14. ABSTRACT
A workshop on the Nucleation of Phase Transformations in Metallic Solids was held in Maui, Hawaii on May 2-7, 2010. The meeting was sponsored by the Asian Office of Aerospace Research and Development (AOARD), the Air Force Research Laboratory (AFRL), the Air Force Office of Scientific Research (AFOSR), and the Lawrence Livermore National Laboratory (LLNL). Representatives attended from the United States, Australia, Singapore, India, and France. The focus of the workshop was to develop research tasks aimed at improving current capabilities in the areas of experimentation, modeling and characterization as they apply to the nucleation of solid phase transformations. The overall objectives of the workshop were to bring together a diverse group of researchers to establish the state of the art in experimenting, characterizing and modeling. Specifics items addressed included (1) what advances are needed in the atomistic/computational modeling area to significantly impact the science? (2) what tools and techniques are required to characterize the formation of nucleants and the local chemical and energy environment? and (3) what opportunities exist for combining advance characterization techniques with experimental validation of nucleation models. The results are provided within this document, including the presentation materials from participants.

Joint AOARD/AFRL/LLNL Workshop on the Nucleation of Phase Transformations in Metallic Solids

Summary

A workshop on the Nucleation of Phase Transformations in Metallic Solids was held in Maui, Hawaii on May 2-7, 2010. The meeting was sponsored by the Asian Office of Aerospace Research and Development (AOARD), the Air Force Research Laboratory (AFRL), the Air Force Office of Scientific Research (AFOSR), and the Lawrence Livermore National Laboratory (LLNL). Representatives attended from the United States, Australia, Singapore, India, and France. The focus of the workshop was to develop research tasks aimed at improving current capabilities in the areas of experimentation, modeling and characterization as they apply to the nucleation of solid phase transformations.   The overall objectives of the workshop were to bring together a diverse group of researchers to establish the state of the art in experimenting, characterizing and modeling. Specifics items addressed included (1) what advances are needed in the atomistic/computational modeling area to significantly impact the science? (2) what tools and techniques are required to characterize the formation of nucleants and the local chemical and energy environment? and (3) what opportunities exist for combining advance characterization techniques with experimental validation of nucleation models?

Findings

The following points were made by the participants during discussions:

1. ***Experimentation and Theory.*** Classical theory has provided tremendous insight into the nucleation process although it has been difficult to experimentally verify specific elemental composition changes, vacancies, and energies associated with nucleant and embryo formation. The use of composition wave functions, understanding of shear, consideration of dynamic nucleation events from atom clustering, knowledge of electronic structures, and spinoidal decomposition events may provide added insight into nucleation. There is a need for improved thermodynamic data, diffusivities, and interfacial energies as well as requirements for statistical analysis of rare events.

2. ***Modeling.*** The modeling discussions centered on the use of phase field approaches that utilize nudged elastic band methods, Langevin noise terms and/or use of monte carlo simulations. There is a need for accurate energy surface representations in addition to better thermodynamic and surface energy terms. The use of these techniques provides nucleation parameters that are very difficult to measure directly. Researchers also identified the need for new techniques for atomistic descriptions of multi-component systems, identifying the transition states, and the need for understanding the interactions between defects and nucleation events.

3. ***Advanced Characterization Techniques.*** Advances with atom probe tomography provides atomic level compositions, critical for evaluation of embryos and nucleants. However efficiency problems with the techniques still present serious issues and should be resolved. Dynamic and hi-resolution transmission electron microscopy techniques have also advanced to the art of

providing structural and chemical information at the atomic level. Although there are issues related to surface and thin film considerations, in situ experiments utilizing these techniques may provide vital information on embryo and nucleant precursors that are critical for model verification.

Presented Experimental and Theory Topics

Experts in the field of experimentation and theory of nucleation presented 4 topics, including 3 plenary speeches. In addition, four sessions were designed to address specific nucleation theory and experimental concerns. The sessions were titled (1) Heterogenieties, (2) Nucleation as a Rare Event, and (3) Experimental Advances.

Dr. Jim Belak (Lawrence Livermore National Laboratory) presented the first Plenary Speech, providing an overview of the field from the first work by Kolmogorov, Johnson. Mehl and Avrami to the work by Cahn, Russel, up to the recent work of today. He was followed by Professor John Perepezko (University of Wisconsin) who gave a plenary presentation on the analysis and modeling of nucleation controlled reactions. Secretary Srikumar Banerjee, PhD, (Government of India) gave a plenary presentation on the structural evolution during nucleation processes. The final plenary presentation was provided by Dr. Alan Ardell (National Science Foundation) on the nucleation and coarsening in normal and inverse Ni-Al alloys. In the Heterogenieties session chaired by Dr. Belak, Dr. Brian Reed (Lawrence Livermore National Laboratory) presented material on grain boundary engineered materials as correlated networks, and the implications of large-scale twin nucleation. Professor Gary Shiflet (University of Virginia) gave a presentation on the control of embryo formation and critical nucleus properties. He discussed the possibilities of developing and applying knowledge of electronic structures and atomic interactions into the modeling of the nucleation process. Professor Julia Hammer (University of Hawaii) combined classical theory and advanced characterization in her presentation on the nucleation of crystals in magma. She discussed the use of high temperature, high pressure furnaces to experimentally validate nucleation models of glass that forms deep beneath the surface in volcanoes.

Presented Modeling Topics

Leaders in the field of modeling presented current problems and successes that have been achieved at the different length scales. There were three classes of modeling: (1) atomistic studies, (2) research at the meso scale, and (3) continuum scale modeling.

Professor Wolfgang Windl (The Ohio State University) presented a briefing on lessons learned from the world of semiconductors. His presentation was followed by Professor Jeff Rickman (Lehigh University) who discussed the kinetics and microstructure associated with heterogenous nucleation and growth. Dr. Alphonse Finel (ONERA, France) provided a briefing on the coarse grain derivation of the phase field equations. Dr. Blas Uberuaga (Los Alamos National Laboratory) discussed the use of accelerated dynamics methods. Professor Srini Srivillipurtha (University of North Texas) followed with a presentation on first principles simulation of beta to omega transformations in titanium alloys. His talk was supported in part by experimental work conducted by Professors Hamish Fraser (The Ohio State University) and Rajarshi Banerjee

(University of North Texas), also in attendance. During the discussion period, Professor Srivillipurtha discussed the need for new approaches to address atomistic modeling of multi-component systems. Professor Yunzhi Wang (The Ohio State University) provided a discussion on the effect of local stress on nucleation and variant selection during solid state transformation with symmetry reductions. His use of the phase field approach was heavily discussed during several of the presentations. Professor Qiang Du (Penn State University) also presented a discussion on the use of phase field, focusing on the prediction of critical nucleus morphologies in solids. His work was followed by a briefing by Dr. Chen Shen (General Electric, USA) on the use of phase field techniques. Professor Greg Olson (Northwestern University) and Dr. Fan Zhang (Computherm Inc.) gave presentations on their meso-scale models. Professor Olson discussed the use of multiscale integration in the study of nucleation engineering. He presented numerous examples where multi-scale modeling had effectively captured the nucleation and growth of phase transformations. Dr. Zhang discussed the use of thermodynamic modeling of multi-component systems and the integration of the modeling into kinetic simulations. She discussed the current challenges facing the use of thermodynamic models in simulations of nucleation events, especially in commercial alloys where specific data on three and four component energy interactions are limited. Dr. S. Ranganathan (National Metallurgical Laboratory, India) spoke about the thermodynamic modeling of the early stages of solid state precipitation in alloy systems. Dr. Dan Miracle (AFRL) presented on the nucleation mechanisms for aluminum crystals in amorphous aluminum alloys.

Presented Characterization Topics

Leaders in the field of advanced characterization presented 11 topics. The major discussions concerned the use of transmission electron microscopes and/or atom probe tomography.

Dr. Thomas LaGrange (Lawrence Livermore National Laboratory) gave a presentation on the quantification of crystallization kinetics using nanosecond time resolved electron microscopy. His talk was followed by Dr. Daniel Orlikowski (Lawrence Livermore National Laboratory) who presented a briefing on high pressure considerations and the use of the dynamic anvil cell. Dr. Barry Muddle (Monash University, Australia) presented material on the heterogenous nucleation of plate shaped transformation products. His characterization techniques employed the high resolution transmission electron microscope. Professor Rajarshi Banerjee (University of North Texas) also used advanced TEM techniques in his presentation on the early stages of nucleation and growth of omega precipitates within the beta matrix of titanium alloys. His work provided the experimental validation for the modeling work presented by Professor Srivillipurtha. Dr. Mike Miller (Oak Ridge National Laboratory) followed with a presentation on the advances in atom probe tomography for nucleation studies. His discussion included an overview of the limitations associated with the techniques. Dr. Babu Viswanathan (UES, AFRL) presented a briefing on the gamma/gamma prime phase transformation in nickel alloys, including the issues with characterizing fine scale precipitates. Professor Dipankar Banerjee (IISC, India) provided a presentation on the alpha and beta transformations in titanium alloys, including the nucleation of alpha during thermal processing. Professor Jian Feng Nie (Monash University, Australia) presented on shape strain and its accommodation during the precipitation of precipitate plates. He relied heavily on the use of hi-resolution TEM techniques as well.   Professor Raju

Ramanujan (Nanyang Technological University, Singapore) presented material on the nucleation of soft magnetic nanomaterials. He highlighted the impact of different elements on the nucleation rate and growth rate of particles. He also suggested the use of a hot stage TEM to further study the concepts.   The final presentation was provided by Professor Hamish Fraser (The Ohio State University) on the use of new characterization techniques. His talk emphasized the need to apply different characterization techniques to validate techniques and offset limitations associated with different approaches. One example was the use of image corrected high resolution TEM systems along with atom probe tomography techniques to determine structural information.

Participants

The workshop was attended by 37 people, including speakers from academia, government laboratories, and industry. The audience was predominantly from the US, although six attendees traveled under the Window on Science program sponsored by AOARD.

Academic Institution Representation. The audience included representatives from 10 academic institutions: Monash University, Nanyang Technological University, India Institute of Science, University of Virginia, Northwestern University, The Ohio State University, University of North Texas, Penn State University, University of Hawaii, and Lehigh University.

Government Laboratory Representation. Seven government laboratories or agencies were represented: Air Force Research Laboratory, Air Force Office of Scientific Research, Asian Office of Aerospace Research and Development, Los Alamos National Laboratory, Lawrence Livermore National Laboratory, Oak Ridge National Laboratory, and the National Science Foundation. In addition the Secretary of Nuclear Energy for India attended (Atomic Energy Commission), and the Deputy Director of the National Metallurgical Laboratory, India, attended.

Industrial Representation. Representatives of 3 private sector entities were also represented: Questek, Computherm, and General Electric Global Research.

International Representation. Five nations were represented in the audience: Singapore, India, France, Australia, and the United States.

Acknowledgments

Presentation Materials

Nucleation and Coarsening in Normal and Inverse Ni-Al Alloys

Alan J. Ardell

Program Director
Metals and Metallic Nanostructures Program
Division of Materials Research
National Science Foundation
Arlington, VA 22201

Outline

- Brief review of the classical theory of homogeneous nucleation

- The nucleation of γ' (Ni$_3$Al) precipitates in normal Ni-Al alloys and γ (Ni-Al solid-solution) precipitates in "inverse" Ni-Al alloys offer the best prospects ever of investigating homogeneous nucleation during precipitation from solid solution---Why and How!!!

    ❖ The Ni-rich region of the Ni-Al phase diagram;

    ❖ How data on coarsening of precipitates in normal and inverse Ni-Al alloys can be used to provide values of parameters that are important in the process of nucleation;

    ❖ Observations that suggest the efficacy of studying nucleation in inverse alloys, and experimental advantages that can be used to inform nucleation studies;

    ❖ Observations that highlight the obstacles to studying nucleation in normal alloys and what can be done to overcome them;

- Presentation of data that might be useful in studies of nucleation in Ni-Al alloys...elastic constants, lattice mismatch

- Musings about diffuse γ/γ' interfaces---might these muddy the waters?

Classical Theory of Nucleation---Energetics

α (X$_\alpha$)   β (X$_\beta$)   X$_\beta$ = atom fraction B in β

γ'   r   X$_\alpha$ = atom fraction B in α
Total change in free energy on formation of a nucleus of radius r is

$$\Delta G = \frac{4\pi r^3}{3}\Delta G_v + 4\pi r^2 \sigma$$

ΔG$_v$ is the difference in the Gibbs free energy/vol of the α and β phases (ΔG$_v$ < 0);

Elastic energy/vol (>0) for coherent precipitates can contribute, but it is usually very small compared to ΔG$_v$

σ is the energy/area of the α - β interface (σ > 0)

ΔG has a maximum value of ΔG* at a critical value of r*, as shown in the diagram below:
$$r^* = \frac{-2\sigma}{\Delta G_V}$$

$$\Delta G^* = \frac{16\pi\sigma^3}{3(\Delta G_V)^2}$$

Interfacial energy opposes the formation of the nucleus, giving rise to an energy barrier, ΔG*, that must be overcome before the nucleus can be considered stable. Nuclei with radii r > r* are always able to grow with a reduction in energy of the system.

It is sometimes more useful to express the change in free energy in terms of n, the number of B atoms in the nucleus:
The variation of ΔG in the vicinity of n^* (or r^*) is relatively small over the range of energy $\Delta G^* - kT$. Nuclei with sizes $n^* \pm \delta/2$ are considered to "random walk" over the energy barrier until they reach a size $n^* + \delta/2$, beyond which the probability that they become subcritical is essentially zero.

It is possible to derive partial differential equation that describes the concentration of nuclei of size n, C_n, at any time t. This equation does not have a formal solution. The Classical Theory assumes a solution of the form

$$J^* = J_s \exp(-t / \tau)$$

J_s is the STEADY STATE NUCLEATION RATE

$$J_s = \beta^* C_{n^*}^o Z$$

β^* is the rate at which B atoms attach themselves to a nucleus of critical size

$$\beta^* = \frac{4\pi(r^*)^2 X_o}{a^4} D_B$$

X_o is the initial concentration of B in α

D_B is diffusion coefficient of B in α

a is the jump distance

C_{n*}^o is the concentration of nuclei containing n* B atoms

$$C_{n*}^o = X_o N_o \exp(-\Delta G_{n*} / kT)$$

N_o is number of atomic sites/vol

Z is the Zeldovich non-equilibrium factor. It takes into account the fact that there is a finite probability that a nucleus can become subcritical until it contains more than n* + δ/2 B atoms and depends on the curvature of the ΔG vs. n curve at n = n*

$$Z = \left[\frac{-1}{2\pi kT} \left(\frac{\partial^2 \Delta G_n}{\partial n^2} \right)_{n*} \right]^{1/2}$$

The incubation time, τ, is

$$\tau = \frac{\delta^2}{2\beta^*} = \frac{2}{\pi Z^2 \beta^*}$$

$$\delta = \left\{ \frac{-8kT}{\left(\dfrac{\partial^2 \Delta G_n}{\partial n^2} \right)_{n=n^*}} \right\}^{1/2} = \frac{2}{Z\sqrt{\pi}}$$

Any attempt to validate the classical theory of nucleation necessarily involves measurements of J_s and τ, preferably as functions of T and X_o, both of which govern the supersaturation of the solid solution.

This in turn involves measurements of the number of precipitates/vol, Nv, vs aging time t, with the expectation that only stable precipitates with n > n* will be detectable.

The expected behavior is shown below:
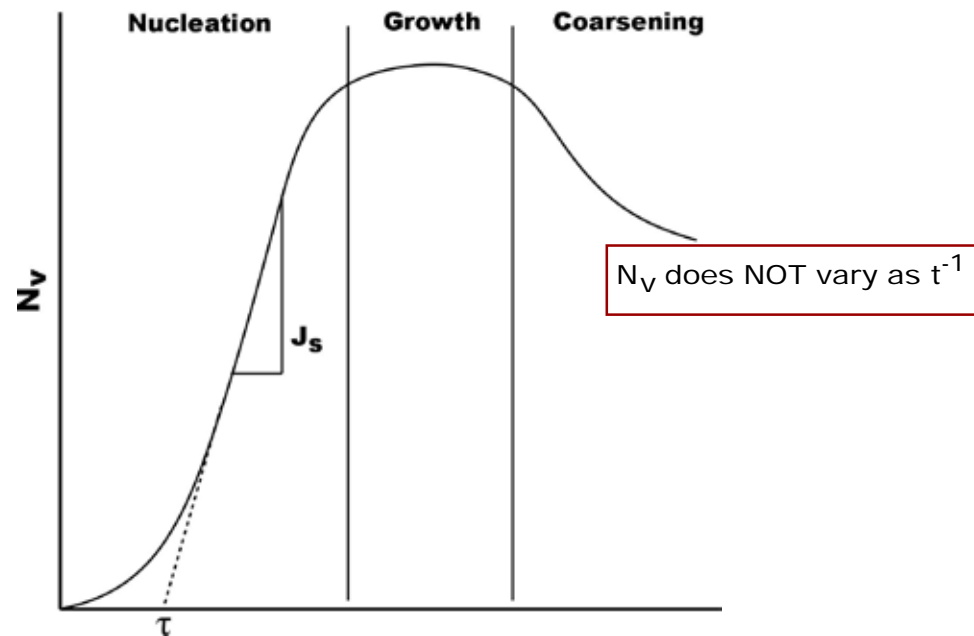

To compare experiment and theory there is a lot we need to know, with many necessary precautions.

The CRUCIAL parameters are σ, ΔG_V and D_B

In Ni-Al alloys σ and D_B can be estimated with reasonable accuracy from data on coarsening, but ΔG_V is tricky.

Free Energy Diagram for Nucleation of an A-B alloy, initial composition X_o
The distance $-DC = \Delta G_m$ = free energy/mol β for nucleation of a β-phase nucleus of equilibrium composition, $X_{\beta e}$.

The distance $-D'C' = \Delta G_{m,max}$ is the maximum value of the driving force for nucleation. But it is for a β-phase nucleus of composition $X_\beta > X_{\beta e}$.

For any β-phase composition $> X_{\beta,min}$ there exists a positive driving force for nucleation (i.e. $\Delta G_m < 0$). This region is represented in green for nucleus compositions up to $X_{\beta e}$.

$G_v = G_m/V_m$; V_m is the partial molar volume of B

Estimating ΔG_v requires knowledge of the Gibbs free energy of mixing of the α and β phases, and is sensitive to the curvatures of the free energy functions

If both phases are ideal solutions

$$\Delta G_v = -\frac{kT}{V_m}\left\{ X_{\beta e}\ln\frac{X_o}{X_{\alpha e}} + \left(1 - X_{\beta e}\right)\ln\left(\frac{1 - X_o}{1 - X_{\alpha e}}\right)\right\}$$

This equation is a very good approximation when α and β are both terminal solid solutions with limited solubility

So...What's the big deal? Why is classical nucleation theory so difficult to verify, and why are we talking about it amost 75 years after Becker and Doring published their paper in 1935[†]:

[†]R. Becker and W. Doring, ANNALEN DER PHYSIK, 24 (1935) 719-752.

The reason is that, at least for precipitation from solid solution, accurate measurements of steady-state nucleation rates and incubation times are DIFFICULT

One important factor is that diffusion is strongly affected by Quenched-in Vacancies, even when every effort is made to minimize their influence!

Some results that illustrate this follow

Alloys quenched directly from solution treatment temperature, 870 °C, to the aging temperature.

fcc Co precipitates are fully coherent, lattice mismatch = -1.7%

Cu-1% Co
The equilibrium volume fraction is ~0.01

The maximum value of N_v is ~$10^{21}/m^3$

F.K. LeGoues and H.I. Aaronson, Acta Metall. 32 (1984) 1855

Steady-state Nucleation Rates
There is reasonably good agreement with theory assuming diffusion of Co at the solution-treatment temperature

F.K. LeGoues and H.I. Aaronson, Acta Metall. 32 (1984) 1855

Incubation Times
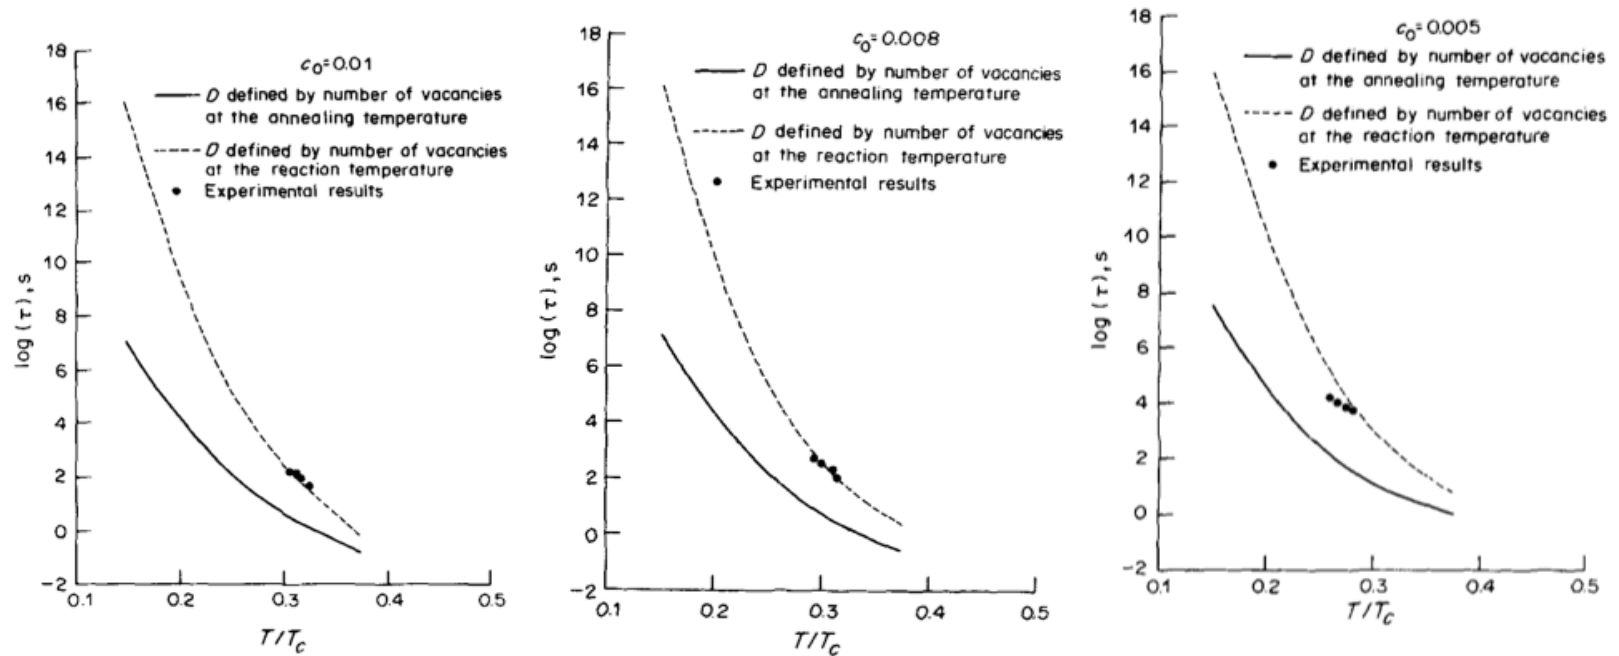

Here there is reasonably good agreement with theory assuming diffusion of Co at the aging temperature

F.K. LeGoues and H.I. Aaronson, Acta Metall. 32 (1984) 1855

Strain energy was included in the previous comparisons with theory. Here it is ignored.
F.K. LeGoues and H.I. Aaronson, Acta Metall. 32 (1984) 1855

Crucial role of excess vacancies on nucleation in Al -5.9% Zn-2.9% Mg alloys
Ternary alloy solution-treated and quenched into boiling water, below the GP zone solvus and held for (a) 0.1 min; (b) 1 min; (c) 15 min; (d) 60 min

The alloy is then aged for 3 hr at 180 °C, ABOVE the GP zone solvus, but where η' is stable, producing these microstructures

GP zones coarsen at 100 °C, aided by quenched-in vacancies, and serve as nuclei for η' at 180 °C. Depletion of excess vacancies at the GB is responsible for the width of the PFZ

G.W. Lorimer and R.B. Nicholson, Acta Metall. 14 (1966) 1009

AFOSR/AFRL/LLNL Workshop, May 2-7 2010
Maui, HI

Despite a heroic effort by LeGoues and Aaronson to test the classical theory, uncertainty remains. Depending on how you look at the results, the disagreement is as much as several orders of magnitude. The role of excess vacancies in the evolution of precipitate microstructures in Al alloys is crucial.

Can we possibly do better in testing the nucleation of precipitates in Ni-Al alloys, avoiding the problems that plague these studies in other alloys?

I think so!
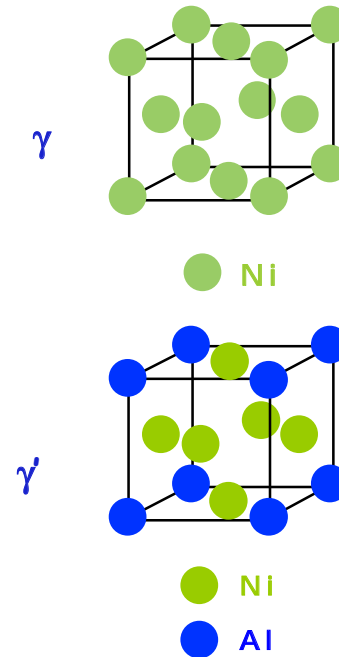

Nearly all the data in the world on the Ni-Ni$_3$Al phase diagram

How do the kinetics of precipitation of γ in γ′ compare with those of γ′ in γ ?

200 nm
Precipitation observed in a dendritic region of an alloy containing 22.25 at.% Al. The specimen was aged for 48 h at 700 °C. The kinetics are much faster in normal alloys. One contributing factor is much slower diffusion in the ordered Ni_3Al matrix in the inverse alloy. Other factors could also be important (the free energy functions for example).

Jaykumar Joshi, 2000

INVERSE ALLOYS

Ni_3Al is the matrix phase, Ni-Al is the precipitate phase

Typical aging experiment for an "inverse" Ni-Al alloy
Results on coarsening of γ precipitates in "inverse" Ni-Al alloys

Y. Ma and A.J. Ardell, Acta Mater 55 (2007) 4419

NSF
Data on the kinetics of coarsening at 650 °C. The slopes of the curves provide values of $k(f_e)$, which clearly increases with increasing f_e.

Y. Ma and A.J. Ardell, Scripta Mater. 52 (2005) 1335

AFOSR/AFRL/LLNL Workshop, May 2-7 2010
Maui, HI
$$k(0) = \frac{8 \tilde{D} v_{Al} \sigma}{9 G''_{m\gamma} \Delta X_e^2}$$

The data on $k(f_e)$ for the 5 inverse alloys aged at 650 °C were fit to the MLSW theory, yielding $k(0) = 1.7065 \pm 0.0917 \times 10^{-31}$ m^{-3}/s. As can be seen, the agreement between the MLSW theory and experiment is quite good.

Y. Ma and A.J. Ardell, Scripta Mater. 52 (2005) 1335

To calculate $\tilde{D}$ we need to know G_m''. For this we used the thermodynamic model of T. Ikeda et al.

$$G_{m\gamma}'' = \frac{4RT}{X_{Al}\left(1-X_{Al}\right)} \Phi$$

$$\Phi = X_{Al}X_{Ni}\left\{24\frac{E}{RT} + \frac{X_{Al}X_{Ni} - \frac{3S^2}{16} - \frac{S}{2}\left(X_{Ni}-X_{Al}-\frac{S}{2}\right)\left(\frac{3}{8}\frac{\partial S}{\partial X_{Al}}-1\right)}{\left(X_{Ni}-\frac{3S}{4}\right)\left(X_{Al}-\frac{S}{4}\right)\left(X_{Ni}+\frac{S}{4}\right)\left(X_{Al}+\frac{3S}{4}\right)}\right\}$$

$$\frac{\left(X_{Ni}-\frac{3S}{4}\right)\left(X_{Al}-\frac{S}{4}\right)}{\left(X_{Ni}+\frac{S}{4}\right)\left(X_{Al}+\frac{3S}{4}\right)} = \exp\left(-8\frac{ES}{RT}\right)$$

$$\frac{\partial S}{\partial X_{Al}} = \frac{S\left(X_{Ni}-X_{Al}-\frac{S}{2}\right)}{X_{Al}X_{Ni} - \frac{3S^2}{16} - 8\frac{E}{RT}\left(X_{Ni}-\frac{3S}{4}\right)\left(X_{Al}-\frac{S}{4}\right)\left(X_{Ni}+\frac{S}{4}\right)\left(X_{Al}+\frac{3S}{4}\right)}$$

S is the long-range-order parameter and E is the ordering energy

Maui, HI

Reasons why experiment on nucleation in inverse alloys are likely to succeed
Ni-22.25 at.% Al alloy solution treated at 1000 °C, quenched and aged at 700 °C for (a) 8 h and (b) 24 h.

Even though the undercooling is large (ΔT > 100 °C), nucleation is slow!
700 °C for 120 h. Only dislocations are visible in the image.
650 °C for 96 h + 730 °C for 1.5 h. Many γ precipitates visible at a small undercooling (~25 to 30 °C)
These results suggest that the incubation time for an alloy containing 22.6 % Al aged exceeds 120 h at 700 °C, but is less than 96 h at 650 °C.

These observations suggest that an investigation of nucleation kinetics in inverse Ni-Al alloys have a very good chance of being successful: f_e is small, incubation times are long, significant concentrations of excess vacancies are avoidable and except for the thermodynamics the physical parameters are reasonably well known.

Assuming that the γ' phase is an ideal solution, I obtain r* = 4.83 and 17.40 nm for the 22.25 and 22.60 % Al alloys aged at 700 °C. These are undoubtedly inaccurate, but suggest that stable nuclei should be readily visible in the TEM by either structure-factor or stain-field contrast

Is there any chance of investigating nucleation in normal Ni-Al alloys?

This was attempted years ago by Kirkwood and co-workers, Wagner & Kampmann and Xiao & Haasen without quantitative success, because nucleation of γ' is typically extremely rapid, occuring during quenching from the solution treatment temperature

It is advantageous to keep f_e small in the hope that N_v will be roughly equal to the values in the experiments of LeGoues and Aaronson ($10^{21}/m^3$). This helps minimize the issue of overlapping diffusion fields during nucleation.

Seidman and co-workers have measured N_v vs. t during the early stages of decomposition of ternary Ni-Cr-Al alloys using APT, f_e ranging from 0.10 to 0.16, N_v as large as $10^{24}/m^3$. Measured nucleation rates are 2 to almost 3 orders of magnitude slower than predicted by theory, but the physical parameters are not well constrained as they are in the binary alloy system.

An Illustration of the effect of small compositional non-uniformity on a γ' dispersion at small undercoolings

Ni-11.78 % Al aged at 630 °C for 273.5 h
The γ' precipitates are much larger in the part of the specimen with the smaller volume fraction as a consequence of the anomalous dependence of coarsening kinetics on f: Region A is slightly depleted in Al while Region B is slightly enriched

A. Maheshwari and A.J. Ardell, *Scripta Metall. Mater.* **27** (1992) 943

Can we devise a heat treatment that eliminates compositional inhomogeneities in the starting alloy, suitable for investigations of nucleation of γ′ precipitates?
Yes...We can first age a concentrated alloy (~16% Al) at a high temperature (~800 °C), producing a homogeneous matrix of γ with a concentration of 13.16% Al

then re-age this same alloy at a lower temperature (~600 °C) to produce a relatively large volume fraction of γ' (~0.17)

This aging sequence produces a bimodal distribution of γ', not unlike the bimodal and trimodal distributions found in commercial superalloys

Ni-15.91 %Al aged first for 16.67 h at 800 °C, followed by aging at 600 °C
for the times indicated
0.5 µm

288 h

D.J. Chellman and A.J. Ardell, in *Materials Architecture*, Proc. 10th Risø International
Symposium on Metallurgy and Materials Science, Roskilde, Denmark, 1989, p. 295.

The small Class II precipitates coarsen as if the large Class I precipitates were not there, until only very few of them remain. The Class I precipitates grow by consuming the Class II precipitates, not by coarsening in the conventional sense
D.J. Chellman and A.J. Ardell, in *Materials Architecture*, Proc. 10th Risø International Symposium on Metallurgy and Materials Science, Roskilde, Denmark, 1989, p. 295.

We can also use the same idea to produce very small volume fractions of γ′, comparable to the volume fractions in the dispersions of Co precipitates in Cu-Co alloys
The alloy containing 11.78 % Al is now first aged at 648 ± 2 °C for 120 h.

It is then re-aged at 630 °C for various times.

The microstructure (f_e = 0.0332) after aging for 120 h is

0.4 μm
Results of experiments on coarsening at small f_e

Specimens containing 11.66, 11.70 and 11.78 % Al were PRE-AGED a few degrees below the best estimate of the solvus temperature for each alloy for 120 to 160 h, then aged for various times at 630 °C
The rate constant DECREASES as f_e increases. It is exactly the opposite of the behavior in inverse alloys. In this sense the coarsening behavior is ANOMALOUS

A. Maheshwari and A.J. Ardell, Acta Metall. Mater. 40 (1992) 2661

Coarsening in pre-aged alloys is anomalous, but the success of the aging sequence in removing compositional fluctuations bodes well for possible investigations of homogeneous nucleation of γ' precipitates in Ni-Al alloys, which has proved heretofore impossible. The possibility of a successful investigation of nucleation is at least feasible.

Inverse alloys are not immune from compositional non-uniformity, as shown below, but they can also be heat-treated to minimize this problem

Different regions of 22.4 % Al alloy aged at 650 °C for 240 h plus 800 °C for 6 h

Summary

- The nucleation of γ′ (Ni₃Al) precipitates in normal Ni-Al alloys and γ (Ni-Al solid-solution) precipitates in "inverse" Ni-Al alloys offer the best prospects ever of investigating homogeneous nucleation during precipitation from solid solution

  ❖ Pre-aging treatments can be used to eliminate compositional variations in the parent matrix phase;

  ❖ Pre-aged normal and inverse alloys can aged at small undercoolings to produce small volume fractions of precipitates, thereby minimizing the influence of excess vacancies on diffusion;

  ❖ The important parameters needed to compare steady-state nucleation rates and incubation times, namely interfacial free energy and chemical diffusion coefficients, are known within reasonable limits for both normal and inverse alloys;

  ❖ The Gibbs free energies of mixing of both phases is perhaps not known with the same certainty, but this is always an issue;

- Just In case data on elastic constants and lattice mismatch might be useful in studies of nucleation in Ni-Al alloys...

There are now well-constrained estimates of the following quantities as well, just in case they are needed:

The "Equilibrium" Elastic Constants for Binary Ni-Al Alloys from 800 to 1200 K
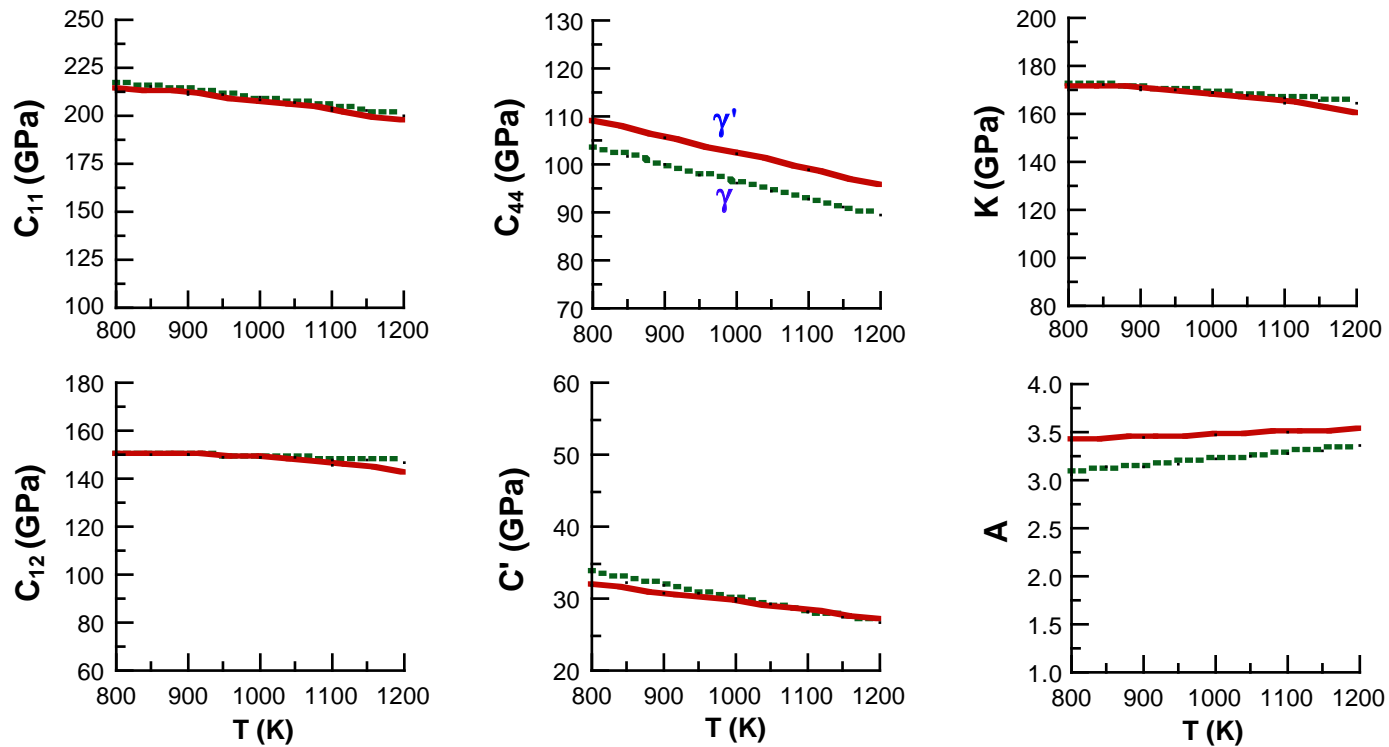

AFOSR/AFRL/LLNL Workshop, May 2-7 2010
Maui, HI

Temperature dependence of the equilibrium lattice mismatch in 4 binary Ni-X alloys

$$\varepsilon = \frac{a_{\gamma'} - a_{\gamma}}{a_{\gamma}}$$
Ferromagnetic Curie temperature as a function of Al concentration in Ni-Al solid solutions
In principle, this offers the prospect of measuring the Al content of γ nuclei

γ/γ' interfaces must become sharper the smaller the particle, e.g. as the critical radius is approached. γ' particles a few unit cells in size should have sharp interfaces to be regarded as particles of a new phase

Thanks for putting up with me!

COLONY STRUCTURES
Does the colony structure originate from elastic interactions?

