INTRODUCTION

Decompression schedules in the MK 16 MOD 1 He-O₂ Decompression Tables of the U.S. Navy Diving Manual, Revision 6^1 were designed to incur a near uniform 2.3% estimated risk of decompression sickness (P_{DCS}) over the tabulated ranges of dive depth and bottom time.² This design objective was achieved by computing the schedules with methods based on the linear-exponential multi-gas probabilistic decompression model parameterized with the nbnmx3g-he8n25 parameter set (LEMhe8n25), but the method differed depending on whether the schedules were included in the depth range over which a capability to plan for repetitive diving had to be supported. For dives to depths greater than 200 feet of seawater (fsw), dives for which no repetitive diving capability was to be supported, schedules were computed by using LEM-he8n25 directly to find the minimum decompression time required to reach but not exceed the 2.3% target P_{DCS} in each schedule.² For dives to depths of 200 fsw or shallower, dives for which a capability to plan for repetitive diving was required, schedules were computed with the Thalmann Algorithm parameterized with XVal-He-4, a maximum permissible tissue tension (MPTT) table derived to force the Thalmann Algorithm to calculate decompression schedules similar to those produced for the same dive by LEM-he8n25 with the 2.3% target P_{DCS}. This adoption of the Thalmann Algorithm allowed ready calculation of the surfacing repetitive groups and surface interval credit and residual gas time tables required to support repetitive diving with the familiar residual gas timetable format³ that has been used in U.S. Navy Diving Manuals since $1959.^{4}$

Traditionally, MPTT tables are constructed from surfacing MPTT values (M_0 -values) that are defined to just allow well accepted no-stop bottom times.⁵ These surfacing values are then projected to depth, generally as linear functions of depth with slopes of one or greater⁶ to ensure that the MPTTs at depth are always greater than the corresponding arterial inert gas tensions. The MPTTs in XVal-He-4 were also constrained to be linear functions of depth, but with surfacing MPTTs and slopes derived in a formal statistical process described in NEDU TR 02-10² with additional details in Appendix A of the present report. This process yielded slopes for several of the XVal-He-4 MPTT generating functions that are less than one (see Figure 1 and Appendix A). As a result, some XVal-He-4 MPTTs may intersect and become less than the arterial inert gas tension at depth, a circumstance which causes the XVal-He-4 Thalmann Algorithm to fail at or deeper than the intersection depths. Because these intersection depths are deeper than 200 fsw for MK 16 MOD 1 dives, this problem did not arise when XVal-He-4 Thalmann Algorithm decompression schedules were calculated for the MK 16 MOD 1 He-O₂ Decompression Tables.

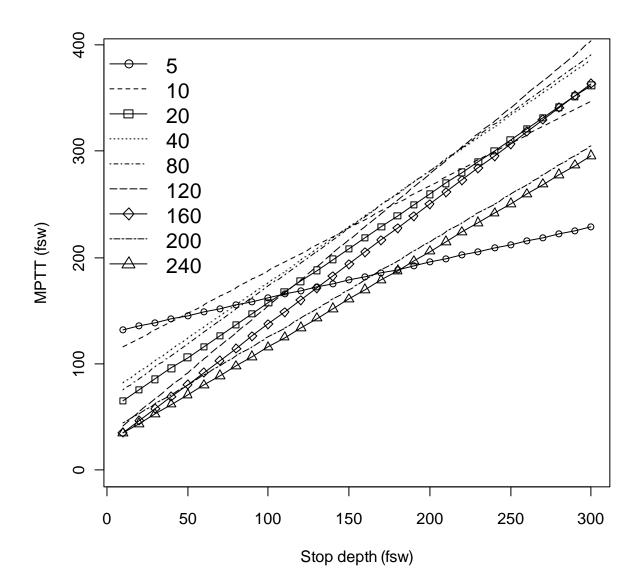

Figure 1. XVal-He-4 MPTTs. MPTTs for compartments that control decompressions in schedules tabulated in the MK 16 MOD 1 He-O₂ Decompression Tables in the *U.S. Navy Diving Manual* are drawn with symbols and solid lines.

