Breast cancer is the most common tumor among women with inherited mutations in the p53 gene (Li-Fraumeni syndrome). The tumors represent the basal-like subtype which has been suggested to originate from mammary stem/progenitor cells. In mouse mammary epithelium, mammosphere-forming potential was increased with decreased dosage of the gene encoding the p53 tumor suppressor protein (Trp53). Limiting dilution transplantation also showed a 3.3-fold increase in the frequency of long-term regenerative mammary stem cells in Trp53/-/- mice. The repression of mammospheres by p53 was apparent despite the absence of apoptotic responses to radiation indicating a dissociation of these two activities of p53. The frequency of long-term label-retaining epithelial cells (LRECs) was decreased in Trp53/-/- mammary glands indicating that asymmetric segregation of DNA is diminished and contributes to the expansion of the mammary stem cells. Progenitor cell was also labeled with let-7c sensor. The knockdown of p53 also significantly increased the number of DsR+/ progenitor cells in vitro. Treatment with an inhibitor of gama-secretase (DAPT) reduced the number of Trp53/-/- mammospheres to the level found in Trp53+/+ cells. These results demonstrate that basal levels of p53 restrict mammary stem/progenitor cells through Notch and that the Notch pathway is a therapeutic target to prevent expansion of this vulnerable pool of cells.

Introduction
Breast cancer is the most frequent cancer among women in the United States\textsuperscript{1}. Understanding the biological behavior of mammary stem cells (MaSCs) and progenitor cells sheds light on the mechanism of mammary gland malignant transformation \textsuperscript{2,3}. A full term pregnancy early in reproductive life can reduce breast cancer incidence in women by up to 50\% \textsuperscript{4}. The research in our lab has shown that the p53 tumor suppressor pathway is a crucial downstream mediator for this protection mechanism \textsuperscript{5,6}. Parous mammary epithelium showed significantly higher apoptotic response to ionizing radiation (IR) which was p53-dependent \textsuperscript{7,8}. Recent research showed p53 also participated in the regulation of tissue-specific stem cells in both hematopoietic system and neural system. Further more, \textit{Arf-Trp53} pathway was shown to restrict the efficiency of reprogramming of induced pluripotent stem cells \textsuperscript{9,10}.

We propose that p53 negatively regulates the proliferation and self-renewal of mammary stem/progenitor cells. The increased p53 activity in parous gland may reduce the mammary progenitor/stem cell pool resulting in decreased risk of mammary tumors. In the past year of research, we focused on testing the role of p53 in our \textit{in vitro} model of TM40A cell line. We confirmed that p53 negatively regulated mammary stem/progenitor cells proliferation and self-renewal in both primary mammary epithelial cells and TM40A cell line. The loss of p53 led to increased mammary stem/progenitor cells population, which may be a vulnerable population of transformation. We further showed that the \(\gamma\)-secretase inhibitor can effectively block the expansion of p53 defective mammary stem/progenitor cells, which can be a potential therapeutic target to prevent the expansion of this vulnerable pool of cells.
**Body**

**Methods**

**Mammosphere culture**

Primary single cells were seeded into ultra-low attachment dishes or plates at a density of 20,000 viable cells/ml. Cells were grown in a serum-free mammary epithelial growth medium (HuMEC, Gibco) supplemented with B27 (Gibco), 20ng/ml EGF (Sigma), 20ng/ml bFGF (Sigma), 4 μg/ml heparin (Sigma), 100u/ml Pen/Strep, 5 μg/ml gentamicin. For the GSI treatment, N-[N-(3,5-Difluorophenacetyl)-L-alanyl]-S-phenylglycine t-butyl ester (DAPT, Sigma) was added into culture medium to the final concentration of 5 μM (final DMSO concentration 0.1%). To passage mammospheres, mammospheres were collected with gentle centrifugation 800rpm for 5m in 7 days after culture and dissociated with 1ml pre-warm ed 0.05%Trypsin-EDTA and 60 μl 1mg/ml DNase I for 5-8min. Cell suspensions obtained from dissociation were sieved through 40 μm cell strainer and seeded at a density of 1,000 viable cells/ml.

**TM40A cell culture and retroviral infection**

TM40A cells were maintained in regular MECL media: DMEM:F12 supplemented with 2% adult bovine serum (Gibco), 10μg/ml Insulin (Sigma), 20ng/ml mEGF, and 100u/ml Pen/Strep..

let-7c sensor plasm ids and the control plasmids are gifts from Dr. Gregory Hannon. pSicoR-PGK-puro vector plasm id was purchased (Addgene, CA). Oligos coding for the p53 knockdown or scram ble shRNA were annealed and cloned into pSicoR-PGK-puro vector. The p53 tar get sequence was 5’-GT ACTCTCCTCCCCCTCAAT-3’ and the scramble sequence was 5’-CGCTACACACTTCTTCTC-3’. The infection of TM40A cells with let-7c sensor plasmid, pSicoR-PGK-puro-p53KD plasm id or the control plasm ids were perform ed as described previously.

**Western blot**

TM40A cell protein lysates were harvested 1 hour after 0-Gy or 10-Gy of γ-irradiation using RIPA buffer (50m M Tris, 150m M NaCl, 1% TritonX-100, 10% glycerol, 0.1% SDS, 0.5% deoxycholate, 1x protease inhibitor (Sigma, p8340) and 1x phosphatase inhibitor (Sigma, P5726)). Protein lysates (80 μg) were separated by 10% SDS-P AGE and transferred to PVDF membrane (Millipore, Billerica, MA). The mem brane was incubated with anti-ph ospho p53 (1:1000, Cell Signaling, 9284), or anti-β-actin (1:4000, Sigma, A1978), followed by incubation with horseradish peroxidase conjugated second ary antibodies (1:5000, GE Healthcare, Little Chalfont, Buckingham shire, UK), and developed using enhanced chem iluminescence (ECL) solution (GE Healthcare) in G:Box imaging system (Syngene, Cambridge, UK).

**PCR and knock down of Notch1 using siRNA**

Notch1 forward primer: 5’-TGGACGACAA TCAGAACGAG-3’, Notch1 reverse primer: 5’-GGAGAACTACTGGCTCCTCAA-3’, Notch4 forward primer: 5’-TCCGTCTGGAGGCTATTC-3’, Notch4 reverse primer: 5’-ACACAGGTACCCCCATGGAG-3’; Hes-1 forward primer: 5’TGCAGCTGATAATGGAGA-3’, Hes-1 reverse primer: 5’-CCATGATAGGCTTTGATGACTTT-3’; PGK forward primer: 5’TACCTGCTGGCTGGATGG-3’, PGK reverse primer: 5’-CGCAGCTCCGGCA TATTCTCT-3’.