C. Shen, J.P. Simmons, and Y. Wang ,2006

Focus: grain boundary nucleation

Is the grain boundary alpha structure(observed variants) nucleation dominated or growth dominated
we can devise critical experiments to test this
then determine the variant selection process under different conditions
identify the configuration at earliest stages of gb alpha formation

Can you predict variant selection at grain boundaries?
Do we have a statistical data base?
What is the structure of the nucleus: coherent or semicoherent?
Do elastic stresses play a role?
Can we understand stress relaxation at grain boundaries?
How accurately do we need to know relevant surface energies, especially grain boundary energy as a function of grain boundary orientation?

What is the origin of the colony structure at low undercooling and high growth rate conditions?
elastic stresses alone?
coupling of stresses and diffusion fields?

RECYSTALLISATION AND STRUCTURE

thermomechanical processing controls distribution and morphology of the two phases

alpha rx, beta rx

no alpha rx, beta rx with special boundaries

alpha rx, no beta rx

However , even when beta and alpha recrystallise statically or dynamically, they do so through the nucleation of recrystallised grains that grow epitaxially from existing beta or alpha phases. This is the origin of microtexture in alpha/beta titanium alloys
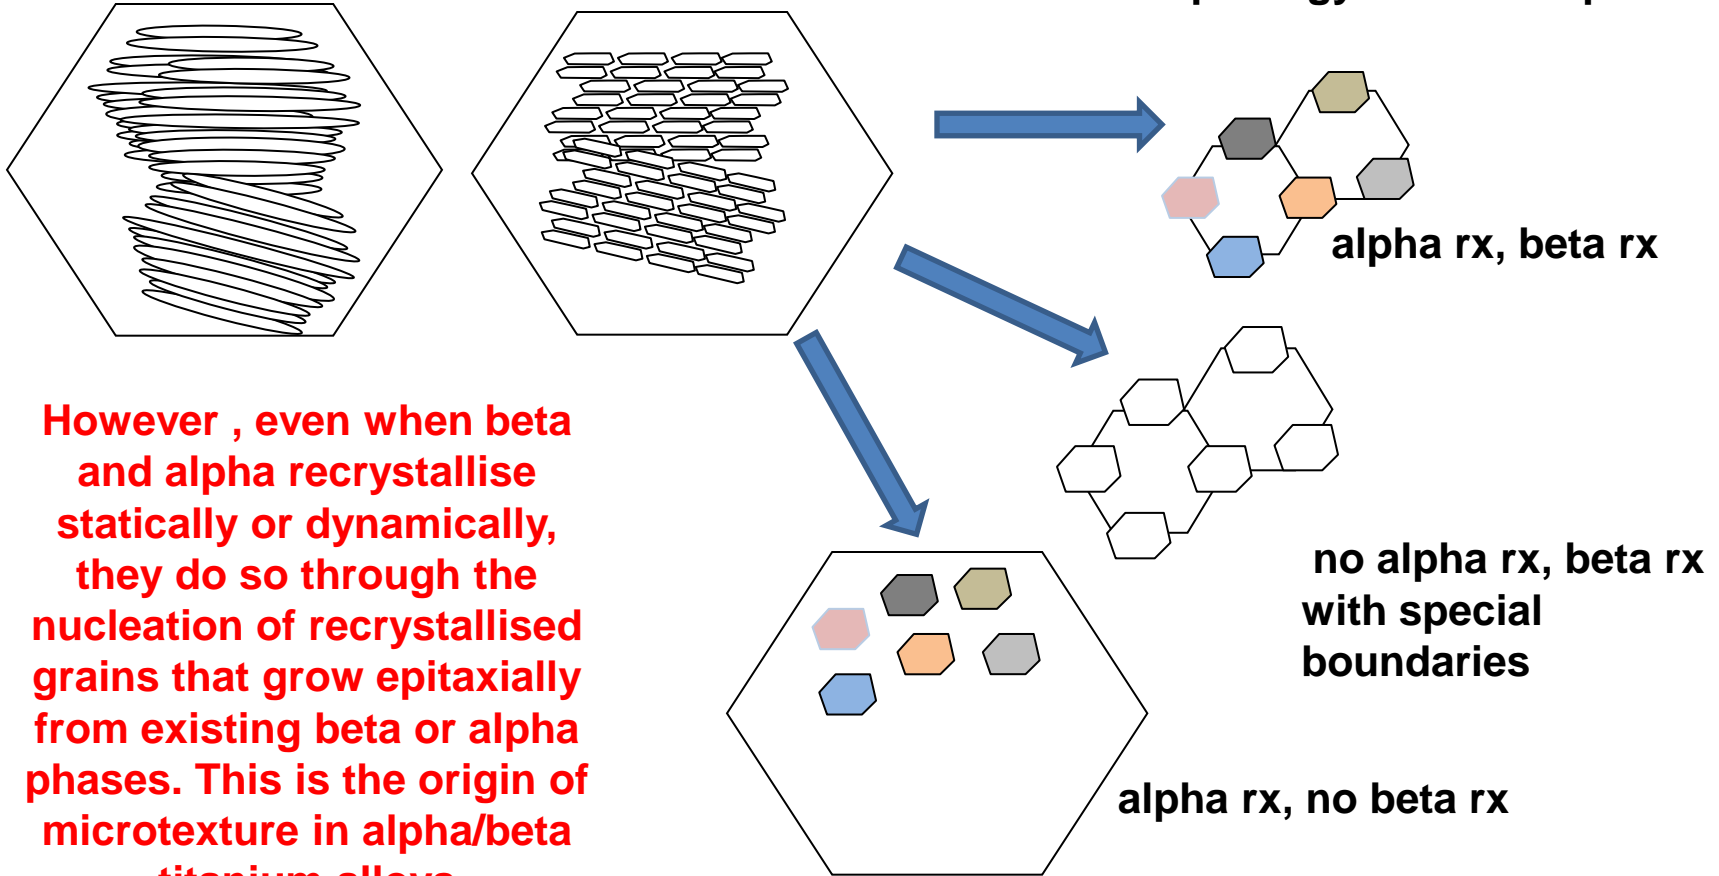

Strategies to eliminate microtexture:
• Control colony size prior to processing (section thickness effects)
• Large superplastic deformation (extensive grain rotation)
• Friction stir processing of surfaces (extensive shear and rotation)

MICROTEXTURE IN EQUIAQXED ALPHA STRUCTURES
Pilchak and Banerjee, OSU
PROCESSING AND STRUCTURE
the initiation of 'recrystallisation'
Weiss and co., 1986
subgrain formation in alpha, beta percolation

BETA RECRYSTALLISATION

The {110} poles of the beta grains are often clustered together and the relative rotation about these poles is about 60°

This happens when beta grains nucleate from parent alpha with the burgers relationship
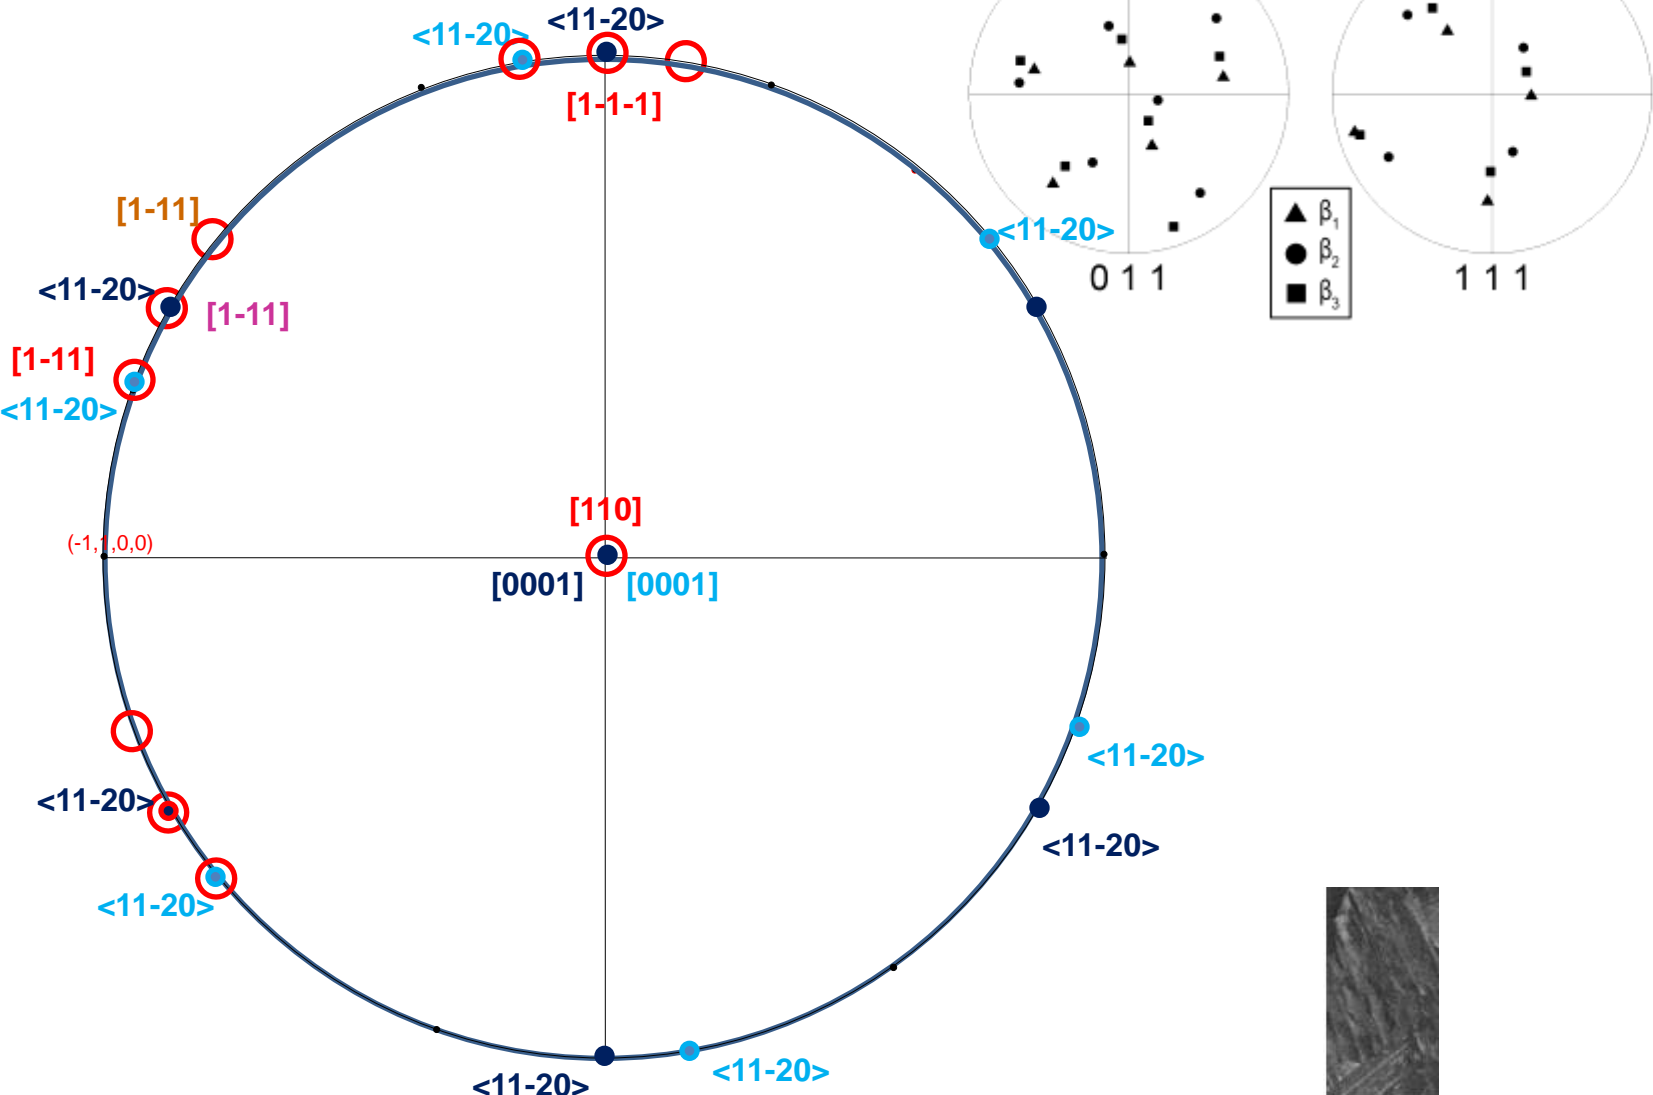

The nucleation of recrystallisation in multiphase materials?

Early Stages of Nucleation and Growth of ω Precipitates within the β Matrix of Titanium Alloys

Summary

➢ **Mechanism of β→ω transformation not completely understood**

➢ **β solutionized and quenched Ti-18Mo exhibits fine scale ω embryos**

  ➢ **Different stages of the collapse of {111} β planes –** *aberration corrected HAADF-STEM*

  ➢ **Clear evidence of Ti-Ti clustering from 3D atom probe –** *3D atom probe*

  ➢ *Phase separation in β matrix prior to ω formation?*

➢ **Subsequent annealing at 475° C/30mins**

  ➢ **well-developed ω precipitates – complete collapse of {111} β planes**

  ➢ **Substantial partitioning of Mo between β and ω**

What do we learn from experiments?

Schematic G – X plot for quenched Ti-Mo
> ➤ **Phase separation in β matrix required for ω formation in Ti-9at%Mo**
> ➤ *Mo-depleted pockets with compositions < T_0 undergo displacive collapse to form ω nuclei*
> ➤ **Is the displacive collapse complete within ω nuclei?**

Schematic G – η plots for Ti-Mo
> *Mo-depleted pockets with compositions < T_0 undergo displacive collapse to form ω nuclei*

> **Extent of displacive collapse can be incomplete within ω nuclei –** *composition dependent amplitude of phonon wave?*

Questions

➢ **Is phase separation in β matrix mandatory for ω formation in Ti-18Mo (or Ti-9at%Mo)?**

➢ **Though ω forms via a displacive collapse of {111} β planes,** *why is the collapse arrested (partial collapse) in quenched ω embryos*

    ➢ **Is the extent of collapse dependent on the composition of the ω pocket? Why?**

➢ **Is there a mixed-mode displacive-diffusional transformation involved in the formation of isothermal ω precipitates?**

➢ *We use first-principles calculations using the Vienna Ab Initio Simulation Package (VASP) coupled with the Nudged Elastic Band (NEB) transition path technique to investigate the β to ω transformation in Ti-Mo system*

Structural Evolution in the Process of Nucleation

Srikumar Banerjee

Department of Atomic Energy, India

Pacific Rim Workshop on Nucleation

May 2-7, 2010

What is Nucleation

- Creation of an assembly of atoms which **'represent'** the product phase
All symmetry elements of the product appear ⟹ At least one unit cell

"Structural Evolution in the Nucleation Process"

means

Probing the embryonic structures appearing during the evolutionary process ahead of nucleation

Outline

❑ How fluctuations in the earlier stage lead to the formation of nuclei ?

    ❑ Chemical Ordering

    ❑ Magnetic Ordering

    ❑ Displacement Ordering

    ❑ Mixed mode-displacement + chemical ordering

❑ Nucleation mediated by defects

Ordering – Chemical, ferromagnetic, ferroelectric

Atoms A & B

Chemical Ordering

Electric/ magnetic moments

Ferromagnetic Ferroelectric Ordering
Ordering & Clustering Processes

Clustering

Ordering
Disordered

Ordering & Clustering tendencies are dictated by sign & magnitude of pair & multisite interaction potentials (J's)
Evolution of Ordering: Discrete Mode (Nucleation & Growth)
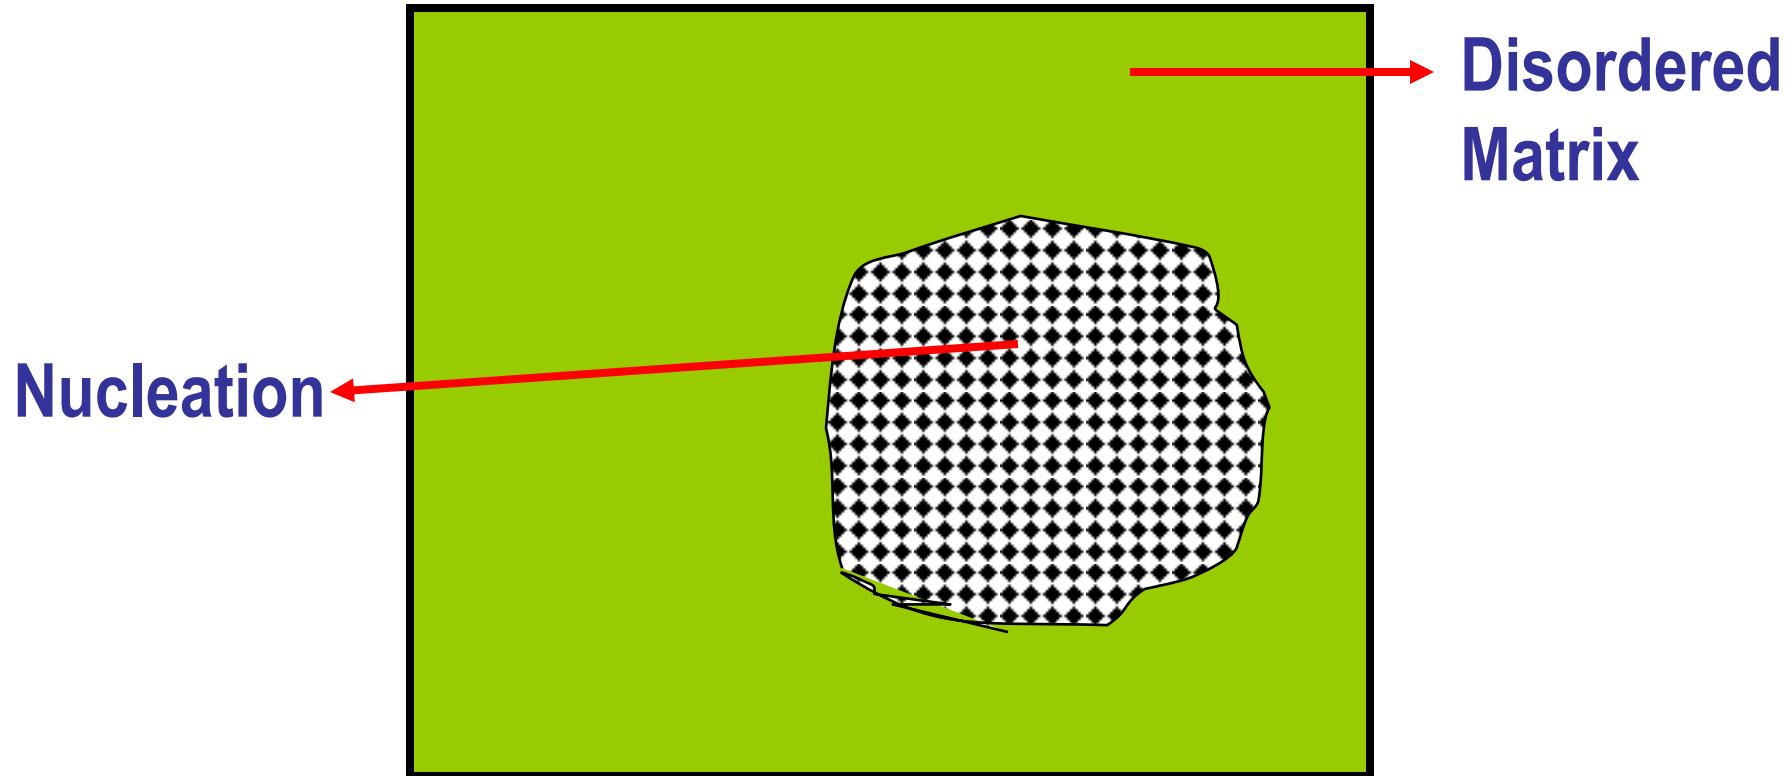

Continuous Ordering – Amplification of concentration wave
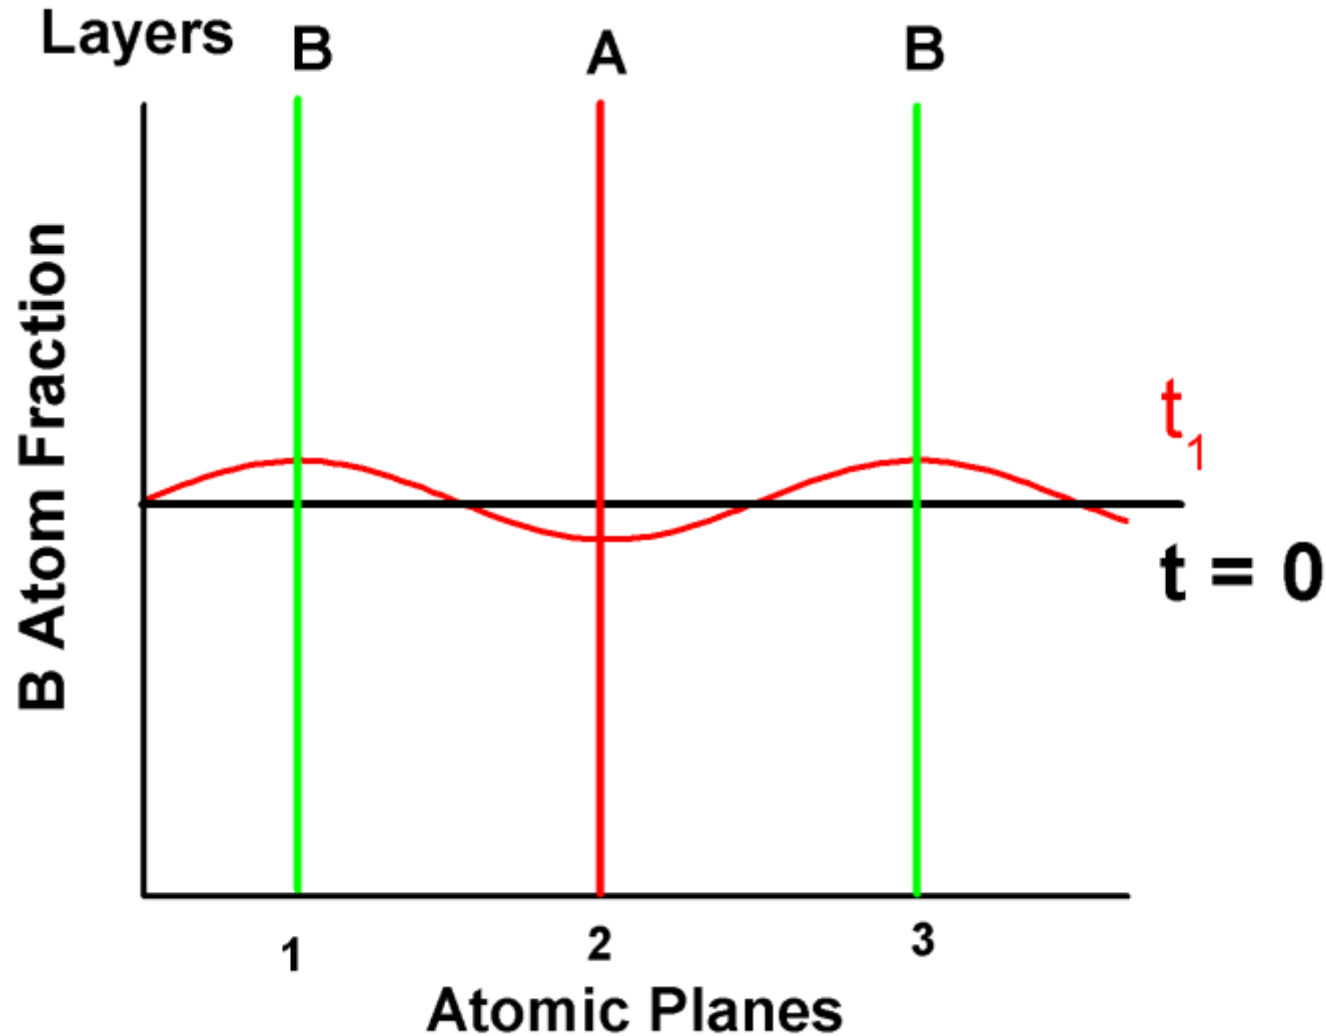

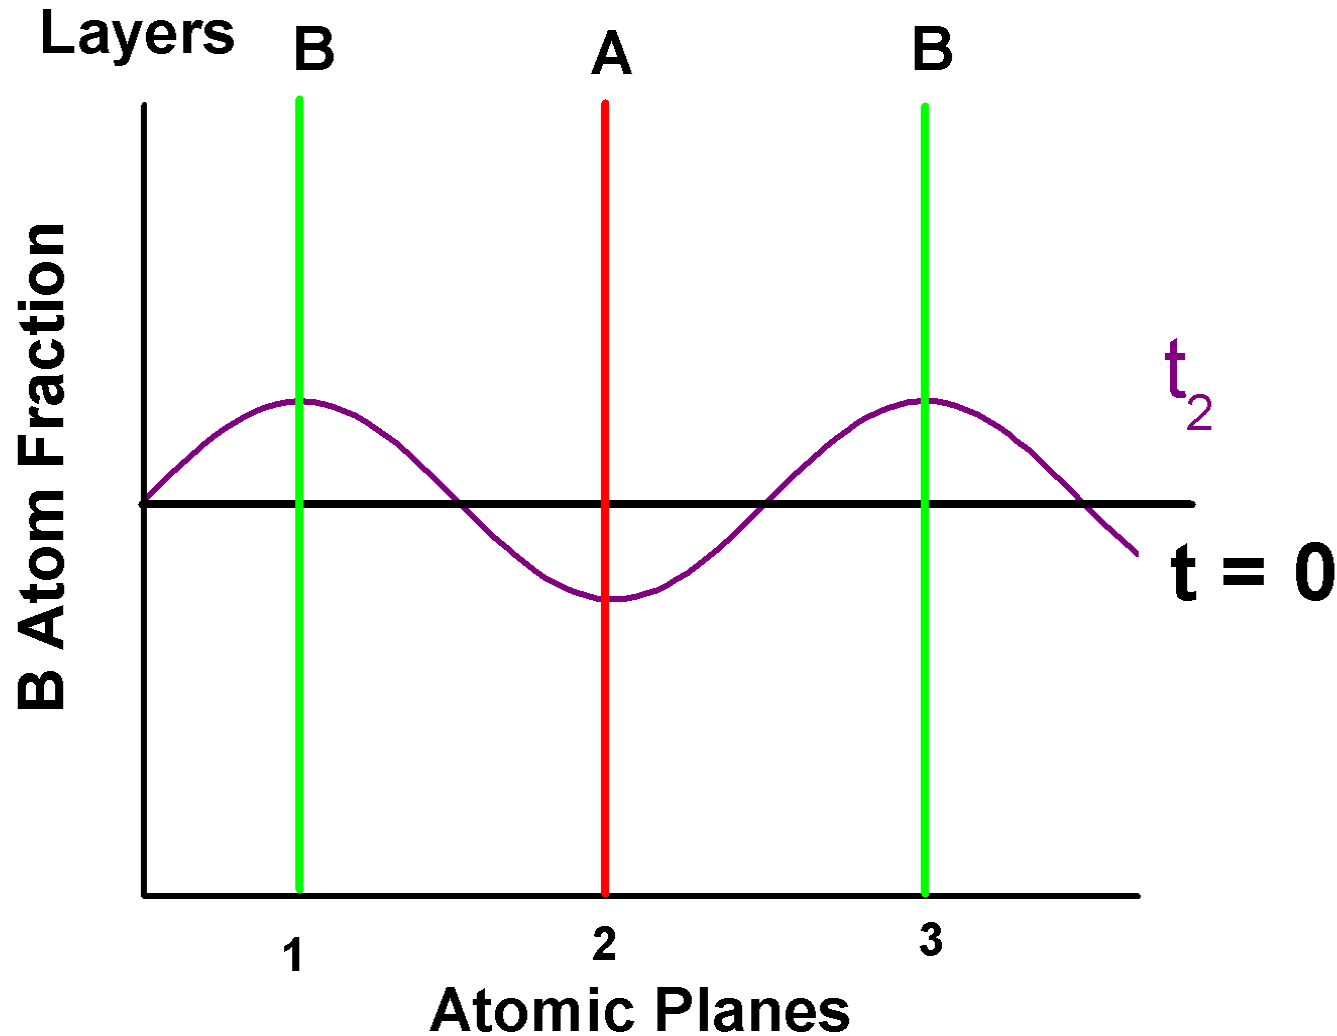

Continuous Ordering –
Amplification of concentration wave
Continuous Ordering –
Amplification of concentration wave
Continuous Ordering – Amplification of concentration wave

Continuous Ordering – Amplification of concentration wave
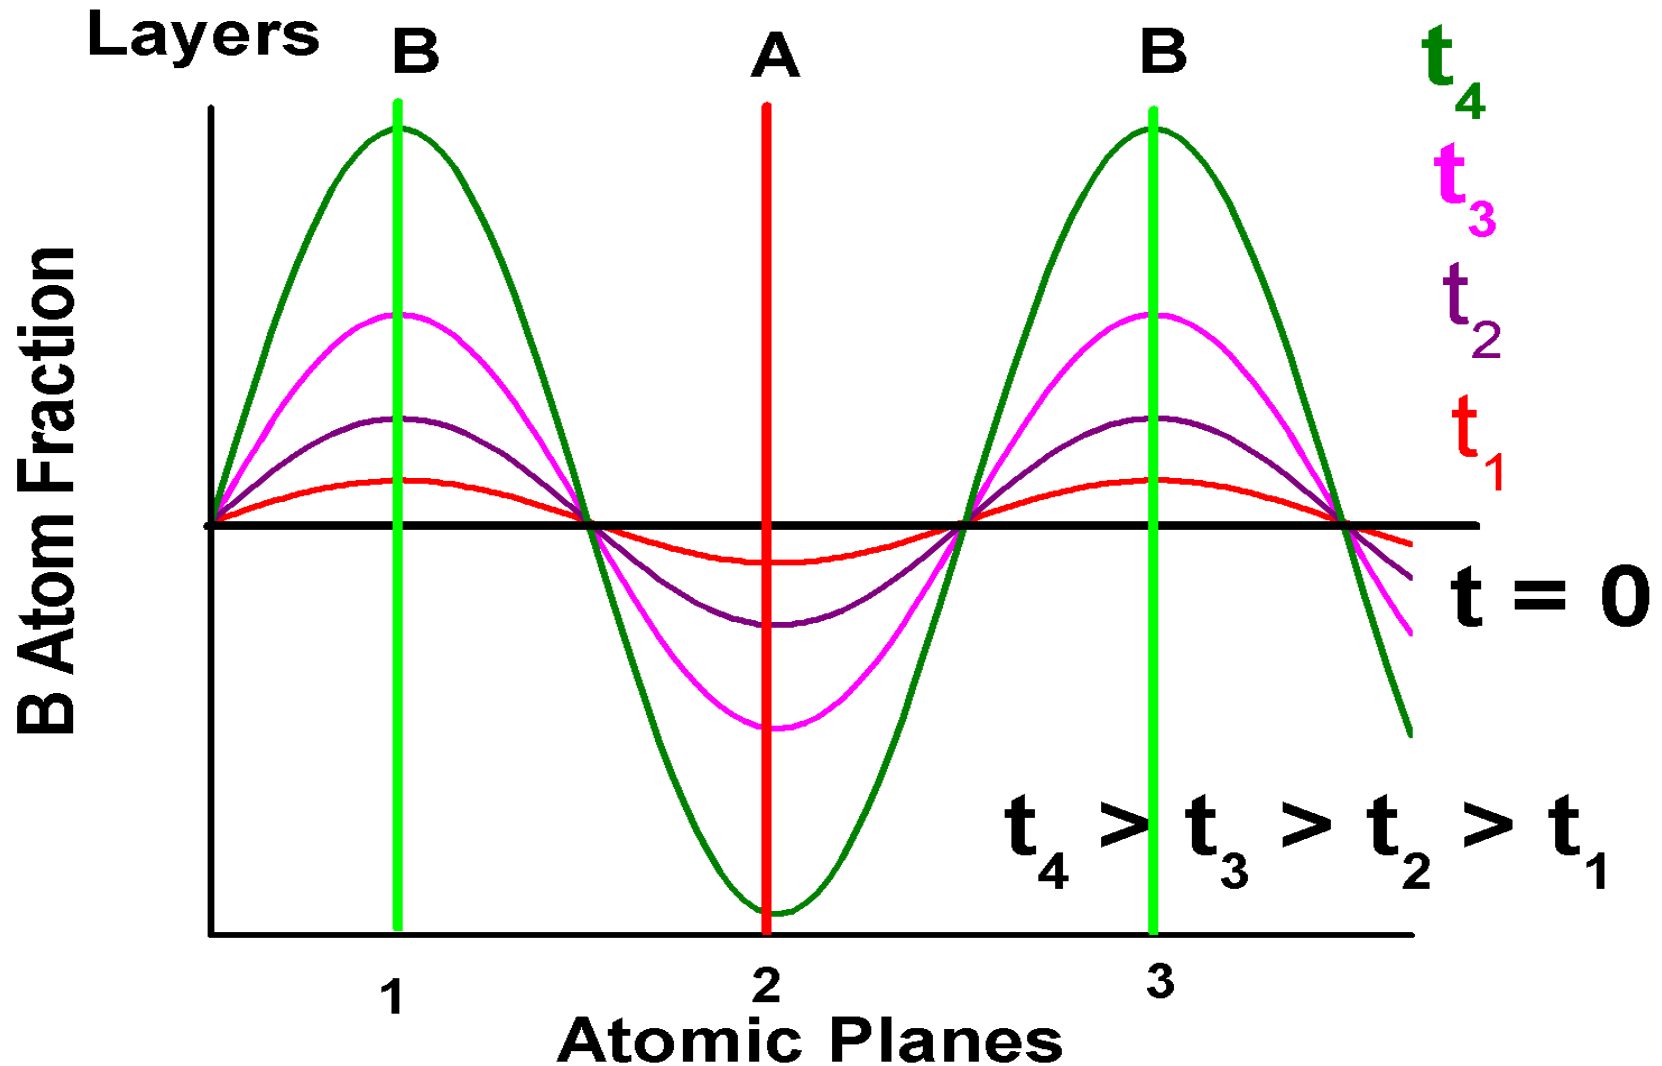

➢ Fluctuations – large in extent – small in degree

classical example – continuous decomposition of a solid solution through

   – SPINODAL DECOMPOSITION

➢ Fluctuations – small in extent – large in degree

– NUCLEATION & GROWTH

GIBB'S Criterion

Originally proposed for unmixing of fluids

If $\partial^2 G / \partial^2 c < 0$: No thermodynamic barrier for continuous phase separation

First & second order transitions: Landau Plots
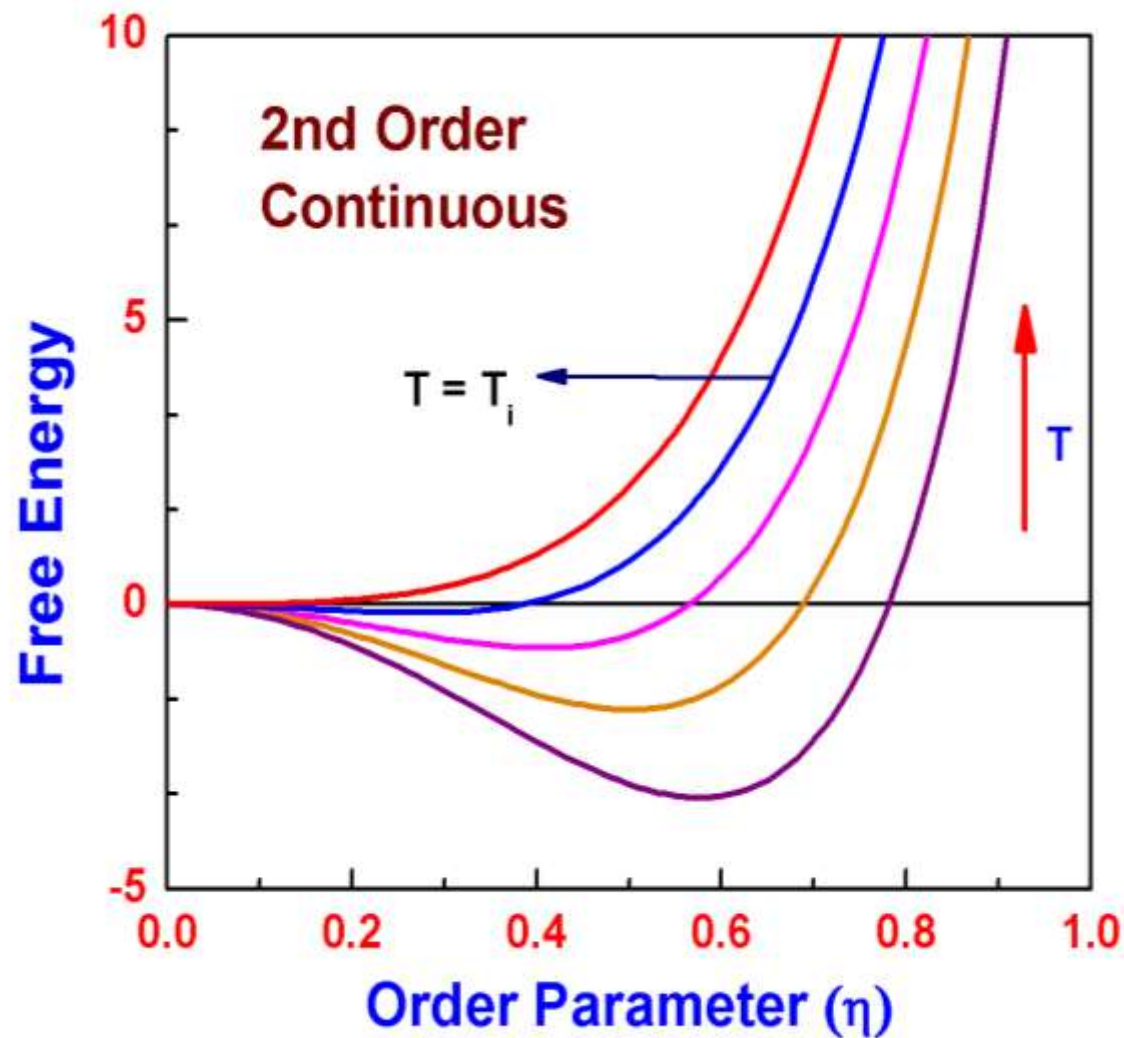

A wide range of phenomena related to order–disorder and magnetic transitions can be explained using the symmetry properties of the pair potentials (Vij).