There has been recent impetus to implement a real-time decompression algorithm in the Navy Dive Computer (NDC) to support MK 16 MOD 1 He-O₂ diving to maximum depths of 200 fsw with approximately one-hour maximum bottom time. Wrist-worn dive computers like the NDC currently have insufficient computing power to calculate probabilistic decompression schedules in real-time and instead run less demanding deterministic decompression algorithms. The NDC and its supporting dive planning tool, the U.S. Navy Thalmann Algorithm Navy Dive Planner (NDP), use implementations of

the deterministic Thalmann Algorithm.^{7,8} XVal-He-4 was developed for use in this algorithm to generate the MK 16 MOD 1 He-O₂ Decompression Tables in the *U.S. Navy Diving Manual*, tables that have been extensively man-tested² and used in the field since before 2005. Implementation of the XVal-He-4 Thalmann Algorithm in currently existing NDC hardware would thus not only be relatively straightforward, but would also provide guidance fully consistent with the existing MK 16 MOD 1 He-O₂ Decompression Tables, making it the most obvious candidate algorithm for a MK 16 MOD 1 He-O₂ NDC.

However, XVal-He-4 was not developed for use in the Thalmann Algorithm to support real-time applications. Indeed, the unconventional structure of XVal-He-4 makes it unsuitable for such applications. This report evaluates the behavior of the Thalmann Algorithm with XVal-He-4 beyond that explored previously² and shows how XVal-He-4 is readily modified and made suitable for use in the Thalmann Algorithm to provide real-time support for MK 16 MOD 1 He-O₂ diving.

METHODS

Decompression tables were generated with the Thalmann Algorithm TBLP7R routine, and compartment gas tensions at each node in the tabulated schedules were obtained from output provided by the Thalmann Algorithm DMDB7 routine.^{7,8} Output of the computed schedules in Augmented NMRI Standard format was used to estimate the P_{DCS} of computed schedules with LEM–he8n25.

RESULTS

XVAL-He-4

The XVal-He-4 Thalmann Algorithm MK 16 MOD 1 He-O₂ Decompression Tables in the *U.S. Navy Diving Manual, Revision 6* have schedules for dives with up to 60 minutes bottom time at 200 fsw and schedules for dives with considerably longer bottom times at shallower depths. These schedules have a mean LEM–he8n25 estimated P_{DCS} of 2.3% (SD = 0.4%) with only five schedules having estimated P_{DCS} of more than three SDs greater than the mean (bottom times near one hour at 190 fsw and 200 fsw, see Figure 2). Although the MK 16 MOD 1 He-O₂ Decompression Tables cover the intended operational depth-time range for a future NDC, a real-time implementation of the XVal-He-4 Thalmann Algorithm must produce reasonable schedules for a small range of longer than intended bottom times or deeper than intended depths in case inadvertent violation of depth and time limits occurs in a dive.

Figure 3 illustrates that in the 150 to 200 fsw depth range, XVal-He-4 produces low P_{DCS} schedules for bottom times substantially longer than one hour. Although DCS risk is not as well controlled at 190 fsw and 200 fsw as at shallower depths, the maximum estimated P_{DCS} is an acceptable 5.1%. For dives to a given depth, the estimated P_{DCS}

peaks at bottom times near one hour and returns to values near 2.3% at longer bottom times.