Mammospheres were cultured as described above. Primary mammospheres were passaged to secondary mammospheres and total RNA were harvested and quantified 3 days after passage. Reverse transcription were done using RT kit(Roche). Quantitative PCR was done using Roche.
Universal library and real-time quantitative PCR system (Stratagene). To knockdown Notch1 in TM40A cells, siRNA (s70698 and s70700) were purchased from Ambion. s70698 siRNA sense sequence: 5’-CUAUGGUACUUAUGUGUtt-3’, antisense sequence: 5’- ACACUUUAAGUACCAUGct-3’. S70700 siRNA sense sequence: 5’-GGAUGUCAAUGUUCGGATT-3’, antisense sequence: 5’-UCCUCGAACAUUGACAUCCat-3’. siRNA oligos were diluted into 100 μM working stock and 3 different siRNA concentrations (12.5 pmol/well, 37.5 pmol/well and 75 pmol/well) were tried for transfection of TM40A cells using Lipofectamin 2000 (Invitrogen). Total RNA were isolated 48 hours after transfection and real-time quantitative PCR was used to confirm the knockdown efficiency.

Results

Label and chase progenitor cells population in vitro using let-7c sensor plasmid

The role of p53 in regulation of mammary stem/progenitor cells was further confirmed in vitro using the TM40A cell line, a mammary epithelial cell line derived from BALB/c mice and retains wild type p53 mRNA (unpublished data, DJJ). TM40A cells form hyperplastic outgrowths when transplanted in vivo (Fig. 1A) but have undetectable tumorigenicity through 20 weeks. The let-7 microRNA family was shown to be depleted in the mammary progenitor cells and highly expressed in the more differentiated cell types and the let-7c sensor plasmid (let7s) has been used to label mammary progenitor population in vitro. After infected with let-7c sensor plasmids, the TM40A-let7s cells contained 0.8% of DsRed positive (DsR+) progenitor cells (Fig. 1B). The mammosphere-forming capacity of DsR+ cells is 3.8-fold greater than DsR− cells (p<0.01) (Fig. 1C), confirming their progenitor feature. Interestingly, most of the cells in the DsR+ mammospheres remained DsR+ (Fig. 1D), suggesting the inhibition of differentiation under the mammosphere culture condition.

TM40A cells as in vitro model to study the role of p53 in the regulation of stem/progenitor cells

We proceeded to determine whether the knockdown of p53 can change the proportion of DsR+ progenitor cells as well. TM40A-let7s cells were infected with a p53 shRNA plasmid (TM40A-let7s-p53KD) or control plasmid (TM40A-let7s-ctrl) as described previously. Infection of TM40A-let7s cells with p53 shRNA plasmid effectively decreased p53 protein to less than 24% of the original level (Fig. 2A). The transactivation activity of p53 also significantly decreased as shown by luciferase assay (Fig. 2B). After the knockdown of p53, the TM40A-let7s-p53KD contained increased numbers of DsR+ cells (2.5%) compared to the TM40A-let7s-ctrl cells (0.8%) (Fig. 3A and B). The number of secondary mammospheres formed by TM40A-let7s-p53KD cells was also 2.2-fold higher than the control cells (p<0.01) (Fig. 3E), further proving that the basal level of p53 inhibits the expansion of mammary progenitor cells. TM40A cells can be a useful in vitro model to study the detailed molecular mechanism of how p53 regulates the self-renewal and proliferation of mammary stem/progenitor cells. Furthermore, the TM40A-let7s cells allowed us to track the behavior of mammary progenitor cells in the future and study the transformation process of mammary progenitor cells.

Notch inhibitor reduced the number of mammary stem/progenitor cells

Increased mammary stem/progenitor cells could be vulnerable targets for carcinogenesis, especially in Li-Fraumeni patients in whom p53-mediated genome surveillance is compromised. We proceeded to test the potential of pharmacological methods to inhibit the expansion of
The Notch pathway has been reported to both promote and limit progenitor cells \(^{14,15}\), therefore we tested whether \(\gamma\)-secretase inhibitors (GSI), could affect the expansion of p53-deficient mammary stem/progenitor cells \(^{16,17}\). The number of TM40A-let7\(^{-}\)-p53KD mammospheres decreased to baseline levels after treatment with DAPT, a GSI (Fig. 3E; \(p<0.01\)) indicating that Notch pathway could be a potential therapeutic target for downregulation of mammary stem/progenitor cells. The number of mammospheres in control cells with wild type p53 was not changed with DAPT treatment showing that inhibition of Notch was not a general effect, but specifically reversed the effect of p53-deficiency (Fig. 3E). DAPT treatment also restricted the expansion of progenitors measured by DsR\(^{+}\) sensor after p53 knockdown. In TM40A-let7\(^{-}\)-p53KD cells, DAPT decreased the DsR\(^{+}\) cells from 2.5% to 1.4% (compare Fig. 3B and D), whereas the proportion of DsR\(^{+}\) cells was not changed by DAPT in the control group (compare Fig.3A and C). Trp53\(^{-/-}\) and Trp53\(^{+/+}\) primary mammary epithelial cells were also treated with 5 \(\mu\)M DAPT or DMSO. Similarly, DAPT significantly inhibited the expansion of Trp53\(^{-/-}\) mammospheres. The number of Trp53\(^{-/-}\) secondary mammospheres decreased significantly from 250±13.4/10,000 cells to 168.3±11.4/10,000 cells after the DAPT treatment (\(p<0.01\)), but the number of Trp53\(^{+/+}\) mammospheres were not affected (Fig. 3F).

Test the level of Notch pathway components in mammospheres of different Trp53 genotype

The inhibition of mammary stem/progenitor cell number by GSI also suggested that the Notch pathway may play role in the regulation of mammary stem/progenitor cells self-renewal. p53 was reported to inhibit the activation of Notch pathway at different levels by either inhibiting the transcription of presenilin-1 or competing with Notch-1 in intracellular domain for coactivator p300/CBP \(^{18-20}\). We hypothesize that Notch may upregulate the self-renewal and proliferation of mammary stem/progenitor cells. The loss of p53 releases the inhibition effects and leads to the increased mammary stem/progenitor cells number (Fig. 3G). In order to test whether the loss of p53 leads to increased activity of Notch pathway, Notch1, Notch4 and Hes-1 primers were designed and used for PCR. We found no significant difference in the level of Notch1, Notch4 or Hes-1 level between Trp53\(^{+/+}\) and Trp53\(^{-/-}\) mammospheres (Fig. 4A and B). We also tried a couple of commercially available antibodies for mice Notch1 or Notch4. However, none of these antibodies gave us specific band. Our previous experiments showed that mammosphere-initiating cell is a very small population among all the cells in mammosphere. It is possible that the Notch pathway may play different roles in different cell types. The mixed cell population can mask the difference of Notch levels in the small stem/progenitor cell population.

Knock down of Notch1 in TM40A cells using siRNA

In order to confirm the role of Notch1 in the regulation of mammary stem/progenitor cells, we tried to knockdown Notch pathway in TM40A cells using siRNA. QPCR was carried out to confirm the knockdown efficiency. Preliminary data showed that the siRNA did not effectively knockdown the Notch1 mRNA level in TM40A cells (Fig. 5A and B). Troubleshooting using FITC-labeled unspecific siRNA showed that the TM40A cells can only be transfected with siRNA at low cell confluence (~30%). For the next step experiments, we will try to knockdown Notch1 at low cell confluency and see if the knockdown of Notch1 can inhibit the expansion of p53-deficient mammary stem/progenitor cells.
Key Research Accomplishments

Jan 2010- Apr 2010 Label mammary progenitor cells *in vitro* using let-7c sensor plasmids and TM40A cells line.