Landau Theory of Continuous Phase Transitions

- The symmetry, **H**, of the ordered phase should be a subset of symmetry, **G**, of the disordered phase (**H** ⊂ **G**)

- The ordering wave vector must be located at the **special points** of the Brillouin zone of the disordered phase, where symmetry elements intersect at a point.

- It must not be possible to find combinations of three members of the **star*** of the ordering wave vector satisfying rule II which will sum (vectorially) to a reciprocal lattice vector (No 3rd order invariant)

  Special points are the points in the Brillouin zone where $\nabla V(k) = 0$
  For simple structures: two symmetry elements intersect at these points

  *The star associated with a vector **k** is a set of vectors obtained by applying all the Rotation or rotation-inversions on **k**.

Special Points, Stars and Ground State Structures

For bcc structure

k-vector Star	Members	Brillouin Zone Points	Ordering Structure
(000)	$[000]$	Γ	
(100)	$[100]$	H	$B2$
$\left(\frac{1}{2}\frac{1}{2}\frac{1}{2}\right)$	$\left[\frac{1}{2}\frac{1}{2}\frac{1}{2}\right]$ $\left[\overline{\frac{1}{2}\frac{1}{2}\frac{1}{2}}\right]$	P	$B32$
$\left(\frac{1}{2}\frac{1}{2}0\right)$	$\left[\frac{1}{2}\frac{1}{2}0\right]$ $\left[\frac{1}{2}0\frac{1}{2}\right]$ $\left[0\frac{1}{2}\frac{1}{2}\right]$		
	$\left[\frac{1}{2}\frac{1}{2}0\right]$ $\left[\frac{1}{2}0\frac{1}{2}\right]$ $\left[0\frac{1}{2}\frac{1}{2}\right]$	N	AB

For fcc structure

k-vector Star	Members	Brillouin Zone Points	Ordering Structure
(000)	$[000]$	Γ	
(100)	$[100]$ $[010]$ $[001]$	X	$L1_2$, $L1_0$
$\left(1\frac{1}{2}0\right)$	$\left[1\frac{1}{2}0\right]$ $\left[\frac{1}{2}01\right]$ $\left[01\frac{1}{2}\right]$	W	A_2B_2
	$\left[\overline{1}\frac{\overline{1}}{2}0\right]$ $\left[\frac{\overline{1}}{2}0\overline{1}\right]$ $\left[0\overline{1}\frac{\overline{1}}{2}0\right]$		
$\left(\frac{1}{2}\frac{1}{2}\frac{1}{2}\right)$	$\left[\frac{1}{2}\frac{1}{2}\frac{1}{2}\right]$ $\left[\frac{1}{2}\frac{\overline{1}}{2}\frac{\overline{1}}{2}\right]$	L	$L1_1$
	$\left[\frac{\overline{1}}{2}\frac{1}{2}\frac{\overline{1}}{2}\right]$ $\left[\frac{\overline{1}}{2}\frac{\overline{1}}{2}\frac{1}{2}\right]$		

Free Energy of Ordering

The configurational free energy, in the simple mean-field theory, can be expanded in a Taylor series about the homogeneous state:

$$\Delta F = F_M - F_o = \frac{N}{2} \sum_h F''(h) |X(h)|^2 +$$

$$\frac{N}{3!} f_o''' \sum_{h,h',h''} X(h) X(h') X(h'') \delta(h + h' + h''; g) +$$

$$\frac{N}{4!} f_o'''' \sum_{h,h',h'',h'''} X(h) X(h') X(h'') X(h''') \times \delta(h + h' + h'' + h'''; g)$$

$X(h)$: Fourier transform of concentration deviation from the mean value, C_o.
$V(h)$: Fourier transform of pair interaction function, V(r).
g :reciprocal lattice translational vector,.

$$F''(h) = 2V(h) + \tau / q_o$$

As amplification rate α(h) of a Fourier Component h is proportional to F''(h), is expected to mimic the V(h) function at relatively lower temperatures
Amplification rate α(h) vs. a/λ for a system inside the spinodal.

The λ_c is the critical wavelength and λ_m is the one receiving the maximum amplification
Amplification rate α(h) vs. a/λ for a Ordering system below the critical temperature

Interference of Concentration Waves Leading to the Formation of Nuclei

➤ Very early stage of the transformation is dictated by the second derivatives of free energy w.r.t. order parameter.

➤ Formation of localized clusters can be a consequence of superimposition of concentration waves. The resulting embryo can be viewed as the transformation nucleus. Superimposition of waves leads to a positive third order coefficients in LL, the condition necessary for ordering of the first kind.

➤ Phase locking causes localization of the nucleation event

➤ The final structure is determined by the deepest well in the free energy space.

**Dislocation showed the presence of nano sized defect phase
in the matrix on compressive stress field of dislocation
Self energy of the dislocation is substantially reduced by the
nucleation of the defect phase**

Possible Mechanism of fcc to bcc Transformation
It can be seen that minor flip flop of structural motifs converts the fcc to bcc with a net drop of 1% lattice parameter.

Micro-mechanical Model of the bcc Defect as Infinite Elliptical Cylinder Running Along the Core of the Dislocation
σ_{ij}^{o} stress due to dislocation at any given point

ε_{ij}^{p} constrained stress at the point due to defect,

σ_{ij} eigen strain of the defect

ε_{ij}^{*} equivalent eigen strain

Driving Force for bcc defect formation, elastic interaction energy, given by

$$W_1 = -\frac{1}{2}\int_{\Omega}\sigma_{ij}^{o}\varepsilon_{ij}^{*}\,dD - \frac{1}{2}\int_{\Omega}\sigma_{ij}\varepsilon_{ij}^{p}\,dD - \int_{\Omega}\sigma_{ij}^{o}\varepsilon_{ij}^{p}\,dD$$

Simulation of Defect Induced Strain
Predicted position of defect

Location of dislocation core
It could be shown that such defect nucleation could indeed reduce over energy of dislocation substantially

The predicted size and strain of the defect phase are close to experimental values

Summary

Homogeneous fluctuations in concentration, displacement and spin correlation mark the early stage of several transformations.

⬇
Interference of waves of different types results in localization of a transformation process

⬇
Cluster/motif mimicking partial symmetry elements of product are created.

Spatial correlations of such clusters allow establishment of all symmetry elements of the product: **Nucleation sets in**

Incommensurate Structures & Lock-in Transitions

➢ If critical star does not correspond to a special point or critical wave vectors are not commensurate with vectors of the reciprocal lattice – LL rules fail

➢ If any incommensurate wave vector, **k'**, is not very different from commensurate wave vector, **k**$_c$, one may obtain third & higher order terms in Landau functional with the possibility that sum of several vectors of the relevant star is equal to a vector of reciprocal lattice.

➢ This yields additional terms in Landau Functional called '**Umklapp'** terms.

➢ It may so happen that quadratic term favors the incommensurate state; while the quartic term favors the commensurate state. Below Tc, the latter terms dominate & one may expect an incommensurate-commensurate transition; where phase φ in the functional gets locked-in at that point.

➢ This is a **lock-in transition** driven by Umklapp terms in Landau functional.

➢ These may be treated by Soliton Theory

Local Free Energy Density $f(\phi) \approx \phi(1-\phi)(1+\phi)$

Order Parameter $\vec{\phi}(r, t)$

$$\frac{\partial \phi}{\partial t} = -\Gamma(-\nabla^2)^a \frac{\delta F}{\delta \phi} + noise$$

Kinetic Equation with Thermal Noise

What does a crystallographic-aware phase-field model of polycrystal solidification look like?

Pusztai et al., have proposed a 3D quaternion-based phase-field model
- Represents crystal orientation with quaternion order parameter
- Quaternions are widely used to analyze crystallography of polycrystal interfaces
- Quaternion algebra is fast, efficient, avoids singularities, …

Free Energy

$$F = \int \left[\frac{\varepsilon_\phi^2}{2}|\nabla\phi|^2 + f(\phi,c,T) + HT[1-p(\phi)]\left(\sum_i (\nabla q_i)^2\right)^{1/2} \right] d^3r$$

Evolution

$$\frac{\partial q_i}{\partial t} = -M_q \frac{\delta F}{\delta q_i} + \zeta_i = M_q\left[\nabla\cdot\left(D\frac{\nabla q_i}{|\nabla q_i|}\right) - 2\lambda q_i\right] + \zeta_i$$

Where q_i is the quaternion order parameter, M_q is the associated mobility and ζ is the fluctuation in q.

We have implemented the Pusztai model in our 3D AMR code
- Enhance energy functional to represent energetics of grain boundaries
- Crystal symmetry aware quaternion mathematics
- Extend energy functional to include elasticity and alloy concentration

Refs: T. Pusztai, G. Bortel, and L. Granasy, "Phase field theory of polycrystalline solidification in three dimensions," Europhys. Lett, 71 (2005) 131-137; R. Kobayoshi and J.A Warren, "Modeling the formation and dynamics of polycrystals in 3D," Physica A 356 (2005) 127-132.

Quaternions are used extensively to represent rotations, e.g. in computer graphics (games)

Complex numbers have the form, a + ib, and multiplying by $e^{i\theta}$ produces rotation by an angle θ in the complex plane
Quaternions have the form, a + ib +jc +kd, where $i^2=j^2=k^2=ijk=-1$. A rotation about the unit vector $\hat{n}$ by an angle θ can be computed using the unit quaternion:

$$(s,v) = (\cos(\frac{\theta}{2}), \hat{n}\sin(\frac{\theta}{2}))$$

We assign to each atom a quaternion that best represents the local value of the Q6 order parameter with the smallest rotation from a reference unit cell.
The associated quaternion enables quick calculation of the rotation between two misoriented grains (c.f. Reed et.al Acta Cryst. (2004) A60, 263-277)

Model Problem: Single Spherical Grain (2D with scalar order-parameter)
We obtain strong scalability to thousands of processors by leveraging LLNL's investment in parallel computing (e.g. SAMRAI)

What is spallation fracture?

HE Shock
Free Surface

Rinehart and Pearson, "Behavior of Metals Under Impulsive Loads," 1954
Gas Gun Impact Experiment

Meyers, "Dynamic Behavior of Materials," 1994, Barbee, 1972

Spallation fracture is an internal rupture process when strong shock waves interact in solids. The dynamic fracture of ductile metals occurs through the nucleation, growth and linking of microscopic voids.

Phase Field Simulation of Critical Nuclei Morphology in Solid State Transformations

Qiang Du

Department of Mathematics, Penn State University

With Lei Zhang, Long-Qing Chen

Joint ARL/AOARD/LLNL Workshop on Nucleation During Solid-Solid Phase transformations, Maui, 2010

Nucleation

Nucleation: a process where clusters of atoms form via fluctuations in a meta-stable phase with those beyond certain critical threshold grow.

Significance: predicting nucleation rate and its dependence on composition and temperature is an interesting and challenging problem in materials sciences, given the complex energy landscape in high dimension and the unstable nature of saddle/transition points.
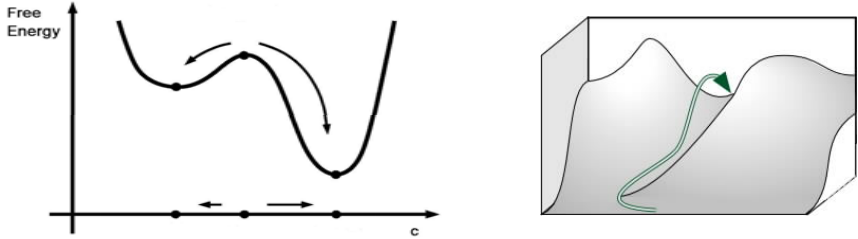

I. Problem/Objective

The importance of the problem and the challenging computational nature motivated our recent studies:

- to build rigorous mathematical foundation to the models of nucleation;

- to develop algorithms needed in the computational study of nucleation in solid state transformations;

- to develop methods and codes for the computation of the critical nucleus shape/size and nucleation rate.

II. Approach: Critical nuclei morphology via the large deviation principle

- **Large Deviation Principle: for a Langevin system, the most probable transition path between local energy wells, in the zero fluctuation limit and without any time limitation, is the minimum energy path (MEP) connecting the equilibria.**

- **The lowest energy barrier is given by the largest energy difference reached on the MEP**

- **Points on the MEP with the highest energy: saddle points (unstable critical point) with a minimax property**

II. Approach: diffuse interface/phase field

- **We work with the diffuse interface/phase field framework.**

- **We develop/implement suitable algorithms (minimax method/constrained string method) to gather information on the saddle point and minimum energy path (transition pathway) which helps to determine the nucleation rate and the critical nuclei profiles**

- **We incorporate the gathered information into phase field simulations of the nucleation and growth processes**

II. Approach: Phase Field and Nucleation

In existing phase field simulations, nucleation mostly are treated either via Monte Carlo or classical theory

Classical theory: nucleus shares the same thermodynamic properties as the equilibrium with assumed shape *a priori* .

Non-classical: Cahn-Hilliard, diffuse interface

Free energy
$$\int_\Omega \left(\frac{\epsilon}{2} |\nabla \phi|^2 + \frac{1}{4\epsilon}(\phi^2 - 1)^2 + \lambda(3\phi - \phi^3) \right) dx$$

λ: driving force ε: interfacial width Ω unit periodic cell

II. Approach: Cahn-Hilliard theory

Nonclassical theory of Cahn-Hilliard considers bulk and interfacial energy contributions but not the contribution due to the anisotropic elasticity energy

$$\int_\Omega \left(\frac{\epsilon}{2}|\nabla\phi|^2 + \frac{1}{4\epsilon}(\phi^2 - 1)^2 + \lambda(3\phi - \phi^3) \right) dx$$
Profile of critical nuclei,

consistent with classical theory
in the thin interface limit

II. Approach: Energy and Nucleation

Solid state phase transformations:

Energy contribution: bulk + interfacial + elastic

$$\int_\Omega \left(\frac{\epsilon}{2} |\nabla \phi|^2 + \frac{1}{4\epsilon}(\phi^2 - 1)^2 + \lambda(3\phi - \phi^3) \right) dx + E_e$$

Misfit Elastic Energy:
 via Khachaturyan's micro-elasticity theory

$$\frac{\beta}{2} \int_{\hat{\Omega}} \frac{dk}{(2\pi)^d} B(n_k) |\hat{\eta}(k) - \hat{\eta}_0(k)|^2$$

III. Examples: first, a proof of concept

- A single order parameter: isotropic/anisotropic elastic energy
- Elastic energy

$$\frac{\beta}{2} \int_{\widehat{\Omega}} \frac{dk}{(2\pi)^d} B(n_k) |\widehat{\eta}(k) - \widehat{\eta}_0(k)|^2$$

$$B(n) = 3(c_{11} + 2c_{12})\epsilon_0^2 - (c_{11} + 2c_{12})^2 \epsilon_0^2 \cdot$$

$$\cdot \frac{1 + 2\zeta s(n) + 3\zeta^2 n_1^2 n_2^2 n_3^2}{c_{11} + \zeta(c_{11} + c_{12})s(n) + \zeta^2(c_{11} + 2c_{12} + c_{44})n_1^2 n_2^2 n_3^2}$$

$$\zeta = (c_{11} - c_{12} - 2c_{44})/c_{44} \quad \text{elastic anisotropic factor}$$

$$s(n) = n_1^2 n_2^2 + n_1^2 n_3^2 + n_2^2 n_3^2$$

ϵ_0 lattice mismatch, $\quad \Omega$ **periodic cell** $\quad \widehat{\Omega}$ reciprocal domain

II. Approach: energy functionals for diffuse/sharp interface
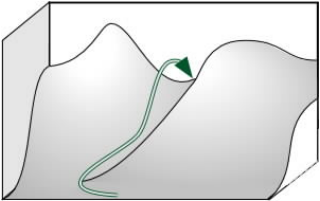

$$E_\epsilon(\eta) = \int_\Omega [\frac{\epsilon}{2}|\nabla\eta|^2 + \frac{1}{4\epsilon}(\eta^2-1)^2 + \frac{\lambda}{2}(3\eta-\eta^3)]dx$$

$$+\frac{\beta}{2}\int_{\widehat{\Omega}} \frac{dk}{(2\pi)^d}B(n_k)|\widehat{\eta}(k)-\widehat{\eta}_0(k)|^2$$

Sharp interface limit: $\varepsilon \longrightarrow 0$

$$E_0(v) = \int_\Omega (\frac{\sqrt{2}}{3}|\nabla v| + \lambda v) + \frac{\beta}{2}\int_{\widehat{\Omega}} B(n)|\widehat{v}(k)-\widehat{\eta}_0(k)|^2$$

if $v \in BV(\Omega, \{\pm 1\})$, and $E_0(v) = \infty$ otherwise.

Zhang-Chen-D. 2007

II. Approach: saddle point of diffuse interface energy

$$E_\epsilon(\eta) = \int_\Omega [\frac{\epsilon}{2}|\nabla\eta|^2 + \frac{1}{4\epsilon}(\eta^2-1)^2 + \frac{\lambda}{2}(3\eta-\eta^3)]dx$$
$$+ \frac{\beta}{2}\int_{\hat\Omega}\frac{dk}{(2\pi)^d}B(n_k)|\hat\eta(k)-\hat\eta_0(k)|^2$$

With periodic boundary condition:
a) the energy satisfies the Palais-Smale condition;
b) for small ε, there is a nontrivial saddle point
   connecting two trivial local minima

Zhang-Chen-Du 2008 J. Sci. Comp., Barrett lecture special issue

II. Approach: numerical method

Most of our algorithms for computing MEP/Saddle point are based on:

Minimax method : classical calculus of variation.
Rabinowitz 1986; Choi, 1993; Lin, 1997; Zhou, 2001

String method: more recently developed
W. E, W. Ren and E. Vanden-Eijnden, 2002

With suitable modifications (for conserved variables) and high order, adaptive implementation

III. Example: first, a proof of concept

- A single order parameter describing structural difference with an anisotropic elastic energy
Critical nuclei with increasing elastic energy contributions
(Zhang, Chen, Du, PRL, 2007, Acta Mater., 2008)

III. Example: effect of anisotropic elasticity – 2d

Zhang-Chen-Du PRL 2007

Formation energy

Insert: critical nuclei shapes
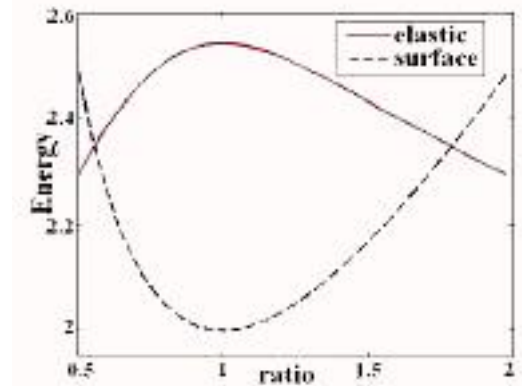

Elastic energy contribution (changing β)

b

b

a<b

a>b

III. Example: simulations of 3D critical nuclei
Saddle point branches with varying elastic energy contribution

III. Example: most probable 3D nuclei morphology
Free energy with various elastic energy contribution

- **Composition profile: c(x)**
- **Total free energy increase:**

$$E_{total}(c) = \int_{\Omega} [f^c(c) + \frac{\alpha}{2}|\nabla c(x)|^2]\, dx + \beta \cdot E^{elastic}$$

where $\quad f^c(c) = f(c) - f(c_0) - \frac{\partial f(c)}{\partial c}\Big|_{c=c_0}$

and $\quad f(c) = \frac{1}{4}(c^2 - 1)^2$
- **The volume constraint is** $\quad \int [c(x) - c_0]\, dx = 0$

- **MEP gets modified when one or more constraints are imposed**

III. Example: an illustration of constrained MEP

- **3-D potential energy** $E(x,y,z) = (1 - x^2)^2 + y^2 + 2z^2$

  with the constraint $x^2 + y^2 + z^2 - 1 = 0$

- **Containing the two energy wells of E:** $(\pm 1, 0, 0)$
MEP without constraint and constrained MEP

- **We developed a constrained string method via augmented Lagrange multipliers to compute MEP**

III. Example: nucleation with a single conserved field

- **Critical nucleus, equilibrium solution, and MEP**

$(1) c_0 = -0.95$
$(2) c_0 = -0.85$
Zhang, Chen, Du, Comm. Comp. Phys., 2010

- **MEP with increasing elastic energy in conserved field**
Critical nuclei morphology can be very different from that of the equilibrium!

- **Compare with critical nuclei in the non-conserved field**
III. Example: nucleation involving multiple order parameters

- **Extensions to more complicated systems, in particular, those with multiple order parameter fields**

  ➢ **A case of two non-conserved phase field order parameters representing different orientation variants**

  ➢ **A case of a conserved field (composition) with a non-conserved field (order parameter):**
  θ' precipitates in Al-Cu alloys
  γ' precipitates in Ni-Al alloys

III.Example: two non-conserved order parameters

Type 1: Critical nucleus

Type I: Equilibrium state

Equilibrium state

One type of critical nuclei
Another type of critical nuclei
III.Example: two non-conserved order parameters

- **Type II: Equilibrium state**

First type of critical nuclei

Third type of critical nuclei
Second type of critical nuclei
III.Example: One conserved + one nonconserved

Applications are now considered for Ni-Al and Al-Cu alloys involving both conserved and nonconserved fields

Example (in progress): θ' precipitates in Al-Cu alloy, with data from L.Q. Chen/T.W. Heo

Parent phase
(Al-Cu solid solution (α phase))

Coherent

θ' precipitate

Semi-coherent
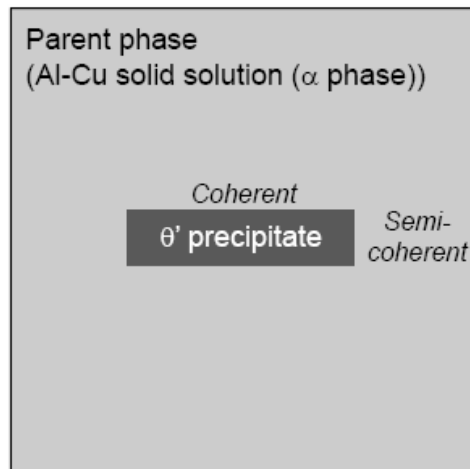

θ' precipitate
$$\eta = 1 \text{ (or -1)}$$
$$c = c_{eq,\theta'}$$

Parent phase (Al solid solution)
$$\rightarrow \eta = 0$$
$$c = c_{eq,matrix}$$

III.Example: integrating dynamic phase field simulations with diffuse-interface nuclei computation

Solving dynamic Allen Cahn equations, using a classical nulceation event sampling (Simmons 2000), but with nucleation via diffuse interface nuclei computation
Heo, Zhang, Du, Chen, 2010 Scripta Mat.

III.Example: integrating dynamic phase field simulations with diffuse-interface nuclei computation

The growth of a single nucleus via Allen-Cahn

700 time steps   39000 time steps

62400 time steps   78000 time steps
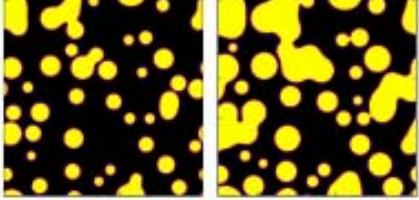

III.Example: phase field simulations with diffuse-interface nuclei and classical nucleation theory

Comparison with the phase transformation kinetics using the classical nucleation and normal growth theory and the Kolmogorov-Johnson-Mehl-Avrami equation

50000 time steps   80000 time steps

100000 time steps   150000 time steps

Legend:
- Diffuse-interface nucleation and growth
- KJMA's interpretation (fixed growth rate)
- KJMA's interpretation (varying growth rate)

$$I = I_0 \exp(-\Delta G^*),$$

$$f(t) = 1 - \exp(-\frac{\pi \cdot I \cdot u^2}{3} t^3),$$

Area fraction ($f(i)$) vs Time step (i)

(b)
IV. Observation/Conclusion: phase field/diffuse interface

- **Phase field type methods are insensitive to topological changes (advantage/deficiency?**

- **How about the detection/control of topology of the implicitly defined surfaces? (or for collecting statistics)**

- **Formulae were developed to detect /control topology change in shape transformation via Euler number**

- **Providing interesting statistics of large scale simulations and connecting geometry with topology: the key is to effectively estimate curvatures in the diffuse interface framework**

Du -Liu-Wang SIAM Appl Math 2005

IV. Observation: Euler-Poincare index in Phase Field

- In 3d:

$$\chi = \frac{1}{4\pi(b-a)} \int_{\Omega_a^b} |\nabla\phi|^{-1} \Lambda(M) d\Omega$$

$$M = c(\nabla^2\phi - (\nabla|\nabla\phi|^2 \cdot \nabla\phi)|\nabla\phi|^{-4}\nabla_i\phi\nabla_j\phi)$$
- In 2d:

$$\chi = \frac{1}{2\pi(b-a)} \int_{\Omega_a^b} F d\Omega$$

$$F = c(\nabla^2\phi + (\nabla|\nabla\phi|^2 \cdot \nabla)|\nabla\phi|^{-2}/2$$

Phase-field Based Euler number!

Simplified versions possible
Du–Liu-Ryham-Wang *2007 CMS*

IV Conclusion

Goals: rigorous mathematical description and robust algorithms and codes for nucleation in solid-state transformation.

Progress: methods to compute diffuse-interface critical nuclei; some stand-alone codes for single order parameter already available; demonstration of integration with phase field dynamic simulations.

Collaborators: L. Zhang, L.-Q. Chen, T.W. Heo

Thanks: support from NSF-ITR (2002-2007), NSF-IUCRC CCMD

A coarse grained derivation of the Phase Field equations

A. Finel

Q. Bronchart , Y. Le Bouar,

Laboratoire d'Etudes des Microstructures
ONERA-CNRS, Chatillon

Why Phase Field modeling (1) ?

→ Mesoscopic modeling:

- large scale simulation (µm³)

- easy to incorporate elastic effects

- extended to dislocation dynamics (plasticity), fracture, voids ...

- polycrystals, grain boundaries...

Microstructures in γ/γ'

Formation and ageing of bimodale microstructures in γ/γ'

$1\mu m$

300 nm
Sequiera et al, Scripta Met. Mat., 30(1994)

0.5 µm
Boussinot et al.,
Acta Mat (2009)

from Chellman et al. (1989)

Directional coarsening under external stress (rafting): phase field + viscoplasticity

$10\ \mu m$
Phase Field + viscoplasticity
Gaubert et al., Phil. Mag. (2010)

Caron et al. (2002)

Why Phase Field modeling (2) ?

→ Mesoscopic modeling:

- large scale simulation (μm^3)

- easy to incorporate elastic effects

- extended to dislocation dynamics (plasticity), fracture, voids ...

- polycrystals, grain boundaries...

Ex : Shape memory alloys: the martensitic transition
→ Phase Field simulation in Ti-Ni:

- heterogeneous precipitation of
  R phase along a screw dislocation
- elastic accomodation
- thermoelastic equilibrium

Questions

→ Transitions driven by fluctuations : nucleation

- how well can the Phase Field method reproduce nucleation ?

- how to intruduce fluctuations in a consistent way ?

- what is the meaning of a local free energy density ?

- which fluctuations are already incorporated into this free energy density ?

Q. Bronchart, Y. Le Bouar, and A. Finel, Phys. Rev. Lett., vol.100 (2008) 015702

Introduction (1)

→ basics of the Phase Field method:

- consider a simple miscibility gap:

- "good" order parameter: concentration field: $c(r,t)$
- free energy:
  (Ginzburg-Landau)

$$F_{tot}(\{c(r,t)\}) = \int d_3r \ f_{homo}[c(r,t)] + \frac{\lambda}{2} \, ||\nabla \, c(r,t)||^2$$

- kinetics:
  (Cahn-Hilliard-Cook)

$$\frac{\partial \, c(r,t)}{\partial \, t} = \nabla M(c)\nabla \frac{\delta F_{tot}}{\delta \, c(r,t)} + \eta(r,t)$$

$$\lim_{t\to\infty} P(\{c(r),t\}) = P_{eq}(\{c(r)\}) \sim \exp(-\frac{F_{tot}(\{c(r)\})}{kT})$$

Fluctuation-dissipation theorem

$$< \eta(r,t) \, \eta(r',t') > = -2 \, kT \, \nabla M(c)\nabla\delta(r - r') \, \delta(t - t')$$
$$\to \qquad f_{homo}(c) = ? \quad \lambda = ?$$

$$M(c) = ?$$

Introduction (2)
$$\rightarrow \quad f_{homo}(c) = ? \quad \lambda = ?$$

→ phenomenological expansion (Landau free energy) and theory with no fluctuations :

fitted on phase diagram, interface energy :
$$f_{homo}(c) = \Delta F \; \frac{(c - c_1)^2 \, (c - c_2)^2}{[\,(c_2 - c_1)\,/\,2\,]^4}$$
interface energy : $\quad \sigma \; = \; \dfrac{2\sqrt{2}}{3} \, (c_2 - c_1) \, \sqrt{\lambda \, \Delta F}$

interface thickness : $\quad \xi \; = \; \dfrac{\sqrt{2}}{4} \, (c_2 - c_1) \, \sqrt{\dfrac{\lambda}{\Delta F}}$

but $\xi_{exp} \simeq 1nm$!!

$$\lambda \quad \nearrow \qquad \Delta F \quad \searrow$$

$$\sigma \; = \; \text{cte}$$
$$\rightarrow \quad f_{homo}(c) = ? \quad \lambda = ?$$

$\rightarrow$ time scale for nucleation:

   interplay noise / nucleation barrier

   (depends on metastable free energies)

$\rightarrow$ phenomenological expansion (Landau free energy) $\rightarrow$ status of metastable regime ?

$\rightarrow$ use of thermo. database in the Calphad spirit (ThermoCalc) $\rightarrow$ status of metastable regime ?

$\rightarrow$ atomistic model (Ising type) + Mean Field + small q expansion $\rightarrow$ status of the fluctuations ?

$\rightarrow$ Questions:

   1. Status of the metastable free energies ?

   2. Critical analysis of the Phase Field equations: mobilities, noise ?

   $\rightarrow$ need a coherent formulation that "solves" simultaneously 1 and 2

Phase Field method: how to get the basic equation (1)

→ Starting point: Microscopic master equation

- atomic configuration:

$$\mathcal{C} = (....p_i.....p_j.....) \qquad p_i = 0 \text{ or } 1 \text{ if } A \text{ or } B \text{ on site } i$$

- kinetic model: direct exchange between A and B on 1st neighbor sites

$$\frac{\partial P(\mathcal{C})}{\partial t} = -\sum_{i,j}^{*} W(\mathcal{C} \to \mathcal{C}^{ij})P(\mathcal{C}) + \sum_{i,j}^{*} W(\mathcal{C}^{ij} \to)P(\mathcal{C}^{ij})$$

- transition probability:

local mechanism:

    direct exchange through saddle point (G. Martin, Phys. Rev. B, 1990)

$$W(\mathcal{C} \to \mathcal{C}^{ij}) = \theta \, \exp -\beta(2E_{saddle} - h_i^A(\mathcal{C}) - h_j^B(\mathcal{C})) \, \delta(p_i)\delta(p_j - 1)$$

$h_i^A(\mathcal{C})$: interaction energy between site i and the other sites if i is occupied
      by atom A

if pair interactions only: $h_i^A(\mathcal{C}) = \sum_{j} V_{ij}^{AA} p_j + V_{ij}^{AB}(1 - p_j)$
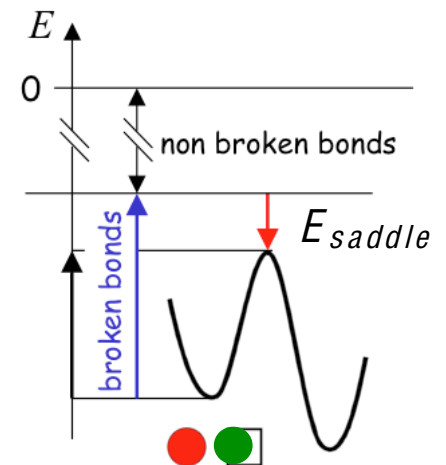

Phase Field method: how to get the basic equation (2)

→ Mesoscopic scale :

cell of volume d^3

d

$N_d = \dfrac{d^3}{a^3}$
mesoscopic ← $\qquad c_n = \dfrac{1}{N_d} \sum_{i \in n} p_i \qquad$ → microscopic

- average out microscopic fluctuations of wavelength < d

- keep mesoscopic fluctuations of wavelength > d

$$\widetilde{\mathcal{C}} = (\dots c_n \dots c_m \dots) \qquad\qquad P(\widetilde{\mathcal{C}}) = \mathrm{Tr}_{\mathcal{C}/\widetilde{c}}\, P(\mathcal{C})$$

→ Mesoscopic master equation:

$$\dfrac{\partial P(\widetilde{\mathcal{C}})}{\partial t} = \mathrm{Tr}_{\mathcal{C}/\widetilde{c}}\, \dfrac{\partial P(\mathcal{C})}{\partial t}$$

Phase Field method: how to get the basic equation (3)

→ need simplification:

site i ⌢ site j

cell n cell m d
1) "quasi-static" approximation: Markov process (time scale available $\tau \gtrsim d^2/D$)

| microscopic fast | $\mathcal{C}$ in quasi-equilibrium with $\widetilde{\mathcal{C}}$ → | mesoscopic slow |
$$P(\mathcal{C}) \simeq P(\widetilde{\mathcal{C}}) \; \frac{\exp -\beta H(\mathcal{C})}{\mathrm{Tr}_{\mathcal{C}/\widetilde{c}} \; \exp -\beta H(\mathcal{C})}$$

mesoscopic averaging:

$$< X(\mathcal{C}) >_{\mathcal{C}/\widetilde{c}} = \frac{\mathrm{Tr}_{\mathcal{C}/\widetilde{c}} \; X(\mathcal{C}) \; \exp -\beta H(\mathcal{C})}{\mathrm{Tr}_{\mathcal{C}/\widetilde{c}} \; \exp -\beta H(\mathcal{C})}$$

2) small fluctuations between cells: *if cells large enough*

$$< ...f(i \in n)...f(j \in m... >_{\mathcal{C}/\widetilde{c}} \sim < ...f(i \in n)... >_{\mathcal{C}/\widetilde{c}} < ...f(j \in m... >_{\mathcal{C}/\widetilde{c}}$$

Phase Field method: how to get the basic equation (4)

→ Master equation becomes:

$$\frac{\partial P(\tilde{\mathcal{C}})}{\partial t} = -N_d \; \frac{a}{d} \; \theta \; e^{-2\beta E_{col}} \; \sum_{n,m}^{*} e^{\frac{\beta}{2}(g_n^A(\tilde{\mathcal{C}})+g_n^B(\tilde{\mathcal{C}})+g_m^A(\tilde{\mathcal{C}})+g_m^B(\tilde{\mathcal{C}}))} \; e^{\frac{\beta}{2}\frac{a}{d}(\mu_m(\tilde{\mathcal{C}})-\mu_n(\tilde{\mathcal{C}}))} \; P(\tilde{\mathcal{C}})$$

$$+ \; (\text{gain term})$$

mobilities   driving force

chemical potentials
of A and B in cell n :

$$g_n^A(\tilde{\mathcal{C}}) \;\; = \;\; \frac{1}{N_d} \sum_{i \in n} kT \; \ln < \;\; \delta(p_i(\mathcal{C})) \;\; \exp \beta h_i^A(\mathcal{C}) >_{\mathcal{C}/\tilde{c}}$$

$$g_n^B(\tilde{\mathcal{C}}) \;\; = \;\; \frac{1}{N_d} \sum_{i \in n} kT \; \ln < \;\; \delta(p_j(\mathcal{C}) - 1) \;\; \exp \beta h_j^B(\mathcal{C}) >_{\mathcal{C}/\tilde{c}}$$

"alloy chemical potential" :
$$\mu_n(\tilde{\mathcal{C}}) = g_n^B(\tilde{\mathcal{C}}) - g_n^A(\tilde{\mathcal{C}})$$

→ look for the equivalent dynamical equation on C (evolution of a single system)

- Kramers-Moyal expansion to 2nd order in a/d to get a Fokker-Planck equation

- Itô calculus to get the equivalent Langevin equation

Phase Field method: how to get the basic equation (5)

→ Results:

$$\frac{\partial c_n}{\partial t} = \frac{a^2}{d^2}\frac{\theta}{kT} \sum_m^{(n)} l_{nm}(\widetilde{\mathcal{C}})\,(\mu_m(\widetilde{\mathcal{C}}) - \mu_n(\widetilde{\mathcal{C}})) \; + \; \xi_n(t)$$

- mobilities:

$$l_{mn}(\widetilde{\mathcal{C}}) = \exp(-2\beta E_{saddle})\exp\frac{\beta}{2}(g_n^A(\widetilde{\mathcal{C}}) + g_n^B(\widetilde{\mathcal{C}}) + g_m^A(\widetilde{\mathcal{C}}) + g_m^B(\widetilde{\mathcal{C}}))$$

- alloy chemical potential:

$$\mu_n(\widetilde{\mathcal{C}}) = g_n^B(\widetilde{\mathcal{C}}) - g_n^A(\widetilde{\mathcal{C}})$$

- gaussian noise:

$$< \xi_n(t) > \;=\; 0$$

$$< \xi_n(t)\,\xi_m(t') > \;=\; 2\theta\,\frac{a^2}{d^2}\,\frac{1}{N}\,g_{nm}(\widetilde{\mathcal{C}})\,\delta(t-t')$$

$$g_{nn}(\widetilde{\mathcal{C}}) \;=\; \sum_m^{(n)} l_{nm}(\widetilde{\mathcal{C}})$$

$$g_{nm}(\widetilde{\mathcal{C}}) \;=\; -\,l_{nm}(\widetilde{\mathcal{C}}) \quad \text{if } n \text{ and } m \text{ are } 1^{st} \text{ neighbors}$$

→ Cahn-Hilliard type equation, but with :

    - multiplicative Langevin noise

    - cell-size dependant quantities: mobility, chem. potentials, amplitude of noise term

Phase Field method: how to get the basic equation (5)

→ Results:

$$\frac{\partial c_n}{\partial t} = \frac{a^2}{d^2}\frac{\theta}{kT}\sum_m^{(n)} l_{nm}(\widetilde{\mathcal{C}})\,(\mu_m(\widetilde{\mathcal{C}}) - \mu_n(\widetilde{\mathcal{C}}))\ +\ \xi_n(t)$$

- mobilities:

$$l_{mn}(\widetilde{\mathcal{C}}) = \exp(-2\beta E_{saddle})\exp\frac{\beta}{2}(g_n^A(\widetilde{\mathcal{C}}) + g_n^B(\widetilde{\mathcal{C}}) + g_m^A(\widetilde{\mathcal{C}}) + g_m^B(\widetilde{\mathcal{C}}))$$