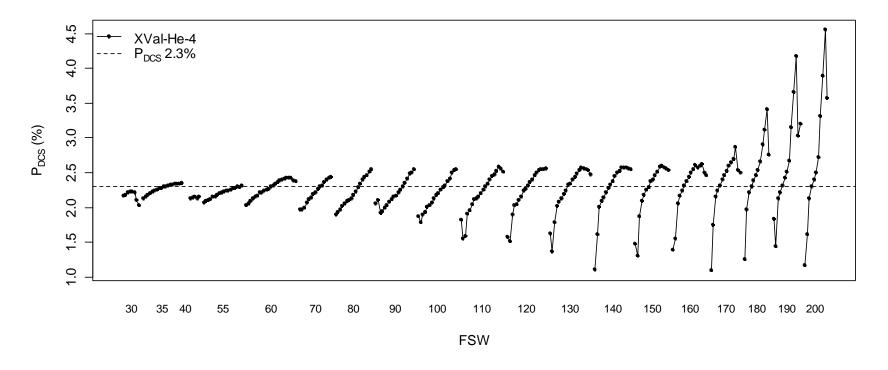

Figure 2. P_{DCS} of XVal-He-4 Thalmann Algorithm MK 16 MOD 1 He-O₂ decompression schedules in the *U.S. Navy Diving Manual, Revision 6.* Points correspond to the LEM–he8n25 estimated P_{DCS} values for schedules with increasing bottom time in each dive depth group indicated on the x-axis. No-stop dives are not shown. The maximum plotted bottom times, in minutes, in the region of interest are (fsw/BT) 150/90, 160/90, 170/80, 180/70, 190/65, and 200/60.

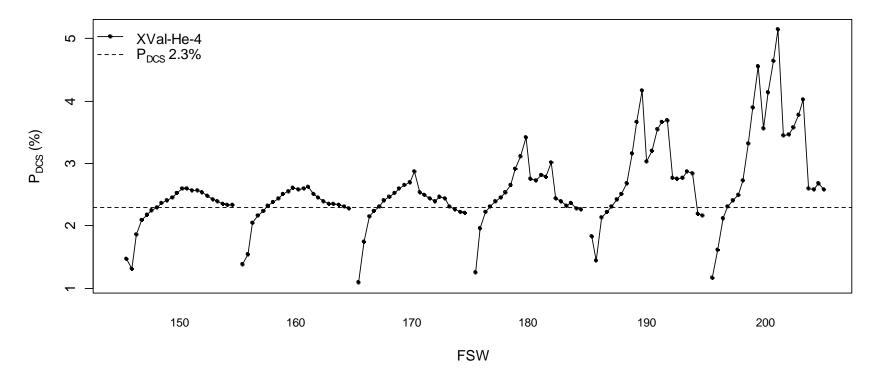

Figure 3. P_{DCS} of XVal-He-4 Thalmann Algorithm MK 16 MOD 1 He-O₂ decompression schedules for extended bottom times. Points correspond to LEM–he8n25 estimated P_{DCS} of decompression schedules at the indicated dive depths with bottom times shown in 5-minute increments up to 120 minutes, presented in the same manner as in Figure 2.

A controlling compartment is one for which a decompression stop is required to allow gas washout to the MPTT for ascent to the next stop before continued ascent. Only the compartments with half-times of 5, 20, 160 and 240 minutes control decompression in the *U.S. Navy Diving Manual* MK 16 MOD 1 He-O₂ Decompression Tables to 200 fsw or less, or in the extended schedules shown in Figure 3. Of these compartments, the 5-minute half-time compartment controls stops only in the 190 fsw and 200 fsw schedules, where it imposes the unconventional deep stops (see Table 1).

Failure of XVal-He-4 deeper than 211 fsw

The XVal-He-4 Thalmann Algorithm will not provide reliable decompression guidance for 1.3 atm constant PO_2 -in-helium dives to depths deeper than 211 fsw, because the arterial helium tension exceeds the 5-minute half-time compartment MPTT at such depths. As the compartment approaches equilibrium with the arterial helium tension, washouts of compartment helium tension to less than the MPTT — and ascents without violation of the MPTT — become impossible. The algorithm consequently inserts an infinite duration decompression stop at the depth where this condition first develops, which may be at maximum depth or at the next shallower decompression stop depth. In either case the diver is "trapped" at depth. This unacceptable situation is a consequence of the low slope of the 5-minute half-time compartment MPTT generating function.

With a 10 fsw stop depth increment and breathing 1.3 atm constant PO₂-in-helium from the MK 16 MOD 1 underwater breathing apparatus (UBA), the shallowest depth at which this problem occurs is 214 fsw, where helium uptake can result in compartmental tension greater than the 5-minute half-time compartment MPTT for 220 fsw. Once these greater tensions occur, the algorithm prescribes that divers take an infinite duration 220 fsw decompression stop which has already been omitted without leaving the bottom. In dives to depths deeper than 220 fsw, this problem first manifests as an infinite duration decompression stop at a depth shallower than bottom depth, but as bottom time increases, infinite duration stops develop at increasing depths that eventually exceed bottom depth.