Apr 2010- Jun 2010 Knockdown p53 in TM40A cells using lentiviral shRNA plasmids and confirm the knockdown efficiency.

Jun 2010- Sept 2010 Test different γ-secretase inhibitor and find that DAPT treatment can effectively inhibit the expansion of p53-deficient mammary stem/progenitor cells *in vitro*.

Jul 2010- Oct 2010 Write manuscript: Repression of Mammary Stem/Progenitor Cells by P53 is Mediated by Notch and Separable from Apoptotic Activity. The manuscript summarized the data and progression of this project so far. Submitted the manuscript to Stem Cells, which accepted the manuscript in October, 2010.

Oct 2010- Dec 2010 Test the level of Notch pathway components in mammosphere cells.

Nov 2010- Jan 2011 Knockdown Notch1 in TM40A cells using commercially available siRNA
Reportable outcomes

1. The manuscript: Repression of Mammary Stem/Progenitor Cells by P53 is Mediated by Notch and Separable from Apoptotic Activity, which is funded by this training grant, has been accepted and published in Stem Cells. (See Appendices)
3. Labeled progenitor cells in TM40A cell line using let-7c sensor plasmids. Get TM40A-let7^ and control cell lines, which will be useful for tracking progenitor cells in vitro.
4. Knockdown p53 in TM40A cells using shRNA. Get TM40A-let7^ -p53KD and control cell lines, which were used to confirm the role of p53 in the regulation of mammary stem/progenitor cells in vitro.
5. Prove that γ-secretase inhibitor (DAPT) can be a therapeutic target to inhibit the expansion of p53-deficient mammary stem/progenitor cells.
6. Test the level of Notch pathway components (Notch1, Notch4 and Hes-1) in Trp53^+/+ and Trp53^-/- mammospheres using QPCR and Western blot.
7. Applied for a sponsored research opportunity in Brigham and Women’s hospital. This position will lead to collaboration between Dr. Jerry’s lab and Dr. Li’s lab to study the potential role of mammary stem/progenitor cells during malignant transformation.
Conclusions

The importance of p53 in breast cancer is highlighted by the dramatic increase of breast cancer risk among women with Li-Fraumeni syndrome. Although the function of activated p53 in mammary epithelium has been extensively studied, its role at basal level under normal conditions is not fully understood, largely due to the extremely low protein level \(^{21-23}\). The comparison of transgenic mice with different Trp53 genotype allows us to study the function of basal level p53 in mammary epithelium. In last annual report, we showed that the basal level p53 is essential for the regulation of mammary stem/progenitor cells self-renewal and proliferation and that the regulation of mammary stem/progenitor cells is independent of the apoptosis-mediating function of p53. Insufficient p53 dosage led to increased mammary stem/progenitor cells, which could be a vulnerable target of transformation.

In the past year, we established an in vitro system to label and track mammary stem/progenitor cells in our model cell line, TM40A. We showed that the let-7c sensor plasmid can be used to label mammary progenitor cells, which are about 0.8% of total TM40A cell population. The progenitor feature of these cells was further confirmed with mammosphere assay. Similar to the primary mammary epithelial cells, the knockdown of p53 in TM40A cells significantly increased the number of DsR+ progenitor cells in the total population, suggesting that the TM40A cells could be used as a valuable in vitro model to study the role of p53 in the regulation of mammary progenitor cells self-renewal and proliferation.

We further tested whether there is any therapeutic target that we can apply to inhibit the expansion of mammary stem/progenitor cells in the p53-deficient background. We found that γ-secretase inhibitor, DAPT, can effectively inhibit the expansion of progenitor cells. In TM40A-let7c-p53KD cells, DAPT treatment effectively brought down the DsR+ cells from 2.5% to 1.4%. By using mammosphere assay, the DAPT treatment also significantly inhibits the mammosphere formation of both Trp53-/- primary mammary epithelial cells and the p53 knockdown TM40A cells, without affecting the mammosphere formation of cells with normal functional p53. Women with Li-Fraumeni syndrome, which is commonly associated with germline heterozygous mutations of TP53, have significantly increased risk of breast cancer \(^{24,25}\). Therefore, the γ-secretase inhibitor can be a good pharmaceutical candidate for Li-Fraumeni syndrome patients, who may benefit from the inhibition of expansion of mammary stem/progenitor cells.

Based on our present data, we hypothesized our working model of disparate functions and roles of p53 in different cell differentiation stages. In differentiated cells, p53 can be activated due to various genotoxic or cellular stresses so that the damaged cells with either be repaired or eliminated through apoptosis, depending on the extent of damage. In contrast, the apoptosis-inducing function of p53 is compromised in the mammary stem/progenitor cells, which may prevent the premature aging process due to DNA damage or other cellular challenges. In these cells, the major tumor suppressor function of p53 is to restrict self-renewal and inhibit inappropriate expansion of mammary stem/progenitor cells, which is independent of the pro-apoptotic role of p53. This function of p53 may either be a direct effect or mediated through the regulation of other pathways, such as Notch, which can be potential therapeutic targets for chemoprevention of breast cancer (Fig. 3G).

γ-secretase inhibitor is commonly used to inhibit the cleavage and activation of Notch pathway. The fact that DAPT can effectively inhibit the expansion of mammary stem/progenitor cells
suggested that the Notch pathway may be an important regulator for the mammary stem/progenitor cells self-renewal and proliferation. We tried to look for the levels of Notch pathway components, such as Notch1, Notch4, and Hes-1, in mammospheres and did not find significant difference. It could due to the mixed cell population in the mammosphere. Notch-Numb pathway was shown to play different roles in cells of different differentiation stages. We may want to sort out the DsR⁺ progenitor cells and try to look for the Notch pathway components level in these cells. We will also need to optimize the knockdown of Notch1 and Notch4 using siRNA and see if it has similar effects as the γ-secretase inhibitor treatment. This will help us to determine whether the γ-secretase inhibitor actually inhibit the expansion of mammary stem/progenitor cells by inhibiting the activation of Notch pathway.

Supporting Data

Figure 1.

**TM40A cells as an in vitro model to test the function of basal level p53.** (A) Whole mount of a TM40A outgrowth 20 weeks after transplantation. (B) The let7c-sensor plasmid was introduced into TM40A cells (TM40A-let7\(^c\)). The TM40A-let7\(^c\) cells contained 0.8% of DsRed positive (Ds R\(^+\)) progenitor cells. Background levels of fluorescence were determined using control cells. (C) The DsR\(^+\) cells gave rise to significantly more mammospheres than DsR\(^-\) cells (p<0.01). (D) Most cells in the DsR\(^+\) mammospheres remained DsRed positive.

Figure 2.