- alloy chemical potential:

$$\mu_n(\widetilde{\mathcal{C}}) = g_n^B(\widetilde{\mathcal{C}}) - g_n^A(\widetilde{\mathcal{C}})$$

- gaussian noise:

$$< \xi_n(t) > = 0$$
$$< \xi_n(t)\,\xi_m(t') > = 2\theta\,\frac{a^2}{d^2}\,\frac{1}{N}\,g_{nm}(\widetilde{\mathcal{C}})\,\delta(t - t')$$
$$g_{nn}(\widetilde{\mathcal{C}}) = \sum_m^{(n)} l_{nm}(\widetilde{\mathcal{C}})$$
$$g_{nm}(\widetilde{\mathcal{C}}) = -\,l_{nm}(\widetilde{\mathcal{C}}) \quad \text{if } n \text{ and } m \text{ are } 1^{st} \text{ neighbors}$$

→ Cahn-Hilliard type equation, but with :

    - multiplicative Langevin noise

    - cell-size dependant quantities: mobility, chem. potentials, amplitude of noise term

How to compute the chemical potentials ? (1)
(*i.e. Ginzburg-Landau free energy*)

→ Chemical potentials $g_n^A(\widetilde{\mathcal{C}})$ and $g_n^B(\widetilde{\mathcal{C}})$ are function of all the cell concentrations c_n :

$$g_n^A(\widetilde{\mathcal{C}}) = g_{homo}^A(c_n) + H^A(c_n)||\hat{\nabla}c_n||^2 + K^A(c_n)\hat{\nabla}^2 c_n + \dots$$

→ $g_n^A(\widetilde{\mathcal{C}})$ and $g_n^B(\widetilde{\mathcal{C}})$ enter into the mobilities and in the alloy chemical potential :

$$l_{mn}(\widetilde{\mathcal{C}}) = \exp(-2\beta E_{saddle}) \exp \frac{\beta}{2}(g_n^A(\widetilde{\mathcal{C}}) + g_n^B(\widetilde{\mathcal{C}}) + g_m^A(\widetilde{\mathcal{C}}) + g_m^B(\widetilde{\mathcal{C}}))$$

$$\mu_n(\widetilde{\mathcal{C}}) = g_n^B(\widetilde{\mathcal{C}}) - g_n^A(\widetilde{\mathcal{C}})$$

→ If cells large enough : inhomo. components can be neglected in mobilities, but are crucial in the alloy chem. potential

- for the mobilities:

$$g_n^A(\widetilde{\mathcal{C}}) \simeq g_{homo}^A(c_n)$$

- for the alloys chemical potential:

$$\mu_n(\widetilde{\mathcal{C}}) \simeq g_{homo}^B(c_n) - g_{homo}^A(c_n) + H(c_n)||\hat{\nabla}c_n||^2 + K(c_n)\hat{\nabla}^2 c_n +$$

How to compute the chemical potentials ? (2)
(*i.e. Ginzburg-Landau free energy*)

$\rightarrow$ Numerical procedure for homogeneous chemical potentials $g_n^A(\widetilde{\mathcal{C}})$ and $g_n^B(\widetilde{\mathcal{C}})$

Widom-like insertion method by Monte Carlo on a single cell $\quad d$
$\rightarrow$ Numerical procedure for the inhomogeneous component of $\mu_n(\widetilde{\mathcal{C}})$

we expect
$$F_{tot}(\widetilde{\mathcal{C}}) = N_d \sum_n \{f_{homo}^d(c_n) + \frac{1}{2}\lambda^d(c_n)||\hat{\nabla}c_n||^2\}$$
with
$$\mu_n(\widetilde{\mathcal{C}}) = \frac{1}{N_d}\frac{dF_{tot}(\widetilde{\mathcal{C}})}{dc_n},$$

thus :
$$\mu_n^d(\widetilde{\mathcal{C}}) = \mu_{homo}^d(c_n) - \lambda^d(c_n)\hat{\nabla}^2 c_n + \frac{1}{2}\frac{\partial\lambda^d(c_n)}{\partial c_n}||\hat{\nabla}c_n||^2$$

C_1

$\rightarrow$ Procedure for $\lambda^d(c_n)$: gaussian fluctuations between cells

C_2 $\qquad C_3$

d
How to compute the chemical potentials ? (3)
ex : simple cubic lattice

→ Simple cubic lattice, 1st neighbor interactions J1

$$H = \frac{1}{2} \sum_{n,m} \sigma_n\, \sigma_m \qquad \sigma_n = +/-1 \qquad T_c \sim 4.51 J_1$$

→ chemical potential : homogeneous part $\mu_{homo}^d(c)$ by Monte Carlo on a single cell + fit

Coarse-grained chemical potential   kT = 4.4 J$_1$

(y-axis) Chemical potetial / J$_1$
(x-axis) Concentration

Legend:
× d = 6
× d = 10
× d = 18
× d = 24
$$\mu_d(c) = 2pJ_1(2c-1) + Ac(1-c)(c-0.5)\{1 + B(c-0.5)^2\} + kT\,\ln\frac{c}{1-c}$$

Free energies as a function of the coarse graining size

ex : simple cubic lattice
How to compute the stiffness coefficient ?
ex: simple cubic lattice

$\rightarrow$ Next: stiffness coefficient $\lambda^d(c_n)$

$$\mu_n^d(\widetilde{\mathcal{C}}) = \mu_{homo}^d(c_n) - \lambda^d(c_n)\hat{\nabla}^2 c_n + \frac{1}{2}\frac{\partial\lambda^d(c_n)}{\partial c_n}||\hat{\nabla}c_n||^2$$

$\rightarrow$ $\lambda^d(c_n)$ governs (in part) fluctuations between cells

$\rightarrow$ Monte Carlo analysis of gaussian fluctuations between cells:
$$\lambda^d(\bar{c}) = A + B\,\bar{c}(1 - \bar{c})$$

Precipitation: from nucleation and growth to coalescence (2)

→ Simulation box 64 x 64 x 64   kT = 4 J1:
Precipitation: from nucleation and growth to coalescence (3)

→ Simulation box 64 x 64 x 64   kT = 4 J1:
Precipitation: from nucleation and growth to coalescence (4)

→ Critical radius : $R_c \sim 1\,d$
Precipitation: from nucleation and growth to coalescence (5)
On the influence of the coarse-graining size
Comparison with classical nucleation theory

$\rightarrow$ Incubation time as a function of sursaturation $(c - c_0)$
$\tau \sim (c - c_0)^{-\alpha}$ $\alpha \simeq 4.8 \pm 0.1$ $CNT : \alpha = 4$

Conclusion

→ "exact" procedure:

- the Phase Field as a coarse-graining procedure

- a stochastic equation with a "simple" noise term (fluctuation theorem)

- Mobility M(c) and noise correlations depend on coarse-graining size and on local concentration

- "stiffness" constant $\lambda^d(c)$ depend on coarse-graining size and on local concentration

- no arbitrary parameters !!!

- reproduces equilibrium fluctuations as well as precipitation

- no need for an extra nucleation flux

→ needed if:

- nucleation and growth mechanism (activated processes)

- if complete time scale needed

Spatial Resolution Improvements using Aberration-Corrected Electron Microscopy

Oxygen octahedron reconstruction in the $SrTiO_3/LaAlO_3$ heterointerfaces investigated using aberration-corrected ultrahigh-resolution transmission electron microscopy

C. L. Jia,[1,*] S. B. Mi,[1] M. Faley,[1] U. Poppe,[1] J. Schubert,[2] and K. Urban[1]

[1]Institute of Solid State Research and Ernst Ruska Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich, D-52425 Jülich, Germany

[2]Institute of Bio- and Nanosystems and Centre of Nanoelectronic Systems for Information Technology, Forschungszentrum Jülich, D-52425 Jülich, Germany

- *Measurement of atom (column) location to within a few picometers precision*

- *To image in this manner (NCSI) requires thin foils of thickness ≈ 4nm*

- *What is the effect of foil thickness on relaxations?*

- *Need for computational assistance to interpret correct result*

Ti-L near-edge : monochromated STEM-EELS

Imaging: filtered (800 V), Mono excitation 0.3
50 μm C2 aperture, no C3 aperture, no C1 slit
Analysis: GIF ap. 2.5mm, CL 36.7mm
Dispersion 0.05 eV/pixel
GIF energy resolution: 0.2 eV
Acquisition time: 10 seconds

But, not possible to perform spatially resolved monochromated EELS in our system:
- need more signal – the high brightness gun

Comparison of monochromated vs. non-monochromated EELS

Ti-L in STO

Ti-L in BTO

- *Need for computational assistance to interpret correct result, i.e., electronic structure*

Cool New Stuff with Experiments

Our Efforts aimed at Improving (ST)EM Imaging & Analysis

Features:

◆ Chromatic-aberration corrected STEM

◆ Lower voltage to reduce damage

◆ Make foil and observe in STEM in same microscope

◆ Accelerated and automated analysis

◆ Foil thickness measurement – supplied to modeling backup

The FEI Magellan SEM, which is the basis of the Helios NG, the proposed acquisition.

500nm
A thin section of pig skin prepared at room temperature by use of a dual-beam FIB imaged (as-FIB'd) in an FEI Magellan, with an accelerating voltage of 350V.
STEM images of an FIB extracted cross-section of a LiFePO cathode from a commercial Li ion battery showing the ability of technique to prepare thin-foils of this delicate, highly porous, multi-scale structure of these cathode materials.

Our Efforts at Novel Approaches to Improving Laser-assisted Atom Probe Analysis
Dramatic improvement in mass spectrum (mass to charge ratio versus number) of W with a decrease in λ, and by use of an improved PSD).
Similar improvement in mass spectrum of ZnO with a decrease in λ
Correlation of laser wavelengths used for different materials and corresponding band gap energies with their electrical resistivities

Question: Have we reached the maximum mass resolution with UV lasers or not?

Cool New Stuff with Experiments

Importance of Coupling of Efforts between Computational folks (unimaginative) and Experimentalists (creative):

- *Provision of accurate and physically relevant mechanistic data*

- *Computational assistance in interpreting experimental data*

- *Validation of predictions – at scale!!*

Quantitative Analysis

Calculation

The relation between the concentration and characteristic X-ray intensity is given by;

$$C = \left\{ \frac{1}{K\left(\dfrac{\sigma\omega a\varepsilon}{A}\right)} \right\}\left(\frac{I}{t}\right)$$

Thin film criterion;

$$\frac{C_A}{C_B} = \frac{A_A(\sigma\omega a\varepsilon)_B}{A_B(\sigma\omega a\varepsilon)_A}\left(\frac{I_A}{I_B}\right)$$

$$\frac{C_A}{C_B} = k_{AB}\left(\frac{I_A}{I_B}\right)$$

Cliff-Lorimer factor;

$$k_{AB} = \frac{(\sigma\omega a\varepsilon / A)_B}{(\sigma\omega a\varepsilon / A)_A}$$

Experiment

The concentration is given by;

$$C = \frac{n}{V}$$

Atom ratio;

$$R = \frac{n_A / V_A}{n_B / V_B}$$

Atom ratio, R_s assuming specimen thickness is constant and where h is layer width;

$$R_S = \left(\frac{h_A}{h_B}\right)\frac{n_A / V_A}{n_B / V_B}$$

Experimental Cliff-Lorimer factor;

$$k_{AB} = \left\{ \frac{I_A^{Total} / I_B^{Total}}{R_s} \right\}$$

Quantitative analysis

XEDS

$$\frac{C_A}{C_B} = k_{AB}\left(\frac{I_A}{I_B}\right)$$

EELS

$$\frac{N_A}{N_B} = \frac{I_A(\beta\Delta)\sigma_B(\beta\Delta)}{I_B(\beta\Delta)\sigma_A(\beta\Delta)}$$

Partial cross-sections for EELS were measured using an experimental spectrum in Gatan DM software

Lawrence Livermore National Laboratory

Quantifying Rapid Solid-state Crystallization Kinetics; Application of the KJMA Equation to High Time Resolution Electron Microscopy Data

Joint AFRL/AFOSR/LLNL Pacific Rim Workshop on Nucleation, May 2nd-7th, 2010

Thomas LaGrange

DTEM TEAM: Geoffrey H. Campbell, Nigel D. Browning, Bryan W. Reed, Melissa Santala, Joseph Mckeown, Katie Jungjohann, Marta Bonds, William J. Dehope, Glenn Huete and Richard Shuttlesworth

At the nanoscale, structural evolution in materials happens quickly because distances are short.

In regimes that have never before been explored, we will observe new and noteworthy features of materials dynamics.

DTEM affords the opportunity to directly study complex transient phenomena in materials

DTEM experiments are on the same length and time scales as large scale atomistic simulation

G. Gilmer, LLNL

H. Van Swengenhoven, PSI

V.Bulatov, LLNL

Lawrence Livermore National Laboratory

Overview: The LLNL DTEM is a nanosecond-scale *in situ* TEM with single-shot capability

DTEM adds two lasers to a conventional TEM to enable:

- Driving sample events with extreme spatiotemporal temperature gradients
- Real-space imaging and diffraction with ~15 ns exposures
- Enough signal in one exposure to form an image (up to 2×10^9 electrons)

Laser-pulse driven photoelectron cathode

Dislocations

500 nm

Dynamical contrast formation allows DTEM to image those defect structures that control properties of materials.

Laser heating can be used to tailor microstructure and properties in NiTi thin films for shape memory applications.

- Laser annealing can be used to crystallize amorphous NiTi film and modify grain size
- DTEM laser pulse produces large spatiotemporal temperature gradients
- Kinetics *do not* extrapolate from low temperature studies

CW laser annealing, Wang et al., *Acta Mater.* 2005

100 sec
750 K

500 nm

1 μm

Pulsed laser annealing in DTEM (~1500 K)

crystallized

10 μm

amorphous

Conventional annealing and *in situ* TEM studies were used to determine the kinetic parameters for crystallization.

- We studied crystallization processes in 250 nm thick amorphous, equiatomic NiTi films.

- Films were annealed at 768K using *in situ* TEM heating holder.

- Crystallization processes were recording using a video camera.

- Comparable crystallization kinetics to CW laser annealing experiments.

2 μm

Conventional *in situ* hot stage microscopy used to determine crystallized fraction as a function time for JMAK analysis

Fit using x(t)=1-exp[-(k*(t-τ))³]
incubation time(τ)= 7s
k=0.053 s⁻¹

$$x(t) = 1 - \exp(-(k(t-\tau)^n)$$

$$\tau = incubation\ time$$

$$n = 3\ avrami\ parameter$$

$$k = k_o \exp(-Q/\kappa T)$$

$$k_o \approx 10^{13} s^{-1}$$

$$Q = 2.3 eV$$

- Crystallization data were fit with the Johnson-Mehl-Avrami-Kolmogorov model to determine the kinetic parameters.
- Consistent with previous reports for NiTi in the literature.
- Kinetic data was extrapolated and compared with DTEM data measured at high temperatures (850-1550K).

Crystallization of amorphous NiTi films occurs on the µs timescale, much faster than expected from known kinetics.

Crystallization kinetics depend strongly on laser fluence, film thickness and heat transport.

t=1.5 μs After drive laser pulse

30 μm

20 μm

10 μm

50 μm

Temperature Evolution in amorphous NiTi as function of radius distance

Legend: 0 um, 10 um, 20 um, 30 um, 40 um, 50um

Y-axis: Temperature, K (800–1300)

X-axis: Time, μs (0–5)

- Temperature rise was calibrated using ex-situ reflectivity measurements and observations of liquefaction.

- Radial temperature and cooling rate calculation assume Gaussian laser energy distribution and heat loss by lateral conduction in an infinite medium.

Time-resolved brightfield imaging used to study rapid nucleation rate under pulsed laser annealing.

- Nucleation rate can be determined by the change in the number of new sites as a function of time normalized to the untransformed volume.

- Requires multiple single-shot experiments.

$$J(t_i) = \frac{1}{1 - X(t_i)} \frac{dN}{dt}$$

$$= \frac{1}{1 - X(t_i)} \frac{(N_i - N_{i-1})}{(t_i - t_{i-1})}$$

t=0s Before laser heating

t=1.5 μs After drive laser pulse

t=∞ After laser heating

Temperature gradient

Crystallization

5 μm

t=0s Before lase...

...er laser heating

5 μm

Increasing Temperature

Frequency, counts

Nuclei diameter, μm

Extraordinarily high nucleation rate occur under pulsed laser heating.

Conventional *In situ* TEM at 768K

$J_0 = 0.045\ \mathrm{um^{-2}\ s^{-1}}$

Pulsed laser heating in DTEM to 1200K

$J_0 \sim 1.0 \times 10^6\ \mathrm{um^{-2}\ s^{-1}}$

- Nucleation rate is 8 orders of magnitude higher under pulsed irradiation.
- Extrapolation of data acquired at 768K using JMAK kinetics still leads to a predicted nucleation rate that is orders of magnitude different. $J_0 \approx 370\ \mathrm{\mu m^{-2}\ s^{-1}}$

Crystallization data were fit with the Johnson-Mehl-Avrami-Kolmogorov model to determine the kinetic parameters.

- Assuming that k_o is the Debye frequency $\sim 10^{13}$ s^{-1},

$$k = k_o \exp(-Q/\kappa T)$$

$$Q_{DTEM} = 1.7 \pm 0.3 \text{ eV}$$

$$Q_{slow\ anneal} = 2.3 \pm 0.17 \text{ eV}$$

- Assuming that n=3 and crystallization occurs under steady state nucleation and growth, the growth rate can be calculated, $V_o = 6.7 \times 10^5$ μm s^{-1}

$$k = \sqrt[3]{(\pi/3)\,J_o V_o^2}$$

- The associated grain size can also be predicted,

$$\bar{d} = 1.2 \sqrt[3]{V_o/J_o} = 1.05\,\mu m$$

Crystallized volume fraction as a function of time at an estimated temperature of 1200K

Fit using x(t)=1-exp[-(k*(t-τ))³]
incubation time(τ)= 408 ns
k=7.78 x 10⁵ s⁻¹

Crystallization rate varies strongly with laser intensity showing a C-curve like behavior which has not been previously observed.

| | 1525 ±110 K | 1275 ±95 K | 1025 ±65 K | 850 ±50 K |

During (1.5µs) crystallization

Microstructure after crystallization

- Final microstructure varies strongly with initial pulsed laser annealing temperature.

- Crystallization rates appear to be highest at temperatures around 1200K.

- The threshold temperature for pulsed laser crystallization is ~850K

C-curve like behavior cannot be predicted from data obtained in the slow-heating experiments.

- Large discrepancy between pulsed laser heating and slow annealing.

- Extrapolation of DSC data using the JMAK equation show that mechanism occurring under pulsed laser annealing are not captured ~~nal thermal~~ ~~havior~~ m results from increased entropy (lower driving force) at high temperatures.

Bulk Melting Tempeature, ~1650K

Pulsed laser Crystallization Data

Temperature, K

Time, μs

Future experiments will strive to measure precise growth rates and approximate interfacial energies.

Conclusions

- Using the DTEM, one can quantitatively measure the nucleation and growth rates associated with phase transformations with <u>ns time resolution.</u>

- We can gain insight into the subtle details of materials processes in previously unexplored regimes (<u>kinetically driven and high temperature states</u>).

- The discrepancy between pulsed laser and slow annealed induced devitrification kinetics is captured by the JMAK analysis and is not understood!

amorphous   **Transforming**   **Crystallized**

Laser heating   Cooling

To follow the microstructural and defect evolution, multiple images must be acquired from drive event.

- Measurement of the growth rates requires multiple images of a moving interface to reveal its velocity.

- A time sequence of multiple images (a movie) allows the position of a given moving interface to be measured and its speed determined.

Movie Mode will let us capture a series of images from a single sample drive event.

AWG Cathode drive laser generates a UV pulse train

Pulse Train of Electrons

9 electron pulses with temporal resolution from 5ns to 10μs and interframe times from 25ns to 250μs

Sample drive laser 1 pulse or drive event

Electrostatic Deflector

High Voltage Electrostatic Deflector rasters pulse train onto the CCD

2kx2k Single-electron Sensitive CCD camera

The CCD is read out at the end of experiment and segmented into frames.

DTEM needs bright sources, but ultimately higher time resolution limits spatial resolution!

Source Brightness

Contrast

Time Resolution

$$\text{Brightness} = \frac{Ne}{(\pi r^2)(\pi \alpha^2)\Delta t}$$

Spatial Resolution

Coherence

Resolution is governed by the fixed normalized brightness of the gun!

Lens aberrations and electron-electron interactions can reduce your effective average brightness in your system.

A high quality image needs N ~ 10^8 electrons.

Suppose r = 1 μm, α = 10 mrad, Δt = 1 ns.

Brightness = 1.6×10^9 A cm^{-2} steradian^{-1}, with 16 mA at the camera.

This is the brightness of a typical field emitter, but with vastly more current.

DTEM currently has brightness of ~1×10^8 A cm^{-2} steradian^{-1}

With high electron currents, electron-electron interactions limit brightness and spatial resolution.

Longitudinal Space Charge

ρ

qE

Cathode

Anode   Anode

Child's Law:
- **Field from recent electrons retards emission**
- **Fundamentally limits current density:**

$$j \propto V^{3/2} / d^2$$
Lateral Space Charge
Defocusing:
- **To first order, it's just a diverging lens**
- **Higher orders create spherical aberration**

Longitudinal Inhomogeneous

Propagation
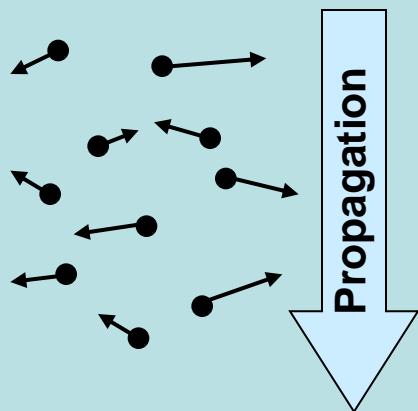

Boersch Effect:
- **Pulse viewed in rest frame**
- **Most velocity is lateral**
- **Equilibration increases ΔE**

Lateral Inhomogeneous
Trajectory Displacement:
- **Random electron-electron scatter**
- **High-resolution information stored in lateral velocities is gradually destroyed**

History: DTEM grew out of developments in time-resolved TEM that date back to the 1960's

- "Stroboscopic" TEM uses many synchronized pulses to capture a cyclic process
  - Magnetic domain wall motion (Spivak et al., *Bull Acad. Sci. USSR* **30**, 822 (1966))
- Groups in Europe and Japan developed pulsed TEM and SEM through the 1980's and 1990's
  - Multi-frame movies with 30 μs exposure, ms interframe time (Takaoka & Ura, *J. Elect. Mic.* **32**, 299 (1983))
  - Nanosecond-scale single-shot TEM with 3-frame movies (Domer & Bostanjoglo, *Rev. Sci. Inst.* **74**, 4369 (2003))
- Advances in lasers, TEM's, and ultrafast techniques have re-ignited the field in the last few years
A femtosecond stroboscopic approach was developed by the Zewail group at Caltech

- **120 keV G12 Twin Tecnai**
- **Gatan Ultrascan 1000 UHS 2048 x 2048**
- **Results reported were acquired with 1 electron per pulse**
- **More recently developed a second-generation machine**

Ultrafast Electron Microscope
Four-dimensional ultrafast electron microscopy

Vladimir A. Lobastov, Ramesh Srinivasan, and Ahmed H. Zewail*

Laboratory for Molecular Sciences, Arthur Amos Noyes Laboratory of Chemical Physics, California Institute of Technology, Pasadena, CA 91125

Contributed by Ahmed H. Zewail, March 30, 2005

Electron microscopy is arguably the most powerful tool for spatial imaging of structures. As such, 2D and 3D microscopies provide static structures with subnanometer and increasingly with Ångstrom-scale spatial resolution. Here we report the development of 4D ultrafast electron microscopy, whose capability imparts another dimension to imaging in general and to dynamics in particular. We demonstrate its versatility by recording images and diffraction patterns of crystalline and amorphous materials and images of but for biological and mesoscopic materials with characteristic length scales ranging from nanometers to micrometers, electron microscopy enjoys unique advantages.

It is the purpose of this paper to report the development of 4D ultrafast electron microscopy (UEM), which provides the ability to nondestructively image complex structures with the spatial resolution of TEM, but as snapshots captured with ultrafast electron packets derived from a train of femtosecond pulses.

PNAS 2005;102[20]:7069-73

Time-resolved electron probes divide roughly into three categories

	Stroboscopic	Intermediate	Single Shot
Example	UFTEM	UED	DTEM
Electrons/Pulse	~1-10³	~10^3-10^6	~10^7-10^9
Pulses/Image	10^5+	Few-100	1
Time Resolution	Sub-ps	sub-ps to few ps	15 ns
Spatial Resolution	Å	Many μm	~10 nm
Energy Spread	~1 eV	~100 eV	~10 eV
Spectroscopy	Yes	Not demonstrated	Not demonstrated
Main Strength	Spatiotemporal resolution	Great for diffraction; systems are simple	Capture unique, irreversible events in real space
Main Weakness	Extremely repeatable processes only	Imaging is difficult	Resolution

Trajectory displacement will limit resolution to at best 5 nm at 1 ns, 200 keV
Analytical formulas were applied to optical model of post-sample lens system.

Result: 5-50 nm resolution limit, depending on current and lens settings
Numerical multi-particle simulation of electron point spread function after sample interaction

Result: 5-50 nm resolution limit, depending on current and spot size

Simulation has suggested the feasibility of ultrafast (< 10 ps) electron imaging

Point Spread Function at 200 keV, 1 ns

-100 nm   -50 nm   0   50 nm   100 nm
Point Spread Function at 5 MeV, 10 ps

-100 nm   -50 nm   0   50 nm   100 nm
For picosecond resolution imaging, relativistic energies may be the only way to obtain high spatial resolution.

Relativistic pulses significantly mitigate stochastic blur.

Blur for 5 million electrons after 5.6 cm of propagation

Blur FWHM (nm) vs. Electron energy (MeV)
Relativistic electrons have a shorter (proper) propagation time, diverge more strongly, and have smaller current density.

A future DTEM might look more like a particle accelerator

Integrated optical pump/probe at sample

Pulse compressor

Fast framing single-electron-sensitive camera system

ps photogun optimized for 0.01-1 A, 1-5 MV, high coherence

Complex multipole lenses (Superconducting?)

Rapid deflection/streaking system

Heavy shielding. Experimenter is not in the room!

NUCLEATION IN AMORPHOUS AI

MODELING OF NUCLEATION SITES

CONCLUSIONS

MULTIFUNCTIONAL METALS OF DISTINCTION

Unique balance of properties distinguish metallic glasses as a distinct class of metals

- **Mechanical**
  - *Very high hardness*
  - *Strength twice that of conventional metals*
  - *Fracture toughness can be very high*
  - *High resilience and low mechanical damping*

- **Magnetic**
  - *High magnetic permeability &low hysteresis losses*
  - *Highly tailorable magnetic properties*

- **Corrosion**
  - *Lack of crystal defects (grain boundaries) and unique formulations give exceptional corrosion behavior*

- **Processing**
  - *High viscosity and low strain rate sensitivity of the supercooled liquid enables thermo-plastic forming that was previously impossible*
  - *Low solidification shrinkage and lack of grain structure gives high precision and finish in castings*

PLASTIC-LIKE PROCESSING OF AMORPHOUS METALS

Conventional metals cannot be practically supercooled for processing
- ❖ Crystal nucleation occurs quickly at low undercooling, followed by rapid growth

The liquid is stabilized far below T_m in metallic glasses
- ❖ Chemical and topological contributions stabilize the metallic glass structure

Enables injection molding to produce net shape metallic components
- ❖ process time increases dramatically after cooling below the 'nose'
- ❖ thick sections (>1 cm) can be formed in bulk metallic glasses

Metal injection molding provides important processing capability
- ❖ enables unitized construction of complex shapes where part volume is important
- ❖ metals compete successfully with plastics for both cost and performance

NUCLEATION IN AMORPHOUS AI
Characteristics
Influence on Properties

MODELING OF NUCLEATION SITES

CONCLUSIONS

In Situ NANOCRYSTALS IN AMORPHOUS METALS

Nanocrystal dispersions can be formed *in situ* in amorphous Al

- ❖ Al nanocrystals are 5-30 nm in diameter
- ❖ Al nanocrystals are at an exceptionally high number density (10^{21} to 10^{23} /m^3)

Improves strength and ductility

- ❖ mechanisms unknown

Nucleation mechanism unknown

- ❖ conventional homogeneous and heterogeneous nucleation do not fit experimental observations

Control of nanocrystalline precipitation gives an approach to control properties of a-Al
A. Inoue, H. Kimura;
Mat. Sci. Eng., 2000

Melt spinning produces amorphous product and crystallization initiates above T_x

Al crystallites are very small (~10-30 nm), and occur at an exceptionally high volume density (~$3 \times 10^{21} m^{-3}$)

- typical volume density for standard metals is ~$10^{16} m^{-3}$

- Heterogenous nucleation unlikely

- Low apparent activation energy for nucleation

- nucleation at "quenched-in features" may be related to Al-like MRO in a-Al (Perepezko and Imhoff, 2009)

- features responsible for nucleation have not been identified
Figure 1: a) Bright-field TEM image and corresponding SAED pattern of as-spun $Al_{92}Sm_8$ ribbon. The analyses do not show any signs of crystallinity. b) Continuous DSC trace of as-spun $Al_{92}Sm_8$ at 20°C.min⁻¹ [18]. The crystallization occurs in two steps. The primary crystallization peak with an onset at 172°C corresponds to the development of a high number density of Al-nanocrystals in the amorphous matrix. The second peak is attributed to the crystallization of the remaining amorphous phase.
Figure 5 : TEM images of $Al_{88}Y_7Fe_5$ a) and b) Bright-field and corresponding SAED images of as-spun samples that have been annealed at 245°C for 10 and 60 min, respectively. c) Dark-field and corresponding SAED images of an as-spun sample that has been cold-rolled to a true strain of ε = -10. Both, thermal treatments and plastic deformation induce the development of Al-nanocrystals. The Dark-field TEM images in the inset show the shape evolution of nanocrystals from a spherical to a dendritic morphology with increasing annealing time.

OBJECTIVE

Provide a structural description of the sites responsible for the high nucleation density in partially devitrified amorphous Al

INTRODUCTION

NUCLEATION IN AMORPHOUS AI

MODELING OF NUCLEATION SITES

CONCLUSIONS

STRUCTURAL MODEL FOR AMORPHOUS METALS

The structure of amorphous Al can be described as an organized arrangement of Y-centered clusters

- Y surrounded by ~14 Al and ~3Ni atoms
- Ni and Y solutes appear to be correlated
- Supported by measurement of partial coordination numbers

Miracle, *Nature Materials*, **3**, 697 (2004).
Miracle, Acta mater., **54**, 4317 (2006).
Miracle, Louzguine, Louzguina, Inoue, *International Materials Review*, In press.

Intercluster regions are Al-rich and have a relatively high free volume

- high free volume produces local high internal energy, and also enables more rapid mass transport
- both of these favor nucleation of crystalline phases

From our readers

SOLVING THE PUZZLE OF EUTECTIC COMPOSITIONS WITH 'MIRACLE GLASSES'

To the editor — The structural model for metallic glasses published in the October issue of *Nature Materials* may account for the observed compositions of binary A$_x$B$_y$ eutectics, which occur most frequently at integer values of x and y. In 1935, D. Stockdale suggested that, in binary alloy phase diagrams, the compositions of eutectic points should correspond with simple whole-number ratios of the two kinds of atoms A (solvent > 50 at.%) and B (solute < 50 at.%). There was insufficient data to confirm this prediction at the time, but in 1960, W. Hume-Rothery and E. Anderson re-examined the Stockdale suggestion by plotting the frequency of occurrence of binary eutectic compositions versus alloy compositions from the handbook of ... found clear maxima ... corresponded to A/B ... 1, 2/1 and 3/2.

Hume-Rothery and Anderson tried to explain this finding on the basis of the local short-range order (SRO) of the atomic structures in binary liquids by postulating that eutectic compositions are likely to form when interatomic interactions are such that B–B nearest neighbours are ...

Miracle, *J. Non-Cryst. Sol.*, 2004.

FREE VOLUME
Free volume is locally highest in the regions between Y–centered clusters. These regions are enriched in Al, and depleted in Y and Ni.

SOLUTE ATOMS DESTABILIZE CRYSTALLINE Al

Local lattice strains associated with solutes destabilize crystal (Egami, Waseda, JNCS, 1984.)
- Magnitude of lattice strains decrease with increasing distance from solute

Rare earth metal (RE) solutes are non-interacting, and may be _randomly_ distributed in the structure
- _Average_ intersolute spacing is ~3 atom spacings
- Spacing between RE atoms will be larger than the average in some cases, producing lower lattice strains and large Al-rich regions
- These regions may be favored for nucleation of crystalline phases

Critical Strain
Critical Al nuclei form in Al-rich areas where Y–Y spacing is sufficiently large to allow formation of a critical cluster

critical nucleus size is generally held to be ~100 atoms

atomic cube ~5 atoms on a side, or atomic sphere ~6 atoms in diameter

Critical Al Nucleus

Critical Strain for amorphization

$\mathcal{E}_{tot}$

$\mathcal{E}_B$ $\mathcal{E}_A$

Al NUCLEI IN A RANDOM ARRAY OF Y ATOMS

Y Atom

Critical Al Nucleus
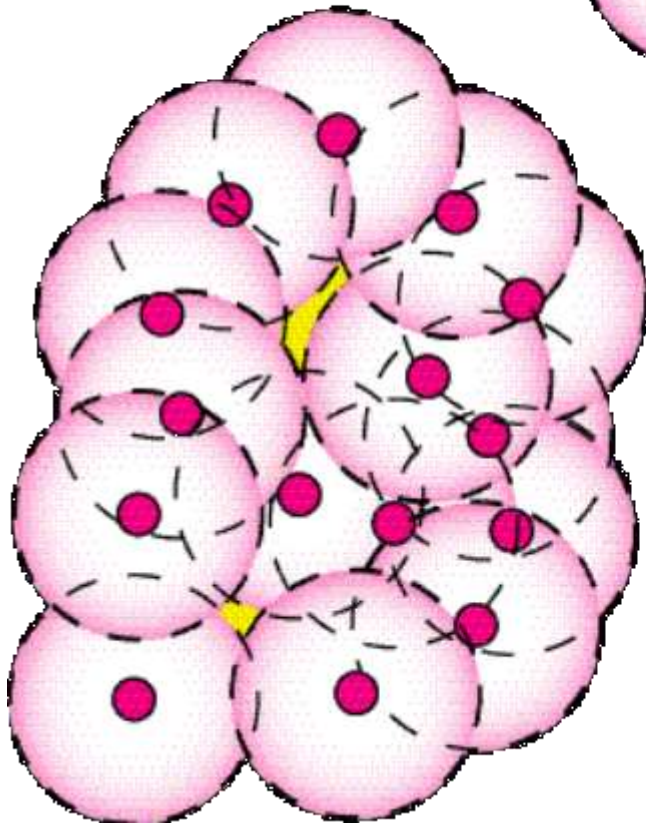

Random Array of Y Atoms
Potential Al Nuclei Sites

Assume a _random_ spatial distribution of discrete Y atoms in a continuous matrix of Al atoms

Search for Y-free regions that are large enough to contain a critical Al nucleus

– Suggest that Al atoms in these regions are non-crystalline, but will arrange into a crystal with only a small activation energy needed to rearrange atoms

– Solute diffusion is not required for nucleation, but will be required for growth

Determine the volume density of such sites as a function of the size of these regions and solute concentration

– Model solute concentrations from 0.04 to 0.10

Compare with experimental value of nucleus volume density

Amorphous alloy model:

– hard spheres

– hard edges

– 10^3 to 10^7 atoms
Random (non-overlapping) spatial distribution of 7 At% Y in Al
Table 1

Showing tabulated data from Fig. 4

Alloy system	ρ_V (m^{-3})	n_a (estimated)	Ref.
$Al_{90}Nd_4Ni_6$	$\sim 10^{23}$	100	[7]
$Al_{90}Gd_5Fe_5$	3.6×10^{23}	70	[2]
$Al_{88}Y_7Fe_5$	$3{-}4 \times 10^{21}$	60	[5]
$Al_{92}Sm_8$	$4 \times 10^{21}{-}3.5 \times 10^{22}$	40–50	[12,25]
$Al_{85}Y_{10}Ni_5$	$\sim 10^{21}{-}10^{22}$	30–40	[7]

Values of ρ_V are from experimental measurements, estimates of n_a are obtained by interpolating the modeled relationships between nucleus number density and RE solute concentration.

INTRODUCTION

NUCLEATION IN AMORPHOUS AI

MODELING OF NUCLEATION SITES

CONCLUSIONS

CLOSING COMMENTS

A simple physical model of the atomic structure responsible for the high volume density of Al nanocrystals in a-Al has been analyzed

– Focuses on random solute distribution

– Thermal defects not addressed but may give similar results

– Does not address nucleation or growth of super-critical nuclei

Observed nucleant volume densities are consistent with critical nuclei containing 40-100 atoms, matching estimated values

Low activation energy conceived thru the local rearrangement of Al atoms

Consistent with subsequent observations of Al-like MRO in a-Al alloys

Need to understand chemical effects that influence solute distribution, especially next-nearest neighbors

THANK YOU!