Because gas exchange in the 5-minute half-time compartment is rapid by definition, these infinite duration stops arise after only relatively short bottom times. Also, the entire time at depth does not need to be spent at 214 fsw or deeper. For instance, after a substantial bottom time at 200 fsw, a brief unplanned excursion to a depth deeper than 214 fsw could result in an infinite duration stop.

XVAL-HE-4B

Three fixes for this behavior are readily implemented. The first is to truncate XVal-He-4 at 200 fsw and set the maximum operating depth of the NDP or NDC to 200 fsw. This would be transparent in the NDP, which will not accept depth entries deeper than the maximum depth in the MPTT table. But this fix would be unacceptable in the NDC as it would preclude NDC support of inadvertent excursions to depths deeper than 200 fsw.

The second fix is to alter the 5-minute compartment MPTTs in XVal-He-4 so that none are less than the arterial helium tension when a diver is breathing from a MK 16 MOD 1 UBA at the corresponding depth. Such a MPTT table, designated XVal-He-4A, was created by altering the 5-minute compartment MPTT values for depths deeper than 170 fsw to values greater than the corresponding arterial helium tension when breathing from MK 16 MOD 1 UBA. Retaining the original values at 170 fsw and shallower allows the Thalmann Algorithm with XVal-He-4A to produce schedules identical to those tabulated in the *U.S. Navy Diving Manual, Revision 6* for depths of 200 fsw or shallower. Beginning the changes deeper than 170 fsw prevents the algorithm from producing schedules with inordinately long decompression stops at depths between 180 and 210 fsw. However, the current implementation of the Thalmann Algorithm in the NDC calculates MPTTs from linear MPTT generating functions that cannot reproduce the XVal-He-4A MPTT. Therefore, details of XVal-He-4A performance are not given in this report.

The third and most satisfying solution is to eliminate the 5-minute compartment from XVal-He-4 since it controls very few schedules in the intended depth range. The resulting MPTT table, designated XVal-He-4B, allows the Thalmann Algorithm to produce schedules identical to those tabulated in the *U.S. Navy Diving Manual, Revision 6* for dives to depths of 180 fsw and shallower. Table 1 gives the decompression schedules for 200 fsw dives as tabulated in the *U.S. Navy Diving Manual, Revision 6* (XVal-He-4 Thalmann Algorithm), as calculated by using the Thalmann Algorithm with XVal-He-4B, and as calculated with LEM–h8n25 at 2.3% target P_{DCS}. Note that XVal-He-4B schedules differ from XVal-He-4 schedules by not having deep one-minute-duration decompression stops. These XVal-He-4 deep stops are unconventional and appear only in the 190 and 200 fsw schedules for MK 16 MOD 1 He-O₂ Decompression Tables. In fact the XVal-He-4B schedules that the XVal sets are intended to emulate. A similar pattern occurs in the 190 fsw schedules which are not given here.

Figure 4 illustrates the estimated P_{DCS} of schedules calculated with the XVal-He-4B Thalmann Algorithm for dives with bottom times up to 60 minutes at depths from 190 to 300 fsw. The estimated P_{DCS} are acceptable for short bottom times such that XVal-He-4B Thalmann Algorithm can support brief excursions deeper than its maximum operating depth of 200 fsw. Estimated P_{DCS} increase to unacceptable levels with increasing bottom time at all depths deeper than 200 fsw. Only compartments with 10, 20, 160 and 240 minute half-times control decompression in the illustrated schedules. Of these compartments, the 10-minute half-time compartment controls stops only for dives to depths of 230 fsw and deeper.