**Knockdown of endogenous p53 using shRNA.** (A) Western blot showed that phosphorylated p53 (phospho-p53) was reduced in TM40A-let7\(^c\)-p53KD cells compared to the control cells (TM40A-let7\(^c\)-ctrl). (B) Luciferase assay showed that the transactivation activity of basal level p53 was significantly reduced in TM40A-let7\(^c\)-p53KD compared to the control cells (pSicoR) (p<0.01).
Inhibit the expansion of mammary stem/progenitor cells with $\gamma$-secretase inhibitor. (A-D) TM40A-let7$^\alpha$-p53KD cells contained more DsR$^+$ progenitor cells compared to the TM40A-let7$^\alpha$-ctrl cells. The expansion of DsR$^+$ progenitors in TM40A-let7$^\alpha$-p53KD cells can be inhibited by the treatment of DAPT, while the DsR$^+$ cells in TM40A-let7$^\alpha$-ctrl cells were not affected. (E) TM40A-let7$^\alpha$-p53KD cells gave rise to significantly more secondary mammospheres than control cells ($p<0.01$). The number of p53KD mammospheres decreased significantly with the treatment of 5 $\mu$M DAPT ($p<0.01$), while the number of control mammospheres were not affected ($p>0.05$). (F) Mammospheres were treated with either 5 $\mu$M DAPT or DMSO control during serial passages. The number of Trp53$^-$/- mammospheres decreased significantly after the treatment of DAPT ($p<0.01$). The number of Trp53$^+/+$ mammospheres was not changed with DAPT treatment. (G) Model of p53 tumour suppression function in different cell types. p53 restricts the self-renewal of mammary stem/progenitor cells; however the p53-mediated apoptosis response is compromised in these cells. In the differentiated cells, the p53-mediated apoptosis pathway becomes functional. Notch may be inhibited by basal levels of p53 in mammary stem/progenitor cells. Insufficient p53 can result in increased Notch activity which leads to the expansion of mammary stem/progenitor cells.
Figure 4.

Level of Notch pathway components in mammospheres of different genotypes. (A) Regular PCR showed no significant difference in the level of Notch1, Notch4 and Hes-1 between Trp53+/+ and Trp53−/− mammospheres. (B) QPCR showed no significant difference in the relative mRNA level of Notch1 and Notch4 between Trp53+/+ and Trp53−/− mammospheres.

Figure 5.

Knockdown of Notch1 in TM40A cells using siRNA. (A, B) Either siRNA 70689 or 70700 effectively knocked down Notch1 in TM40A cells under recommended transfection condition.

ABSTRACT
Breast cancer is the most common tumor among women with inherited mutations in the p53 gene (Li-Fraumeni syndrome). The tumors represent the basal-like subtype which has been suggested to originate from mammary stem/progenitor cells. In mouse mammary epithelium, mammosphere-forming potential was increased with decreased dosage of the gene encoding the p53 tumor suppressor protein (Trp53). Limiting dilution transplantation also showed a 3.3-fold increase in the frequency of long-term regenerative mammary stem cells in Trp53-/- mice. The repression of mammospheres by p53 was apparent despite the absence of apoptotic responses to radiation indicating a dissociation of these two activities of p53. The effects of p53 on progenitor cells were also observed in TM40A cells using both mammosphere-forming assays and the DsRed-let7c-sensor. The frequency of long-term label-retaining epithelial cells (LRECs) was decreased in Trp53-/- mammary glands indicating that asymmetric segregation of DNA is diminished and contributes to the expansion of the mammary stem cells. Treatment with an inhibitor of γ-secretase (DAPT) reduced the number of Trp53-/- mammospheres to the level found in Trp53+/- cells. These results demonstrate that basal levels of p53 restrict mammary stem/progenitor cells through Notch and that the Notch pathway is a therapeutic target to prevent expansion of this vulnerable pool of cells.
Mammary stem cells have been identified that are capable of regenerating the entire mammary ductal tree and repopulating the mammary fat pad [1, 2]. The mechanisms and pathways regulating self-renewal and differentiation of mammary stem cells are of great interest for its potential application in tissue replacement therapies as well as the prevention and treatment of breast cancer. The Wnt pathway was found to regulate the self-renewal of mammary stem/progenitor cells. Ectopic expression of Wnt1 resulted in an increased population of mammary stem/progenitor cells in the mammary gland and eventually induced mammary tumors [3]. Another breast cancer related gene, BRCA1, was reported to play a critical role in the differentiation of mammary stem/progenitor cells to luminal cells. Loss of both BRCA1 alleles resulted in expansion of stem/progenitor cells in the breast epithelium of women and increased breast cancer risk [4]. The Notch pathway has also been implicated as regulator of mammary stem/progenitor cells self-renewal and differentiation but its function is controversial. Dontu et al reported that the activation of Notch signaling with DSL peptide resulted in 10-fold increase of mammosphere-forming activity [5]. Conversely, Bouras et al showed that the inhibition of Notch pathway by knockdown Cbf-1 in CD29<sup>hi</sup>CD24<sup>+</sup> cells resulted in increased transplantation efficiency, suggesting that the Notch pathway may restrict mammary stem/progenitor cells expansion [6].

The p53 protein is a central regulator for multiple tumor suppressor pathways. The role of activated p53 in mediating cell cycle arrest and apoptosis has been studied extensively [7-9]. In response to DNA damage, oncogene activation or other stresses, p53 accumulates in nucleus and transactivates downstream genes, such as p21 and PUMA, and directs the fate of damaged cells resulting in repair or elimination [10, 11]. In addition to the importance of activated p53 under stress conditions, the basal level p53 under normal conditions may also play an essential role in tumor suppressor function. In both hematopoietic system and neural system, basal levels of p53 were shown to negatively regulate the self-renewal of tissue-specific stem cells [12, 13]. The Arf-Trp53 pathway was shown to restrict the efficiency of reprogramming of induced pluripotent stem cells [14, 15].

Disruption of the gene encoding p53 (designated TP53 in human and Trp53 in mouse) predisposes normal mammary epithelium to tumorigenesis. Women with Li-Fraumeni syndrome, which is most commonly associated with germline heterozygous mutations of TP53, have significantly increased risk of breast cancer [16, 17]. Mutations and deletions of TP53 are the most common alterations in cancers. The rate of p53 mutation is as high as 82% in the basal-like subtype of breast cancer, whereas in luminal A subtype, p53 mutations are found in only 13% patients suggesting that p53 mutation promotes basal-like breast cancer [18]. This class of aggressive tumors express gene signatures enriched in embryonic stem cells, and thus, have been proposed to originate from progenitor cells [19]. Mammary tumors from p53 heterozygous mouse models mimic Li-Fraumeni syndrome in women and the tumors share gene expression patterns with tumors from Brca1-deficient and Wnt1 transgenic mice and human basal-like breast cancer, suggesting that mammary tumors...
from p53-deficient mice may also originate from the stem/progenitor cells [18, 20-22].