Four topologically distinct atomic species and sites

- Solvent atoms (Ω)
- Primary (α) solutes produce the structure-forming unit clusters
- Cluster-octahedral interstices (β)
- Cluster-tetrahedral interstices (γ)
- $r_\alpha > r_\beta > r_\gamma$

Solute atoms occupy ~ordered sites

- Provides basis for observed medium range atomic ordering (MRO)
- Variable cluster-cluster separation degrade cluster ordering beyond a few cluster diameters

Preferred atom positions introduces the possibility of structural defects

- Vacancy and anti-site point defects
- Constitutional and thermal
"Ninety-nine percent loyalty is 100% disloyalty."
Napoleon Bonaparte

"He's not dead. I said he's *mostly* dead. BIG difference."
Miracle Max, from "The Princess Bride"

"The Pirate's Code is more what you'd call 'guidelines' than actual rules."
Captain Barbossa, from "The Pirates of the Caribbean"
Count the number of cubic volumes of side Q within the model system which contain no Y atoms

Considerations :

– fixed lattice

– cubic volume, (Q^3) not spherical volume ($4/3\pi r_{cluster}^3$)

Bounded Problem:
Q = 2.89 d$_{Al}$ **Q = 3.52 d$_{Al}$**   **Q = 5 d$_{Al}$**
Direct Counting:

- – limited by size of domain

- – computationally intensive

- – fixed lattice

$Al_{0.93}Y_{0.07}$

number of clusters per unit volume (m⁻³) vs $d_{cluster}$ (Al dia.)
PROBABILISTIC METHOD

Measure the distribution of local V_f at length scale Q:
Random (non-overlapping) spatial distribution of 11 At% Y in Al sampled at length scale $Q = 2.29 \, d_p$ (4096 volume elements)

Model the distribution of local V_f :

$$\phi(f) = \frac{1}{\sqrt{2\pi\sigma_f}} \exp\left[-\left(f - f_0\right)^2 \Big/ 2\sigma_f^2\right] \qquad \textbf{(Gaussian)}$$

Calculate statistics :
– mean $V_f = f_0$
– std. dev. of $V_f = \sigma_f$
Calculate the probability of finding V$_f$ = 0, over a length scale Q:

$$\Pr\{f : f + \Delta f\} = \int_{f}^{f+\Delta f} \phi(f)\, \mathrm{d}f$$
Assumptions :
- $f = 0$
- $\Delta f = 0.005$

Probabilistic Method:

– limited by statistical model

– fixed lattice

$Al_{0.93}Y_{0.07}$

number of clusters per unit volume (m^{-3})

$d_{cluster}$ (Al dia.)
Future Work:
– close the gap!
– new compositions
– multiscale effects: clustered clusters

Configurations producing a Y–Y separation of 2Al atoms

- *Link adjacent clusters by nestling an Al atom from one cluster in a low-energy position of a 2nd cluster, then rotating to a final low-energy configuration*
  - ➤ *. . . into a trigonal array yields a tetrahedron*
    - trigonal arrays exist in all clusters, so this may be a common linking configuration
  - ➤ *. . . into a four-fold array yields an octahedron*
    - these are intrinsic to the $Al_{15}Y$ cluster, and can occur in terminations of all other clusters discussed
  - ➤ *. . . into a five-fold array forms a portion of a low-energy icosahedron*
- *Another possibility is to link two trigonal arrays to form an Al_6 octahedron*

Configurations producing a Y–Y separation of 1Al atom

- *Adjacent Y atoms share a common trigonal array of Al atoms*

Configurations producing adjacent Y–Y atoms

- *Substitute an Al or Ni atom in a Y–centered cluster with Y*
- *"Linear molecules" obtained by stacking a given cluster upon itself*
  - ➤ *can be accomplished with each of the four clusters discussed*

Significant structural diversity is enabled via linking

Inter-Solute Spacing

– Consider a regular distribution of solute atoms of concentration, c_i, which occupy the corners of a cube of edge length, x_i atoms. Then:

$$c_i = 1/x_i^3$$

– If we know C_i, then we can determine the mean inter-solute spacing, x_i:

$$x_i = 1/c_i^{1/3} = c_i^{-1/3}$$

– for $C_j = 0.09$, $L_j = 2.2$ atoms; for $C_j = 0.13$, $L_j = 2.0$ atoms

  ➢ *on the average, every Y atom is separated by 1 – 1.2 other atom diameters*
For $L_i = 2$,

$C_i = 1/8 = 0.125$

Each Y and its nearest neighbors may be treated as a RVE

Formation of γ′ Phase (Ag₂Al) in Al-Ag Alloys
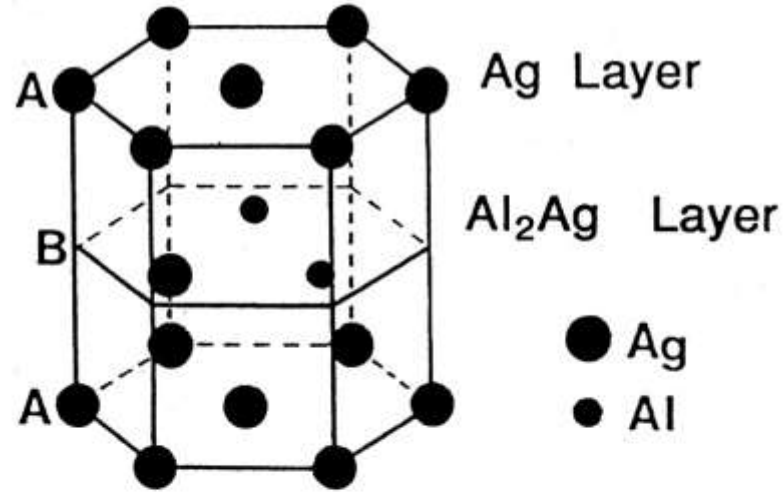

Fig. 2—Schematic representation of the crystal structure proposed for the γ phase (Ag₂Al) in Al-Ag alloys.[23]
Fig. 3—Schematic representation of the lattice correspondence between parent and product lattices for the fcc to hcp transformation.

Muddle, Nie, Hugo, *Metall.* Mater. Trans. **25A** p. 1841 (1994)
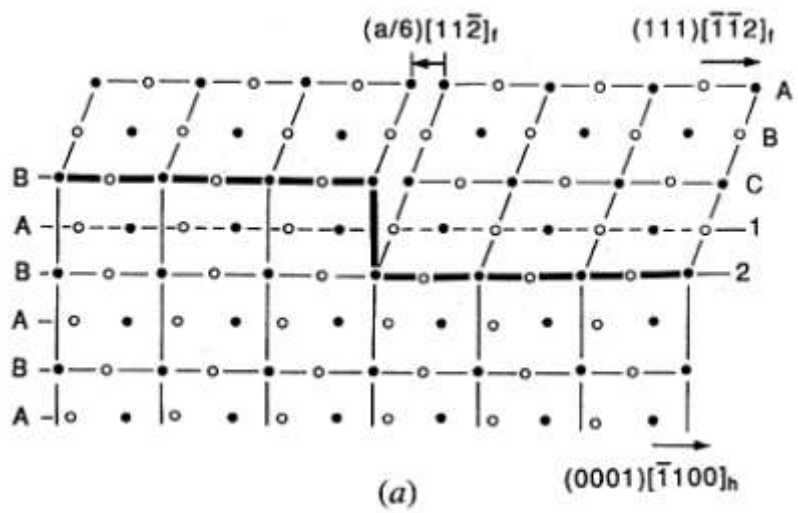

$$\mathbf{b_T} = hm\mathbf{d} = h\tau\mathbf{t} + h\xi\mathbf{n}$$

$$\mathbf{b_T} = \frac{a}{6}\langle 112\rangle + \frac{2\xi a}{3}\langle 111\rangle$$
Muddle, Nie, Hugo, *Metall.* Mater. Trans. **25A** p. 1841 (1994)   Howe, Dahmen, Gronsky, *Philos. Mag.* **56A** p. 31 (1987)

Consider a platelet of the product phase to take the form of a thin oblate spheroid, with radius a and semi-thickness c, and an aspect ratio, $A = c/a$, such that $a \gg c$.

$$\Delta F^0 = \frac{4}{3}\pi a^3 A(\Delta F_v + E_{el}) + 2\pi a^2 [1 + f(A)]\gamma_s$$

$$f(A) = \frac{A^2}{\sqrt{1-A^2}} \tanh^{-1}\sqrt{1-A^2}$$

Unconstrained transformation strain is an invariant plane strain, comprising a uniaxial expansion ξ normal to the invariant plane and a simple shear τ in the habit plane

J.K. Lee, H.I. Aaronson and D.M. Barnett, *Metall. Trans.* 8A(6), pp. 963-70, 1977

For small A, the **shape-independent energy due to the uniaxial expansion** alone may be expressed in the form:

$$E_\xi = \frac{\pi}{4(1-\nu)} A \mu \xi^2$$

μ – shear modulus

ν – Poisson's ratio

The **strain energy per unit volume for the constrained shear τ** is given by:

$$E_\tau = \frac{\pi(2-\nu)}{8(1-\nu)} A \mu \tau^2 \qquad\qquad E_\tau >> E_\xi$$

The **total elastic strain energy** $E_{el} = E_\xi + E_\tau$ tends to a minimum of zero as the aspect ratio A goes to zero. However, surface energy of a thin plate-like form:

$$E_\gamma = 2\pi a^2 (1+A)\gamma_s$$

increases with square of plate radius. Equilibrium shape at nucleation will be that which achieves an appropriate balance in the competing needs to minimize both elastic strain energy and surface energy.

J.W. Christian, *Acta Metall.* **6** pp. 377-9 (1958)

$$\Delta F^0 = \frac{4}{3}\pi a^3 A(\Delta F_v + E_{el}) + 2\pi a^2 \left[1 + f(A)\right]\gamma_s$$

Under the combined influence of interfacial energy and elastic strain energy, the energy barrier to nucleation $\Delta F*$ may be considered a function of the critical values $a*$ and $A*$ which simultaneously satisfy the conditions

$$[\partial(\Delta F^o)/\partial a]_A = 0 \quad \text{and} \quad [\partial(\Delta F^o)/\partial A]_a = 0$$

$$a* = \frac{-2\gamma_s}{(\Delta F_v + E_{el})}\frac{1 + f(A)}{A}$$

In the limit of $A \rightarrow 1$ $a* = -2\gamma_s/(\Delta F_v + E_{el})$

The corresponding ($a = a*$) value of ΔF_o is:

$$\Delta F* = \frac{2}{3}\frac{\pi\gamma_s^{\ 3}}{(\Delta F_v + E_{el})^2}\frac{[1 + f(A)]^3}{A^2}$$

J.K. Lee, H.I. Aaronson and D.M. Barnett, *Metall. Trans.* 8A(6), pp. 963-70, 1977

Accommodation of shear strain energy may occur through:

- self accommodation

or **heterogenous nucleation**:

- coherent nucleation in association with pre-existing defects providing an appropriate strain field

- sympathetic nucleation

- autocatalytic nucleation

- cluster-assisted nucleation

Self Accommodation
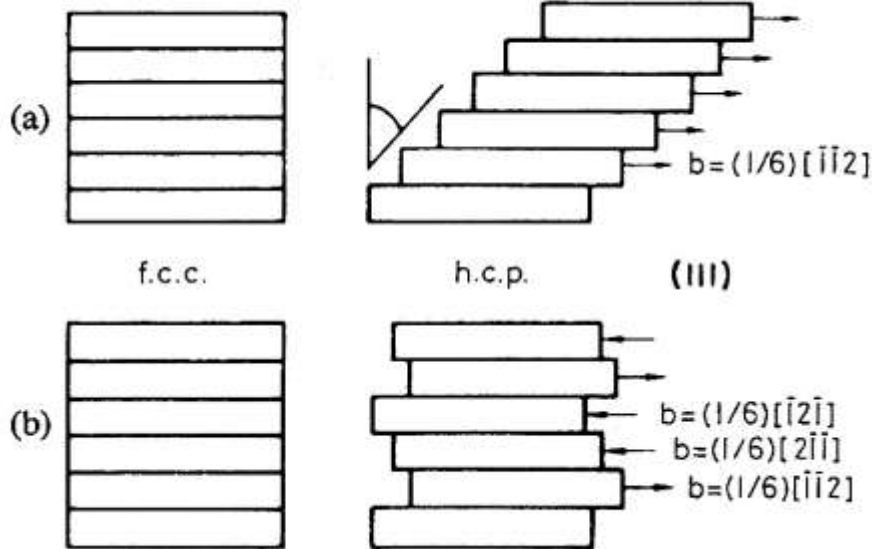

Christian, *The Theory of Transformations in Metals and Alloys* Pergamon (2002)

Howe, Dahmen, Gronsky, *Philos. Mag.* **56A** p. 31 (1987)

Heterogeneous Nucleation

Nucleation at non-random, preferred sites providing assistance in surmounting activation barrier

1. Nucleation at Pre-existing Static Sites

▪ 1-, 2-, 3-D Structural Defects (in excess of equilibrium concentration)

- incoherent nucleation releasing strain energy of the defect
- coherent or partially coherent nucleation utilizing the strain field of the defect
- nucleation on stacking faults

▪ Sequential Precipitation

- e.g. GP zone/θ''/θ'/θ in Al-Cu
- nucleation on interphase boundaries
- sympathetic nucleation

Christian, *Progress in Materials Science* **42** p. 101 (1997)

Summary

- those transformations giving rise to plate- or lath-shaped transformation products, and classically regarded as *diffusional*, are likely ***diffusional-displacive*** with a significant shear component

- at nucleation, the accommodation of shear strain energy may be at least as important as interfacial energy and may play a critical role in determining equilibrium nucleus shape – nucleation likely involves formation of 'loop' of transformation dislocation of critical form

- accommodation of shear strain energy may occur through:

    (i) self-accommodation

    (ii) coherent nucleation in association with pre-existing defects providing an appropriate strain field

    (iii) autocatalytic nucleation

    (iv) cluster-assisted nucleation

Basic *PrecipiCalc* Equations: Particle Growth

Growth: $\dfrac{dR}{dt} = \dfrac{\left(1 + R\sqrt{4\pi N_v \langle R \rangle}\right)}{\left(R\Gamma + s(R)\Big/\left(M_0 \exp \dfrac{-Q}{RT}\right)\right)}\left\{\Delta G_m - \dfrac{2\sigma(R)\overline{V}_m^{\beta}}{R}\right\}$

where $\Delta G_m = \left[\overline{\Delta C_i}\right]^T \left[\dfrac{\partial^2 \overline{G}^{\alpha}}{\partial C_i \partial C_j}\right]\left[\Delta C_j^{\infty}\right] + \left[\overline{C}_m^{\beta}\right] \bullet \left(\left[\overline{\mu}_m^{\alpha}\right] - \left[\overline{\mu}_m^{\beta}\right]\right)$

$\Gamma = \left[\overline{\Delta C_i}\right]^T \left[\dfrac{\partial^2 \overline{G}^{\alpha}}{\partial C_i \partial C_j}\right]\left[\overline{D}_{jk}\right]^{-1}\left[\Delta C_k^e\right]$

Thermodynamics

Diffusivity

Interfacial Property
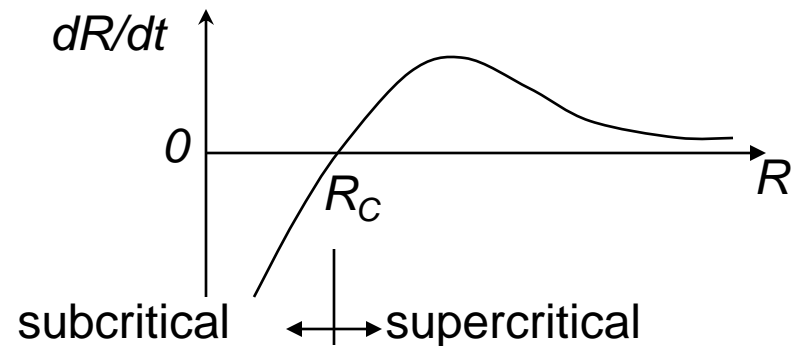

Basic PrecipiCalc Equations:
Classical Homogeneous Nucleation

Steady State Nucleation Rate $J_{SS} = Z\beta^* \dfrac{N_a}{V_m^\alpha} e^{\frac{-W_R^*}{k_B T}} = \displaystyle\int_0^\infty \overline{J}_{SS}(R)\,dR$

where Zeldovitch factor $Z = \left[\dfrac{V_m^{\beta^2}\sigma}{4\pi^2 N_a{}^2 k_B T R_C{}^4} \right]^{1/2}$

work to form a critical nucleus $W_R^* = \dfrac{16\pi\sigma^3}{3\left(\Delta G_m \middle/ V_m^\beta \right)^2}$

rate of atomic impingement $\beta^* = 4\pi R_C \dfrac{N_a}{V_m^\beta} \dfrac{\Delta G_m}{\Gamma}$

N_a is Avogadro's number, k_B is Boltzmann's constant

R_C is critical radius where $dR/dt = 0$, T is temperature

nucleation rate distribution is a normal distribution with mean and variance scaled by (R_{kT} - R_C), where $dR/dt=0$ at R_C

$\overline{J}_{SS}(R)$

$R_{kT} = \left[R_C{}^3 + \dfrac{3V_m^\beta}{4\pi\sqrt{\pi}N_a Z} \right]^{1/3}$

Incubation Time τ calculated from
$$\begin{cases} \displaystyle\int_0^\tau \beta^*(t')\,dt' = \dfrac{1}{\theta Z(t)^2}, & \text{if } \tau < t \\[2em] \displaystyle\int_0^\tau \beta^*(t')\,dt' + \beta^*(t)(\tau - t) = \dfrac{1}{\theta Z(t)^2}, & \text{if } \tau > t \end{cases}$$
, where $2 < \theta < 4\pi$

which gives $\tau = \dfrac{1}{\theta\beta^* Z^2}$, at isothermal conditions. Note $t = 0$ at the start of incubation.

Phase Transition

Summary/ Objectives

We plan to bring together the necessary components for a

Melt-line phase transition model:

- Spans nanosec to microsec time scales.
- Atomistic, phase-field, crystallographic and continuum modeling will be used.
- Understand missing physics.
- Verify with experiments.
- Understand sensitivities at the continuum level.

A comprehensive, physics-based model would incorporate

I) Probabilistic Nucleation size/shape distribution

II) Kinetics of the surface

III) Percolation

IV) Over-pressurization and relaxation

V) Amorphous formation or freezing

VI) Strength

Some Concerns::

Time: why is the delay time different---Exp. And Simulations
Rare events?

Ion-interaction descriptions: what needs to be included
---viscosity, transition path ways
⟹ DFT and metadynamics

Sensitivities: errors, "real" system variations, ….

The overly ambitious path

To develop a robust continuum phase transition model that incorporates modern theory and simulates recent observations of pressure-induced phase transitions....

I)   Probabilistic variations
        Nucleation size/shape distribution

II) Kinetics of the surface

III) Percolation

IV) Over-pressurization and relaxation

V) Amorphous formation or freezing

VI) Strength

Interaction energy influences response and microstructure (Barton)

See von Bargen & Boehler, *High Pres. Res.*, 1990.

## Phase Field modeling is time-dependent Ginzburg-Landau theory

Solid   **Liquid**

$$F(\phi) = \int dx [\frac{1}{2}|\nabla\phi|^2 + f(\phi,P,T) + f_{GB}(\nabla\theta) + f_{el}]$$

Total Free Energy of multi-phase material

Local Free Energy Density $f(\phi) \approx \phi(1-\phi)(1+\phi)$

Order Parameter $\phi(r,t)$

$$\frac{\partial\phi}{\partial t} = -\Gamma(-\nabla^2)^a \frac{\delta F}{\delta\phi} + noise$$

Kinetic Equation with Thermal Noise

Pusztai et al., have proposed a 3D quaternion-based phase-field model

- Represents crystal orientation with quaternion order parameter
- Quaternions are widely used to analyze crystallography of polycrystal interfaces
- Quaternion algebra is fast, efficient, avoids singularities, …

Free Energy

$$F = \int \left[\frac{\varepsilon_\phi^2}{2} |\nabla \phi|^2 + f(\phi, c, T) + HT[1 - p(\phi)] \left(\sum_i (\nabla q_i)^2 \right)^{1/2} \right] d^3r$$

Evolution

$$\frac{\partial q_i}{\partial t} = -M_q \frac{\delta F}{\delta q_i} + \zeta_i = M_q \left[\nabla \cdot \left(D \frac{\nabla q_i}{|\nabla q_i|} \right) - 2\lambda q_i \right] + \zeta_i$$

Where q_i is the quaternion order parameter, M_q is the associated mobility and ζ is the fluctuation in q.

## We have implemented the Pusztai model in our 3D AMR code

- Enhance energy functional to represent energetics of grain boundaries
- Crystal symmetry aware quaternion mathematics
- Extend energy functional to include elasticity and alloy concentration

For example:

Armstrong *et al.*, *JAP*, 2009

Barton *et al.*, *MSMSE*, 2009

- Initially cube-oriented alpha single crystal
- Pressure BC on loading face: peak pressure of 20 GPa, 4 ns pulse duration
- Periodic lateral BCs
- 100 microns in depth
With P(V,T) = P(V,T=0) + Pe(V,T) + Pi(V,T) + Pie(V,T)

There are several contributions that effect the final density rho(P,T) or rho(P,E):

- The cold and the electron (Pe) and/or ion (Pi) thermal contributions (blue solid)
- The material strength also contributes to the entropy or heat (blue dashed)
- The kinetics associated with every traversed phase line (red solid line)

    Delays in transition, developing shocks, not fully transformed material

We think we know (reasonably):

The cold contribution P(V,T=0), comparison to DAC

And to some extent the thermal contributions, comparison to Hugoniots

    and to *known* phase lines

Kinetics will contribute a min. of 100 ns in wave propagation arrival time,

    Comparison to experiment(J. Nguyen)

Unknown aspects:

The phase diagram in general is not well determined

    ---liquid-liquid transition, high temperature phases (suggested),

        high pressure melt line

The strength is not well defined b/c of the unknown phases and

    still is under development theoretically

Kinetics are completely unknown

    ---general theory is still developing, experiments are minimal to zero

Continuing LLNL's tradition as a forerunner…

Pressure component of phase transitions has not been significantly studied:

➡ gives new insights into Classical Nucleation Theory(CNT) via pressure

➡ asserts LLNL as an authority in phase transitions at pressure

➡ begins to understand pressure-dependent kinetic barriers

Improved understanding and modeling enables:

➡ new materials on demand to be obtained/understood from high pressure

➡ significant computational resources for *quantitative results*

and analysis to overlap with experiments, in length and time.

➡ models that are high impact for Stockpile Stewardship Science and Boost

(a) large Ni- base single-crystal droplet after 20ºC/min cooling from a very pure melt; (b)/(c) laser processed Al-26%Si, laser velocity 100 mm/s (b) and 500 mm/s (c), showing fine equiaxed silicon crystals surrounded by a-Al cells and distributed in a fibrous eutectic matrix (plane view); (d)/(e) AlY_7Fe_5 droplets, cooled in the DTA with two intermetallic particles surrounded by a eutectic matrix (d) or water quenched with numerous intermetallic particles (e); (f) AlY_7Fe_5 melt spun ribbon after an isothermal annealing treatment for 10 min at 275ºC, density of nanocrystals is greater than 10^{22} m^{-3}.

Classical Nucleation Theory

- ## **Kinetic Model**
- Clusters of particles originate when two atoms come together.
- These clusters are in equilibrium with the surroundings and can grow or shrink by the addition or removal of single particles.
- Most clusters will break up into single particles, but there will be some (small) probability that a cluster will grow large enough (i.e. to the critical size) that the number of particles that leave the cluster will just equal those that come to it.
- If the cluster grows larger that this critical size, it will not shrink, but will grow to a macroscopic size particle.

Nucleation Kinetics

In nucleation cluster size is a configurational coordinate. A flux is the net number of clusters/cm³-sec. growing from size n to (n+1).Let C(n,t) represent the number of clusters of size n that exist in the system at time t. Then,

$$\frac{\partial C}{\partial t} = \beta A'(n-1)C(n-1,t) + \alpha A'(n)C(n+1,t) - \beta A'(n)C(n,t) - \alpha A'(n-1)C(n,t)$$

Where β is the impingement frequency of a monomer (for nucleation in vapors) α is the evaporation frequency and A'(n) is the area of space around the cluster which will hold an impingement monomer. This procedure is called <u>Detailed Balancing</u>. By definition, at equilibrium ∂c/∂t=0 and C=Co. Thus, at equilibrium:

$$\beta A'(n-1)Co(n-1,t) + \alpha A'(n)Co(n+1,t) = \beta A'(n)Co(n,t) + \alpha A'(n-1)Co(n,t)$$

If there is no steady state growth of clusters through the size classes (i.e. for steady state conditions), the preceding equation can be made more restrictive,

$$\beta A'(n-1)Co(n-1,t) = \alpha A'(n-1)Co(n,t)$$

or

$$\alpha = \beta \frac{Co(n-1,t)}{Co(n,t)}$$

It should be noted that by using an equilibrium condition, α has been determined by invoking the <u>principle of time reversibility</u>. This principle requires that at equilibrium every microscopic process takes place at the same rate as its reverse. Substituting for a in the rate equation

$$\frac{\partial C}{\partial t} = \beta A'(n)Co(n,t)\left[\frac{C(n+1,t)}{Co(n+1,t)} - \frac{C(n,t)}{Co(n,t)}\right]$$

$$= \beta A'(n-1)Co(n-1,t)\left[\frac{C(n,t)}{Co(n,t)} - \frac{C(n-1,t)}{Co(n-1,t)}\right]$$

The preceding is the difference-differential equation for nucleation. This equation can be greatly simplified if we assume that C/Co and Dco vary slowly with n and if we disregard terms of higher than second order. To proceed, we define

$$D(n) = \beta A'(n) = \beta A(n)$$

where A(n) is the surface area for size n, A'(n) is the area around a cluster of size n that can accept a monomer, and D(n) is the diffusion coefficient of cluster in cluster size space. Now, we expand in a Taylor series about n the following functions

$$\frac{C(n+1)}{Co(n+1)} \qquad \frac{C(n-1)}{Co(n-1)} \qquad D(n-1)Co(n-1)$$

Substituting these into the difference differential equation yields:

$$\frac{\partial C}{\partial t} = \frac{\partial}{\partial n}\left[D(n)Co(n)\frac{\partial\left(\dfrac{C(n)}{Co(n)}\right)}{\partial n}\right]$$

The above is the isothermal nucleation equation and has the form of Fick's 2nd law of diffusion in a force field. This observation is consistent with the view that nucleation is a random-walk process through cluster size space.

We can rewrite the nucleation equation as an equation of continuity as follows:

$$\frac{\partial C}{\partial t} + \frac{\partial J(n)}{\partial n} = 0 \qquad and \qquad J(n) = -DCo\frac{\partial}{\partial n}\left(\frac{C}{Co}\right)$$

where J(n) is the net number of clusters growing from size n to (n+1).
Equation (4) can also be written as:

$$J(n) = -D\frac{\partial C}{\partial n} + UC \qquad and \qquad U = D\frac{1}{Co}\frac{\partial Co}{\partial n} = D\frac{\partial}{\partial n}(\ln Co)$$

random walk term   drift velocity, U, term

The Steady State

We now consider the possibility that a steady state current of clusters exists without any change in C (i.e. In order to produce such a situation, we must continuously supply monomers to keep C(1) constant and remove all the clusters equal to or larger than a certain size, n, so that size will not go to infinity). This scheme was first proposed by Becker and Döring, Ann. Physik, 24, 719 (1935). Using the equation for the nucleation rate we have.

$$J_S = -DCo \frac{\partial}{\partial n}(Cs/Co)$$

where the subscript s indicates steady state. Also, from the steady state model we can write

$$\left(C_S / Co\right)_{n=1} = 1 \qquad and \qquad \left(C_S / Co\right)_{n=\hat{n}} = 0$$

Integrating the equation for J_s yields

$$\int_{n=1}^{n=\hat{n}} -\frac{J_S}{DC_O} dn = \int_1^{\hat{n}} d(Cs/Co) = -1 \qquad or \qquad J_S = \frac{1}{\int_1^{\hat{n}} dn/DCo}$$

In general

$$Co(n) = C(1)\exp\left[\frac{-\Delta G(n)}{kT}\right]$$

Where C(1) is the number of monomers and $\Delta G(n)$ is the free energy to form a cluster of size n. C_o has a sharp minimum when ΔG is maximized, or when $n=n_c$. Thus, we can set $D=D_c$ and approximate C_o by expanding $\Delta G(n)$ about n_c to the second order to get

$$J_S = D_c C_O(n_c)\left[\frac{\frac{\partial^2 \Delta G(n_c)}{\partial n^2}}{2\pi kT}\right]^{1/2} = DC_oZ$$

where

$$Z = \left[\frac{\frac{\partial^2 \Delta G(n_c)}{\partial n^2}}{2\pi kT}\right]^{1/2} = \left[\frac{-1}{2\pi}\left(\frac{\partial^2 \ln C_o(n_c)}{\partial n^2}\right)\right]^{1/2}$$

Z is generally called the <u>Zeldovich Factor</u>.

Nucleation Product Phase Size Distribution
Of ten, observations on nucleation processes yield a product phase size distribution. However, the usual analysis of nucleation does not seem to treat this result in a clear manner. We expect that the size distribution is Gaussian in nature. To develop an analytical expression we can examine a spherical nucleus geometry as an illustration.

The work to form a cluster of radius, r is given by at the critical size, $d\Delta G(r)/dr = 0$ and

$$\Delta G(r) = 4\pi r^2 \sigma + \frac{4}{3}\pi r^3 \Delta G_v$$

which yields

$$r^* = -2\sigma / \Delta G_v$$

$$\Delta G^* = \frac{16\pi\sigma^3}{3\Delta G_v^2}$$

Now, ΔG^* can be expressed in terms of r^* by substituting $\Delta G_v = -2\sigma/r^*$ so that

$$\Delta G^* = \frac{4\pi\sigma r^{*2}}{3}$$

Thus, the nucleation barrier is 1/3 of the surface energy of the cluster. Also , the concentration of clusters is given by

$$c\left(r^*\right)=c\left(1\right)\exp\left(\frac{-\Delta G^*}{kT}\right)$$

where c(1) is the concentration of monomers. If we examine cluster sizes near r^* (i.e. (r^*-r)) and expand $\Delta G(r)$ we obtain

$$G\left(r\right)=\Delta G\left(r^* - \Delta r\right)=\Delta G\left(r\right)_{r^*}+\left[\frac{d\Delta G\left(r\right)}{dr}\right]_{r^*}\Delta r+\left[\frac{d^2\Delta G\left(r\right)}{dr^2}\right]_{r^*}\frac{\Delta r^2}{2}$$

Since $\left[\dfrac{d\Delta G\left(r\right)}{dr}\right]_{r^*}=0$

$$\Delta G\left(r\right)=\frac{4\pi\sigma r^2}{3}+\left[\frac{d^2\Delta G\left(r\right)}{dr^2}\right]_{r^*}\frac{\Delta r^2}{2}$$

We can also note that

$$\left[\frac{d^2\Delta G\left(r\right)}{dr^2}\right]_{r^*} = 8\pi\sigma + 8\pi r^* \Delta G_v = 8\pi\sigma + 8\pi r^* (-2\sigma/\Delta G_v)\, \Delta G_v = -8\pi\sigma$$

then,

$$\Delta G(r) = \frac{4\pi\sigma r^2}{3} - 8\pi\sigma\frac{\Delta r^2}{2}$$

so that

$$c(r) = c(r^*)\exp\left(\frac{4\pi\sigma\Delta r^2}{kT}\right)$$

The normal distribution is

$$P(x) = \frac{1}{s(2\pi)^{1/2}}\exp\left(-\frac{\left(x - \bar{x}\right)^2}{2s^2}\right)$$

which indicates that

$$s = \left(\frac{kT}{4\pi\sigma}\right)^{1/2} \qquad \text{and that} \qquad \bar{x} = r^*$$

Thus, the measured distribution parameters can be used to determine r^* and σ which in turn will give ΔG^* and J.

Nucleation Theorems

Most of the existing methods of analyzing nucleation behavior are linked to specific models. Nucleation theorems developed by Kashchiev offer a general model independent analysis to determine properties of the critical nucleus. Since the initial introduction, several variants have been developed

1ˢᵗ Nucleation Theorem

$$\frac{\partial W^*}{\partial \mu_{oi}}\bigg|_T = -\Delta n_i^*$$

Δn^* is the excess number of atoms of type i in the nucleus over that present in the same volume of the original phase

1st Nucleation Theorem (cont'd)

$$\frac{\partial W^*}{\partial T}\bigg|_{\mu} = -\Delta S^*$$

$$\frac{\partial W^*}{\partial P}\bigg|_{T} = -v_0 \Delta n^*$$

Application

$$J = A\exp(-W^* / k\mathrm{T})$$

$$W^* = -k\mathrm{T}\ln J + k\mathrm{T}\ln A$$

$$-\Delta n^* = \frac{\partial W^*}{\partial \mu_{oi}}\bigg|_{\mathrm{T}} = -\frac{\partial(k\mathrm{T}\ln J)}{\partial \mu_{oi}} + \frac{\partial(k\mathrm{T}\ln A)}{\partial \mu_{oi}}$$

Binary Systems

- Measure "critical supersaturation" (or constant J)

$$k\mathrm{T}d\ln J = \mathrm{O} = k\mathrm{T}d\ln A - dW^* \cong -dW^*$$

$$W^* = f(a_1, a_2)$$

$$\mathrm{O} = -dW^* = -\left(\frac{\partial W^*}{\partial \ln a_1}\right)_{\mathrm{T}} d\ln a_1 - \left(\frac{\partial W^*}{\partial \ln a_2}\right)_{\mathrm{T}} d\ln a_2$$

Binary Systems (cont'd)

$$kTd \ln a_1 = d\mu_{o,1} \quad \text{and} \quad kTd \ln a_2 = d\mu_{o,2}$$

$$O = \Delta n_1^* d \ln a_1 + \Delta n_2^* d \ln a_2$$

or

$$\left(\frac{\partial \ln a_2}{\partial \ln a_1}\right)_{T,J} = -\frac{\Delta n_1^*}{\Delta n_2^*}$$

2$^{\text{nd}}$ Nucleation Theorem

$$\left(\frac{\partial(W^*/\mathrm{T})}{\partial \mathrm{T}}\right)_p = -\frac{1}{\mathrm{T}^2}\,(\Delta E^* - h_0 \Delta n^*)$$

ΔE^* is the energy change through creation of the critical cluster and h_0 is the enthalpy per atom in the parent phase.

$$\left(\frac{\partial \ln J}{\partial \mathrm{T}}\right)_{P_0} = \left(\frac{\partial \ln A}{\partial \mathrm{T}}\right)_{P_0} + \frac{1}{k\mathrm{T}^2}(\Delta E^* - n^* L_f)$$

Delay Time and Steady State Nucleation

$$J = Z\beta C(n^*) \qquad \tau = (\theta\beta Z^2)^{-1}$$

$$J\tau = C(n^*)/\theta Z$$

$$Z = [\Delta G(n^*)/(3\pi k\mathrm{T})n^{*2}]^{1/2}$$

$$Z = (1/8\pi v_b)(\sigma/kT)^{-3/2}(\ln S)^2$$

$$\ln(J\tau) = \ln(N_0/\theta Z) - (16\pi\sigma^3 v_b^3/3k^3)/[\mathrm{T}^3(\ln S^2)]$$

$\rho = $ MRO number densty

$\beta = 4\pi r^{*2} D C_0 a^{-4} = $ Attachment Frequency

$$Z = \frac{\Delta G_V^2 v_a}{8\pi\sqrt{k_B T \sigma^3}} = \text{Zeldovich factor}$$

$$J_{SS} = \frac{\rho 4\pi r^{*2} D C_0 \Delta G_v^2 v_a}{8 a^4 \pi \sqrt{k_B T \sigma^3}} \exp\left(\frac{-\Delta G^*}{k_B T}\right)$$
Transient Nucleation

- Changes in MRO number density do not account for nucleation enhancement
- The base model can now be used to analyze number densities observed at different temperatures

$$J_t = J_{SS} \exp\left(-\frac{\tau}{t}\right)$$

Solving for τ,

$$\tau = \frac{1}{\beta Z^2} = \frac{8 k_B T \sigma a^4}{D \Delta G_v^2 C_0 v_a^2}$$
Transient Nucleation

▶ Transient time constant evaluated for AlYFe.

$$J_T = J_{SS} \exp\left(-\frac{\tau}{t}\right)$$

$$\tau = \frac{1}{\beta Z^2} = \frac{8 k_B T \sigma a^4}{D \Delta G_v^2 C_0 v_a^2}$$

Without site saturation effects
Growth Modeling

- Rapid size increase due to interfacial growth mechanism

- Diffusion controlled growth of larger particles

- Growth inhibited by diffusion field impingement.

- Interfacial instability leads to dendritic type growth

200 nm   200 nm   200 nm
Spherical growth   Dendritic growth

Current status of combined model

- Crystallization start temperatures can be reproduced over a range of compositions and heating rates.

- Poor fitting during the later stages of the reaction is attributed to the complicated growth.

- Improved growth/transport analysis will also aid the interpretation of nucleation

0.0

2

Nucleation Product Density Calculation

Extended Volume Fraction: $X_e = \int_0^t J_s \frac{4\pi}{3}[v(t-\tau)]^3 \, dt = \frac{4\pi J v^3}{3} \int_0^t t^3 \, dt$

$$X_e = \frac{\pi}{3} J v^3 t^4$$

Now, X, the real volume fraction transformed is:
$$X = 1 - \exp(-X_e)$$

For $X = 0.99 \, ; \, X_e \sim 5$

The number density, ρ, of nanocrystals is given by

$$\rho = \int_0^t J(1 - X(t)) \, dt = J \int_0^t \exp(-X_e) \, dt$$

to find the maimum in ρ we let $t \to \infty$

$$\rho_m = J \int_0^\infty \exp\left(\frac{-\pi}{3} J v^3 t^4\right) dt = J \int_0^\infty \exp(-k t^4) \, dt$$

$$k = \frac{\pi}{3} J v^3$$

Product Density Continued

Where: $\int\limits_0^\infty \exp(-y)\, y^{-3/4}\, dy$ is the Γ function

$$\Gamma(n) = \int\limits_0^\infty e^{-y}\, y^{n-1}\, dy \qquad \text{So,}$$

$$n-1 = -3/4 \quad ; \quad n = 1/4$$

$$\Gamma(1/4) = \Gamma\frac{(1.25)}{0.25} = \frac{0.9064}{0.25} = 3.63$$

$$\rho = \frac{3.63\,J}{4\,k^{1/4}} = 0.897\left(\frac{J}{v}\right)^{3/4}$$

For $\rho = 2.9*10^{21}$

$$\frac{J}{v} = 4.7*10^{28} \quad \text{For } J = 10^{18} \text{ and } v_a = 10^{-10}\,\text{(m/s)}$$

Now, for 1 hr, $d = 21\,nm$

$$\frac{r}{t} = \frac{10\ \text{nm}}{3600\ \text{s}} = 2.7*10^{-3}\,\text{nm/s} = 2.7*10^{-12}\,\text{m/s}$$

For $v = 2.7*10^{-12}$ m/s

$$J \rightarrow 1.2*10^{17}\ \text{m}^{-3}$$

Transport Question

- The magnitude of change in the transient behavior is very large ($>10^{2)}$) for a single atomic percent substitution. This is puzzling if it is dependent upon the simple change in diffusion.