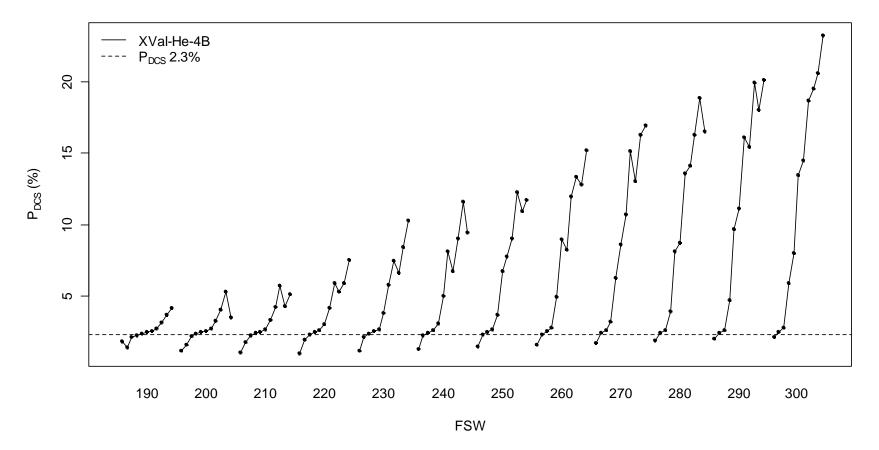

Figure 4. P_{DCS} of XVal-He-4B Thalmann Algorithm MK 16 MOD 1 He-O₂ decompression schedules for depths to 300 fsw. Points correspond to LEM–he8n25 estimated P_{DCS} of decompression schedules at the indicated dive depths with bottom times shown in 5-minute increments from 10 to 60 minutes, presented in the same manner as in Figure 2.

10

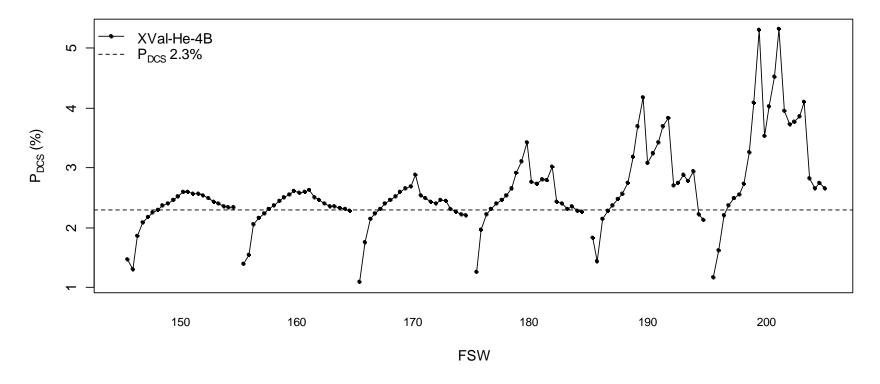

Figure 5. P_{DCS} of XVal-He-4B Thalmann Algorithm MK 16 MOD 1 He-O₂ decompression schedules for extended bottom times. Points correspond to LEM–he8n25 estimated P_{DCS} of decompression schedules at the indicated dive depths with bottom times shown in 5-minute increments up to 120 minutes, presented in the same manner as in Figure 2.

Figure 5 illustrates the estimated P_{DCS} of schedules calculated with the XVal-He-4B Thalmann Algorithm for dives with bottom times up to two hours at depths in the 150 to 200 fsw range. In the 150 to 180 fsw range, XVal-He-4B schedules and estimated risks are identical to those of XVal-He-4 (see Figure 2). At 190 and 200 fsw, XVal-He-4B schedules have mean estimated P_{DCS} 0.07% greater than XVal-He-4 schedules, but the maximum estimated P_{DCS} among the XVal-He-4B schedules is an acceptable 5.3%. Thus a real-time implementation of the XVal-He-4B Thalmann Algorithm will produce reasonable decompression guidance for dives to maximum depths of 200 fsw with bottom times up to at least 120 minutes.

Figure 3 and 5 show that the highest P_{DCS} occurs for dives to a given depth with bottom times near one hour, and that the estimated P_{DCS} returns to values near 2.3% for dives with longer bottom times. This pattern holds for schedules prescribed by either the XVal-He-4 or XVal-He-4B Thalmann Algorithm. The peak P_{DCS} values generally occur as a result of high accumulation of risk following ascent from the 40 fsw or 30 fsw decompression stops. The lower risks at longer bottom times — risks that are back in accord with the target 2.3% — result from substantial lengthening of these stops. For instance, a principal difference between the 200 fsw/55-minute schedule ($P_{DCS} = 5.3\%$) and the 200 fsw/60-minute schedule ($P_{DCS} = 3.6\%$) prescribed by the XVal-He-4B Thalmann Algorithm is a substantially longer 30 fsw decompression stop (see Table 1). The relatively abbreviated decompression stops in the higher risk schedules are always controlled by the 160-minute half-time compartment MPTT, indicating that a higher slope in the MPTT generating function for this compartment would be inappropriate.