In this study, BALB/c-Trp53+/+, Trp53+-/ and Trp53-- mice were used to test the role of p53 in regulating the mammary stem/progenitor cells. We found that decreased p53 dosage resulted in increased frequency of mammary stem/progenitor cells, suggesting that basal levels of p53 inhibited self-renewal of mammary stem/progenitor cells. As the mammosphere-initiating cells of different Trp53 genotypes were resistant to ionizing radiation (IR), p53-mediated apoptosis is comprised in these cells. Therefore, expansion of the mammary stem/progenitor cells population cannot be attributed to differences in apoptosis. Similarly, the decrease in the pool of label-retaining cells in Trp53-- mammary epithelium also suggest that survival is not increased, but rather asymmetric segregation of DNA is diminished in the absence of p53 leading to dilution of the label during expansion of mammary stem/progenitor cells. We also showed that γ-secretase inhibitors (GSI) can be used to inhibit the expansion of Trp53--/mammary stem/progenitor cells. The results demonstrate that p53 regulates self-renewal of mammary stem/progenitor cells and that insufficient basal levels of p53 can lead to expansion of the pool of mammary stem/progenitor cells, which are especially vulnerable to tumorigenesis without the proper surveillance of p53. Therefore, the Notch pathway is a potential therapeutic target to inhibit expansion of mammary stem/progenitor cells and reduce breast cancer risk.

**MATERIALS AND METHODS**

**Animals**

BALB/c-Trp53+/+, Trp53+-/ and Trp53-- mice were generated by backcrossing (C57BL/c x 129/Sv) Trp53-- mice onto the BALB/cMed strain as described before [23]. Wild type 3 weeks old BALB/c recipient mice for transplantation were purchased from Jackson lab.

**Isolation of primary mouse mammary cells**

Mammary gland harvested from 8-10 weeks old virgin mice were minced and dissociated in DMEM:F12 (Sigma, St. Louis, MO) supplemented with 5% Fetal Bovine serum (Gibco, Paisley, UK), 2mg/ml collagenase (Worthington Biochemicals, Freehold, NJ), 100u/ml hyaluronidase (Sigma), 100u/ml pen/strep (Gibco) and 100 μg/ml gentamicin (Gibco) for 6 hours. The cell pellet was collected and further dissociated with 1ml pre-warmed 0.05% Trypsin-EDTA (Gibco) and 200μl 1mg/ml DNase I (Roche, Mannheim, Germany). Cell suspensions were sieved through a 40μm cell strainer to obtain single cell suspension.

**Mammosphere culture**

Primary single cells were seeded into ultra-low attachment dishes or plates at a density of 20,000 viable cells/ml. Cells were grown in a serum-free mammary epithelial growth medium (HuMEC, Gibco) supplemented with B27 (Gibco), 20ng/ml EGF (Sigma), 20ng/ml bFGF (Sigma), 4μg/ml heparin (Sigma), 100u/ml Pen/Strep, 5μg/ml gentamicin [24]. For the GSI treatment, N-[N-(3,5-Difluorophenacetyl)-L-alanyl]-S-phenylglycine t-butyler (DAPT, Sigma) was added into culture medium to the final concentration of 5μM (final DMSO concentration 0.1%). To passage mammospheres, mammospheres were collected with gentle centrifugation 800rpm for
Regulation of mammary stem/progenitor cells by p53

5 min 7 days after culture and dissociated with 1 ml pre-warmed 0.05% Trypsin-EDTA and 60 µl 1 mg/ml DNase I for 5-8 min. Cell suspensions obtained from dissociation were sieved through 40 µm cell strainer and seeded at a density of 1,000 viable cells/ml. To test the IR responses of mammosphere-initiating cells, single cell suspensions received 0-Gy (control group) or 5-Gy dose (radiation group) of γ-irradiation from a cesium-137 source before being plated.

Limiting dilution and transplantation
Primary mammary epithelial cells (MECs) were freshly isolated as described above and resuspended in DMEM:F12 with 5% FBS. Six different cell concentrations were used: 50,000/10 µl, 10,000/10 µl, 5,000/10 µl, 2,500/10 µl, 1,000/10 µl, 100/10 µl. Trp53+/+ cell suspensions were injected into right side of #4 cleared fat pads of 3 weeks old recipient mice and the same concentration of Trp53-/− cell suspensions were injected into the contralateral left side fat pad. The transplanted fat pads were harvested and stained with Carmine Alum solution 8 weeks after transplantation [25]. Outgrowths that occupied >5% of the fat pad were regarded as a successful outgrowth [26]. Two methods were used to estimate the frequency of long-term regenerative mammary stem cells. The L-Calc software (Stemcell Tech, Vancouver, Canada) has been reported previously [27]. We also used a generalized linear model approach assuming an underlying Poisson distribution of stem cell frequency to model the limiting dilution data using Stata (Stata Corp, College Station, TX). The regression model included a term for the multiplicative effect of Trp53+/+ (relative to Trp53−/−) and model adequacy was assessed using the link test. The Wilcoxon signed-rank test was used to compare the percentage of filled fat pad between Trp53+/+ and Trp53−/− epithelium. The model was not adjusted for the paired design where Trp53+/+ and Trp53−/− transplants are tested within each animal. The paired design would bias results in the direction of the null hypothesis resulting in a conservative estimate of statistically significant findings.

TM40A cell culture and retroviral infection
TM40A cells were maintained in regular MECL media: DMEM:F12 supplemented with 2% adult bovine serum (Gibco), 10 µg/ml Insulin (Sigma), 20 ng/ml mEGF, and 100 u/ml Pen/Strep. Oligos coding for the p53 knockdown or scramble shRNA were annealed and cloned into pSicoR-PGK-puro vector (Addgene, Cambridge, MA). The p53 target sequence was GTACTCTCCTCCCCTCAAT and the scramble sequence was CGCTACACACTTCTTCTCC. The infection of TM40A cells with let-7c sensor plasmid, pSicoR-PGK-puro-p53KD plasmid or the control plasmids were performed as described previously [28, 29].

Flow cytometry and cell sorting
Cells were freshly collected and resuspended in DMEM:F12 supplemented with 1 mM EDTA, 25 mM HEPES, 1% FBS and 100 u/ml Pen/Strep. The FACS data were collected using LSRII (Becton Dickinson, San Jose CA). A total 100,000 events were collected and analyzed using BD FACSDiva software (Becton Dickinson). Cell sorting was performed using a FACSVantage SE (Becton Dickinson).

Western blot
TM40A cell protein lysates were harvested 1 hour after 0-Gy or 10-Gy of γ-irradiation using RIPA buffer (50 mM Tris, 150 mM NaCl, 1% TritonX-100, 10% glycerol, 0.1% SDS, 0.5% deoxycholate, 1x protease inhibitor (Sigma, p8340) and 1x phosphatase inhibitor (Sigma,
P5726)). Protein lysates (80µg) were separated by 10% SDS-PAGE and transferred to PVDF membrane (Millipore, Billerica, MA). The membrane was incubated with anti-phospho p53 (1:1000, Cell Signaling, 9284), or anti-β-actin (1:4000, Sigma, A1978), followed by incubation with horseradish peroxidase conjugated secondary antibodies (1:5000, GE Healthcare, Little Chalfont, Buckinghamshire, UK), and developed using enhanced chemiluminescence (ECL) solution (GE Healthcare) in G:Box imaging system (Syngene, Cambridge, UK).