- How do we consider cluster development by atomic addition in this partially ordered environment with different time constants?
Intermediate Phase Nucleation During Interdiffusion

- Initial Phase Establishes Phase Sequence

- Role of 👍C – Precursor Stage
  $$\text{i.e. } r^* \propto \Delta C / 👍C$$

- Influence of ΔD

Al88Y7Fe4.5Cu0.5 Annealed at 205C/478K
Nucleation and Growth Model

- Measured nanocrystal and MRO densities and sizes act as the direct input to develop the model

- Analysis results are tested to reproduce the measured data
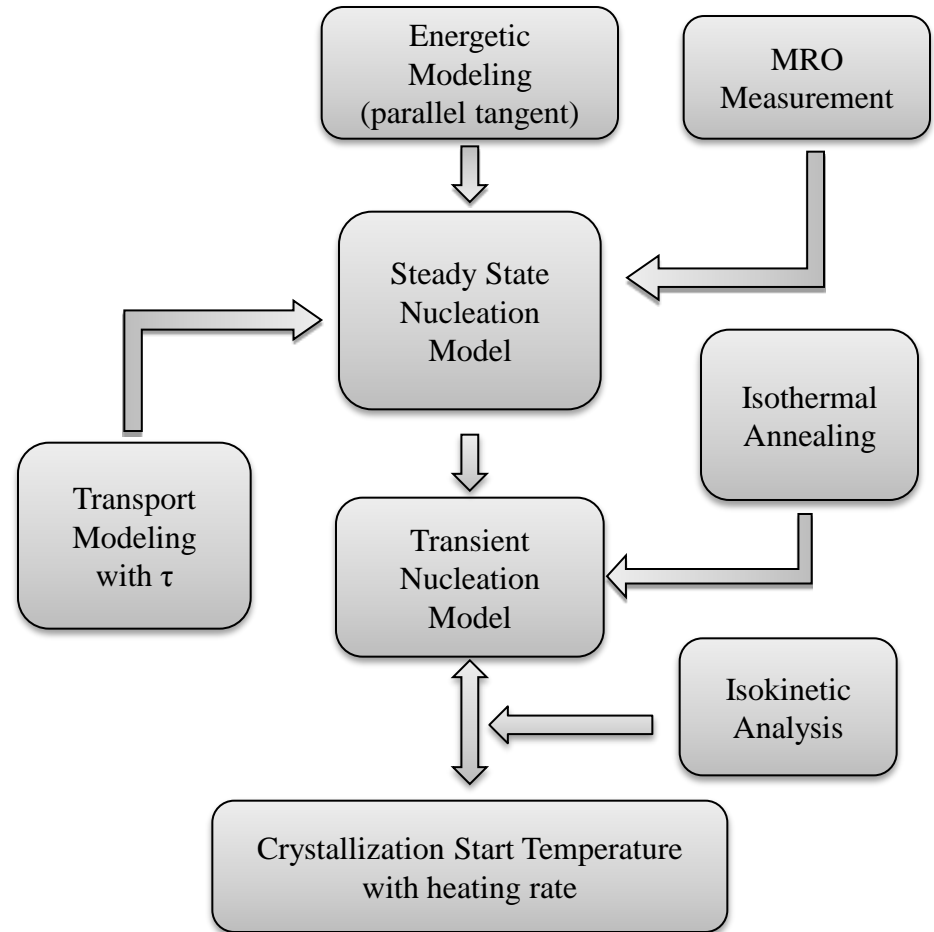

Volume per transformation zone: $10^{-28} m^3$ Heat per t. zone: $10^{-20} J$

With 10^{26} transformation zones per m^3 Heat released: $10^6 J/m^3$

MRO and FEM mode

• Medium range order in $Al_{88}Y_7Fe_5$ and with Cu substitution refers to Al crystal-like structure (0.6 to 2 nm in d)

• In nanodiffraction FEM mode, we can control the resolution by controlling the probe size

• Advantages in nanodiffraction mode:
1. Enhanced coherence
2. Resolution can vary continuously
3. High k range

Soft Magnetic Nanomaterials

- Applications
  - Energy devices
    - Generators
    - Transformers
    - Motors
  - Electromagnetic shielding
  - Data Storage
  - Biomedical devices
  - Surveillance tags

- $\uparrow$ energy efficiency by making softer magnetic materials
- Solution: Go Nano!

What do we want?

- Many amorphous magnetic materials are very soft
- High density of soft magnetic nanocrystals in a soft magnetic amorphous matrix ➔ magnetically softer!
- High nucleation rate of crystals + low growth rate
- Herzer Model: Nano ppts: H_C ~ (crystal size)^6
- Crystallize amorphous magnetic material by heat treatment
Challenge

- Can a microstructure of high density of soft magnetic precipitates in a soft magnetic amorphous matrix be magnetically softer than the famous
  - Permalloy (Fe-Ni)
  - Fe-Co for high temp. aircraft applications
  - Fe-Si-B (transformer steel)

  YES!
- Which elements will increase nucleation rate and reduce growth rate of precipitates?
- Commercial nanocrystalline magnetic alloys
  - $Fe_{73.5}Si_{13.5}Nb_3B_9Cu_1$ (FINEMET)
  - $Fe_{88}Zr_7B_4Cu_1$ (NANOPERM)
  - $Fe_{44}Co_{44}Zr_7B_4Cu_1$ (HITPERM)

Application of nucleation and growth concepts to produce soft magnetic nanostructures

– Fe-Ni-B-Mo

– Fe-Co-B-Zr

– Fe-Si-B-Nb-Cu

Nucleation in Permaloy based Fe-Ni-B-Mo magnetic nanomaterials

Objective

- Fe-Ni-B-Mo

  – To understand role of Mo and B in producing high nucleation rate and low growth rate

J. Alloys Compounds, 425, 251-260 (2006)
J. Non-Crystalline Solids, 351, 3105-3113 (2005)

- Fe-Co-B-Zr
- Fe-Si-B-Nb-Cu

Nanocrystallization of HiTperm
$Co_{44.5}Fe_{44.5}Zr_7B_4$

Nanocrystallization of initially amorphous HiTperm Co$_{44.5}$Fe$_{44.5}$Zr$_7$B$_4$
- **High nucleation rate, low growth rate**

Application of nucleation and growth concepts to produce soft magnetic nanostructures

- Fe-Ni-B-Mo
- Fe-Co-B-Zr
- Fe-Si-B-Nb-Cu

Finemet type alloys

- Fe-Si-B-Cu-Nb alloys (transformer steel based)

- Excellent magnetic properties with **combined** Cu & Nb alloying additions in Fe-Si-B alloy due to nanostructure formation

- Conventional (incorrect) view:
  - Role of Cu is to $\uparrow$ nucleation
  - role of Nb is to $\downarrow$ growth.

Objective

- What is the role of Cu and Nb alloying additions in nanostructure formation in Fe-Si-B-Cu-Nb alloys?

Methodology

- Effects of alloying additions: 1 at% Cu and 3 at% Nb in amorphous Fe-Si-B-Cu-Nb alloy.

Morphology after primary crystallization

Fe-Si-B
Fe-Si-B-Cu

Fe-Si-B-Nb
Fe-Si-B-Cu-Nb

Equiaxed to dendrite morphological transition in Fe-Si-B
Fe-Si-B alloy

- Dendrites of closely spaced Fe-Si crystals, spacing ~ nanometers.

- In-situ hot stage TEM: equiaxed → dendritic morphological transition at critical size of ~ 45 nm . Explained by morphological stability theories.

Effect of Cu addition

In-situ hot stage TEM of Fe-Si-B-Cu

- **400ºC for 306s**

- **400ºC for 318s**
- **450ºC for 600s**

Unstable interface of spheroidal crystal when crystal size > than 100nm.

Effect of Cu alloying addition
Free energy G-curve for amorphous matrix and crystallization product

Fe-Si-B-Cu

- Cu addition influenced **both** nucleation and growth
  - spheroidal crystals ~ 100 nm, rough interfaces .

- Crystal density ↑, crystal size ↓. However, crystal density << than in Fe-Si-B-Nb-Cu.

- Driving force for nucleation ↑.

Effect of Nb addition

Eutectic crystallization of Fe-Si-B-Nb alloy
(1)   (2)

TEM micrographs of the alloy with **Nb**, after heat treatment at 550 °C for (1)0.5 h and (2)24 h

Equiaxed

Effect of Nb addition
Free energy G-curve for amorphous matrix and crystallization product

Fe-Si-B-Nb

- Eutectic crystallization:Fe-Si, Fe_3B and $Fe_{23}B_6$

- Greater $\uparrow$ in crystal density, $\downarrow$ of crystal size compared to Cu addition.

- But, cannot obtain high crystal density and small crystal size of Fe-Si-B-Nb-Cu.

- Hence, synergetic effects of combined Cu and Nb additions key to nanostructure formation

Effect of both Cu and Nb additions

Cu and Nb EELS map at initial stage of crystallization

Maximum crystal size as function of annealing time: (1)Fe-Si-B (2)Fe-Si-B-Cu (3)Fe-Si-B-Nb (4)Fe-Si-B-Nb-Cu alloy at 500 $^{\circ}$C

The number of crystal per unit volume as function of annealing time: (1) Fe-Si-B -Nb-Cu (2) Fe-Si-B-Nb (3) Fe-Si-B-Cu (4) Fe-Si-B alloy at 500 $^{\circ}$C

Johnson-Mehl-Avrami-Kolmogorov Plot

- JMAK equation

    $X = 1 - exp[(Kt)^n]$

- Avrami exponent

    $n = 0.25$

    Usual value 1-4
Conclusions

- Alloying with Cu, Nb had dramatic effects on nanostructure formation in iron-based soft magnetic materials

- Studied by DSC, XRD, EDX , EELS, conventional & in-situ hot stage TEM.

Fe-Si-B-Nb-Cu

Novel mechanism of nanostructure formation (synergetic effects of combined Cu and Nb)

- Contrary to most models, we find that **both** Nb and Cu influence nucleation and growth processes.

- Combined additions ➔ small crystal size and high crystal density.

- High nucleation rate ➔ **both** Cu and Nb rich regions ➔ high number of heterogeneous nucleation sites.

- Low growth rate due to strong interaction of Cu, Si, Nb and B atoms, consistent with Hunziker model.

Summary

- A high density of soft magnetic nanoprecipitates in an amorphous matrix yield superior soft magnetic properties
- Nucleation and growth concepts have been used to produce novel soft magnetic nanostructures in iron and Co based soft magnetic materials

What is grain boundary engineering?

- **Simple processing can enhance resistance to intergranular failure/degradation by 3X-5X or more**

- **Based on using "special" grain boundaries (e.g. coherent twin) to break up the network of weaker "random" grain boundaries**

- **Works on many different failure modes**
  - **Stress corrosion cracking**
  - **Impurity embrittlement**
  - **Microstructural coarsening**
  - **Magnetic flux penetration in superconductors**

Key concept: Context matters!
The grain boundary *network* is essential.

Consider two grain boundary networks.

Suppose red boundaries are strong, blue boundaries are weak.
If this boundary fails, not much happens.

If this boundary fails, the whole material can come apart.
Focus of this talk: What does nucleation and growth of twins do on the scale of the grain boundary network?

Given the characteristics of the nucleation and growth, . . .

- Crystallography

- Anisotropy and texturing

- Combinatorics governed by crystallographic constraints

- Dominant morphologies

. . . what does this do to the network properties?

- Special/random percolation thresholds

- Correlation lengths and supra-grain structure

- Large-scale resistance to intergranular degradation

For many metals, the dominant special boundary is the $\Sigma 3$ {111} twin

- Low stacking fault energy fcc materials (e.g. Cu, Ni)
- Two mirror-image grains sharing a {111} plane
- Twins form as deformed material anneals
- Twin boundaries tend to be large, flat, smooth, and stable
- When $\Sigma 3$'s meet, they can generate $\Sigma 9$'s, $\Sigma 27$'s, etc.
- $\Sigma 3^n$ "twin-related" grain boundaries dominate the statistics

Non-$\Sigma 3^n$ CSL

Definition: CSL = Coincident Site Lattice
Cyclic thermomechanical processing enhances the populations of twin-related boundaries
Initial microstructure
~45% special
Multi-step thermomechanical processing sequence[*]
Final microstructure
~80% special

Rolling
5 - 20% reduction

Repeat
3 - 7 times
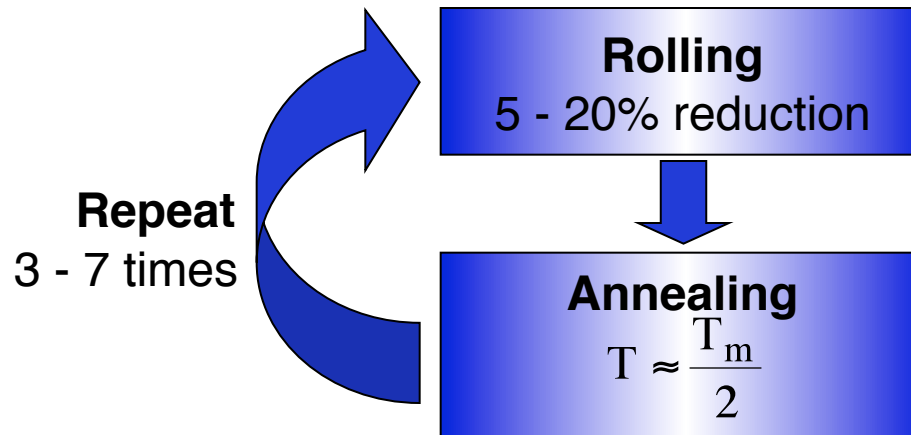

Annealing
$$T \approx \frac{T_m}{2}$$

Red = $\Sigma 3$ boundaries
Black = Random boundaries

[*]*G. Palumbo, US Patent 5,702,543 (1997); and Kumar, King, Schwartz Acta Materialia (2000)*

There are two often-cited mechanisms for nucleating annealing twins in fcc materials

- **Growth accidents**
  - One layer of hcp within fcc (ABCBA stacking)
  - Possible mechanism: Shockley partials forming on moving, faceted boundaries
  - Often makes simple morphologies ("back-and-forth" twinning)

- **Recrystallization**
  - Driven by plastically stored energy
  - Nucleation frequently at existing boundaries or triple junctions
  - More isotropic; which variant you gets depends on unknown local factors

Simple Twinning   Complex Twinning

CBA

ABC

(a)   (b)

(c)   (d)

(e)   (f)

Key to grain boundaries
— Σ3
— Σ9
— Σ27
— Random
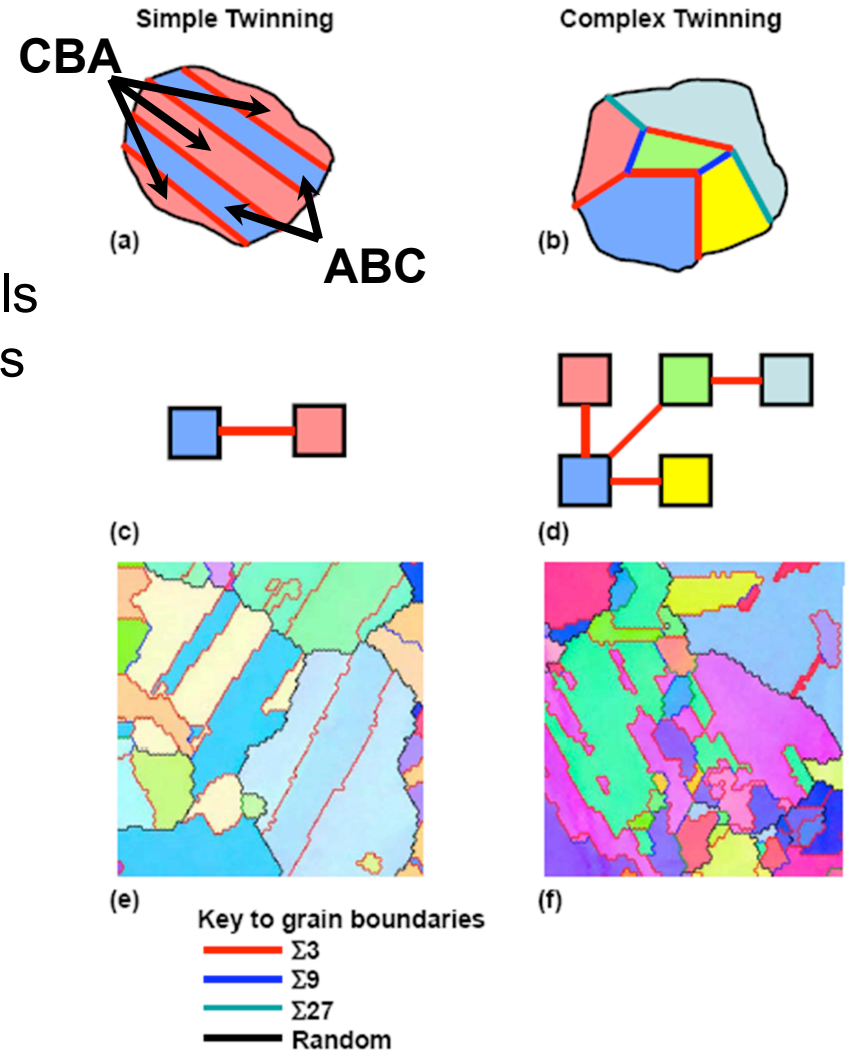

Recrystallization produces twins that have far more interesting effects on the boundary network

- **Nucleate at boundaries (or junctions)**
- **Nucleation can be far more isotropic than for growth accidents**
  - This facilitates cross-twinning, including creation of $\Sigma 9$, $\Sigma 27$, etc.
- **Fueled by dislocation energy, leaving behind well-annealed crystal**
- **$\Sigma 3$ boundaries include both coherent and incoherent segments**
  - Complex morphology facilitates more complex network
  - Mobile incoherent segments can move into neighboring grains
TEM image of annealing twins in steel, from A. R. Jones, J. Mat Sci 16, 1374 (1981)

The grains develop into clusters that we call Twin-Related Domains (TRD)
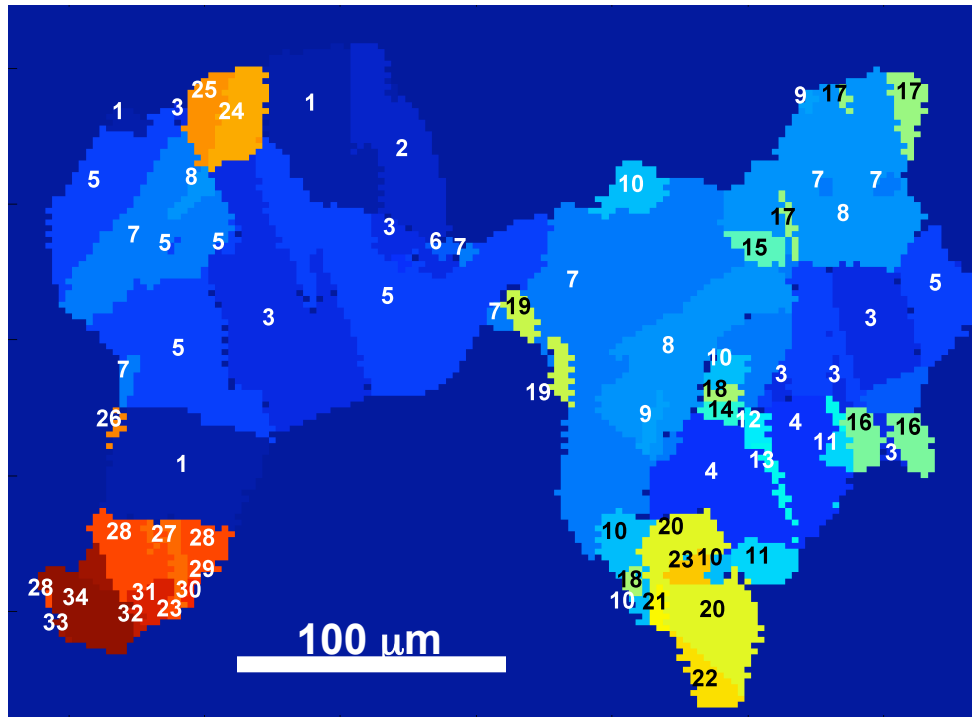

An initial grain grows and forms multiple twins, making an extended complex structure with hundreds of grains

When the domains are well developed, we pass through a percolation threshold.
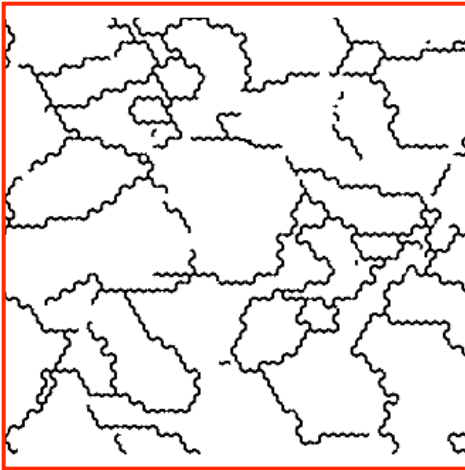

As received	2 processing cycles	4 processing cycles	
			Random Boundaries
			Special Boundaries
$f = 0.44$	$f = 0.52$	$f = 0.62$	
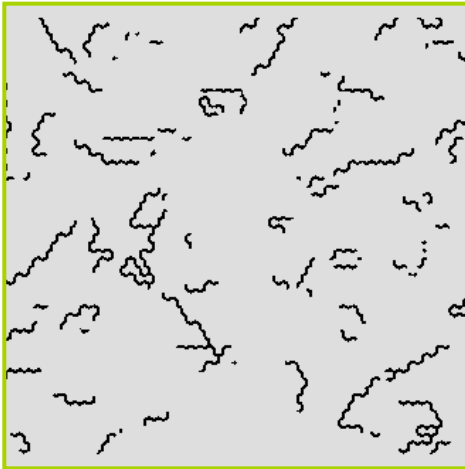

The surfaces created by intergranular cracking look completely different in normal and engineered materials
Normal Material

- Anisotropic ridges parallel to crack propagation over wide range of length scales

Engineered Material

- Isotropic, uniform, more randomly rough (like a random walk)

Conventional representations of grain orientations don't handle multiple twinning well.

- **There are specific mechanisms that produce, for a given grain, one of four variant twin orientations**
- **These are high-angle grain boundaries (60° <111>) that aren't going to be found in a local fluctuation**
- **The new misorientation is very nearly perfect, usually within 1°**

> **You want to have a representation that explicitly includes these exact, discrete possibilities; nucleating "by chance" in quaternion space will waste a lot of CPU cycles.**

> **Real microstructures can have twin chains 10 or 11 units long! This needs *a lot* of orientations to be in the ensemble.**

Importance of misorientation relationships: To stop a random boundary path in two dimensions, you need a "J_2" triple junction

J_0 J_1 J_2 J_3

Preferred crack paths (red arrows) only stop at J_2's
M_1 M_2 M_3

But there's a constraint:

$$M_1 M_2 M_3 = I$$

And special misorientations tend to be related to each other.

$$\Rightarrow J_2 \text{ is suppressed!}$$

$J_2/(1-J_3)$ correlates with clustering behavior.
(Kumar, King, Schwartz Acta Mater. 48, 2081 (2000))

The Σ combination rule governs Coincident Site Lattice combinations allowed at a triple junction

If two boundaries at a triple junction are CSL boundaries, then so is the third.

The three Σ values are related:

$$X\,Y = k^2 Z,$$

$$\frac{X}{k}, \frac{Y}{k} \text{ are integers}$$

Grain A   ΣX   Grain B

ΣY   ΣZ

Grain C

Allowed:

Σ3 / Σ3 Σ9   Σ9 / Σ9 Σ9   Σ3 / Σ9 Σ27

Disallowed:

Σ3 / Σ3 Σ3   Σ3 / Σ9 Σ9   Σ3 / Σ5 Σ9

Lawrence Livermore National Laboratory

LLNL-PRES-430016
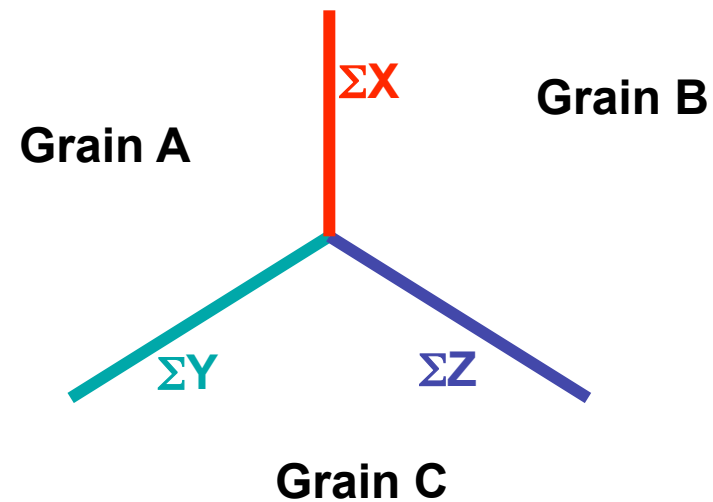

The Σ combination rule alone significantly alters the statistical properties of the network.

(From Minich, Schuh, and Kumar, Phys. Rev. B **66,** 052101 (2002) and Schuh, Minich, and Kumar, Phil. Mag. **83,** 711 (2003).)
Triple Junction Distributions
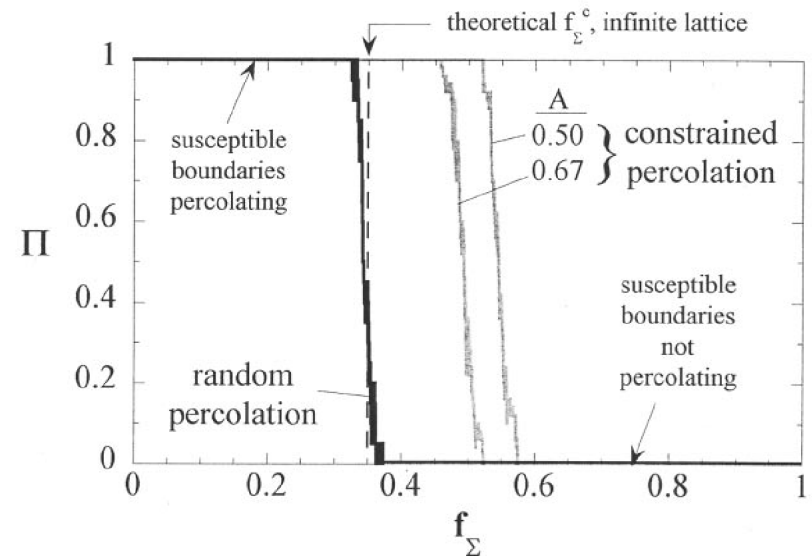

Weak Boundary Percolation
Probability vs. Special Fraction

Simple model:
Σ combination rule at triple junctions
Σ3, Σ9, Σ27, Random
Explains most of the observed correlations.

But how many more correlations are hiding?

The Σ combination rule can be generalized by working out the structure of the entire group.

Vertex = grain orientation

Link = one of the four Σ3 twinning operations (a,b,c,d)

Each vertex has exactly 4 neighbors

There are no loops

Tree is infinite and highly symmetric

Reed, Minich, Rudd, Kumar, Acta Crystallographica A (2004)
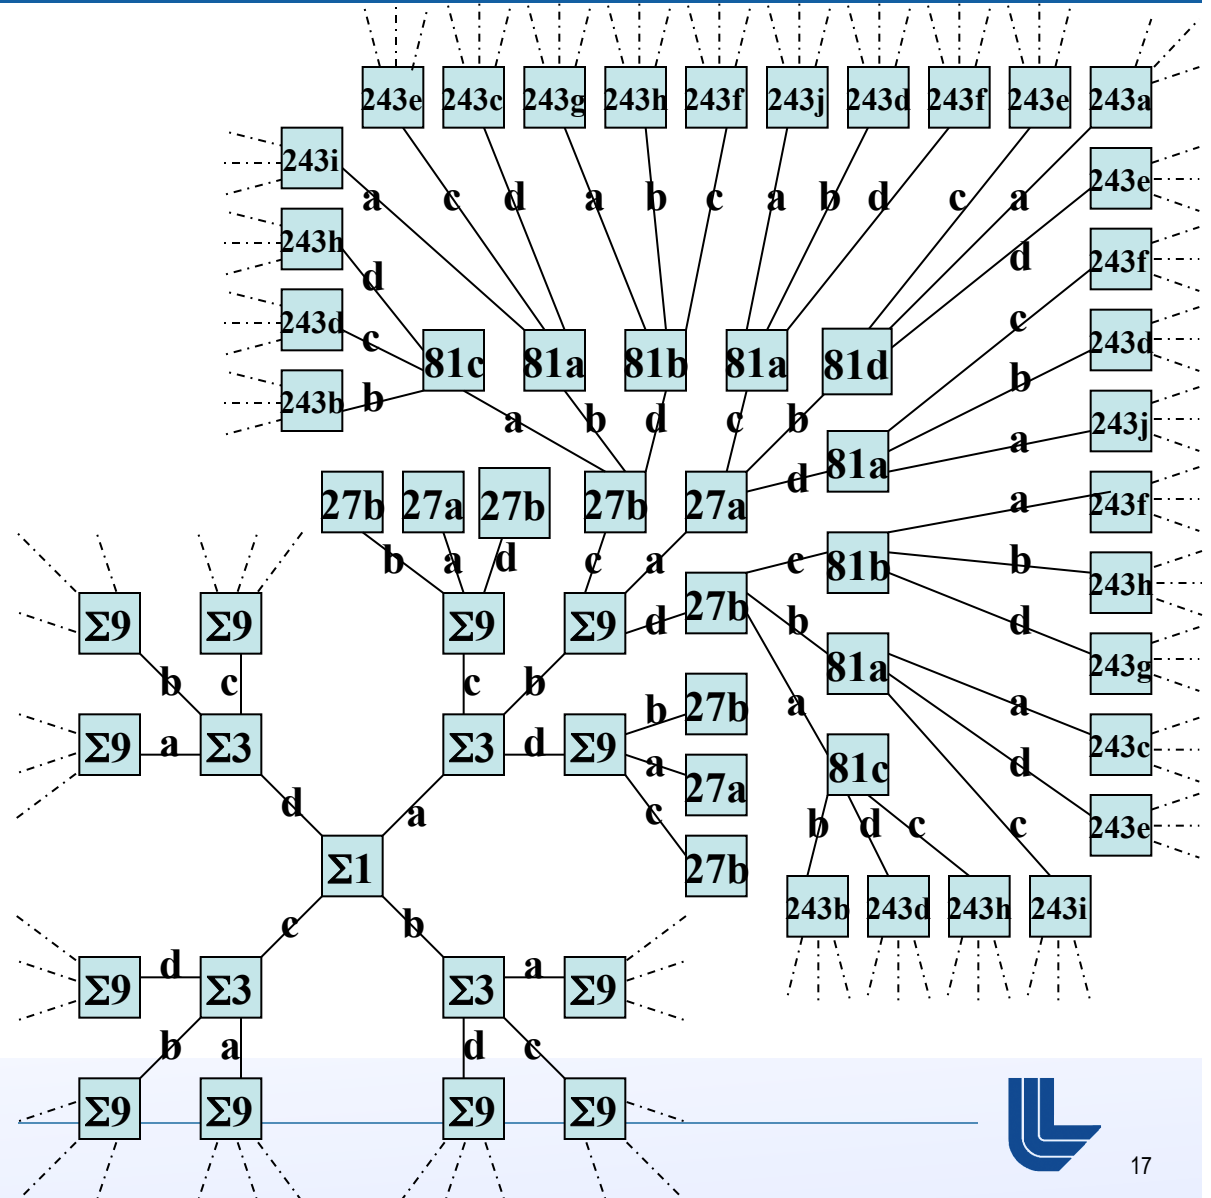

There is potentially an infinite number of constraints on the network.

Σ combination rule satisfied, yet triple junction invalid
All triple junctions valid, yet quadruple node invalid
All quadruple nodes valid, yet larger cluster invalid
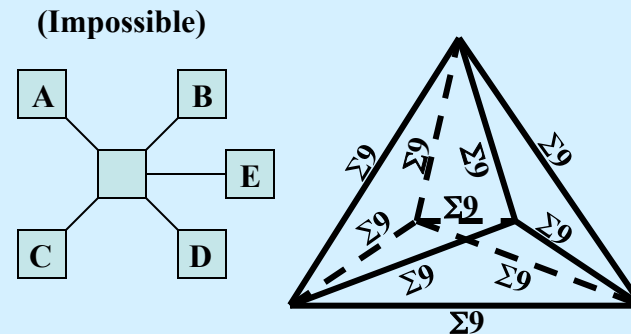

It's possible to efficiently account for the constraints in a model developed for highly-twinned materials.

- **Treat everything as a perfect $\Sigma 3^n$ orientation**
- **Use string representation with 4-letter alphabet**
- **Define energy metric:**

Σ	Comment	Typical Energy
1	No boundary at all	-1 (grain growth) or ∞ (static topology)
3	Perfect twin	-0.9 (Cu) to -0.3 (Al)
9	Twin variant	-0.5 to -0.2
27	2nd twin variant	-0.3 to -0.1
81+	Random	0

- **Pick a topology (2-D or 3-D, random or ordered)**
- **Assign initial orientation strings to each grain**
- **Pick a temperature $1/\beta$ and run a Metropolis Monte Carlo calculation**

The Potts-like Monte Carlo simulations yield statistically realistic microstructures with very few free parameters

Potts-like model including grain growth and twinning, efficiently calculated using $\Sigma 3^n$ strings, and guaranteed to satisfy all constraints

(a) Experiment   (b) Model

- Designed to mimic topology of a specific engineered Cu sample
- 5 free parameters
- <10 CPU-seconds to generate

- Designed to match detailed statistics of a specific engineered Cu sample
- ~10 CPU-hours to optimize over 5-parameter space
- All metrics match within uncertainty

Work in progress: Combine the twin nucleation algebra with phase field modeling

- Monte Carlo run rapidly produces statistically realistic initial structure and a useable ensemble of grain orientations

- Phase field evolves this using a grain boundary energy and mobility metric

  - Multi-variable phase-field model for grain growth distinguishes among random boundaries, special boundaries and vicinal boundaries.

  - Assign GB energies and mobilities that depend on misorientation and will include grain boundary plane dependence in near future

  - Track evolution of grain size, GB character distribution, and network connectivity in phase-field simulations

- Progress towards efficient simulation of crystallographically realistic multiple-twinning model including nucleation of new twin grains

Adjusting the energy is not enough—low special boundary mobility is important for realistic stabilization of the network

Initial microstructure from Monte Carlo
Scenario 1:
Random and special boundaries have different mobilities and different energies

Realistic Pinning
Scenario 2:
Random and special boundaries have different energies

Unrealistic Results

Legend:
- **Random** (purple)
- **Σ3** (red)
- **Σ9** (orange)
- **Σ27** (yellow)
Grain boundary plane anisotropy is necessary to get the model to nucleate while remaining stable

No GB Plane Anisotropy

To nucleate twins, a transition like this should be energetically favorable:
But then nothing stops the triple junctions from "unzipping" out of existence!
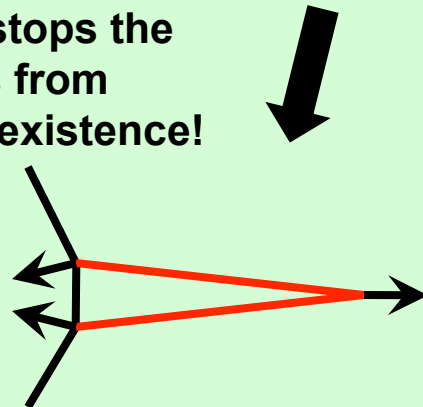

Σ3
Σ9
Random

GB Plane Anisotropy

In reality, a Σ3 is only really low energy close to a particular {111} plane

{111}

Very stable triple junction

{1$\bar{1}\bar{1}$}
The most interesting morphologies depend on some parts of the boundary being far more mobile than others

{111}

{111}

Fast-moving incoherent Σ3 boundary segment
Multiply-twinned nanoparticles offer clues for making a finite orientation ensemble for the phase field model

- **Many fcc nanoparticles (< 10 nm) form icosahedral multi-twinned structures**

- **20 grains, 10 grain orientations, 30 twin boundaries, 12 twin pentajunctions**

- **Each grain exposes low-energy {111} faces to the outside world and to its neighbors**

- **Each link in the graph is a 72° <110> rotation, a good approximation to the 70.5° <110> $\Sigma 3$**

- **Downsides:**
  - **Each grain is rhombohedrally distorted**
  - **Each orientation only has 3 neighbors in the network instead of 4**
  - **Pentajunctions are far too easy to form**
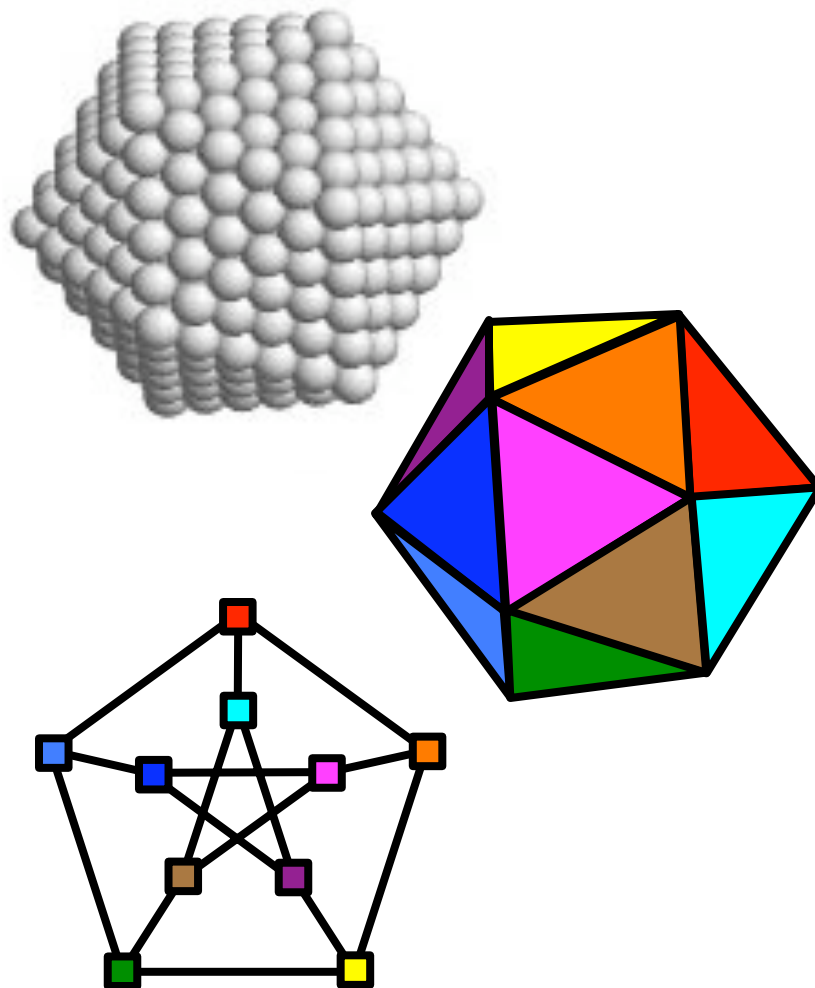

X. Yang et. al, J. Phys. Chem. A. 111 (2007) 5048
C. Y. Yang, J. Crystal Growth 47, 274 (1979)
D. Reinhard et al., Phys. Rev. B 55, 7868 (1997)
K. J. Koski et al., Phys. Rev. B 78, 165410 (2008)

Summary and Future Directions

- Grain boundary engineered materials have complex network properties that depend heavily on mathematical constraints on twin nucleation, growth, and interaction

- These properties produce supra-grain correlations that are important for large-scale material properties

- We are developing simulation approaches that efficiently handle the mathematics of multiple twinning

  - Capturing the essence of the network constraints is demonstrated

  - Group theoretical formalism handles twin nucleation efficiently in Monte Carlo simulations

  - More predictive phase field simulations are under development

- Realistic network properties are easy to get. Realistic evolution needs a great deal more physics to be in the model.

