cdc42 and 8.3 μM MBP for an additional 5 min. Kinase reactions were started by addition of unlabeled ATP and 1–10 μCi [γ-^{32}P]ATP per reaction for 10 min at 30°C. Final DMSO concentration was 1%. Kinase reactions were stopped on dry ice. Under these conditions, MBP phosphorylation was linear with time.

Kinase assays for Figure 4 were carried out as follows. Condition A: Pak1 was incubated for 5 min at room temperature with compound followed by addition of 4 μM Cdc42 and ATP for 20 min at 30°C. Condition B: Pak1 was incubated with Cdc42 for 20 min at 30°C, followed by addition of compound for 5 min. Condition C: Pak1 was incubated with Cdc42 and ATP for 20 min at 30°C, followed by addition of compound for 5 min. These incubations were followed by addition of 8.3 μM MBP and a mixture of ATP and [γ-^{32}P]ATP for 10 min at 30°C. Final conditions for all reactions were 1% DMSO, 1 mM ATP, and 1–10 μCi [γ-^{32}P]ATP. Reaction products were analyzed by scintillation counting (Rennefahrt et al., 2007) or by phosphorimager analysis (Fujifilm). Background counts from no kinase controls were subtracted from all values (scintillation counting assays) and kinase activity was reported as phosphate incorporation onto MBP expressed as a ratio to MBP phosphorylated in the presence of solvent alone. Phosphorimager background values were defined as the signal density of an area surrounding each individual phospho-MBP band and were subtracted from the corresponding phospho-MBP band.

Pak1 Autophosphorylation Assays

Recombinant Pak1 (571 nM final) in assay buffer was incubated with either DMSO or the indicated compound in DMSO (1% DMSO final). This mixture was incubated for 5 min at room temperature followed by the addition of either 4 μM Cdc42-GTPγS or 50 μM sphingosine (Avanti Polar Lipids) for 5 min. Kinase reactions were started by the addition of 1 mM ATP. Reactions were stopped by addition of SDS sample buffer (62.5 mM Tris [pH 6.8], 70 mM SDS, 100 mM DTT, 10% glycerol) and boiled at 95°C for 5 min. Samples were subjected to SDS-PAGE and western blotting analysis using phospho-specific antibodies against the activation loop autophosphorylation site threonine 423 (Cell Signaling Technology). Total Pak1 was detected with anti-Pak antibodies (C19, Santa Cruz).

Spectral Analysis of IPA-3

IPA-3 was diluted to 20 μM in 50 mM Tris (pH 8.0) containing the indicated concentration of DTT. Samples were vortexed and analyzed in a Cary 50 Bio spectrophotometer (Varian). IPA-3 spectral traces were background subtracted from traces of buffer containing DMSO alone (0.1%). Individual traces were normalized to 0 absorbance units at 600 nm.

The absorption spectrum of IPA-3R was obtained by preparing a fresh 20 mM DMSO stock from powder that was immediately diluted into degassed 50 mM Tris (pH 7.5) to 20 μM (0.1% DMSO). This sample was vortexed and the spectrum was obtained as described above either immediately or after incubation for 15 min on the benchtop.

Thr423 Accessibility Assay

Pak1 (571 nM) in assay buffer was incubated with compound and Pak5-AM (692.5 nM final), ATP or N^6-benzyl-ATP (25 μM; Axxora), and 125 μM sphingosine or DMSO at 30°C for 20 min. Samples were analyzed by immunoblot analysis using antibodies against Pak1 phospho-Thr423.

For determination of Pak1 kinase activity, samples prepared as above received DMSO or 2 μM 1NM-PP1 (Calbiochem) (3% final DMSO), 8.3 μM MBP, and a mixture of ATP and [γ-^{32}P]ATP (25 μM). Samples were incubated for 10 min at 30°C. Pak1 kinase activity was determined via phosphorimager analysis.

Dephosphorylation of Recombinant Pak2

To obtain inactive, dephosphorylated Pak2, 100 nM recombinant full-length Pak2 was treated with 100 U λ protein phosphatase (New England Biolabs) for 30 min at 30°C in assay buffer supplemented with 3.25 μM $MnCl_2$. Dephosphorylation of Pak2 was confirmed by western blot using phospho-specific antibodies against Pak T423. Phosphatase activity was inhibited by addition of 50 μM $NaVO_4$ and 1 mM β-glycerophosphate.

Z-Lyte Assay

The Z-Lyte assay was performed by Invitrogen. Percent inhibition was expressed as a ratio of phosphorylated product formed in the presence of 10 μM IPA-3 compared to phosphorylated product formed in reactions containing 1% DMSO. Inhibition data reflect mean kinase inhibition from two independent trials.

Cell Treatment with IPA-3

Mouse embryonic fibroblasts immortalized with SV40 large T antigen were grown in DMEM + 10% serum. Cells at 60%–80% confluency were starved for 18 hr in serum-free DMEM. Cells were pretreated with DMSO or 30 μM compound for 10 min, followed by addition of PDGF-BB (10 ng/ml; Sigma) for 5 min. Cells were washed in ice-cold PBS and lysed into Roberts buffer (50 mM Tris [pH 8], 10% glycerol, 1 mM EDTA, 137 mM NaCl, 1% NP-40 plus aprotinin, 1 mM PMSF, 1 mM $NaVO_4$). Insoluble material was removed by centrifugation, and protein concentration was determined by BCA assay (Pierce). Equal protein amounts were subjected to SDS-PAGE and western blotting using anti-Pak1 (C19, Santa Cruz), anti-phospho-PDGFR (3161), anti-phospho-Akt (9271), anti-phospho-ERK (9102) (Cell Signaling Technologies), and anti-ERK (V1141, Promega). In-gel kinase assays were performed as described (Beeser et al., 2005) with MBP as substrate.

Additional methods can be found in the Supplemental Experimental Procedures.

SUPPLEMENTAL DATA

Supplemental Data include four figures, one table, Supplemental Experimental Procedures, and Supplemental References and can be found with this article online at http://www.chembiol.com/cgi/content/full/15/4/322/DC1/.