**Label retaining cells**

3 weeks old BALB/c-\textit{Trp53}+/+ and BALB/c-\textit{Trp53}+-/- mice were injected with BrdU (Sigma) 300µg/10g body weight for 7 days. Mammary glands were harvested 9 weeks after the final injection. 5 \textit{Trp53}+/+ mice and 3 \textit{Trp53}+-/- mice were used in this experiment. BrdU staining was done using the BrdU staining kit (Invitrogen, Carlsbad, CA) and the whole slides were counted for the total epithelial cells and LRECs.

**RESULTS**

\textbf{p53 inhibits the expansion of mammary stem/progenitor cells}

In order to examine the effect of p53 on mammary stem/progenitor cells, mammosphere formation capacity was compared among BALB/c-\textit{Trp53}+/+, \textit{Trp53}+-/- and \textit{Trp53}+-/- mice. During serial passages, \textit{Trp53}+-/- epithelial cells gave rise to significantly higher numbers of secondary and tertiary mammospheres than wild type epithelium (p<0.01) (Fig. 1A), suggesting that p53 restricts expansion of mammary stem/progenitor cells. \textit{Trp53}+-/- epithelium also gave rise to higher numbers of mammospheres than \textit{Trp53}+/+, indicating the importance of p53 dosage with respect to regulation of mammary stem/progenitor cells. Furthermore, the \textit{Trp53}+-/- mammospheres are also larger than \textit{Trp53}+/+ mammospheres, suggesting more extensive proliferation (Fig. 1B).

To estimate the frequency of long-term regenerative mammary stem cells, we performed limiting dilution and transplantation to test the ability of cells to reconstitute the mammary gland. Total mammary cells were isolated from 8-10 week old aged-matched BALB/c-\textit{Trp53}+/+ and \textit{Trp53}+-/- donor mice. The cells were transplanted into cleared mammary fat pads of 3-week old wild type BALB/c recipients. Both \textit{Trp53}+/+ and \textit{Trp53}+-/- outgrowths showed normal ductal structure in both whole mounts (Fig.1 D, F) and HE staining (Fig.1 E, G). Using L-Calc Software, the frequency of mammary stem cell in BALB/c-\textit{Trp53}+/+ epithelium was estimated to be 1 in 8,085 (± 1S.E. 6,508 - 10,045) compared to 1 in 2,445 (± 1S.E. 2,033 - 2,940) in BALB/c-\textit{Trp53}+-/- epithelium (Fig. 1C, H). The frequency of long-term regenerative mammary stem cells in \textit{Trp53}+-/- epithelium was 3.3-fold higher than the \textit{Trp53}+/+ epithelium (p<0.001), suggesting that basal levels of p53 inhibit the expansion of mammary stem cells and that insufficient p53 dosage results in increased numbers of mammary stem cells between these genotypes. A generalized linear model approach was also applied and produced similar estimates of the difference in frequency of mammary stem cells. It is also noticeable that \textit{Trp53}+-/- outgrowths occupied a significantly higher percentage of the gland than the \textit{Trp53}+/+ outgrowth (p<0.01), suggesting increased regenerative capacity of the \textit{Trp53}+-/- mammary stem cells (Fig. 1H).
**p53-mediated apoptosis pathway is compromised in mammary stem/progenitor cells**

Ionizing radiation (IR) causes DNA double strand breaks, which induces preferentially p53-dependent cell cycle arrest and apoptosis. To test whether the different number of mammospheres may be an artifact of defective apoptosis in Trp53-/- cells, we used IR to trigger DNA damage and apoptosis. Upon serial passages, mammosphere cell suspensions were treated with either 0-Gy or 5-Gy $\gamma$-irradiation then seeded in parallel. Surprisingly, the number of secondary or tertiary mammospheres was not affected by IR in any of the genotypes (p>0.05) (Fig. 2A, B), suggesting that the mammosphere-initiating cells are resistant to IR and that the p53-mediated apoptosis pathway is compromised in these cells. These results indicate that the increase in mammary stem/progenitor cells is not attributed to differences in apoptosis or survival in Trp53-/- cells and that p53 acts by a distinct mechanism to limit the mammary stem/progenitor cells.

**Trp53-/- mammary epithelium contained fewer label retaining epithelial cells (LRECs)**

Non-random segregation of chromatids was reported in both embryonic stem cells and multilineage progenitor cells [30]. It has been postulated that the tissue specific stem cells maintain their “stemness” and protect themselves from mutation through asymmetric segregation of their template DNA strands [31, 32]. LRECs have been reported in mammary gland by using either $[^{3}\text{H}]$-thymidine or BrdU labeling [33]. We labeled BALB/c-Trp53+/- and Trp53-/- mice with BrdU when 3 weeks old and chased for 9 weeks. Both genotypes exhibited similar incorporation of BrdU immediately after the labeling period. After 9 weeks of chasing, the BrdU-retaining epithelial cells were found in both luminal and basal compartments and the distribution of LRECs was similar among both genotypes (Fig. 3A, B). However, Trp53-/- mammary glands contained significantly fewer LRECs (1.26±0.09%) than the Trp53+/+ mammary glands (2.56±0.18%) (p<0.01, Fig. 3C), indicating that asymmetric segregation of DNA is impaired in the absence of p53 resulting in dilution of the BrdU label.

**TM40A cells as an in vitro model to test the function of basal level p53**

The role of p53 in regulation of mammary stem/progenitor cells was further confirmed *in vitro* using the TM40A cell line, a mammary epithelial cell line derived from BALB/c mice and retains wild type p53 mRNA (unpublished data, DJJ). TM40A cells form hyperplastic outgrowths when transplanted *in vivo* (Fig. 4A) but have undetectable tumorigenicity through 20 weeks. The let-7 microRNA family was shown to be depleted in the mammary progenitor cells and highly expressed in the more differentiated cell types and the let-7c sensor plasmid (let7s) has been used to label mammary progenitor population *in vitro* [28]. The TM40A-let7s cells contained 0.8% of DsRed positive (DsR+) progenitor cells (Fig. 4B). The mammosphere-forming capacity of DsR+ cells is 3.8-fold greater than DsR- cells (p<0.01) (Fig. 4C), confirming their progenitor feature. Interestingly, most of the cells in the DsR+ mammospheres remained DsR+ (Fig. 4D).

We proceeded to determine whether the knockdown of p53 can change the proportion of DsR+ progenitor cells. TM40A-let7s cells were infected with a p53 shRNA plasmid (TM40A-let7s-p53KD) or control plasmid (TM40A-let7s-ctrl) as described previously [29].
The p53 shRNA decreased p53 protein to less than 24% of the original level (Fig. 4E). The TM40A-let7-p53KD contained increased numbers of DsR+ cells (2.5%) compared to the TM40A-let7-ctrl cells (0.8%) (Fig. 5A and B). The number of secondary mammospheres formed by TM40A-let7-p53KD cells was also 2.2-fold higher than the control cells (p<0.01) (Fig. 5E), further proving that the basal level of p53 inhibits the expansion of mammary progenitor cells.