Neighboring TRD's are usually separated by random boundaries

200.0 µm = 80 steps
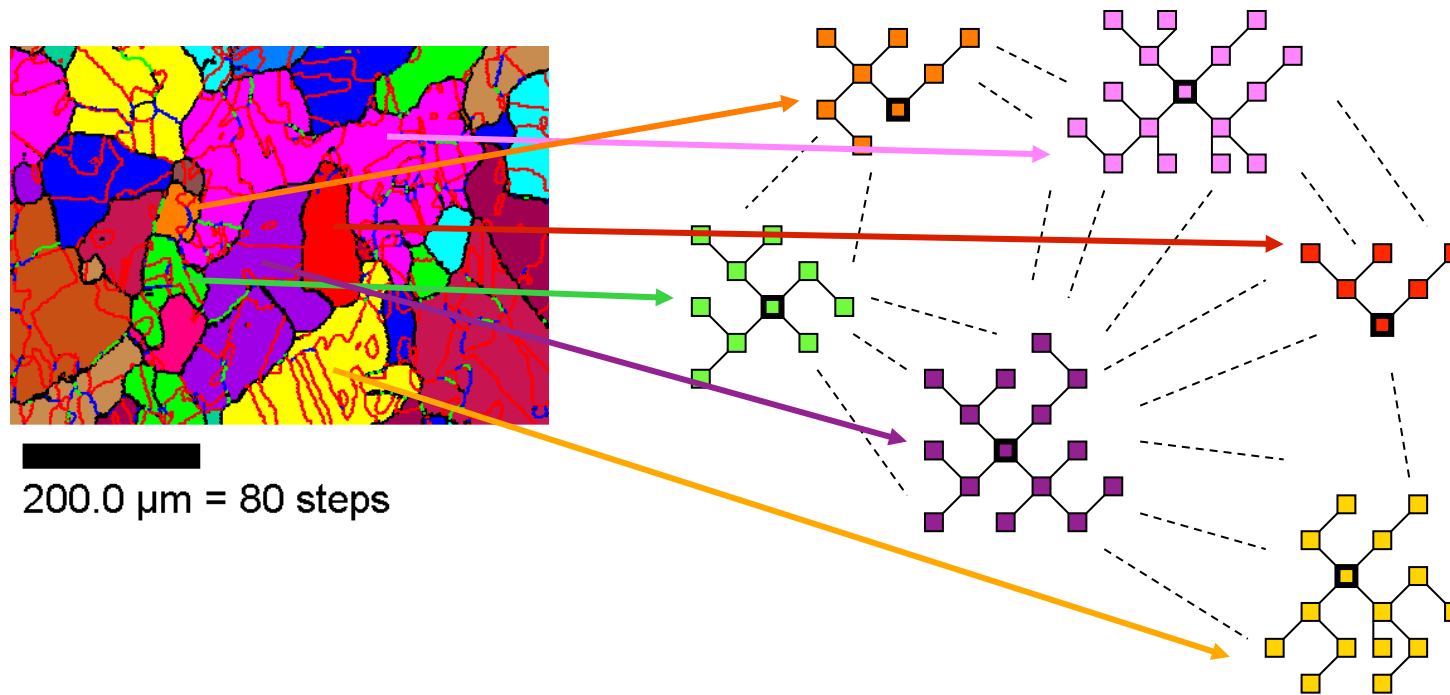

- The grain orientations in neighboring TRD's are unrelated.
- They still form special boundaries occasionally, breaking up the random boundary clusters.

Grain boundary networks in conventional and engineered materials are qualitatively different
300 μm   Normal Material, *f* = 0.49
300 μm Engineered Material, *f* = 0.60

- Mostly flat Σ3's, twinning back-and-forth on the same {111} planes
- Simple intra-TRD networks
- Few distinct orientations in each TRD

- Highly complex intra-TRD networks
- More frequent inter-TRD special boundaries
- Many distinct orientations in each TRD

Definition: *f* = fraction of CSL boundaries

Weak boundary paths exist on length scales that match measurements of fracture surface roughness

- **Red boundaries are strong (special)**
- **Black boundaries are weak (random)**
- **Background colors are twin-related domains**
Size Scales

Grain diameter 35-70 μm

TRD diameter 70-160 μm

Isolated Random Boundary 10-20 μm

Shows up in the roughness scaling of both materials

Large Random Boundary Cluster 140-160 μm

Shows up in the roughness scaling of the normal material

Example results from Reed et al., Acta Mat. 56, 3278 (2008)

The group structure can be efficiently represented by strings on a four-letter alphabet

- There are four "generators." Call them a, b, c, and d.
- Each represents a twin on a specific {111} plane.
- Each is its own inverse. $aa = bb = cc = dd = \phi$
- Any orientation in the group can be reached by a finite string of these 4 letters.
- Any orientation at all can be approximated by a string of length <16.
- After doing maximal pair cancellation, the string is unique, and the "type" of the rotation is $\Sigma 3^{\text{string length}}$
  - Example: abccbd = abbd = ad is a $\Sigma 3^2 = \Sigma 9$
- The inverse of a string is the same string in reverse order
- The misorientation between two strings is $\text{String}_1^{-1}\text{String}_2$
  - Example: Misorientation between abd and abcd is $(abd)^{-1}abcd = dbaabcd = dbbcd = dcd$, which is a $\Sigma 27$.

> **These are <u>all</u> of the rules. Following these lets you efficiently handle all twin-related orientations while guaranteeing crystallographic consistency.**

Connection with Nucleation & Growth Models

Initial (Precoarsened) States

- site-saturation kinetics $\longrightarrow$ narrow distribution

- constant nucleation rate $\longrightarrow$ wide distribution

Input For Coarsening Models
1.) Start with a coalesced microstructure from a nucleation and growth simulation

2.) Map onto a spin model

$$E = \frac{1}{2} \sum_{i}^{N} \sum_{j}^{26} e(s_i, s_j).$$

Q-state Potts Hamiltonian

Voxels: s = 1,2,...,Q

Srolovitz et al. (1983)
Anderson et al. (1984)
Rollett et al. (1989)

3.) Evolve in time to minimize energy.

Example: Liquid-Phase Sintering
Temporal Evolution

- 128x128x128

-Initial solid fraction: 0.7

-Liquid matrix omitted for visualization.

-Only a portion of the particles present in (a)-(e).

- kT = 1.6

Conclusions

- Concepts from stochastic geometry are useful for describing phase transformation kinetics and associated microstructure.

- In some cases it is possible to deduce nucleation and growth conditions from kinetic data and coalesced microstructures.

-Computer simulation can be used to generate configurations needed for averaging and visualizing microstructures.

- Insights from stochastic geometry can help to tailor transformation microstructures in thin films.

Coarsening

Q-state Potts Model

Used to study grain growth phenomena:

Srolovitz et al. (1983)
Anderson et al. (1984)
Rollett et al. (1989)

- spin orientation $\longrightarrow$ **local phase information**
liquid, solid (grain orientations)

- Hamiltonian: $\qquad E = \dfrac{1}{2} \sum_{i}^{N} \sum_{j}^{26} e(s_i, s_j).$ **sum of interfacial energies**

Wetting conditions are modeled by fixing interfacial energies

Early Work

- **Ostwald Ripening MC Potts Model: Tikare and Cawley (1998)**

    - two-dimensional model
    - fully-wetting condition (interface energy relations)

- **MC Potts Model of Solid-State Sintering of Ceramics: Xiangge et al. (2005)**

    - coarsening in eutectic microstructures

- **Geometrical MC Method: Aldazabal et al. (2004)**

    - simulation of liquid-phase sintering
    - no distinction among orientations

Potts Model

Digitized Initial Microstructure

a possible initial state

- Voxel spin value reflects phase and, for solids, orientation

Liquid voxels: $s = -1$
Solid voxels: $s = 1, 2, \ldots, Q$

- Interface Energies

$e_{ij}=0, \ s_i=s_j$

$e_{ij}=0.8, \ s_i s_j < 0$ (solid/liquid interface)

$e_{ij}=2.0, \ s_i s_j > 0, \ s_i = s_j$ (solid/solid interface)

- Significance of Transitions

dissolution
diffusion
precipitation

Size of Critical Nucleus

kT=1.8

Number of particles larger
than critical nucleus
- Determine <V> as a function of time for identical particles.
 - V_c is the volume where d<V>/dt = 0.
- V_c as a function of temperature

Particle Size Distribution

Summary

Non-classical nucleation theory + NEB is a quite open platform to study nucleation in some details

- greater flexibilities to handle nucleus structure details
- leverage new techniques from phase-field community
- combine new data from other computational methods (ab initio, CALPHAD) or from experiment (e.g., 3DAP)
- at thermodynamic level. Perhaps the only way in the near future to handle chemically complex (multi-component) alloys

Commonality with other 'non-nucleation' problems

Can we control embryo properties?

….it is assumed that solids are so complex that it is better to make approximations first, and then try to show they are consistent with the basic rules of quantum mechanics, and that they yield properties consistent with measured values.

**John Gilman "Electronic Basis of the Strength of Materials"**

Effect of Trace Additions Cd, In and Sn on the Interfacial Structure and Kinetics of Growth of q' Plates in Al-Cu Alloy; R Sankaran and C Laird, Materials Science and Eng. 1974.

1- Nucleation of θ' takes place by the coalescence of mobile impurity –Cu– vacancy clusters and growth of the precipitates by the movement of these clusters [Hardy 1950; Nobel 1968]

2- Trace elements modfy the α:θ' interface giving an easier match with the matrix lattice, so that the critical size and energy barrier height for nucleation are reduced [Silcock et al; 1955 and Hardy 1956]

3- In the presence of impurity elements, vacancies in the quenched Al-Cu alloy condense to form finer distribution of dislocation loops. An increased density of of θ' precipitate can result from their nucleation on the loops.[Nuyten 1967]

Effect of lattice disregistry variation on the late stage phase transformation behavior of precipitates in nickel-aluminum-molybdenum alloys. Conley, J. G.; Fine, M. E.; Weertman, J. R. Acta Metallurgica (1989), 37(4), 1251-63.

Use controlled lattice disregistry (tune Al+Mo) to affect precipitate morphology (cubes vs spheres) and coarsening kinetics
$$\delta = (a_p - a_m)/a_m$$

mostly affected Ni matrix

A variety of exptl. techniques were applied to examine how compositional variations in lattice disregistry (**d**) **affect the coarsening kinetics and particle morphol. evolution of g'-particles in several Ni-Al-Mo alloys. Mo segregates to and increases the lattice parameter of the g-matrix in 2 phase Ni-base Al alloys. Controlled ternary addns. of Mo to dil. binary Ni-Al alloys permit variation of the lattice parameter disregistry between the Ni-base solid soln. and the Ni3Al ordered ppts. Compns. were selected to maintain an approx. .apprx.10 vol.% of the 2nd phase. The coarsening rate of the g'-phase decreases with decreasing lattice disregistry and decreasing Al/Mo ratio. The implications of this observation are discussed with ref. to differences in solid soly., diffusivity, and interfacial energy. The g'-particle shape in low coherency strain alloys is spherical and independent of particle size. In an alloy exhibiting appreciable d and coherency strain, the g'-particles evolve from randomly distributed spheres to sharply aligned cubes and rods as particle size increases. d Increases with aging time. Compression creep of [100] single crystals at 750° did not affect the shape of particles in the low coherency strain alloys while in a higher disregistry alloy, a highly oriented array of plates grew with long edges perpendicular to the applied stress direction. These findings are discussed with regard to stress and thermodn. considerations.**

The precipitate Ω-phase in aluminum-copper-magnesium-silver alloys.
## *Muddle, B. C.; Polmear, I. J.* Acta Metallurgica (1989), 37(3), 777-89.

The combined addn. of small concns. of Ag and Mg to Al-Cu alloys promotes pptn. of a phase, Ω–πηασε, that forms as thin, hexagonal-shaped plates on matrix {111ña planes. The structure, morphol., and compn. of this phase were examd. in 2 quaternary alloys using TEM, electron microdiffraction and energy dispersive x-ray spectroscopy. Electron microdiffraction patterns from the ppt. phase are indexed in accordance with an orthorhombic structure (a = 0.496 nm, b = 0.859 nm, c = 0.848 nm) and the orientation relationship between ppt. and matrix lattices is such that (001)W||(111)a and [010]Ω||[10.hivin.1]a. The morphol. of the ppt. phase is consistent with the intersection point group (2/m) defined by symmetry elements common to the 2 lattices in the obsd. orientation relationship. The plate shape parallel to (111)a is detd. by a pinacoid parallel to the common 2-fold axis, [010]W. The hexagonal form in this plane is defined by 4 equiv prism facets with a common direction perpendicular to [010]W and the truncation of this prism section by a second pinacoid normal to this 2-fold axis. The 6 facets thus defined are equiv. geometrically and are assocd. with the hexagonal lattice on which the orthorhombic structure of the ppt. phase is based. Energy dispersive x-ray microanal. indicates that the Ag in quaternary alloys partitions to the W phase during aging and there is evidence that segregates at the interface with the matrix. On the other hand, Ag does not partition to the phase q' when it coexists with W in these alloys or is present alone in the ternary alloy Al-Cu-Ag. There is also evidence to suggest that Mg assocs. itself with the Ω phase.

# On the origin of the high coarsening resistance of Ω plates in Al-Cu-Mg-Ag Alloys.

Hutchinson, C. R.; Fan, X.; Pennycook, S. J.; Shiflet, G. J..   Department of Materials Science and Engineering, University of Virginia, Charlottesville, VA, USA.   Acta Materialia (2001), 49(14), 2827-2841.

The thickening kinetics of W plates in an Al-4Cu-0.3Mg-0.2Ag (wt.%) alloy were measured at 200, 250 and 300°C using conventional transmission electron microscopy techniques. At all temps. examd. the thickening showed a linear dependence on time. At 200°C the plates remained less than 6 nm in thickness after 1000 h exposure. At temps. above 200°C the thickening kinetics are greatly increased. At. resoln. Z-contrast microscopy has been used to examine the structure and chem. of the (001)W.dblvert.(111)a interphase boundary in samples treated at each temp. In all cases, two at. layers of Ag and Mg segregation were found at the broad face of the plate. The risers of the thickening ledges and the ends of the plates were free of Ag segregation. The necessary redistribution of Ag and Mg accompanying a migrating thickening ledge occurs at all temps. and is not considered to play a decisive role in the excellent coarsening resistance exhibited by the W plates at temps. up to 200°C. Plates transformed at 200°C rarely contained ledges and usually exhibited a strong vacancy misfit normal to the plate. A large increase in ledge d. was obsd. on plates transformed at 300°C, concomitant with accelerated plate thickening kinetics. The high resistance to plate coarsening exhibited by W plates at temps. up to 200°C, is due to a prohibitively high barrier to ledge nucleation in the strong vacancy field normal to the broad face of the plate. Results also suggest that accommodation of the large misfit that exists normal to the broad face of the plate is unlikely to provide the driving force for Ag and Mg segregation.

Heterogeneous nucleation of δ ' on dislocations in a dilute aluminum-lithium alloy.

δ ' nucleation and growth on low-angle dislocation boundaries in Al-Li.
Wang, Z. M.; Shiflet, G. J.. Physica Status Solidi A: (1995), 149(1), 105-22.
the reacted dislocation has a large edge component and at the site of the network plane where the dilatation stress is compressive. This is confirmed by calcn. of the dilatation stress field of the dislocation nodes which also further clarifies and is consistent with the exptl. observations.

The effect of plastic deformation on aluminum-copper-lithium Al$_2$CuLi (T1) precipitation.
Cassada, W. A.; Shiflet, G. J.; Starke, E. A., Jr.; Metallurgical Transactions A: Physical Metallurgy and Materials Science (1991), 22A(2), 299-306.

The enhancement of T1 pptn. in Al-Li-Cu alloys by plastic deformation prior to aging (i.e., cold work) and the subsequent increase in alloy strength is investigated. The increased understanding of the role of matrix dislocations in the nucleation and growth of T1 plates, discussed in a previous paper, permits a detailed study of the phenomenon. The effect of different levels of plastic strain on the T1 particle distributions as a function of aging time at 190° is quantified, and the subsequent influence on tensile properties is thereby described. Plastic deformation decreased the T1 plate length and thickness, increased the no. d. by .apprx.2 orders of magnitude, increased the yield strength by 100 MPa, while simultaneously reaching peak strength in 20% of the time required without plastic deformation.

On the Roles of Clusters during Intragranular Nucleation in the Absence of Static Defects
Nie, Muddle, Aaronson, Ringer and Hirth Metall. Mater. Trans, 2002.

- Clusters form and disappear on timescale shorter than embryos

- clusters another form of nucleation site and so are involved in 'cluster-aided intragranular nucleation' heterogeneous nucleation

- reduction of shear strain energy attending precipitate nucleation through segregation of trace solutes and vacancies bound to them to regions of the precipitate interfaces under compressive or tensile strains

Based on all we learned about bonding from amorphous metals – can we transfer ideas to nucleation in conventional alloys?

Balance between calculations and experiments*

- **Focused** calculations are necessary
  - Phase diagrams (partial phase diagrams)
  - Element associations (electronic)
  - Cluster formation f(T)
  - Elastic properties of clusters
  - If working with a modeler –they must work on the problem!
- Experiments are essential
  - Validation of calculations by small adjustments
 - Proof of concept predictive NOT postdictive

P- $L_{2,3}$ edge

Two humps corresponding to P-$L_{2,3}$ edge are observed for Fe_3P crystalline alloy. $Fe_{71}Mo_5P_{12}C_{10}B_2$ ribbon shows similar but less clear humps of $L_{2,3}$ edge as Fe_3P, indicating the Fe-P bond is the major bond of the bonding surrounding P atom.
As Mo content increases, these two humps are smeared off. This might be due to the formation of stronger Mo-P bonds and thus reduce Fe-P interactions in amorphous structure. (Verified by the increasing 3d white line intensities of Fe with increasing Mo content).
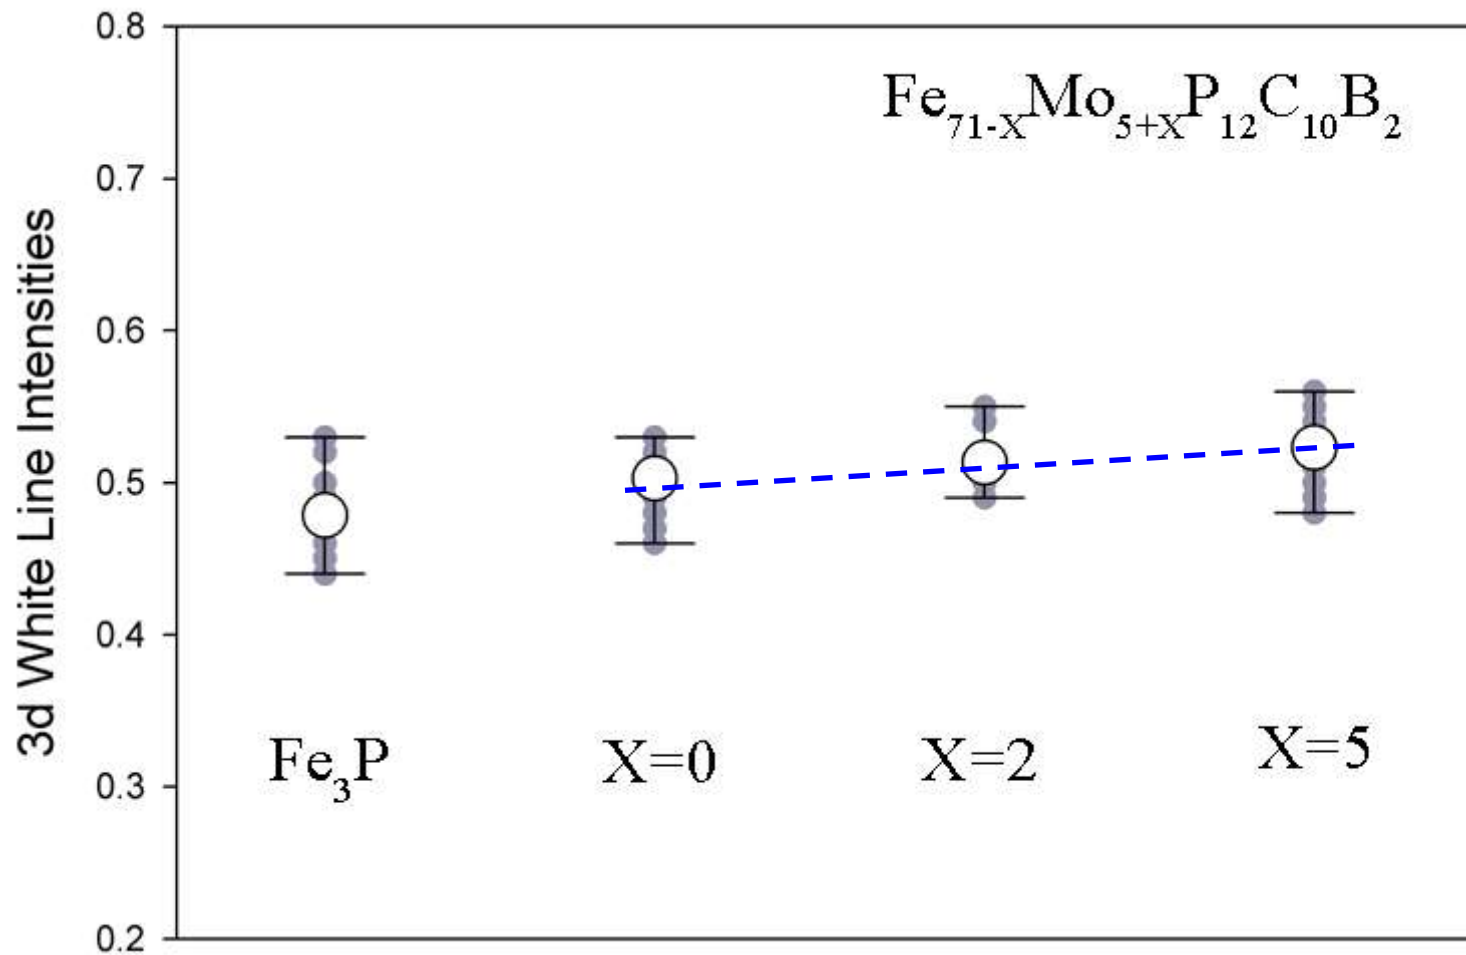

Fe 3*d* white line intensities calculations show a slight increase of Fe 3*d* white line intensities and a decrease of L_3/L_2 ratio with increasing Mo content for as-spun $Fe_{71-X}Mo_{5+X}P_{12}C_{10}B_2$ ribbons.

3*d* electrons number decreases with increasing Mo content, indicating less Fe-P interactions, supporting the P-$L_{2,3}$ edge results.

Summary of Experimental Work

➢ Mechanism of $\beta \rightarrow \omega$ transformation not completely understood

➢ β solutionized and quenched Ti-9at%Mo exhibits fine scale ω embryos

- Different stages of {111} β plane collapse – *aberration corrected HAADF-STEM*

- Clear evidence of Ti-Ti clustering – *3D atom probe*

- *Phase separation in β matrix prior to ω formation?*

➢ Subsequent annealing at 475°C/30mins

- well-developed ω precipitates – complete collapse of {111} β planes

- Substantial partitioning of Mo between β and ω

# What do we learn from experiments? – Schematic G – X plot for quenched Ti-Mo
➤ Phase separation in β matrix required for ω formation in Ti – 9 at% Mo

➤ Mo-depleted pockets with compositions < T_0 form ω nuclei by displacive collapse

➤ Is the displacive collapse complete within ω nuclei?

Summary of Experimental Work: Schematic G – η plots for Ti-Mo
➢ Mo-depleted pockets with compositions < T_0 form ω nuclei by displacive collapse

➢ Extent of displacive collapse can be incomplete within ω nuclei – composition dependent amplitude of phonon wave?
Questions

➤ Is phase separation in β matrix mandatory for ω formation in Ti-9at%Mo?

➤ Though ω forms via a displacive collapse of {111} β planes, why is the collapse arrested (partial collapse) in quenched ω embryos

  • Does the extent of collapse depend on ω pocket composition? Why?

➤ Is there a mixed-mode displacive-diffusional transformation involved in the formation of isothermal ω precipitates?

Simulations Approach Used

➢ We use first-principles calculations using the Vienna Ab Initio Simulation Package (VASP)   (Kresse and Hafnet, PRB 1993)

➢ β to ω transition path transformation in Ti-Mo system was determined using the Nudged Elastic Band (NEB)   (Jónsson , Mills , Jacobsen, 1996)

➢ We use Projector Augmented Wave (PAW) potentials   (Kresse and Joubert, PRB 1999)

➢ Generalized Gradient Approximation PBE (GGA-PBE) was used (Perdew, Burke, Ernzerhof, PRL 1996)

➢ Performed convergence tests to determine optimal parameters such as energy of plane wave cutoffs (400eV used) and K-mesh for integration

➢ Our energy converged to 1 meV /atom

Hexagonal (ω) Phase Precipitation in BCC (β) Titanium

NOTE: Figures Not Drawn to Scale
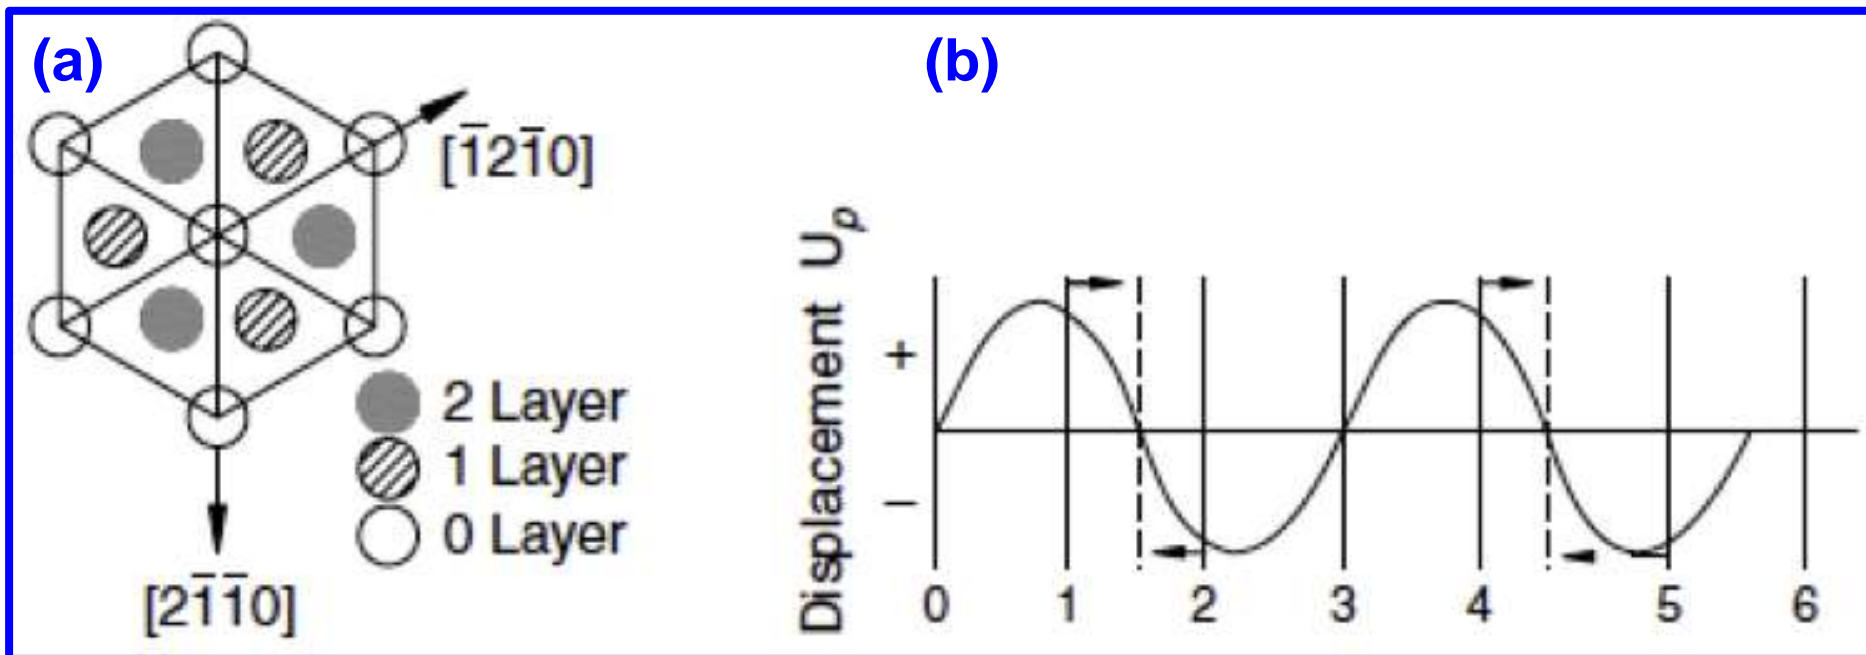

(a) Completed collapsed {222} planes exhibit a 6-fold symmetry and an partial collapse leads to a 3-fold symmetry along <111> axis

(b) The displacement of {222} planes are visualized as a sinusoidal wave with upward and downward motions shown as positive and negative displacements respectively

Discover the power of ideas.

Nudged Elastic Band (NEB) Method

- The nudged elastic band (NEB) is a method for finding saddle points and minimum energy paths (MEP) between <u>known</u> reactants and products

- NEB works by first constructing a "chain of images" of the system

- Each image connects to the previous and next image by '*springs*' along the path

- Springs prevent images from sliding down to the nearest minima and forces them to find the lowest energy possible while maintaining equal spacing to their neighbors

- Minimization of the entire system, but with the end structures fixed, provides a MEP
Our Past Success with NEB: Minimum energy path for cross slip of a screw dislocation in Cu

Primary Glide Plane (1-11)

Cross-Slip Plane (-111)
(a) Initial configuration with parallel Shockley partials in the primary glide plane

Our Past Success with NEB: Understanding α to ω transformation in Pure Titanium

Popular Silcock Mechanism (Acta Metall., 1958)

(a) α phase   (b) ω phase
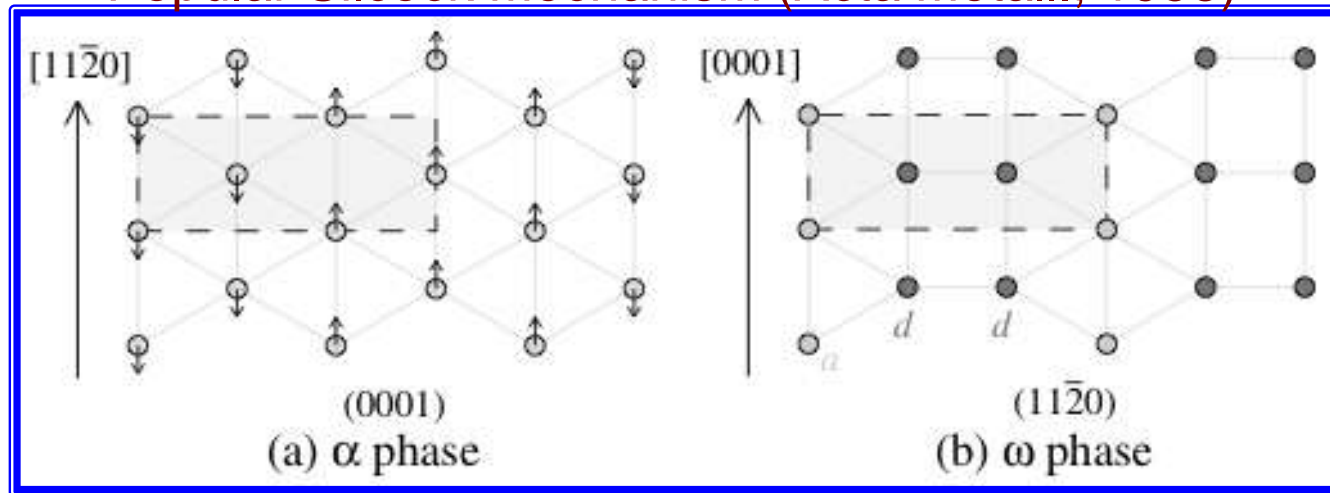

- **In each stacking plane, 3 out of every 6 atoms shuffle by 0.74 Å along [11-20]$_\alpha$ while the other 3 shuffle along [-1-120]$_\alpha$**

- **This shuffle is accompanied by a strain ε_{xx} = 0.05 along [1-100]$_\alpha$ and ε_{yy} = -0.05 along [11-20] to produce a hexagonal ω cell with the correct c/a ratio.**

Our Past Success with NEB: Understanding α to ω transformation in Pure Titanium
- The TAO-1 path gives the smallest barrier by a factor of 4 at 0 GPa.

- Silcock pathway have larger barriers at from 0 GPa to 40 GPa

Our Past Success with NEB: Understanding α to ω transformation in Pure Titanium

Usikov and Zilbershtein $\alpha \rightarrow \omega$ transition path
(Usikov & Zilbershtein, Phys. Status Solidi A 1973)

➤ Mechanism: $\alpha \rightarrow \beta \rightarrow \omega$ transition via an unstable intermediary β-phase

➤ $\alpha \rightarrow \beta$ transition occurs via an *inverse Burgers mechanism*, and is followed by $\beta \rightarrow \omega$ transition via collapse of 2 out of 3 $(111)_\beta$ planes

➤ This produces 2 unique pathways called variant-I and variant-2, depending on the direction of $\{111\}_\beta$ planes collapse.

➤ Allowing variants-1 and 2 to <u>*relax away*</u> from the β-phase yields our TAO-1 and TAO-2 direct transformation pathways

Our Past Success with NEB: Understanding how impurities block α to ω transformation in Titanium
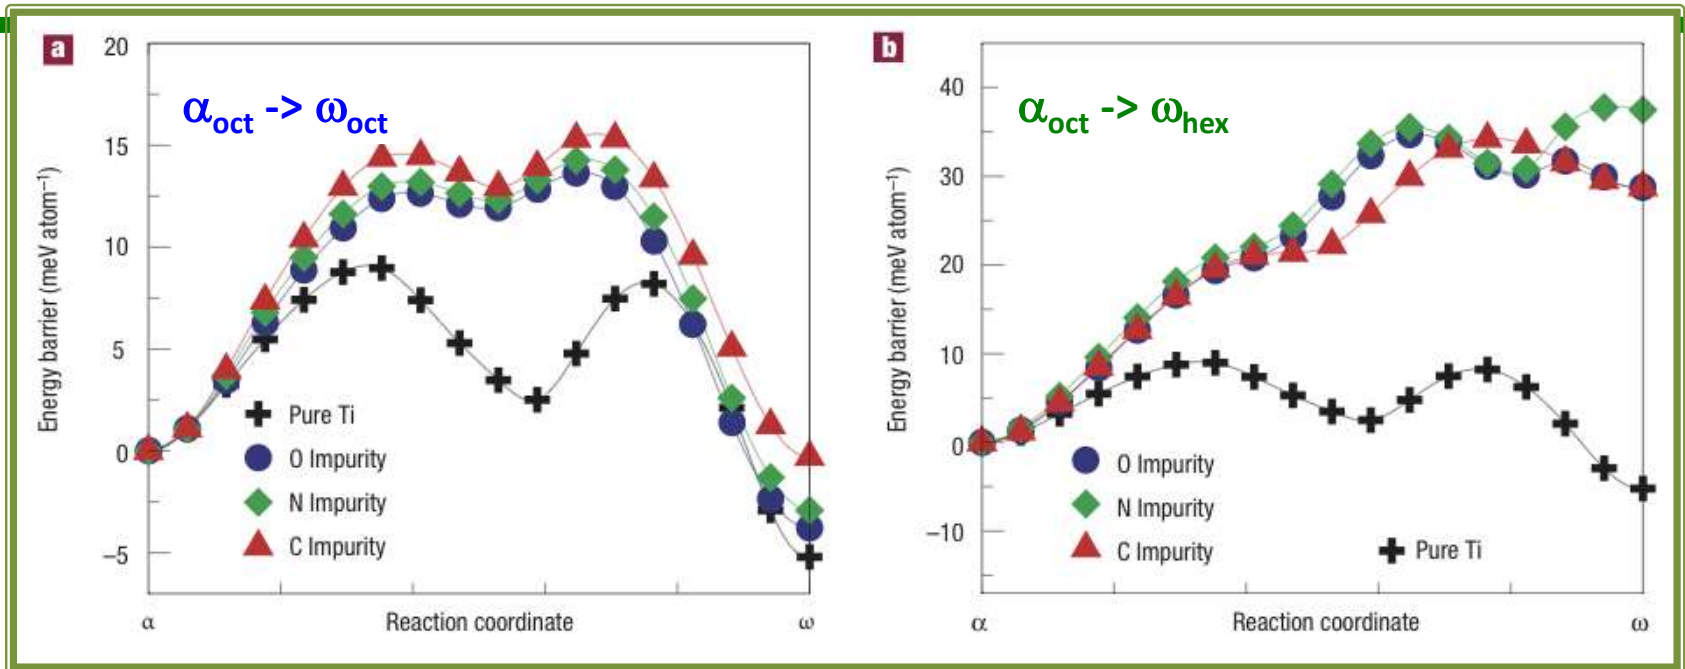

- ➤ C, N, O impurities suppresses the ⟨□⟩ transformation by:
  - increasing both the ⟩ energy relative to ⟨ and the energy barrier
- ➤ Despite different chemistry, C, N, O increase the energy barrier and the relative energy by nearly the same amount
- ➤ This indicates that their primary effect is *steric*

Our Past Success with NEB: Understanding how impurities block α to ω transformation in Titanium
Interstitials in α and ω Ti

- Octahedral (o), tetrahedral (t), and hexahedral (h) sites for interstitial impurities

- A and B are substitutional impurity sites

Hennig et al, Nature Materials (2005)

UNT

Pure Ti Lattice Parameter and Energy

parameter	Ti beta super cell	Ti omega supercell	% change
a	4.5995	4.5773	0.5349 %
b	4.5995	4.5773	0.5349 %
c	5.6335	5.6595	-0.369 %
Supercell Energy (ev)	-46.693196	-47.380604	688 meV

➢ Beta to omega transformation involves:

  • Contraction of 0.53% along a and b axis

  • Expansion of 0.37% along c axis of supercell.