DISCUSSION

The Thalmann Algorithm parameterized with XVal-He-4 produces acceptable PDCSconstrained decompression schedules for dives to depths with bottom times that span the depth/time ranges for which it was developed. It also produces acceptable schedules for dives to depths in the 150 to 200 fsw range with bottom times considerably longer than previously explored.² This success results in part from the unconventional structure of XVal-He-4. Conventional MPTT tables have M₀-values that decrease monotonically with increasing compartment half-time and MPTT generating function slopes that may also decrease monotonically with increasing compartment halftime, but that remain of value one or greater. Represented graphically as functions of depth, conventional MPTTs for different compartments do not intersect as do the XVal-He-4 MPTTs (Figure 1). Algorithms parameterized with conventional MPTT tables or similar safe ascent criteria prescribe decompression schedules with estimated P_{DCS} values that increase with increasing depth and bottom time.⁹ In contrast, the low slopes of some of the XVal-He-4 MPTT generating functions produce lower MPTTs that result in more conservative, lower P_{DCS} decompression schedules than would be obtained with MPTTs generated from functions with higher slopes. Indeed the 160-minute halftime MPTTs, which were generated with the highest slope of any controlling compartment in XVal-He-4, are marginally too permissive and result in occasional abbreviated decompression stops and associated higher risk schedules.

XVal-He 4 has five "silent" compartments (10-, 40-, 80-, 120, and 200-minute half-times) that never control decompression. These compartments result from the development technique that forced parameterization of nine compartments to describe a standard set of decompression schedules that are adequately described with fewer compartments. The unconventional pattern of M_0 -values in XVal-He-4, a pattern in which the M_0 -values do not decrease monotonically with increasing compartment half-time, arises largely from these silent compartments and is therefore inconsequential.

The low slopes of the XVal-He-4 MPTT generating function do cause problems if XVal-He-4 is applied at depths deeper than the range for which it was developed. At such depths, MPTT can be less than the arterial helium tension and can cause the Thalmann Algorithm to prescribe infinite-duration decompression stops. Eliminating the largely silent 5-minute half-time compartment from XVal-He-4 (and thus creating XVal-He-4B) prevents the Thalmann Algorithm from prescribing infinite-duration stops at depths from 220 to 300 fsw. Although some of the remaining XVal-He-4B compartments (10-, 200-, and 240-minute half-times) have MPTT generating functions with slopes less than one and are therefore susceptible to this same problem, none of these MPTT generating functions intersect the arterial helium tension at depths shallower than 372 fsw. This depth is well beyond the maximum operating depth of XVal-He-4B (200 fsw) or of the MK 16 MOD 1 UBA (300 fsw).

Although the XVal-He-4B 120-minute half-time compartment does not control any decompression, it is retained because it is the reference compartment for repetitive dive calculations and allows the NDP implementation of XVal-He-4B-Thalmann Algorithm to calculate repetitive groups consistent with the MK 16 MOD 1 He-O₂ decompression tables in the *U.S. Navy Diving Manual*.¹ The remaining silent compartments in XVal-He-4B could be eliminated without altering the decompression prescriptions, but they have been retained.

CONCLUSIONS AND RECOMMENDATIONS

- The XVal-He-4 Thalmann Algorithm cannot reliably prescribe decompression schedules for dives to depths deeper than 211 fsw. It should therefore not be used in a diver-worn NDC intended to support MK 16 MOD 1 He-O₂ dives to depths up to 200 fsw, in case this depth is inadvertently exceeded. This issue is solved by removing the 5-minute compartment from XVal-He-4, producing XVal-He-4B.
- 2. XVal-He-4B produces decompression guidance to maximum depths of 200 fsw that is consistent with the MK 16 MOD 1 He-O₂ Decompression Tables in the U.S. Navy Diving Manual.
- 3. The XVal-He-4B Thalmann Algorithm will reliably produce decompression schedules to depths of 300 fsw, but it should not be used for planning dives to depths deeper than 200 fsw.