**Notch inhibitor reduced the number of mammary stem/progenitor cells**

Increased mammary stem/progenitor cells could be vulnerable targets for carcinogenesis, especially in Li-Fraumeni patients in whom p53-mediated genome surveillance is compromised. We proceeded to test the potential of pharmacological methods to inhibit the expansion of mammary stem/progenitor cells. The Notch pathway has been reported to both promote and limit progenitor cells [5, 6], therefore we tested whether γ-secretase inhibitors (GSI), could affect the expansion of p53-deficient mammary stem/progenitor cells. The number of TM40A-let7-p53KD mammospheres decreased to baseline levels after the treatment with DAPT, a GSI (Fig. 5E; p<0.01) indicating that Notch pathway could be a potential therapeutic target for downregulation of mammary stem/progenitor cells. The number of mammospheres in control cells with wild type p53 was not changed with DAPT treatment showing that inhibition of Notch was not a general effect, but specifically reversed the effect of p53-deficiency (Fig. 5E). DAPT treatment also restricted the expansion of progenitors measured by DsR+ sensor after p53 knockdown. In TM40A-let7-p53KD cells, DAPT decreased the DsR+ cells from 2.5% to 1.4% (compare Fig. 5B and D), whereas the proportion of DsR+ cells was not changed by DAPT in the control group (compare Fig. 5A and C). Trp53-/- and Trp53+/+ primary mammary epithelial cells were also treated with 5μM DAPT or DMSO. Similarly, DAPT significantly inhibited the expansion of Trp53-/- mammospheres. The number of Trp53-/- secondary mammospheres decreased significantly from 250±13/10,000 cells to 168±11/10,000 cells after the DAPT treatment (p<0.01), but the number of Trp53+/+ mammospheres were not affected (Fig. 5F).

**DISCUSSION**

The importance of p53 in breast cancer is highlighted by the dramatic increase of breast cancer risk among women with Li-Fraumeni syndrome [16, 17]. Although the function of activated p53 in mammary epithelium has been extensively studied, its role at basal levels under normal conditions is not fully understood. Both the mammosphere and limiting dilution data showed that insufficient basal levels of p53 resulted in increased numbers of mammary stem/progenitor cells. A gene dosage effect was also detected with the frequency of mammosphere-forming activity being intermediate for Trp53+/− mammary epithelium compared to the Trp53+/+ and Trp53−/−.

Label-retaining cell assays provide a measure of the asymmetric divisions of stem cells. Smith et al reported that by using [3H]-thymidine as the first label for LRECs and BrdU as secondary label for recently proliferating cells, most LRECs were actively synthesizing DNA yet retained their [3H]-thymidine labeled strands, suggesting that asymmetrically dividing cells contribute to most of LRECs [33]. Organ specific stem cells could also be static and divide less frequently, which may also contribute to their label-retaining
Recently, reports showed that p53 is essential for maintaining quiescence of mammary stem cells as well as hematopoietic stem cells [34, 35]. In our experiment, the frequency of LRECs in wild type mice was 2.56±0.18%, which is close to that reported by Smith et al using [3H]-thymidine. We showed that Trp53-/ epithelium contained fewer LRECs than wild type epithelium. This could be explained by increased proliferation of Trp53-/ mammary stem cells, which dilute the BrdU after 9 weeks of chasing. Alternatively, p53 may regulate the asymmetric segregation of sister chromatids during mitosis, which could be vital for the fate decision of daughter cells. Loss of p53 may result in the disruption of this asymmetric segregation, leading to the loss of BrdU labeling after several rounds of division.

As p53 plays a prominent role in apoptosis, it was possible that differences in cell survival could contribute to the apparent increase in mammary stem/progenitor cells. However, radiation treatment failed to alter the number of secondary or tertiary mammospheres in any Trp53 genotype suggesting that p53-mediated apoptosis is compromised in the mammary stem/progenitor cell population. Previous studies have also demonstrated the resistance of mammary progenitors to therapeutic doses of ionizing radiation [36, 37]. Furthermore, if differences in apoptosis were responsible for the apparent expansion of mammary stem/progenitor cells, the frequency of LRECs would be expected to be increased, but were in fact decreased significantly. Therefore, the expansion of mammary stem/progenitor cells cannot be attributed to altered survival of p53-deficient cells.

These results highlight the disparate functions and roles of p53 in different cell types. It was reported that ES cells could not activate p53-dependent responses to ionizing radiation because p53 protein was sequestered in the cytoplasm [38]. Nonetheless, under basal conditions p53 was found to suppress expression of Nanog and induce differentiation of mouse ES cells [39]. In mammary gland, irradiation triggers p53-mediated apoptosis in ductal epithelium [40], but this surveillance activity of p53 was not detectable in mammary stem/progenitor cells (Fig. 2). Nonetheless, the ability of basal levels of p53 to restrict the pool of progenitors was retained (Fig. 1). Therefore, the tumor suppressor function of p53 can be divided into two different aspects. In differentiated cells, p53 can be activated due to various genotoxic or cellular stresses so that the damaged cells will either be repaired or eliminated through apoptosis, depending on the extent of damage. In contrast, the apoptosis-inducing function of p53 is compromised in the mammary stem/progenitor cells, which prevents the loss of tissue-specific stem cells and the premature aging process due to DNA damage or other cellular challenges. In these cells, the major tumor suppressor function of p53 is to restrict self-renewal and inhibit inappropriate expansion of mammary stem/progenitor cells, a function that is independent of the pro-apoptotic function of p53 (Fig. 5G).

The elucidation of mammary stem cells and breast cancer stem cells has stimulated greatly the discussion of the cellular origins of breast cancers [21, 41]. In small intestine, the deletion of the adenomatosis polyposis coli gene (Apc) in intestinal stem cells showed much higher transformation efficiency than in short-lived transit-amplifying cells, providing direct
evidence of the stem cell origin of intestinal cancer [42]. In mammary gland, the complexity of breast cancer subtypes and mammary epithelial cell hierarchy makes it hard to identify the cellular origins of breast cancer. Type I human breast epithelial cells (HBECs) express features of luminal stem/progenitor cells and show a greater potential for immortalization and transformation by oncogenes [43-45]. The pathologic features of tumors also appear to differ among populations sequentially immortalized and transformed with TERT, SV40-T-antigen and activated Ras [46]. These observations suggest that the mammary stem/progenitor cells are sensitive to oncogenic transformation, although the possibility of transformation of differentiated epithelial cells can not be ruled out. Therefore, modest increases in the prevalence of stem/progenitor cells would be anticipated to increase risk of breast cancer and are a likely source of cancer stem cells.