➢ For pure Ti beta is 688 meV higher than omega

Mo substitution in Ti super cells

➢ Beta to omega transformation in pure Ti involves:

  • Contraction of 0.53% along a and b axis

  • Expansion of 0.37% along c axis of supercell.

➢ For pure Ti beta is 688 meV higher than omega
Beta to omega transformation in Pure Ti
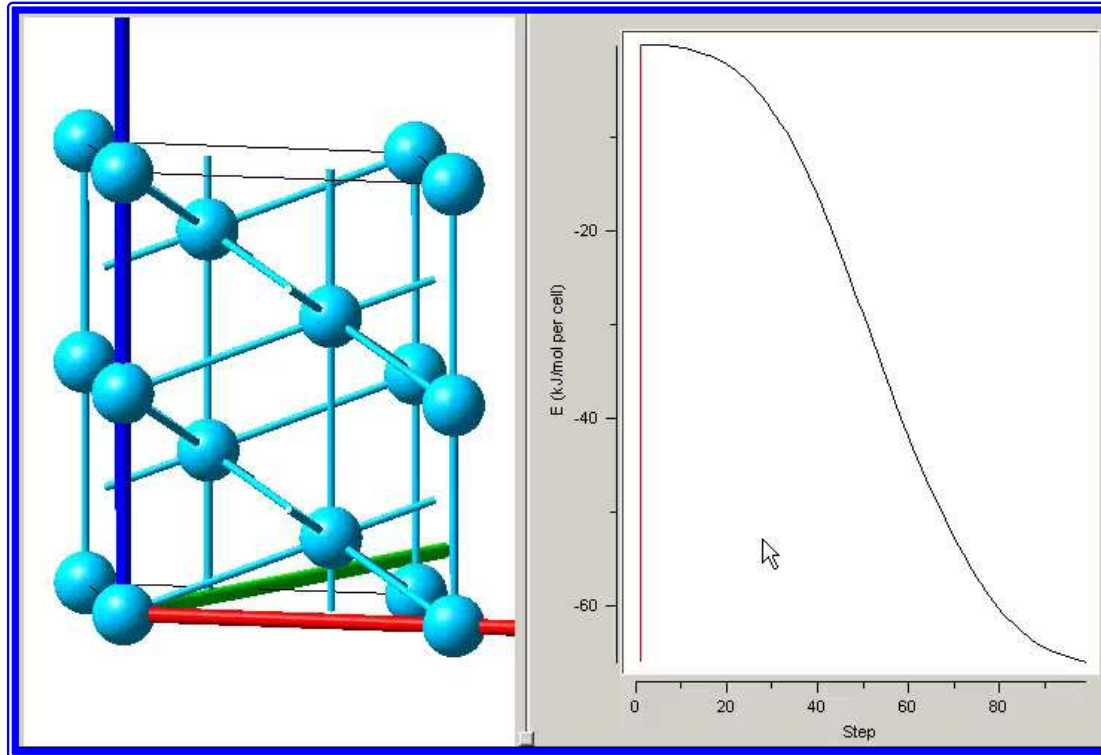

No activation barrier observed in the nudge elastic
band method for pure Ti beta to omega transformation

Ti – 16 at% Mo System (1 Mo + 5 Ti atoms in supercell)

- Energy of beta is lower than omega

- Systems with Mo substituted in the collapsing plane positions show same energy

- The omega structure with Mo in noncollapsing planes has a higher energy than omega with Mo in collapsing planes
A local minima at 21% partially collapsed structure observed near beta

Ti – 8.33 at% Mo System (1 Mo + 11 Ti atoms in supercell)

- Beta has a higher energy than omega

- A 30 meV activation barrier must be overcome by beta to transform to omega

- There is a local minima close to omega (41 meV) that must be overcome by system to transform fully to omega
Ti – 5.6 at% Mo System (1 Mo + 17 Ti atoms in supercell)
CALCULATIONS NOT CONVERGED
NEB work summary

➤ In pure Ti beta omega transformation is thermodynamically favorable

➤ Trends observed in Ti-Mo alloys are

  – 4.16% Mo: Similar to pure Ti, Roll down with some minima close to omega

  – 5.55%Mo: in progress

  – 8.33%Mo: Similar to pure Ti, Roll down with some minima close to omega

  – 16.66%Mo: Opposite to pure Ti, minima close to beta

Points to Ponder …..

- Our preliminary calculations point to the ability of VASP + NEB calculations to determine activation barriers and order parameters for the beta to omega transformations rigorously

- As seen, our current systems are too small to allow variation of composition through out the supercell

- We are currently increasing our systems sizes to a couple of hundred atoms

- Such large systems may not be sufficient

- We may have to use semi-empirical atomisitic models such as MEAM, tight binding, MGPT or bond-order potentials to handle larger systems

- Need to couple these atomistic methods with combinatorial approaches to investigate effect of local compositional environment on saddle points in model binary systems

Thank you for your Attention

Accelerated Molecular Dynamics: Methods and Examples

Blas Pedro Uberuaga

Los Alamos National Laboratory

Atomistic Dynamical Simulations 101

- **Goal: simulate time evolution of a system of atoms**

- **Foundations:**
  - Interatomic potential
    - Parameters fit to experiment, high quality calculations
  - Newton's Second Law
    - Tells how system evolves under forces
    - Can directly integrate to get time evolution

- **But!**
  - Can only perform ~2000 force evaluations/second (on Opteron)
  - Typical vibrational period of an atom is 10-100 fs
  - Need ~10 force evaluations per vibrational period for accurate integration
    - Each force evaluation advances system time by 1-5 fs
  - 10^{11} years to simulate 1 second!

MD may *never* get to relevant time scales

Accessible simulated time*

* 1-week simulation of 1000-atom metal system, EAM potential

NNSA
Brief Introduction to Accelerated Dynamics

- **Many processes occur on much longer timescales than accessible via MD (ps-ns-μs)**
  - e.g. surface growth
  - radiation damage annealing
  - nucleation
  - Etc.

- **Need method to reach experimentally relevant timescales**

- **Three accelerated dynamics methods developed at LANL (Art Voter's team)**
  - Parallel-Replica Dynamics
  - Hyperdynamics
  - Temperature Accelerated Dynamics (TAD)

Infrequent Event System
- The system vibrates in 3N-dimensional basin

- Occasionally it escapes, crossing through a dividing surface to a new basin

- This behavior characterizes solid-state diffusion, as well as many other processes

Accelerated Molecular Dynamics Methods

Common Themes: - reduce waiting time for a transition to order of picoseconds; - let trajectory find transitions "naturally"

Introduction to Hyperdynamics

- **Builds on umbrella-sampling techniques (e.g., Valleau 1970's); takes it into the time domain**

- **Assumptions:**
  - infrequent events
  - transition state theory (no recrossings)

- **Procedure:**
  - design bias potential ΔV
    - zero at dividing surfaces
    - causes no recrossings
  - run thermostatted trajectory on the biased surface ($V+\Delta V$)
  - accumulate hypertime as

$$t_{hyper}= \Sigma \Delta t_{MD} \exp[\Delta V(R(t))/k_B T]$$

- **Result:**
  - state-to-state sequence correct (because relative rates are preserved)
  - time converges on correct value in long-time limit (vanishing relative error)

$V+\Delta V$

V

Los Alamos
NATIONAL LABORATORY
EST.1943

NNSA
Hyperdynamics - characteristics

- **Key challenge is designing a bias potential that:**
  - meets the requirements of the derivation
  - is computationally efficient.

- **Bias potential can be a function of**
  - the shape of the energy surface (AFV, 1997)
  - the energy (Steiner, Genilloud and Wilkins, 1998)
  - the geometry (e.g., bond lengths, Miron and Fichthorn, 2003, 2005)

- **Must be careful that bias is zero on all dividing surfaces or dynamics will be wrong.**

- **When barriers are high relative to T, boost can be many orders of magnitude.**

Introduction to Parallel-Replica Dynamics

- **Offers parallel speed-up in simulation time**
  - Not as "glamorous" as other methods which offer exponential speed-up on a single processor

- **However, parallel-replica can be applied to systems not suited to the other methods**
  - Rough potentials
  - Floppy systems with fast transitions
  - Driven systems

- **Assumptions:**
  - infrequent events
  - transitions can be detected
  - correlation time known
  - distribution of first-escape times is exponential

Detecting a Transition

- **Best method depends on the system**

- **Simple method for EAM metal systems:**
  - periodically perform minimization
  - see if geometry at basin minimum has changed
- **Other Methods:**
  - change in bond connectivity/length (covalent systems) (Kum, Uberuaga)
  - change in energy fluctuations (Pande)

Examples of Parallel Replica Simulations

- **Vacancy void annealing in Cu**
  - Motivation
    - Examine void kinetics to understand void swelling under irradiation

- **Stretching of Ag nanowire**
  - Motivation
    - Understand tensile behavior of nano-sized wires

Los Alamos
NATIONAL LABORATORY
EST. 1943

Voids in Cu:
Long time annealing of 20 vacancy

- **EAM Cu**

- **Parallel-replica simulation of 20-vacancy void annealing at 400 K**
  - 20 vacancies is one too many for "perfect" void

- **Total simulation is 7.82 μs**

- **At 1.69 μs, void transforms to SFT**

- **Run on 39 processors for 15 days**

- **Efficiency = 79%**

- **Equivalent single processor time: 1.3 years**
Uberuaga, et. al., *PRL* **99**, 135501 (2007)

Voids in Cu:
Transformation pathway for 20 vacancy void

- **Full path for transformation to SFT calculated with NEB**

- **Initial barrier is > 2 eV**
  - Should have taken >105 years at 400K to occur (assuming standard prefactor)

- **Vineyard prefactor for first step is 2×10^{36} s^{-1}**
  - Vineyard rate is faster than one time step at 500K!
Uberuaga, et. al., *PRL* **99**, 135501 (2007)

Voids in Cu:
Origin of Prefactor for Transformation

- **View material containing void as partitioned into two regions**
  - Region I: Cu
  - Region II: void

- **Before transition, volume of Cu is Region I volume**

- **After, volume of Cu is Region I + Region II**

- **Entropy change ΔS due to volume change ΔV: $\Delta S = \alpha B \Delta V$**
  - α=coefficient of thermal expansion, B=bulk modulus

- **Assuming ΔV=10 atomic volumes $\Rightarrow$ ΔS=67.5/kB $\Rightarrow$ prefactor enhanced by factor of 10^{29}**

- **Consistent with observed/calculated prefactor of $\sim 10^{40}$**
Uberuaga, et. al., *PRL* **99**, 135501 (2007)

Ag nanowire:
ParRep of stretching nanowire

Danny Perez, Chun-Wei Pao, Sriram Swaminarayan, AFV

- **Run on LANL Roadrunner (1 PFLOPS if using all 12,240 cell processors)**

- **Boost good at first; drops as events become more frequent.**

- **Outer edge atoms clamped, advanced 0.01A at regular intervals**

- **Preliminary results…**

Ag[110] nanowire, 1.d5 A/s, 1 us per frame
Ag nanowire:
Pulling slower changes behavior

At stretching speeds below ~10^6 Å/s, the system can thin down to four layers, coming back to perfect fcc. At higher speeds, it disorders or necks, never recovering perfect fcc again.

Summary - Parallel-Replica Dynamics

- **Most exact of the accelerated dynamics methods**
  - no harmonic approximation
  - goes beyond TST to include correlated dynamical events
  - no assumption that barrier is energetic - can be entropic

- **Easy to implement – requirements:**
  - transition detection
  - good estimate of correlation time

- **Very general applicability**
  - any system with exponentially distributed events

- **Good match to increasing availability of parallel processing power, distributed computing, etc.**

Limitations - Parallel-Replica Dynamics

- **Only get parallel boost**
  - If statistics are necessary such that number of samples is equal to or greater than number of processors, better to do MD

- **Boost drops off when events are frequent (or become frequent because so many processors)**
  - Requires "tuning" number of processors to temperature of interest

- **Boost especially limited if correlation time is long**

- **For complex systems (e.g., proteins) even transition detection can be tricky**

Introduction to Temperature Accelerated Dynamics (TAD)

- **Concept:**
  - System characterized by deep energy wells
  - Run basin constrained MD at high temperature
  - Extrapolate behavior to low temperature

- **Approximations:**
  - Harmonic Transition State Theory $\left(k = v e^{-\Delta E / k_B T} \right)$
  - Assumed minimum prefactor in system ν_{min}
  - Uncertainty level δ of missing the correct event

- **Very powerful when barriers are high relative to temperature**
Basin Constrained MD (BCMD)

$T=T_{high}$

E_1

E_2
- Run dynamics at T_{high}

- When event occurs, reflect trajectory back into basin

- Continue high-T dynamics

- Reflect trajectory after any other events

- Requires:
  - Detecting transition
  - Finding energy barrier

Los Alamos
NATIONAL LABORATORY
EST.1943

NNSA

TAD algorithm
- Do MD at T_{high} until see an event

- Find barrier, extrapolate to T_{low}, find time t_1

- Continue at T_{high} to next event

- Find barrier, extrapolate to T_{low}, find time t_2

- Continue at T_{high} until earlier event not possible (within δ)

- Accept event with earliest time (t_2)

Examples of TAD Simulations

- **Interstitial clustering in MgO**
  - Motivation
    - Use MgO as model ceramic to understand radiation damage evolution

- **Interstitial emission at grain boundaries in Cu**
  - Motivation
    - Determine role of GBs in radiation tolerance of nanocrystalline materials

MgO:
Defect aggregation

- **Using standard Buckingham potential with long range Coulomb interaction**

- **Begin with I_2 and I_4**
  - Defects found at end of collision cascade

- **I_2 attracted to I_4, binds forming I_6**

- **Metastable I_6 diffuses very quickly**
  - ns timescale at 300 K
  - diffusion is 1D along <110>
  - decay to ground state takes years

- **Boosts on the order of 10^9**

- **Red=oxygen, Blue=magnesium**

- **Dark=interstitial, Light=vacancy**

MgO: Di-Interstitial + Tetra-Interstitial

t = 000 . 000 000 000 000 second

MgO Di-Interstitial

MgO Tetra-Interstitial

Summary - Temperature Accelerated Dynamics

- **Potentially most powerful AMD method**
  - Extremely large boosts when temperature is small compared to barriers

- **Basic algorithm is easy to implement – requirements:**
  - transition detection
  - Basin constrained MD
  - Saddle finding method

Limitations - Temperature Accelerated Dynamics

- **Least exact of the accelerated MD methods**
  - Assumes *harmonic* transition state theory

- **For full optimization, requires many bells and whistles**
  - Detect revisited states
  - Ensure events do not involve double jumps, etc

- **Requires the potential to be relatively smooth for efficient saddle point calculations**

AMD characteristics/challenges

- **All three methods can give very large boost factors when events are very infrequent.**

- **Basically, the MD time to next event (+overhead) is collapsed to ~ps time scale.**

$$\text{ps} \qquad \text{ns} \qquad \mu\text{s} \qquad \text{ms} \qquad \text{s}$$

- **Low barriers mean low boost.**

- **Systems with persistent low barriers are our biggest ongoing challenge**
  - e.g., soft-matter systems

- **In principle, electronic structure forces can be used, but they are still pretty expensive**
  - If we cannot reach ~10 ps, we cannot see any events

- **Larger systems are also harder, although we are making progress**
  - ParTAD (Shim, et. al. 2007)
  - TAD-KMC (Chatterjee and Voter, 2010),
  - Local hyperdynamics (Kim, Perez, AFV, 2010).

AMD characteristics/challenges

- **All three methods can give very large boost factors when events are very infrequent.**

- **Basically, the MD time to next event (+overhead) is collapsed to ~ps time scale.**

- **Low barriers mean low boost.**

- **Systems with persistent low barriers are our biggest ongoing challenge**
  - e.g., soft-matter systems

- **In principle, electronic structure forces can be used, but they are still pretty expensive**
  - If we cannot reach ~10 ps, we cannot see any events

- **Larger systems are also harder, although we are making progress**
  - ParTAD (Shim, et. al. 2007)
  - TAD-KMC (Chatterjee and Voter, 2010),
  - Local hyperdynamics (Kim, Perez, AFV, 2010).

Comparing AMD Methods: Accuracy

- **Parallel-Replica is most accurate**
  - Only assumes first order kinetics
    - Doesn't even assume TST
  - Accounts for correlated events

- **Temperature Accelerated Dynamics least accurate**
  - Assumes harmonic approximation to TST
  - Has known upper bound to error quantified by δ and ν_{min}

- **Hyperdynamics is intermediate**
  - Assumes TST
    - no harmonic approximation…
    - …but no correlated events
  - Error may creep in via definition of bias potential

Los Alamos
NATIONAL LABORATORY
EST. 1943

Comparing AMD Methods: Efficiency

- **Temperature Accelerated Dynamics possibly most efficient**
  - Large boost when barriers are high relative to T_{low}

- **Efficiency of hyperdynamics really depends on bias potential**
  - With Art's bias potential, computational cost is very high
  - Bond-boost bias overcomes costs

- **Currently, parallel-replica least efficient**
  - Only linear boost with number of processors
  - Right now, typically don't have enough processors to compete with TAD or hyperdynamics
  - In future, this limitation should be reduced
  - Harder to tune accelerating parameter
    - TAD: high temperature
    - Hyperdynamics: bias potential strength
    - Parallel-replica: number of processors

- **All limited by smallest barrier/fastest event in system**

Summary

- **Accelerated molecular dynamics concept:**
  - Let the trajectory find an appropriate way out of state, but coax it into doing so more quickly

- **Significant speedup over standard MD when barriers are high relative to temperature**

- **Often encounter unexpected behavior**
  - Many mechanisms that would be left out of e.g. KMC if intuition alone is used
    - High mobility of interstitial clusters in MgO
    - Transformation of void to stacking fault tetrahedron in Cu
    - Interstitial emission near GBs in Cu
    - Thinning of Ag nanowires

- **Ongoing challenges**
  - low barriers and pesky local minima
  - cuspy potentials
  - scaling with system size

Atomistic Simulations of γ/γ′ Interface Structure

EAM simulations of Ni/Ni₃Al interface

Y.Mishin, *Acta Materialia*, 52 (2004), 1451
Order-disorder transition ~ 6-8 planes

Monte Carlo simulations of γ/γ' interface structure in binary Ni-Al system
A.J. Ardell, V. Ozolins, *Nature Materials*, 4 (2005) 309
Order-disorder transition ~ 10 planes

- Atomistic simulations predict "ragged", non-abrupt interface structure
- Observed experimental results in very good agreement with atomistic simulations - *partially ordered γ/γ' interface of finite width - slows down diffusivity?*

Organization

- γ' precipitation during continuous cooling from single γ phase field
  - Water-quenched (rapid cooling)
  - Slow cooling

- Evolution of the γ/γ' interface
  - *Compositional gradient (or width) across the interface*
  - *Order-disorder transition width*

- **Application to real multi-component engineering alloys => *study on Rene88 alloy (turbine disk alloy)***
  - **56.53Ni-16.24Cr-13.27Co-3.92Ti-2.09Al-4.08Mo-3.92W-0.76Nb (wt%)**
  - ***Primary alloying elements are Cr, Co, Ti, Al, Mo***

Coarsening Microstructures

Cooling rate → WQ   FC   SC

Before aging
760°C 200 hr
Significant changes in γ' size, morphology as f (cooling rate, aging time)

Experimental coarsening behavior
- Coarsening kinetics investigated as f (cooling rate)
- Aging treatment: 760^{0}C for 25,50,100 and 200 hours
- Distinction made between growth and pure coarsening (>25 h aging)

Coarsening kinetics - LSW Model

Classical LSW Model ($r^3 - r_o^3 = kt$)

R³ vs t

$y = 0.0157x + 1669.8$
$R^2 = 0.97626$

$y = 0.0057x + 453.87$
$R^2 = 0.93629$

$y = 0.0049x + 164.67$
$R^2 = 0.97296$
Slopes yield coarsening rate constant, *k*

Experimental rate constants

$k_{WQ} = 0.0157\ nm^3 s^{-1}$

$k_{FC} = 0.0049\ nm^3 s^{-1}$

$k_{SC} = 0.0057\ nm^3 s^{-1}$

Key Assumptions

- Pure coarsening regime
- Constant volume fraction of γ'
- Equilibrium matrix composition

Modeling of Coarsening Kinetics - LSW Model

Coarsening rate constant, k $= \dfrac{A.D.C_e.\gamma_i.V_m}{RT}.10^{27}$

Obtained via 3DAP studies

D is the diffusion coefficient of solute in the matrix ($m^2 s^{-1}$)

C_e is the atomic fraction of solute in equilibrium with the precipitate

γ_i is the precipitate/matrix interface energy,

V_m is the molar volume of the precipitate ($m^3\ mol^{-1}$),

R is the universal gas constant (J mole^{-1}-K^{-1})

T is the absolute temperature (K).

Substituting experimental values for D, C_e and γ_i the analytically derived coarsening rate constants for primary γ' in WQ sample

k = 0.002 nm^{3}s^{-1} (using D_{Al})
k = 0.005 nm^{3}s^{-1} (using D_{Cr})

$\xrightarrow[\text{Agreement}]{\text{Good}}$

Experiment
k = 0.0157 nm^{3}s^{-1}

Coarsening Kinetics - TIDC Model

Trans-Interface Diffusion Controlled ($r^2 - r_0^2 = kt$) - _(Ardell and Ozolins, 2005)_
Slopes yield experimental coarsening rate constant, k

Plot legend and fit equations:
- WQ (◆), FC (■), SC (▲)
- Linear (WQ), Linear (FC), Linear (SC)
- $y = 0.0006x + 161$, $R^2 = 0.9828$
- $y = 0.0003x + 71.326$, $R^2 = 0.8745$
- $y = 0.0003x + 54.3$, $R^2 = 0.9686$

Y-axis: R^2 (nm²) — X-axis: Time (sec)

Experimental rate constants

$k_{WQ} = 0.0006 \ nm^2 s^{-1}$

$k_{FC} = 0.0003 \ nm^2 s^{-1}$

$k_{SC} = 0.0003 \ nm^2 s^{-1}$

Key Assumptions
- Independent of volume fraction
- Diffusion across interface is rate limiting
- Existence of a non-abrupt, ragged interface

Modeling of Coarsening Kinetics - TIDC Model

Coarsening rate constant $\quad k^i = \dfrac{32 \tilde{D}_i\, \tilde{l}_\gamma}{81\,\colorbox{yellow}{$\Delta X_e \delta$}} 10^{18}$

$\tilde{D}_i$ is the trans interface diffusion coefficient $(m^2 s^{-1})$
l_γ is capillary length
ΔX_e is the difference in the equilibrium solute concentration
     between γ and γ'
δ is width of the interface

Obtained via 3DAP studies

Substituting experimental values for k^i, ΔX_e and δ the analytically calculated "effective" interface diffusivity in WQ sample is

$D_i \sim 4.33 \times 10^{-19}\ m^2 s^{-1}$

(between the diffusivity values for Al in Ni and Ni_3Al)

Summary

- **Nucleation during continuous cooling from above the solutionizing temperature:**
    - ➤ Long range equilibration of γ composition fields away from growing γ' precipitates plays a significant role
    - ➤ Fast cooling rate results in monomodal distribution of γ' precipitates
    - ➤ Slower cooling rates result in bimodal or multi-modal γ' precipitates

- *Multiple nucleation bursts are different undercoolings clearly identified by coupling SEM, EFTEM, and 3DAP*

- **HRSTEM and 3DAP investigations clearly reveal two distinct transition widths associated with the γ/γ' interface**
    - ➤ order-disorder transition width
    - ➤ compositional gradient width

Effect of Coherency and Local Stress on Nucleation

Nucleation in solids is the toughest nut to crack!

K.C. Russell

Challenges:

- Coherency state and defect structure at interfaces/Interfacial energy anisotropy

- Orientation relationship and lattice correspondence

- Concentration non-uniformity in an embryo

- ...
Usefulness and limitations of the phase field approaches:

- Langevin dynamics is qualitative in nature

- Interaction energy calculation is at most semi-quantitative

- Phase field total energy functional + Nudged Elastic Band (NEB) – quantitative but energetic only, feeding to explicit algorithm based on classical nucleation theory for kinetics

What we could do using phase field method to study nucleation

I. Quantitative calculation of activation energy and critical nucleus configuration

II. Qualitative understanding of autocatalytic effect and collective nucleation

III. Semi-quantitative study of effects of local stress and pre-existing microstructure on nucleation

Phase Field Modeling of Nucleation

Free Energy of a Nonuniform System. I. Interfacial Free Energy

JOHN W. CAHN AND JOHN E. HILLIARD
General Electric Research Laboratory, Schenectady, New York
(Received July 29, 1957)

Free Energy of a Nonuniform System. III. Nucleation in a Two-Component Incompressible Fluid

JOHN W. CAHN AND JOHN E. HILLIARD
General Electric Research Laboratory, Schenectady, New York
(Received February 16, 1959)

Comment by Mullins: The fundamental properties associated with an interface and a critical nucleus are expressed in terms of the parameters in the free energy model and there is no need to introduce the artificial dividing surface of Gibbs, nor to define a separate interfacial energy, nor to model the nucleus as homogeneous

Phase field description of defects

Order parameter $\phi(\mathbf{r})$

Chemical non-uniformity: $c(\mathbf{r}), \rho(\mathbf{r}), V_m(\mathbf{r}), ...$

Structural non-uniformity: $\eta(\mathbf{r}), \mathbf{u}(\mathbf{r}), \boldsymbol{\varepsilon}(\mathbf{r}), \mathbf{M}(\mathbf{r}),$

Examples: Martensitic transformation or dislocation, order parameter = inelastic displacement (or strain) $\mathbf{u}(\mathbf{r})$ *or* $\boldsymbol{\varepsilon}(\mathbf{r})$

Total energy

Chemical or inelastic energy:

$$F^{ch} = \int [f(\phi(\mathbf{r})) + \kappa |\nabla \phi(\mathbf{r})|^2] d\mathbf{r}$$

Elastic energy: $\varepsilon_{ij}^T(\mathbf{r}) = \sum_p \varepsilon_{ij}^T(\phi_p(\mathbf{r}))$

$$E^{el} = \frac{1}{2} \sum_{pq} \int \frac{d^3k}{(2\pi)^3} \begin{bmatrix} C_{ijkl}\varepsilon_{ij}^{00}(p)\varepsilon_{kl}^{00}(q) \\ -n_i\sigma_{ij}^{00}(p)\Omega_{jk}(\mathbf{n})\sigma_{kl}^{00}(q)n_l \end{bmatrix} \{\phi_p^m(\mathbf{r})\}_k \{\phi_q^m(\mathbf{r})\}_k^*$$

Kinetics

Phase field approach is a superset of the Cahn–Hilliard description of chemical inhomogeneities and the Peierls description of displacive inhomogeneities.

NEB + Phase Field

Starting image

End image
Summary

Phase field approach could be applied at several levels to develop fundamental understanding of nucleation behavior during solid state processes:

- At a **qualitative** level the Langevin dynamics could be applied to study effect of arbitrary chemical and structural non-uniformity in existing microstructure on nucleation. The examples given showed stress-induced collective and correlated nucleation, as well as autocatalytic effect. In particular, spatial distribution of different variants of the α phase was shown to correlate strongly with stress distribution in a polycrystalline sample. Under certain conditions, certain α variants may percolate through the entire sample.

- At a **semi-quantitative level**, the interaction energy calculation allows for systematic investigation of effect of stress fields associated with arbitrary existing microstructure on nucleation

- At **a quantitative level** the microscopic phase field model (in combination with NEB technique) could be applied to characterize activation energy and critical nucleus configuration. But this is energetic only. Need to put the activation energy into the framework of classical nucleation theory to predict nucleation (see next page for details)

Transition State Theory (TST)

TST escape rate =
equilibrium flux through
dividing surface at $x = q$
$$r_{A \to B}^{HTST} = \upsilon_0 \exp(-\Delta E / k_B T)$$

(harmonic approx.)

- classically exact rate if no recrossings or correlated events

- no dynamics required

- excellent approximation for materials diffusion

- can also exploit TST formalism to develop methods that do not require knowing in advance where the dividing surface is

Laidler, JPC (89).

How To Find Saddle Points

"Drag method": Guess final state & diffusion path (reaction coord.)

$\Delta E \sim 0.4$ eV
Reliable search for diffusion path: "Nudged elastic band method (Jónsson *et al*.).
$$\mathbf{r}_{0.5} = 0.5\,(\mathbf{r}_i + \mathbf{r}_f)$$

Final state unknown $\Rightarrow$ Dimer method, (accelerated) MD
Prefactor

- **Necessary:** vibrational frequencies at minimum & saddle point (harmonic TST, Vineyard (1957))

$$D = \frac{p \cdot d^2}{12} \upsilon \exp\left(-\frac{\Delta S}{k_B}\right) \exp\left(-\frac{\Delta E}{k_B T}\right)$$

$$\upsilon = \frac{\prod\limits_{j=1}^{N} \upsilon_j^{\mathbf{A}}}{\prod\limits_{j=1}^{N-1} \upsilon_j^{\mathbf{S}}}$$

Min. **A**   **S**   Min. **B**
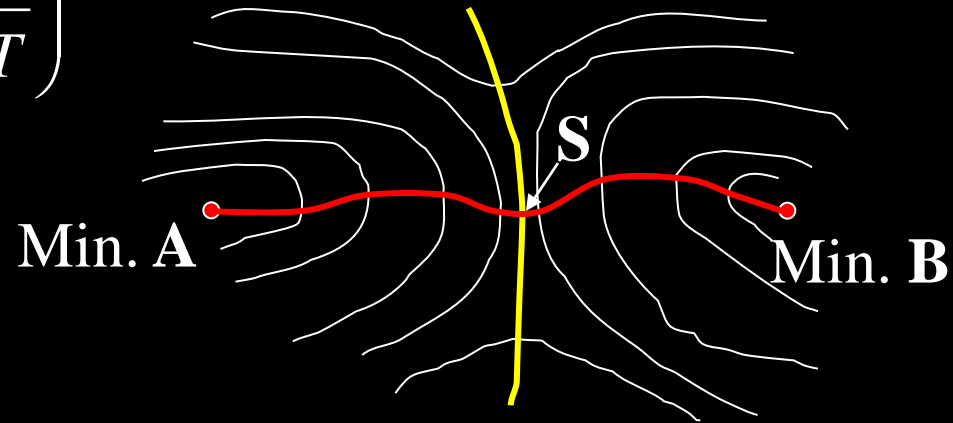

$$S = k_B \sum_{i=1}^{3N} \left\{ \frac{\hbar \upsilon_i}{2 k_B T} \coth\left(\frac{\hbar \upsilon_i}{2 k_B T}\right) - \ln\left[2\sinh\left(\frac{\hbar \upsilon_i}{2 k_B T}\right)\right] \right\}$$

Uberuaga et al. PSS (02), Stoddard et al, PRL (05).

Sub-Microscopic Boron Clusters

Experimental situation:
- Structures too small to be seen in EM
  - $\Rightarrow$ only "few" atoms
    - New phase wants to nucleate, but decays quickly
- Clustering dependent on B concentration and interstitial concentration
  - $\Rightarrow$ formation of $B_m I_n$ clusters postulated; experimental estimate: $m / n \sim 1.5$*

$\Rightarrow$ *Approach*:
- Calculate clustering energies from first principles up to "max." m, n
- Build kinetic Monte Carlo / continuum model from it

*S. Solmi *et al.*, JAP **88**, 4547 (2000).

Summary

Semiconductors:

- Kinetic parameters from ab initio calculations today standard, including
  - charge effects
  - temperature effects (non-Arrhenius)
- Clustering/nucleation kinetics doable and helpful, demonstrated for
  - Pre-nucleation
  - Growth

Metals???

What Does It Take to Do Same Calculations for Metals?

- Start from different initial structure (e.g., fcc instead of diamond)
- Do not use pseudo-potential file for silicon, but for metal
- Do same
Example: Superdiffusers
Explanation for superfast diffusion of Au in Pb: Interstitial mechanism

Final Summary

- Semicondutor research good guidance (e.g. irradiation to enhance supersaturation of solutes ("pre-amorphization implants")

- Diffusion and rate constants from DFT doable

- Reliance on "knowledge" of processes (reaction paths) dangerous – need good initial data and sensible modeling tasks

- Complimentary experiments necessary

- Modeling essential for full interpretation of experiments

Thermodynamic Modeling of Multi-component Systems and Its Integration with Kinetic Simulation

Fan Zhang, W. Cao, K. Wu, S. Chen, Y. Yang, and Y. A. Chang
CompuTherm, LLC

Present at
Nucleation Workshop at Maui, Hawaii
May 5, 2010

Outline

➢ Introduction to the CALPHAD Approach

➢ Integration of Thermodynamic Calculation with Kinetic Models for the Simulation of Nucleation, Growth and Coarsening

➢ Are Those Gibbs Energies Developed by the CALPHAD Approach Trustworthy?

Why CALPHAD Approach?

Ni-Al binary
Ni-Al-Cr Ternary

Ni-Al-10Co-5Cr-2Re (at%)

CALPHAD: **CAL**culation
of **PHA**se **D**iagram

CALPHAD Approach

| Thermodynamic data of a binary or ternary | Phase equilibrium data of a binary or ternary |

Self-consistent Gibbs energy functions for all the phases in the system (Thermodynamic Description)

Reproduce experimental diagrams and thermo-dynamic properties of the binaries and ternaries

More importantly – extrapolate the Gibbs energies of lower order systems to higher order systems to predict properties of higher order systems
Three Binaries To Form A Ternary

Muggianu Model:
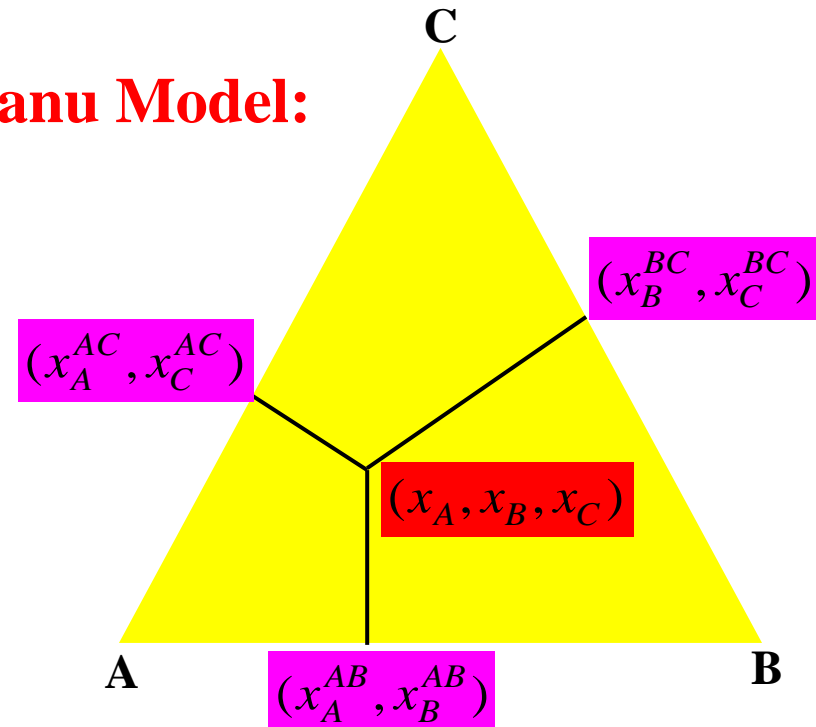

$$G(x_A, x_B, x_C) = \frac{x_A \cdot x_B}{x_A^{AB} \cdot x_B^{AB}} G^{AB}(x_A^{AB}, x_B^{AB}) + \frac{x_B \cdot x_C}{x_B^{BC} \cdot x_C^{BC}} G^{BC}(x_B^{BC}, x_C^{BC}) + \frac{x_A \cdot x_C}{x_A^{AC} \cdot x_C^{AC}} G^{AC}(x_A^{AC}, x_C^{AC})$$

Integration of Thermodynamic Calculation with Kinetic Simulation
Microstructure Modeling: Fast-acting Model

The Fast-acting Model:

- Concurrent nucleation, growth and coarsening

- Evolution of average quantities: volume fraction, number density, particle size

- Average particle size change with time
The KWN (Kampmann-Wagner Numerical) Model:

- **Concurrent nucleation, growth and coarsening**

- **Evolution of average quantities: volume fraction, number density, particle size**

- **Evolution of PSD: Particle Size Distribution**

- **Many size classes**

size classes R_i
Nucleation Rate

Classical nucleation theory:

$$J = N_v Z \beta^* e^{-\frac{\Delta G^*}{kT}} e^{\frac{-\tau}{t}}$$

N_v : **Number of nucleation sites per unit volume**
Z : **Zeldovich factor accounting for decay of supercritical particles**
β^* : **Rate of solute atoms joining the critical nucleus**
τ : **Incubation time**
ΔG^*: **Activation energy for nucleation**

Growth Rate

Growth rate of multi-component alloys (small super-saturation)*

$$v = \frac{dR}{dt} = \frac{K}{R}\left(\frac{1}{R^*} - \frac{1}{R}\right)$$

$\Delta Gm > 0$, R < R* → Dissolution

$\Delta Gm > 0$, R > R* → Growth

R: particle radius   **R*: critical nucleus radius**

$$K = \frac{2\sigma V_m}{\left(\Delta C^{\alpha\beta}\right]\left[M\right]^{-1}\left[\Delta C^{\alpha\beta}\right)}$$ **kinetic parameter**

(ΔC$^{\alpha\beta}$] : row vector of the solute concentration difference between α and β

[ΔC$^{\alpha\beta}$) : column vector of the solute concentration difference between α and β

[M]   : chemical mobility matrix

Coarsening Rate

Coarsening Rate of Multi-Component System

$$\overline{R}^3 - \overline{R}_0^3 = \frac{4}{9}Kt \quad \text{or} \quad \frac{d\overline{R}}{dt} = \frac{4}{27}\frac{Kt}{R^2}$$

$\overline{R}$: **average particle radius at time t**

$\overline{R}_0$: **average particle radius at the onset of coarsening**

K : **kinetic parameter**

Conclusions

➢ **The CALPHAD approach has been applied to multi-component systems with some success**

➢ **Thermodynamic modeling can be integrated with kinetic models, microstructure models, mechanical property models for the simulation of materials properties**

➢ **Are there problems and concerns with the current CALPHAD approach? Yes**

➢ **Are there other better approaches for describing multi-component systems at this moment? No**

➢ **What can we do? Continue to improve this approach**