- 4. The XVal-He-4B Thalmann Algorithm will provide reasonable decompression guidance in cases of inadvertent and short-duration excursions to depths deeper than 200 fsw. Decompression schedules for dives with bottom times longer than 20 minutes at these depths have P_{DCS} that can be substantially above 3%.
- 5. The XVal-He-4B Thalmann Algorithm will produce DCS risk-constrained decompression guidance for dives to maximum depths of 200 fsw with bottom times of more than one hour.
- 6. The XVal-He-4B Thalmann Algorithm is recommended for incorporation into the NDC and NDP to support MK 16 MOD 1 He-O₂ diving operations to planned depths up to 200 fsw and with one-hour maximum time deeper than 140 fsw.

APPENDIX A CALCULATION OF XVAL-HE-4B

A full explanation of XVal-He-4 MPTT table development is given in NEDU TR 02-10.² Surfacing MPTTs for a fixed number of nine hypothetical gas exchange compartments with assumed gas exchange half-times ranging from 5 to 240 minutes, and slopes for projecting these surfacing MPTTs to depth according to the linear relationship first forwarded by Workman⁶ were found by closest fit to the highest tissue tension prevailing among the compartments at the end of each decompression stop in a standard set of LEM-he8n25 2.3% P_{DCS} iso-risk decompression schedules. The number of compartments (*ntiss* = 9) and their half-times were the same as in the VVal-18 MPTT table used with the Thalmann Algorithm to compute MK 16 MOD 0 and MK 16 MOD 1 N₂-O₂ decompression tables. In NEDU TR 2-10, there is an inconsistency in notation between the description of this method and the results given in Tables 9 and 10 of that report, which is reconciled below.

In a Thalmann Algorithm MPTT table, the MPTTs for the i = 1, 2, ..., ntiss compartments at depth D, $M_{i,D}$, are offset by one stop depth increment (*DINC*) to depth D+DINC, because it is at this deeper depth that the $M_{i,D}$ are used to assess when ascent to depth D will be allowed. Thus, for DINC = 10 fsw, the surfacing $M_{i,0}$ (often called M₀-values, here designated $M0_i$) values appear in the 10 fsw row. For stops at depths D equal to integral multiples of DINC ($D = \lambda \cdot DINC$; $\lambda = 1, 2, 3, ...$), the offset MPTT values are given generally by

$$M'_{i,D_{\lambda}} = M_{i,D_{\lambda-1}}, \qquad (1)$$

where the offset values are designated with a prime and

$$M_{i,D_{\lambda-1}} = M \mathcal{O}_i + a_i D_{\lambda-1} \,. \tag{2}$$

Eq. (2) is Workman's original expression for the MPTTs at depth D not offset by DINC (equation 7 in NEDU TR 02-10). In comparison, the following equation of form similar to the combined Eq. (1) and Eq. (2) was fit to obtain the XVal-He-4 Thalmann Algorithm MPTT table:

$$M_{i,D_{\lambda}} = \beta_{0,i} + a_i D_{\lambda}.$$
(3)

Noting that $D_{\lambda} - DINC = D_{\lambda-1}$, Eq. (3) reduces to the combined Eq. (1) and Eq. (2) with

$$\beta_{0,i} = M \,\mathcal{O}_i - a_i \cdot DINC \,. \tag{4}$$

The fitted parameters for Eq. (3) are given in Table A.1 reproduced from Table 10 of NEDU TR 02-10. The label for the intercept column is changed from M_0 (=M0) in the original to β_0 to correct a notational inconsistency that obfuscated the relationship between $M0_i$ and $\beta_{0,i}$ in Eq. (4).

The XVal-He-4B table (Appendix B) is obtained from the XVal-He-4 table simply by deleting the 5-minute half-time compartment.

Compartment	Extracted par	ameters