Germline heterozygous mutations in TP53 or BRCA1 significantly increase breast cancer risk. BRCA1 was also shown to regulate self-renewal and cell fate decision of mammary stem/progenitor cells. Loss of heterozygosity (LOH) of BRCA1 resulted in histologically normal lobules, which are comprised of progenitor cells and have higher transformation risk [4]. Similarly, loss of p53 function is associated with basal-like breast cancers that express markers of embryonic stem cells [18, 19]. Mammary tumors from p53-deficient mouse models also appear to develop from bipotent progenitor cells and have gene expression patterns similar to embryonic stem cells [22, 41]. Our lab showed that 62% of spontaneous mammary tumors from Trp53+-/- mice contained mixture of cells expressing either K5 or K8/18 [22]. It is likely that the expansion of mammary stem/progenitor cells resulting from loss of p53 activity contributes to the great breast cancer risk due to their long life span and the ability to give rise to multiple lineages of differentiated cells. Therefore the inhibition of mammary stem/progenitor cell expansion may be a key target for prevention of hereditary breast cancers. Expression of Notch pathway members were especially prominent in the gene expression patterns in mammary tumors of p53-deficient mice [22] suggesting that this pathway may contribute to the expansion of mammary stem/progenitor cells. We found that treatment of Trp53-/- primary cells and TM40A-let7+-p53KD cells with DAPT significantly downregulated the mammosphere-forming activity and the number of DsR⁺ progenitor cells. However DAPT did not change the mammosphere number of Trp53+/- or TM40A-let7+--ctrl cells. This data agreed with the report of Dontu et al, which demonstrated that the Notch pathway upregulated the number of mammary stem/progenitor cells [5]. The p53 protein has been reported to inhibit activation of the Notch pathway at different levels by either inhibiting the transcription of presenilin-1 (PS1) or competing with Notch-1 intracellular domain for co-activator p300/CBP [47-49]. Similar mechanisms may lead to the inhibition of Notch pathway by p53 in mammary stem/progenitor cells. In the absence of p53, this inhibition is released, which allows expansion of mammary stem/progenitor cells. While in the presence of p53, the inhibition mechanism is intact and the treatment of DAPT did not affect the self-renewal of mammary stem/progenitor cells (Fig. 5G).

Researchers have tried to apply GSI on breast cancer treatment and showed that GSI is effective in suppression of breast cancer stem cells and inhibition of breast cancer growth [50, 51]. The GSI-sensitive signature suggested that pathways,
including the Notch pathway and chemokine signaling pathway may contribute to the sensitivity of breast cancer to GSI [51]. However, it remains possible that other targets of γ-secretase are important. Our results suggest that the Notch pathway is a potential therapeutic target to inhibit the expansion of mammary stem/progenitor cells and GSI may be applied to prevent breast cancer in patients with Li-Fraumeni syndrome.

### SUMMARY

Proper regulation of the pool of progenitor cells is increasingly recognized as a factor in determining risk of breast cancer. We show that decreased p53 gene dosage results in increased numbers of progenitor cells through a mechanism that involves loss of asymmetric divisions and apparent increases in Notch activity, but not alterations in apoptosis. Inhibition of Notch signaling with a γ-secretase inhibitor reversed the effect of p53 loss resulting in restriction of the number of mammary stem/progenitor cells. As inhibition of Notch limited the pool of mammary stem/progenitor cells in p53-deficient mammary epithelium but had no effect in Trp53+/+ cells, it appears to be an effective treatment to prevent mammary tumors due to loss of p53 function with minimal consequences to cells with wild type p53.

### ACKNOWLEDGMENTS

We thank Dr. Daniel Medina for inspiring critiques and background information on TM40A cells, Dr. Gregory Hannon for the gift of let7c-sensor and control plasmids.

### Disclosure of Potential Conflicts of Interest

The authors indicate no potential conflicts of interest.

Fig. 2. p53-mediated apoptosis is compromised in mammary stem/progenitor cells. Single cell suspensions were treated with 0-Gy or 5-Gy γ-irradiation before being plated and the number of secondary (A) and tertiary (B) mammospheres were compared. The mammospheres of different p53 genotypes showed no difference between control (NO-IR) and irradiated (IR) samples (p>0.05). The data shown represent 12 replicates for each treatment. The results were reproduced in a second independent experiment.
Fig. 3. *Trp53*−/− mammary epithelium contained fewer label-retaining epithelial cells (LRECs). LRECs were found in both luminal and basal compartments and the distribution of LRECs were similar among *Trp53*+/+ (A) and *Trp53*−/− (B) mammary glands. Quantitative analysis showed that the *Trp53*−/− glands contained significantly lower number of LRECs than the *Trp53*+/+ glands (C) (p<0.01).
Fig. 4. TM40A cells as an in vitro model to test the function of basal level p53. (A) Whole mount of a TM40A outgrowth 20 weeks after transplantation. (B) The let7c-sensor plasmid was introduced into TM40A cells (TM40A-let7s). The TM40A-let7s cells contained 0.8% of DsRed positive (DsR+) progenitor cells. Background levels of fluorescence were determined using control cells. (C) The DsR+ cells gave rise to significantly more mammospheres than DsR- cells (p<0.01). (D) Most cells in the DsR+ mammospheres remained DsRed positive. (E) Western blot showed that phosphorylated p53 (phospho-p53) was reduced in TM40A-let7s-p53KD cells compared to the control cells (TM40A-let7s-ctrl).
Fig. 5. Inhibition of mammary stem/progenitor cells with γ-secretase inhibitor. (A-D) TM40A-let7s-p53KD cells contained more DsR⁺ progenitor cells compared to the TM40A-let7s-ctrl cells. The expansion of DsR⁺ progenitors in TM40A-let7s-p53KD cells can be inhibited by the treatment of DAPT, while the DsR⁺ cells in TM40A-let7s-ctrl cells were not affected. (E) TM40A-let7s-p53KD cells gave rise to significantly more secondary mammospheres than control cells (p<0.01). The number of p53KD mammospheres decreased significantly with the treatment of 5μM DAPT (p<0.01), while the number of control mammospheres were not affected (p>0.05). (F) Mammospheres were treated with either 5μM DAPT or DMSO control during serial passages. The number of Trp53-/— mammospheres decreased significantly after the treatment of DAPT (p<0.01). The number of Trp53+/+ mammospheres was not changed with DAPT treatment. (G) Model of p53 tumor suppression function in different cell types. p53 restricts the self-renewal of mammary stem/progenitor cells; however the p53-mediated apoptosis response is compromised in these cells. In the differentiated cells, the p53-mediated apoptosis pathway becomes functional. Notch may be inhibited by basal levels of p53 in mammary stem/progenitor cells. Insufficient p53 can result in increased Notch activity which leads to the expansion of mammary stem/progenitor cells.
Regulation of mammary stem/progenitor cells by p53

A. TM40A-let7s ctrl + DM50
B. TM40A-let7s p53KD + DM50

C. TM40A-let7s ctrl + DAPT
D. TM40A-let7s p53KD + DAPT

E. Number of mammospheres (200,000 cells)

F. Number of mammospheres (200,000 cells)

G. Mammary stem/progenitor cells → Differentiated cells

Notch → R → Trp53 → apoptosis
